Theorem 2.1 (Mazur)**.** *If E is semistable and $p \geq 11$, then $\overline{\rho}_{E,p}$ is surjective.*

Proof. See [Maz78, Thm. 4]. □

Example 2.2. Mazur's theorem implies that the representations $\overline{\rho}_{E,p}$ attached to the semistable elliptic curve $E = X_0(11)$ are surjective for $p \geq 11$. Note that $\overline{\rho}_{E,5}$ is reducible.

Theorem 2.3 (Cojocaru, Kani, and Serre)**.** *If E is a non-CM elliptic curve of conductor N, and*

$$p \geq 1 + \frac{4\sqrt{6}}{3} \cdot N \cdot \prod_{\textit{prime } \ell | N} \left(1 + \frac{1}{\ell}\right)^{1/2},$$

then $\overline{\rho}_{E,p}$ is surjective.

Proof. See Theorem 2 of [CK], whose proof relies on the results of [Ser72]. □

Example 2.4. When $N = 11$, the bound of Theorem 2.3 is ~ 38.52. When $N = 997$, the bound is ~ 3258.8. For $N = 40000$, the bound is ~ 143109.35.

Proposition 2.5. *Let E be a non-CM elliptic curve over $\mathbb{Q}$ of conductor N and let $p \geq 5$ be a prime. For each prime $\ell \nmid p \cdot N$ with $a_\ell \not\equiv 0 \pmod{p}$, let*

$$s(\ell) = \left(\frac{a_\ell^2 - 4\ell}{p}\right) \in \{0, -1, +1\},$$

where the symbol $\left(\frac{\cdot}{\cdot}\right)$ is the Legendre symbol. If -1 and $+1$ both occur as values of $s(\ell)$, then $\overline{\rho}_{E,p}$ is surjective. If $s(\ell) \in \{0, 1\}$ for all ℓ, then $\mathrm{Im}(\overline{\rho}_{E,p})$ is contained in a Borel subgroup (i.e., reducible), and if $s(\ell) \in \{0, -1\}$ for all ℓ, then $\mathrm{Im}(\overline{\rho}_{E,p})$ is a nonsplit torus.

Proof. This is an application of [Ser72, §4], where we use the quadratic formula to convert the condition that certain polynomials modulo p be reducible or irreducible into a quadratic residue symbol. □

For computational applications we apply Proposition 2.5 as follows. We choose a bound B and compute values $s(\ell)$; if both -1 and $+1$ occur as values of $s(\ell)$, we stop computing $s(\ell)$ and conclude that $\overline{\rho}_{E,p}$ is surjective. If for $\ell \leq B$ we find that $s(\ell) \in \{0, 1\}$, we suspect that $\mathrm{Im}(\overline{\rho}_{E,p})$ is Borel, and attempt to show this (see Section 2.1.1). If for $\ell \leq B$, we have $s(\ell) \in \{0, -1\}$, we suspect that $\mathrm{Im}(\overline{\rho}_{E,p})$ is contained in a nonsplit torus, and try to show this by computing and analyzing the p-division polynomial of E. If this approach is inconclusive, we can alway increase B and eventually the process terminates. In practice we often apply some theorem under the hypothesis that $\overline{\rho}_{E,p}$ is surjective, which is something that in practice we verify for a particular p using Proposition 2.5.

Example 2.4 suggests that the bound of Theorem 2.3 is probably far larger than necessary. Nonetheless, it is small enough that in a reasonable amount of time we can determine whether $\overline{\rho}_{E,p}$ is surjective, using the above process, for all p up to the bound. In this way we determine the exact image of Galois.

Remark 2.6. We can also determine surjectivity of the mod 2 and mod 3 representations directly using the 3-division polynomial of E. For $p \leq 3$ one can show that $\overline{\rho}_{E,p}$ is surjective if and only if the p-division polynomial (of degree n) has Galois group S_n.

Theorem 2.7 (Serre)**.** *If $p \geq 5$ is a prime of good reduction, then $\rho_{E,p}$ is surjective if and only if $\overline{\rho}_{E,p}$ is surjective.*

Proof. This is proved in greater generality as [Ser72, Thm. 4′, pg. 300]. □

Remark 2.8. This result does not extend to $p = 3$ (see [Ser98, Ex. 3, pg IV-28]). In fact, there are infinitely many elliptic curves with $\overline{\rho}_{E,p}$ surjective, but $\rho_{E,p}$ not surjective (see forthcoming work of Noam Elkies).

2.2. Special Values of L-Functions.

Let E be an elliptic curve over $\mathbb{Q}$ of conductor N, and let $f = \sum a_n q^n$ be the corresponding cusp form.

The following lemma will be useful in determining how many terms of the L-series of E are needed to compute the L-series to a given precision. (We could give a strong bound, but for our application this will be enough, and is simplest to apply in practice.)

Lemma 2.9. *For any positive integer n, we have $|a_n| \leq n$.*

Proof. For p prime we know that $a_p = \alpha + \beta$, where α and β are the roots of $x^2 - a_p x + p = 0$. Note that $|\alpha| = |\beta| = \sqrt{p}$.

Since a_n is multiplicative, it is enough to show $|a_n| \leq n$ for prime powers p^r. Let $r > 1$. Then $a_{p^r} = a_p a_{p^{r-1}} - p a_{p^{r-2}}$, and by induction,

$$a_{p^r} = \frac{\alpha^{r+1} - \beta^{r+1}}{\alpha - \beta}.$$

Then

$$|a_{p^r}| \leq \frac{2p^{(r+1)/2}}{|\alpha - \beta|} = \frac{2p^{(r+1)/2}}{\left|\sqrt{4p - a_p^2}\right|}.$$

Note that the sign is changed since we only deal with absolute values. We need to show that this is $\leq p^r$. This happens if

$$\frac{2}{\sqrt{4p - a_p^2}} \leq p^{(r-1)/2}.$$

Since $a_p^2 < 4p$ the difference is at least 1 so it is enough to show that $2 \leq p^{(r-1)/2}$. This is true as long as $p > 3$. For $p = 2$ and $p = 3$ note that a_p is an integer with $|a_p| < 2\sqrt{p}$. For $p = 2$ this integer is at most 2 and so $4p - a_p^2 \geq 4$. Similarly for $p = 3$ this is at most 3 and so $4p - a_p^2 \geq 4$. Therefore it is enough to show that $1 \leq p^{(r-1)/2}$, which is true for all $r > 1$. □

Suppose E has even analytic rank. By [Cre97, §2.13] or [Coh93, Prop. 7.5.8], we have

$$L(E,1) = 2\sum_{n=1}^{\infty} \frac{a_n}{n} e^{-2\pi n/\sqrt{N}}, \tag{2.1}$$

where a_n are the Fourier coefficients of the normalized eigenform associated with E. Using the bound $|a_n| \leq n$ of Lemma 2.9, we see that if we truncate the series (2.1) at the kth term, the error is at most

$$\varepsilon = 2\sum_{n=k}^{\infty} e^{-2\pi n/\sqrt{N}} = \frac{2e^{-2\pi k/\sqrt{N}}}{1 - e^{-2\pi/\sqrt{N}}},$$

and the quantity on the right can easily be evaluated.

Next suppose E has odd analytic rank. In [Cre97, §2.13] or [Coh93, Prop. 7.5.9] we find that

$$L'(E,1) = 2\sum_{n=1}^{\infty} \frac{a_n}{n} G_1(2\pi n/\sqrt{N}).$$

We have

$$G_1(x) = \int_1^{\infty} e^{-xy}\frac{dy}{y} = \int_x^{\infty} e^{-y}\frac{dy}{y} \leq e^{-x},$$

and we obtain the same error bound as for $L(E,1)$. (In fact, $G_1(x) \leq e^{-x}/x$ but we will not need this stronger bound.)

2.3. **Mordell-Weil Groups.**

If E is an elliptic curve over $\mathbb{Q}$ of analytic rank ≤ 1, there are algorithms to compute $E(\mathbb{Q})$ that are guaranteed to succeed. This is because $\#Ш(E)$ is finite, by [Kol91]. Independent implementations of these algorithms are available as part of `mwrank` [Creb] and MAGMA [BCP97]. We did most of our computations of $E(\mathbb{Q})$ using `mwrank`, but use MAGMA in a few cases, since it implements 3-descents, 4-descents and Heegner points methods (thanks to work of Tom Womack, Mark Watkins, and others).

2.4. **Other Algorithms.**

We use many other elliptic curves algorithms, for example, for computing root numbers and the coefficients a_n of the modular form associated to E. For the most part, we used the PARI (see [ABC$^+$]) C-library via SAGE (see [Ste]). For descriptions of these general elliptic curves algorithms, see [Coh93, Cre97].

3. The Kolyvagin Bound

In this section we describe a bound due to Kolyvagin on $\#Ш(E)$, and compute it for many specific elliptic curves over $\mathbb{Q}$. In fact, the bound is on $\#Ш(E/K)$, where K is a quadratic imaginary field; this is not a problem, because the natural map $Ш(E/\mathbb{Q}) \to Ш(E/K)$ has kernel of order a power of 2, so the bound is also a bound on the odd part of $\#Ш(E)$.

Let E be an elliptic curve over $\mathbb{Q}$ of conductor N. For any quadratic imaginary field $K = \mathbb{Q}(\sqrt{-D})$, let E^D denote the twist of E by D. If E is defined by $y^2 = x^3 + ax + b$, then E^D is defined by $y^2 = x^3 + D^2ax + D^3b$, and

$$L(E/K,s) = L(E,s)\cdot L(E^D,s).$$

Definition 3.1 (Heegner Hypothesis)**.** We say that K satisfies the *Heegner hypothesis* for E if $K \neq \mathbb{Q}(\sqrt{-1}), \mathbb{Q}(\sqrt{-3})$, and every prime factor of N splits as a product of two distinct primes in the ring of integers of K. (The condition $K \neq \mathbb{Q}(\sqrt{-1}), \mathbb{Q}(\sqrt{-3})$ is not necessary for some of the results below, but we include it for simplicity.)

If K satisfies the Heegner hypothesis for E, then there is a Heegner point $y_K \in E(K)$, which is the sum of images of certain complex multiplication (CM) points on $X_0(N)$ (see [GZ86, §I.3]). Properties of this point impact the arithmetic of E over K.

3.1. **Bounds on $\#\text{Ш}(E/K)$.** Suppose that K is an imaginary quadratic extension of $\mathbb{Q}$ that satisfies the Heegner hypothesis for E. Kolyvagin proved the following theorem in [Kol90]:

Theorem 3.2 (Kolyvagin)**.** *Let $R = \mathrm{End}(E/\mathbb{C})$ and let $F = \mathrm{Frac}(R)$, so if E is non-CM then $F = \mathbb{Q}$. If p is an odd prime unramified in F such that $\mathrm{Gal}(F(E[p])/F) = \mathrm{Aut}_R(E[p])$, i.e., $\mathrm{Im}(\overline{\rho}_{E,p})$ is as large as possible, then*

$$\mathrm{ord}_p(\#\text{Ш}(E/K)) \leq 2 \cdot \mathrm{ord}_p([E(K) : \mathbb{Z}y_K]).$$

Note that if E does not have complex multiplication, the hypotheses of both these theorems imply that $p \nmid \#E(K)_{\mathrm{tor}}$ (see Lemma 5.7).

Cha [Cha03, Cha05] extended Kolyvagin's method to provide better bounds on $\text{Ш}(E/K)$ in some cases. Let K be a number field, let D_K be the discriminant of K, and let N be the conductor of E.

Theorem 3.3 (Cha)**.** *If $p \nmid D_K$, $p^2 \nmid N$, and $\overline{\rho}_{E,p}$ is irreducible, then*

$$\mathrm{ord}_p(\#\text{Ш}(E/K)) \leq 2 \cdot \mathrm{ord}_p([E(K) : \mathbb{Z}y_K]).$$

As we will see in the proof of Theorem 4.3 below, there is one curve that satisfies the hypotheses of that theorem, but for which we cannot use Theorem 3.2 to prove $\mathrm{BSD}(E, 5)$. The problem is that $\overline{\rho}_{E,5}$ is not surjective. We can use Cha's theorem though:

Lemma 3.4. *Let E be the elliptic curve* 608B*, which has rank* 0*. Then* $\mathrm{BSD}(E, 5)$ *is true for E.*

Proof. Since E admits no 5-isogeny (see [Cre97]), $\overline{\rho}_{E,5}$ is irreducible. Also, $5^2 \nmid 608$, so for any Heegner K of discriminant coprime to 5 we can apply Theorem 3.3. Taking $K = \mathbb{Q}(\sqrt{-79})$, we find that the odd part of $[E(K) : \mathbb{Z}y_K]$ is 1, so $5 \nmid \#\text{Ш}(E/K)$. It follows that $5 \nmid \#\text{Ш}(E)$, so $\mathrm{BSD}(E, 5)$ is true, according to Theorem 1.7. □

Cha's assumption on the reduction of E at p and that $p \nmid D_K$ is problematic when there is a prime $p \geq 5$ of additive reduction or one uses only one K. This situation does occur in several cases, which motivated us to prove the following theorem:

Theorem 3.5. *Suppose E is a non-CM elliptic curve over $\mathbb{Q}$. Suppose K is a quadratic imaginary field that satisfies the Heegner hypothesis and p is an odd prime such that $p \nmid \#E'(K)_{\mathrm{tor}}$ for any curve E' that is $\mathbb{Q}$-isogenous to E. Then*

$$\mathrm{ord}_p(\#\text{Ш}(E)) \leq 2\,\mathrm{ord}_p([E(K) : \mathbb{Z}y_K]),$$

unless $\mathrm{disc}(K)$ *is divisible by exactly one prime* ℓ*, in which case the conclusion is only valid if* $p \neq \ell$*.*

Since the proof of Theorem 3.5 is somewhat long and technical, we defer the proof until Section 5.

Remark 3.6. If in Theorem 3.5, $\overline{\rho}_{E,p}$ is irreducible, then $p \nmid \#E'(K)_{\mathrm{tor}}$ for all E' isogenous to E. This is because the isogeny $E \to E'$ has degree coprime to p, so $E[p] \cong E'[p]$. Also, since $E[p]$ is irreducible, if $E'(K)$ were to contain a p-torsion point, it would have to contain all of them, a contradiction since $\boldsymbol{\mu}_p \not\subset K$ (recall that we exclude $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(\sqrt{-4})$).

Theorem 3.7 (Bump-Friedberg-Hoffstein, Murty-Murty, Waldspurger)**.** *There are infinitely many quadratic imaginary extensions* $K/\mathbb{Q}$ *such that* K *satisfies the Heegner hypothesis and* $\mathrm{ord}_{s=1} L(E/K) = 1$*.*

Proof. If $\mathrm{ord}_{s=1}L(E,s) = 0$, then the papers [MM91] and [BFH90] both imply the existence of infinitely many K such that y_K has infinite order. If $\mathrm{ord}_{s=1}L(E,s) = 1$, then a result of Waldspurger ([Wal85]) applies, as does [BFH90]. □

Theorem 3.7 is not used in our computations, but ensures that our procedure for bounding $\#Ш(E)$, when E has analytic rank ≤ 1, is an algorithm, i.e., it always terminates with a nontrivial upper bound.

3.2. **The Gross-Zagier Formula.** We use the Gross-Zagier formula to compute the index $[E(K) : \mathbb{Z}y_K]$ without explicitly computing y_K.

The modularity theorem of [BCDT01] asserts that there exists a surjective morphism $\pi : X_0(N) \to E$. Choose π to have minimal degree among all such morphisms. Let $\pi^*(\omega)$ be the pullback of a minimal invariant differential ω on E. Then $\pi^*(\omega) = \alpha \cdot f$, for some constant α and some normalized cusp form f. By [Edi91, Prop. 2], we know that $\alpha \in \mathbb{Z}$.

Definition 3.8 (Manin Constant)**.** The *Manin constant* of E is $c = |\alpha|$.

Manin conjectured in [Man72, §5] that $c = 1$ for the optimal curve in the $\mathbb{Q}$-isogeny class of E.

Theorem 3.9 (Gross-Zagier)**.** *If* K *satisfies the Heegner hypothesis for* E*, then the Néron-Tate canonical height of* y_K *is*

$$h(y_K) = \frac{\sqrt{D}}{c^2 \cdot \int_{E(\mathbb{C})} \omega \wedge \overline{i\omega}} \cdot L'(E/K, 1).$$

Proof. Gross and Zagier proved the following formula in [GZ86] under the hypothesis that D is odd. For the general assertion see [Zha04, Thm. 6.1]. □

3.3. **Remarks on the Index.** Suppose that E is an elliptic curve over $\mathbb{Q}$ of conductor N and that E has analytic rank 1 over a quadratic imaginary field K that satisfies the Heegner hypothesis. In [McC91], McCallum rephrases the analogue of Conjecture 1.1 for E over K using the Gross-Zagier formula as follows:

Conjecture 3.10 (Birch and Swinnerton-Dyer)**.** *Suppose* K *is a quadratic imaginary field that satisfies the Heegner hypothesis, and that* E *has analytic rank* 1 *over* K*. Then*

$$\#Ш(E/K) = \left(\frac{[E(K) : \mathbb{Z}y_K]}{c^2 \cdot \prod_{p \mid N} c_p} \right)^2 .$$

Here the c_p are the Tamagawa numbers of E over $\mathbb{Q}$, c is the Manin constant of E, and $\mathbb{Z}y_K$ is the cyclic group generated by y_K.

Remark 3.11. A serious issue is that Conjecture 3.10 implies that the index $I_K = [E(K) : \mathbb{Z}y_K]$ will be divisible by the Tamagawa numbers c_p. One sees using Tate curves that these Tamagawa numbers can be arbitrarily large. In many cases when E has analytic rank 0, we could instead apply Theorem 4.1 below, but when E has analytic rank 1 a new approach is required, e.g., computation of p-adic regulators and use of results of P. Schneider and others toward p-adic analogues of the BSD conjecture. This will be the subject of a future paper.

Remark 3.12. Conjecture 3.10 has interesting implications in certain special cases. For example, if E is the curve 91B, then $c_7 = c_{13} = 1$. Also $c = 1$, as Cremona has verified, and $\#E(\mathbb{Q})_{\mathrm{tor}} = 3$. Thus for any K, we have $3 \mid [E(K) : \mathbb{Z}y_K]$. If y_K has infinite order, then Conjecture 3.10 implies that $3^2 \mid \#Ш(E/K)$. For $K = \mathbb{Q}(\sqrt{-103})$, the point y_K is torsion, and in this case $E(K)$ has rank 3 and (conjecturally) $Ш(E/K)[3] = 0$. See Remark 3.23 for another example along these lines.

3.4. **Mordell-Weil Groups and Quadratic Imaginary Fields.** Let E be an elliptic curve over $\mathbb{Q}$ and $K = \mathbb{Q}(\sqrt{D})$ a quadratic imaginary field such that $E(K)$ has rank 1. In this section we explain how to understand $E(K)$ in terms of $E(\mathbb{Q})$ and $E^D(\mathbb{Q})$.

Proposition 3.13. *Let $R = \mathbb{Z}[1/2]$ and $K = \mathbb{Q}(\sqrt{D})$. For any squarefree integer $D \neq 1$, we have*

$$E(K) \otimes R = (E(\mathbb{Q}) \otimes R) \oplus (E^D(\mathbb{Q}) \otimes R).$$

Proof. Let τ be the complex conjugation automorphism on $E(K) \otimes R$. The characteristic polynomial of τ is $x^2 - 1$, which is squarefree, so $E(K) \otimes R$ is a direct sum of its $+1$ and -1 eigenspaces for τ. The natural map $E(\mathbb{Q}) \hookrightarrow E(K)$ identifies $E(\mathbb{Q}) \otimes R$ with the $+1$ eigenspace for τ since $E(K)^{G_\mathbb{Q}} = E(\mathbb{Q})$; likewise, $E^D(\mathbb{Q}) \hookrightarrow E(K)$ identifies $E^D(\mathbb{Q}) \otimes R$ with the -1 eigenspace for τ. □

The following slightly more refined proposition will be important for certain explicit Heegner point computations (directly after Equation 3.1).

Proposition 3.14. *Suppose $E(K)$ has rank 1. Then the image of either $E(\mathbb{Q})_{/\,\mathrm{tor}}$ or $E^D(\mathbb{Q})_{/\,\mathrm{tor}}$ has index at most 2 in $E(K)_{/\,\mathrm{tor}}$.*

Proof. Since $E(K)$ has rank 1, Proposition 3.13 implies that exactly one of $E(\mathbb{Q})$ and $E^D(\mathbb{Q})$ has rank 1 and the other has rank 0. We may assume that $E(\mathbb{Q})$ has rank 1 (otherwise, swap E and E^D). Let i be the natural inclusion $E(\mathbb{Q}) \hookrightarrow E(K)$, and let τ denote the automorphism of $E(K)$ induced by complex conjugation. Then $P \mapsto (1+\tau)P$ induces a map $E(K) \to E(K)^+ = E(\mathbb{Q})$ that, upon taking quotients by torsion, induces a map $\psi : E(K)_{/\,\mathrm{tor}} \to E(\mathbb{Q})_{/\,\mathrm{tor}}$. Let P_1 be a generator for $E(\mathbb{Q})_{/\,\mathrm{tor}}$ and P_2 a generator for $E(K)_{/\,\mathrm{tor}}$, and write $i(P_1) = nP_2$, for some nonzero integer n. Then

$$[2]P_1 = \psi(i(P_1)) = \psi(nP_2) = [n]\psi(P_2) = [nm]P_1 \pmod{E(\mathbb{Q})_{\mathrm{tor}}},$$

for some nonzero integer m. Thus $2 = nm$, so $n \leq 2$. □

If D satisfies the Heegner hypothesis, then by computing the residue symbol $\left(\frac{N}{D}\right)$ and understanding how the sign of the functional equation changes under twist, we see that

$$\operatorname{ord}_{s=1} L(E,s) \not\equiv \operatorname{ord}_{s=1} L(E^{(D)},s) \pmod 2.$$

Suppose K satisfies the Heegner hypothesis and $\operatorname{ord}_{s=1} L(E/K,s) = 1$. Then work of Kolyvagin (see [Kol91, Kol88]) implies that $E(K)$ has rank 1.

The root number $\varepsilon_E = \pm 1$ of E is the sign of the functional equation of $L(E,s)$. If $\varepsilon_E = +1$, then the analytic rank $\operatorname{ord}_{s=1} L(E,s)$ is even, and if $\varepsilon_E = -1$, then it is odd.

Proposition 3.15. *Let E be an elliptic curve, let $D = D_K$ be a discriminant that satisfies the Heegner hypothesis such that $\operatorname{ord}_{s=1} L(E/K,s) = 1$, and let $R = \mathbb{Z}[1/2]$. Then*

(1) *If $\varepsilon_E = +1$, then a generator of $E(K) \otimes R$ is the image of a generator of $E^D(\mathbb{Q}) \otimes R$ and $L'(E/K,1) = L(E,1) \cdot L'(E^D,1)$.*

(2) *If $\varepsilon_E = -1$, then a generator of $E(K) \otimes R$ is the image of a generator of $E(\mathbb{Q}) \otimes R$ and $L'(E/K,1) = L'(E,1) \cdot L(E^D,1)$.*

We will use the above proposition to relate computation of $E(K) \otimes R$ to computation of Mordell-Weil groups of elliptic curves defined over $\mathbb{Q}$.

3.5. **Computing the Index of the Heegner Point.** A key input to the theorems of Section 3.1 is computation of the index $[E(K) : \mathbb{Z}y_K]$. We have

$$[E(K)_{/\mathrm{tor}} : \mathbb{Z}y_K]^2 = h(y_K)/h(z), \tag{3.1}$$

where z is a generator of $E(K)_{/\,\mathrm{tor}}$.

In the Gross-Zagier formula we have $h = h_K$, the Néron-Tate canonical height on $E(K) = E^D(K)$ relative to K. Let $h_{\mathbb{Q}}$ denote the height on $E(\mathbb{Q})$ or $E^D(\mathbb{Q})$. Note that if $P \in E(\mathbb{Q})$ or $E^D(\mathbb{Q})$, then

$$h_{\mathbb{Q}}(P) = \frac{1}{[K:\mathbb{Q}]} \cdot h_K(P) = \frac{h_K(P)}{2}. \tag{3.2}$$

Using Proposition 3.14 and algorithms for computing Mordell-Weil groups (see Section 2.3), we can compute z or $2z$, so we can compute $h(z)$ or $2h(z)$. In practice, even for curves of conductor up to 1000, it can take a huge amount of time to compute z. This section about practical methods to either compute the index or at least bound it.

It is not difficult to compute $h(y_K)$, without computing y_K itself, using the Gross-Zagier formula (Section 3.2). We compute $L'(E/K,1)$ by computing L-functions of elliptic curves defined over $\mathbb{Q}$ as explained in Proposition 3.15. It remains to compute

$$\alpha = \frac{\sqrt{|D|}}{c^2 \int_{E(\mathbb{C})} \omega \wedge \overline{i\omega}}. \tag{3.3}$$

3.5.1. *The Manin Constant.* Manin conjectured that the Manin constant c for any optimal elliptic curve factor E of $X_0(N)$ is 1, and there are bounds on the possibilities for c (see, e.g., [Edi91, ARS05]). There is an algorithm to verify in any particular case that $c = 1$, as explained in the proof of the following proposition.

Proposition 3.16 (Cremona)**.** *If E is an optimal elliptic curve of conductor at most 80000, then the Manin constant of E is 1.*

Proof. For each level $N \leq 80000$ we do the following. Using the modular symbols algorithms of [Cre97], we enumerate the rational newforms $f_1, \ldots, f_d$, which correspond (via the modularity theorem) to the optimal elliptic curves $E_1, \ldots, E_d$ of conductor N, respectively. For each f_i we compute approximations to **xxx** decimal digits of the c_4 and c_6 invariants of the lattice Λ_{E_i} attached to the optimal curve in the isogeny class. We then guess integers c_4' and c_6' that are close to the computed approximations, and verify that the elliptic curve E_i' with invariants c_4', c_6' is an elliptic curve of conductor N. We also compute the full isogeny class of E_i' using the program `allisog`. Repeating this procedure for each newform f, we obtain d distinct isogeny classes of elliptic curves of conductor N, and by modularity these must be in bijection with the newforms f_i. However, at this point we have not *proved* that $E_i = E_i'$ or even that E_i' is an optimal quotient. However, we have provably found all elliptic curves over $\mathbb{Q}$ of conductor N.

We next compute the c_4 and c_6 invariants of all curves of conductor N, and observe that the first 12 digits of the c-invariants for these curves are sufficient to distinguish them. (12 digits is enough for every curve up to conductor 80000.) If we had guessed c_4' and c_6' incorrectly above, so that $E_i' \neq E_i$, there would be two curves of conductor N both of whose c-invariants have the same initial **xxx** decimal digits, which is impossible since 12 digits of precision are sufficient to distinguish any two. Thus $E_i' = E_i$, and the c_4', c_6' we computed are the correct invariants of the optimal quotient attached to f_i.

Finally, we observe that c_4' and c_6' are the invariants of a minimal Weierstrass equation, which implies that the Manin constant of E_i is 1. □

3.5.2. *The Integral.* We have the following lemma regarding the integral in (3.3):

Lemma 3.17. *We have* $\int_{E(\mathbb{C})} \omega \wedge \overline{i\omega} = 2 \cdot \mathrm{Vol}(\mathbb{C}/\Lambda)$, *where the volume* $\mathrm{Vol}(\mathbb{C}/\Lambda)$ *is the absolute value of the determinant of a matrix formed from a basis for the lattice in* $\mathbb{C}$ *obtained by integrating the Néron differential* ω_E *against all homology classes in* $\mathrm{H}_1(E, \mathbb{Z})$.

Proof. Fix the Weierstrass equation $y^2 = 4x^3 + g_4 x + g_6$ for E, so $x = \wp(z)$ and $y = \wp'(z)$. First note that

$$\omega = \frac{dx}{y} = \frac{d\wp(z)}{\wp'(z)} = \frac{\wp'(z)dz}{\wp'(z)} = dz.$$

Thus

$$\begin{aligned}\int_{E(\mathbb{C})} \omega \wedge \overline{i\omega} &= \int_{\mathbb{C}/\Lambda} dz \wedge \overline{idz} \\ &= -i \int_{\mathbb{C}/\Lambda} (dx + idy) \wedge (dx - idy) \\ &= -i(2i) \int_{\mathbb{C}/\Lambda} dx \wedge dy = 2 \cdot \mathrm{Vol}(\mathbb{C}/\Lambda).\end{aligned}$$

□

Note that $\mathrm{Vol}(\mathbb{C}/\Lambda)$ can be computed to high precision using the Gauss arithmetic-geometric mean, as described in [Cre97, §3.7].

3.5.3. *Mordell-Weil Groups and Heights.* For the curves that we run our computation on, we use [Creb] (via [Ste]), which computes a basis for $E^D(\mathbb{Q})$, and not just a basis for a subgroup of finite index.

Cremona describes the computation of heights of points on curves defined over $\mathbb{Q}$ in detail in [Cre97, §3.4]. There is an explicit bound on the error in the height computation, which shrinks exponentially in terms of the precision of approximating series, and can be made arbitrarily small. For the L-function computations, see Section 2.2.

3.5.4. *Indexes of Heegner Points on Rank* 1 *Curves.* Suppose E is an elliptic curve over $\mathbb{Q}$ of analytic rank 1, and we wish to compute indexes $i_K = [E(K)_{/\,\mathrm{tor}} : \mathbb{Z}y_K]$ for various K. Assume that $E(\mathbb{Q})$ is known, so we can compute $h(z)$ to high precision, where z generates $E(\mathbb{Q})/_{\mathrm{tor}}$. Then computing the indexes i_K is relatively easy. For each K, compute $h(y_K)$ as described above using the Gross-Zagier formula, so

$$h(y_K) = \alpha \cdot L'(E,1) \cdot L(E^D,1).$$

Then

$$i_K = \sqrt{\frac{h(y_K)}{h(z)}} = \sqrt{\frac{h(y_K)}{2h_{\mathbb{Q}}(z)}}.$$

We emphasize that computation of the Heegner point itself is not necessary. For the results of this index computation for E of conductor ≤ 1000, see Section 3.6.1.

Example 3.18. Let E be the elliptic curve 540B, which has rank 1, and conductor $540 = 2^2 \cdot 3^3 \cdot 5$. The first K that satisfies the Heegner hypothesis is $\mathbb{Q}(\sqrt{-71})$. The group $E(\mathbb{Q})$ is generated by $z = (0,1)$, and we have $h_{\mathbb{Q}}(z) \sim 0.656622630$. We have

$$\alpha \sim \frac{\sqrt{71}}{2 \cdot 3.832955} \sim 1.09917,$$

so

$$h(y_K) \sim 1.09917 \cdot 1.9340458 \cdot 5.559761726 \sim 11.819.$$

Thus

$$i_K = \sqrt{\frac{11.819}{2 \cdot 0.656622630}} \sim \sqrt{8.99999} \sim 3.$$

3.5.5. *Indexes of Heegner Points on Rank* 0 *Curves.* Assume that the analytic rank of E is 0. In practice, computing the indexes of Heegner points in this case is substantially more difficult than the rank 1 case. For a Heegner quadratic imaginary field $K = \mathbb{Q}(\sqrt{D})$, we have

$$i_K = [E(K)_{/\,\mathrm{tor}} : \mathbb{Z}y_K]^2 = \frac{h(y_K)}{h(z)} = \alpha \cdot \frac{L(E,1) \cdot L'(E^D,1)}{h(z)},$$

so one method to find i_K is to find a generator $z \in E^D(\mathbb{Q})$ exactly using descent algorithms, which will terminate since we know that $Ш(E^D)$ is finite, by Kolyvagin's theorem. However, since E^D has potentially large conductor and rank 1, in practice the Mordell-Weil group will sometimes be generated by a point of large height, hence be extremely time consuming to find. One can use 2-descent, 3-descent, 4-descent, and Heegner points methods (i.e., explicitly compute the coordinates of the Heegner point as decimals and try to recognize them using continued fractions.) In some cases these methods produce in a reasonable amount of time an element of

$E^D(\mathbb{Q})$ of infinite order, and one can then saturate the point using [Creb] to find a generator z.

Example 3.19. Let E be the curve 11A. The first field that satisfies the Heegner hypothesis is $K = \mathbb{Q}(\sqrt{-7})$. The conductor of $F = E^{-7}$ is 539, and we find a generator $z \in F(\mathbb{Q})$ for the Mordell-Weil group of this twist. This point has height $h_{\mathbb{Q}}(z) \sim 0.1111361471$. We have

$$\alpha \sim \frac{\sqrt{7}}{2 \cdot 1.8515436234} \sim 0.71447177.$$

The height over K of the Heegner point is thus

$$h(y_K) \sim 0.71447177 \cdot 0.25384186 \cdot 1.225566874 \sim 0.2222722925.$$

Thus by (3.2)

$$i_K = \frac{h(z)}{h(y_K)} = \frac{2h_{\mathbb{Q}}(z)}{h(y_K)} \sim 1.$$

There is a trick to bound the index i_K without computing *any* elements of $E(K)$. This is useful when the algorithms mentioned above for computing a generator of $E^D(\mathbb{Q})$ produce no information in a reasonable amount of time. First compute the height $h(y_K)$ using the Gross-Zagier formula. Next compute the Cremona-Prickett-Siksek [Pri04, Ch. 4] bound B for E^D, which is a number such that if $P \in E^D(\mathbb{Q})$, then the naive logarithmetic height of P is off from the canonical height of P by at most B. Using standard sieving methods implemented in [Creb], we compute all points on E of naive logarithmic height up to some number h_0. If we find any point of infinite order, we saturate, and hence compute $E^D(\mathbb{Q})$, then use the above methods. If we find no point of infinite order, we conclude that there is no point in $E^D(\mathbb{Q})$ of canonical height $\leq h_0 - B$. If $h_0 - B > 0$, we obtain an upper bound on i_K as follows. If z is a generator for $E^D(\mathbb{Q})$, then $h_{\mathbb{Q}}(z) > h_0 - B$, so using (3.2) we have

$$h_{\mathbb{Q}}(z) = \frac{1}{2} \cdot h_K(z) = \frac{h(y_K)}{2 \cdot i_K^2} > h_0 - B.$$

Solving for i_K gives

$$i_K < \sqrt{\frac{h(y_K)}{2(h_0 - B)}}, \tag{3.4}$$

so to bound i_K we consider many K (e.g., the first 30), and for each compute the quantity on the right side of (3.4) for a fixed choice of h_0. We then use a K that minimizes this quantity.

Remark 3.20. Another approach to finding some Heegner point, which we discussed with Noam Elkies, is to search for small points on $E(K)$ over various fields K, until finding a K that satisfies the Heegner hypothesis and is such that $E(K)$ has rank 1. For example, if E is given by $y^2 = x^3 + ax + b$, and x_0 is a small integer, write $y_0^2 \cdot D = x_0^3 + ax_0 + b$, where y_0 and D are integers, and D is square free. Then (x_0, y_0) is a point on the quadratic twist of E by D. We did not use this approach, since it was not necessary in order to prove Theorem 1.8.

Example 3.21. Let E be the elliptic curve 546E. Then $K = \mathbb{Q}(\sqrt{-311})$ satisfies the Heegner hypothesis, since the prime divisors of $546 = 2 \cdot 3 \cdot 7 \cdot 13$ split completely in K. We compute the height of the Heegner point y_K. Let F be the quadratic twist of E by -311. We have

$$\alpha \sim \frac{\sqrt{311}}{2 \cdot 0.0340964942689662168001} \sim 258.60711587$$

Thus

$$\begin{aligned} h(y_K) &\sim \alpha \cdot L(E,1) \cdot L'(F,1) \\ &\sim 258.60711587 \cdot 2.2783578 \cdot 12.41550 \sim 7315.20688, \end{aligned}$$

where in each case we compute the L-series using enough terms to obtain a value correct to $\pm 10^{-5}$. Thus 7320 is a conservative upper bound on $h(y_K)$. The Cremona-Prickett-Siksek bound for F is $B = 13.0825747$. We search for points on F of naive logarithmic height ≤ 18, and find no points. Thus (3.4) implies that

$$i_K < \sqrt{7320/(2 \cdot (18 - 13.0825747))} \sim 27.28171 < 28.$$

It follows that if $p \mid i_K$, then $p \leq 23$. Searching up to height 21 would (presumably) allow us to remove 23, but this might take much longer.

For the results of our computations for all E of conductor ≤ 1000, see Section 3.6.2.

3.6. **Results of Computations.**

3.6.1. *Curves of Rank* 1. First we consider curves of rank 1. Recall from Conjecture 1.6 that we expect Ш to be trivial for all optimal rank 1 curves of conductor at most 1000.

Proposition 3.22. *Suppose (E, p) is a pair with E an optimal elliptic curve of conductor up to* 1000 *of rank* 1*. Let I be the greatest common divisor of $[E(K)_{/\,\mathrm{tor}} : \mathbb{Z}y_K]$ for the first four quadratic imaginary fields $K = \mathbb{Q}(\sqrt{D})$ that satisfy the Heegner hypothesis. If $p \mid I$, then*

$$p \mid 2 \cdot \#E(\mathbb{Q})_{\mathrm{tor}} \cdot \prod_{q \mid N} c_{E,q},$$

except if (E, p) is $(540B, 3)$ or $(756B, 3)$.

Proof. For each rank 1 curve E of conductor up to 1000 we perform the following computation.

1. Let R_E be the regulator of E, correct to precision at least 10^{-10}, which we look up in the `allbsd` table of [Crea].
2. List the first four discriminants $D = D_0, D_1, D_2, D_3$ such that $K = \mathbb{Q}(\sqrt{D})$ satisfies the Heegner hypothesis. For each $D = D_i$ do the following computation:
   - (a) Compute $L'(E,1)$ to some bounded precision ε, using $2\sqrt{N}+10$ terms. The bound ε is determined as explained in Section 2.2.
   - (b) Compute $L(E^D,1)$ to some bounded precision ε' using $2\sqrt{N}+10$ terms.
   - (c) Compute $\alpha = \sqrt{|D|}/(2\,\mathrm{Vol}(\mathbb{C}/\Lambda))$ to precision at least 10^{-10} using PARI.

(d) Using a simple implementation of classical interval arithmetic (in [Ste]) and the bounds above, we compute an interval in which the real number

$$\alpha \cdot L'(E,1) \cdot L'(E^D,1)/(\mathrm{Reg}_E/2)$$

must lie. If there is a unique integer in this interval, by Theorem 3.9 this must be the square of the index $[E(K) : \mathbb{Z}y_K]^2$. If there is no unique integer in this interval, we increase the precision of the computation of L' and L and repeat the above steps. In all cases in the range of our computation, we find a unique integer in the interval; as a double check on our calculations we verify that the integer is a perfect square.

□

Remark 3.23. For the curves 540B and 756B there is no 3-torsion, but there is a rational 3-isogeny. In each case we verified in addition that 3 divides the GCD of the indexes for at least the first 16 fields K that satisfy the Heegner hypothesis. Thus as in Remark 3.12, Conjecture 3.10 asserts that $9 \mid \#\text{Ш}(E/K)$ for the first sixteen K. This illustrates that not only Tamagawa numbers but also isogenies can be an obstruction to applying Kolyvagin's theorem to bound $\#\text{Ш}(E)$, even if the irreducibility hypothesis on $\overline{\rho}_{E,p}$ is removed.

Proposition 3.24. *Suppose E is a non-CM optimal curve of conductor ≤ 1000 and p is an odd prime such that $\overline{\rho}_{E,p}$ is irreducible but not surjective. If E has rank 0 then (E,p) is one of the following:* (245B,3), (338D,3), (352E,3), (608B,5), (675D,5), (675F,5), (704H,3), (722D,3), (726F,3), (800E,5), (800F,5), (864D,3), (864F,3), (864G,3), (864I,3). *If E has rank 1, then (E,p) is one of the following:* (245A,3), (338E,3), (352F,3), (608E,5), (675B,5), (675I,5), (704L,3), (722B,3), (726A,3), (800B,5), (800I,5), (864A,3), (864B,3), (864J,3), (864L,3). *There are no curves of rank ≥ 2 with the above property.*

Proof. Using Proposition 2.5 we make a list of pairs (E,p) such that $\overline{\rho}_{E,p}$ might not be surjective, and such that if (E,p) is not in this list, then $\overline{\rho}_{E,p}$ is surjective. Then using the program `allisog`, we compute for each curve E, a list of all degrees of isogenies emanating from E, and remove those pairs (E,p) for which p divides the degree of one of those isogenies. The curves listed above are the ones that remain. □

Remark 3.25. In Proposition 3.24, the non-surjective irreducible (E,p) come in pairs, one of rank 0 and one of rank 1 having the same conductor. Each pair of curves are related by a quadratic twist. This pattern is common, but does not always occur. For example, (1184F,3) and (1184H,3) are both of rank 0 and have non-surjective irreducible representation, and no curve of conductor 1184 and rank 1 has this property. Note that $1184 = 2^5 \cdot 37$ and 1184F and 1184H are quadratic twists of each other by -1.

Remark 3.26. Proposition 3.24 suggests that it is rare for $\overline{\rho}_{E,p}$ to be non-surjective yet irreducible. When this does occur, frequently $p^2 \mid N$, though not always. Continuing the computation to conductor 10000 we find that $p^2 \mid N$ about half the time in which $\overline{\rho}_{E,p}$ is non-surjective yet irreducible. This gives a sense of the extent to which Theorem 3.3 improves on Theorem 3.2.

Theorem 3.27. *Suppose (E,p) is a pair consisting of a rank 1 non-CM elliptic curve E of conductor ≤ 1000 and a prime p such that $\rho_{E,p}$ is irreducible and p does not divide any Tamagawa number of E. Then $\mathrm{BSD}(E,p)$ is true.*

Proof. By Theorem 3.31 we may assume that p is odd. The pairs that do not satisfy the Heegner point divisibility hypothesis in Proposition 3.22 are those in $S = \{(540B,3),(756B,3)\}$. However, both of these curves admit a rational 3-isogeny, so are excluded by the hypothesis of Theorem 3.27.

Let

$$\begin{aligned} T = \{&(245A,3),(338E,3),(352F,3),(608E,5),(675B,5),(675I,5),\\ &(704L,3),(722B,3),(726A,3),(800B,5),(800I,5),(864A,3),\\ &(864B,3),(864J,3),(864L,3)\}. \end{aligned}$$

Then Proposition 3.24, Theorem 1.7, and Theorem 3.2 together imply $\mathrm{BSD}(E,p)$ for all pairs as in the hypothesis of Theorem 3.27, except the pairs in $S \cup T$. Note that for each $(E,p) \in T$, we have $p^2 \mid N$, so Theorem 3.3 does not apply either. We eliminate the pairs

$$(245A,3),(338E,3),(352F,3),(608E,5),(704L,3),(864J,3),(864L,3)$$

from consideration because in each case $p \mid \prod c_\ell$.

For each $(E,p) \in T$ the representation $\overline{\rho}_{E,p}$ is irreducible and E does not have CM, so the hypothesis of Theorem 3.5 are satisfied. For the pairs

$$\{((245A,3),(338E,3),(352F,3),(608E,5),(704L,3),(864J,3),(864L,3)\}$$

we have $p \mid [E(K) : \mathbb{Z}y_K]$ for the first six Heegner K, but that is not a problem since we eliminated these pairs from consideration. For the remaining pairs, in each case we find a K such that $p \nmid [E(K) : \mathbb{Z}y_K] \cdot \mathrm{disc}(K)$, so Theorem 3.5 implies that $p \nmid \#\text{Ш}(E)$, so $\mathrm{BSD}(E,p)$ is true. □

3.6.2. *Curves of Rank* 0.

Proposition 3.28. *Suppose (E,p) is a pair with E an optimal elliptic curve of conductor ≤ 1000 of rank 0. Let I be the greatest common divisor of $[E(K)_{/\mathrm{tor}} : \mathbb{Z}y_K]$ as K varies over quadratic imaginary fields that satisfy the Heegner hypothesis. If $p \mid I$ and $\overline{\rho}_{E,p}$ is irreducible, then*

$$p \mid 2 \cdot \#E(\mathbb{Q})_{\mathrm{tor}} \cdot \prod_{q \mid N} c_{E,q},$$

except possibly for the curves in the following table:

E	$p \mid I$?	D used	E	$p \mid I$?	D used
258E	3	-983	777B	3	-215
378G	3	-47	780B	3,7	-191
594F	3	-359	819D	3,5	-404
600G	3	-71	850I	3	-151
612D	3	-359	858D	5, 7	-95
626B	3	-39	858K	7	-1031
658A	3	-31	900A	3	-71
676E	5	-23	906E	$p \leq 19$	-23
681B	3	-8	924A	5	-1679
735B	3	-479	978C	3	-431
738B	3	-23	980I	3	-671
742F	3, 5	-199			

In this table, the first column gives an elliptic curve, the second column gives the primes p (with $\overline{\rho}_{E,p}$ irreducible) that might divide the GCD *of indexes, and the third column gives the discriminant used to make this deduction.*

Proof. We use the methods described in Section 3.5.5, and precision bounds as in the proof of Proposition 3.22. In many cases we combined explicit computation of a Heegner point for one prime, with the bounding technique explained in Section 3.5.5, or only computed information using the bound.

For the curve 910E, we used four-descent via MAGMA to compute the point $(3257919871/16641, 133897822473008/2146689)$ on the -159 twist E^D, found using [Creb] that it generates $E^D(\mathbb{Q})$, and obtained an index that is a power of 2 and 3. Since 3 divides a Tamagawa number, we do not include 910E in our table. Likewise, for 930F and $D = -119$, we used MAGMA's four-descent commands to find a point of height ~ 85.3, and deduced that the only odd prime that divides the index is 11; since 11 is a Tamagawa number, we do not include 930F. Similar remarks apply for 966J with $D = -143$. We were unable to use 4-descent to find a generator for a twist of 906E1. (Fortunately, $906 = 2 \cdot 3 \cdot 151$, so Theorem 4.3 implies $\mathrm{BSD}(E, p)$ except for $p = 2, 3, 151$, and for our purposes we will only need that 151 does not divide the Heegner point index.) □

Remark 3.29. We could likely shrink the table in Proposition 3.28 further using MAGMA's four descent command. However, we will not need a smaller table for our ultimate application to the BSD conjecture (Theorem 4.4).

Theorem 3.30. *Suppose (E, p) is a pair with E a rank 0 non-CM curve of conductor ≤ 1000 and p a prime such that $\overline{\rho}_{E,p}$ is irreducible and p does not divide any Tamagawa number of E. Then* $\mathrm{BSD}(E, p)$ *is true except possibly if (E, p) appears in the table in the statement of Proposition 3.22, i.e., E appears in column 1 and p appears in the column directly to the right of p.*

Proof. The argument is similar to the proof of Theorem 3.27. By Theorem 3.31 we may assume that p is odd. Let S be the set of pairs (E, p) in the table in Proposition 3.22. Let

$$\begin{aligned} T = \{&(245B, 3), (338D, 3), (352E, 3), (608B, 5), (675D, 5), (675F, 5), \\ &(704H, 3), (722D, 3), (726F, 3), (800E, 5), (800F, 5), (864D, 3), \\ &(864F, 3), (864G, 3), (864I, 3)\}. \end{aligned}$$

Then Proposition 3.24, Theorem 1.7, and Theorem 3.2 together imply $\mathrm{BSD}(E,p)$ for all pairs as in the hypothesis of Theorem 3.27, except the pairs in $S \cup T$, since the representation $\overline{\rho}_{E,p}$ is surjective and we have verified that $p \nmid [E(K) : \mathbb{Z}y_K]$ for some K. We eliminate the pairs $(722D, 3)$ and $(726F, 3)$ from consideration because in each case $p \mid \prod c_\ell$.

For each $(E,p) \in T$ the representation $\overline{\rho}_{E,p}$ is irreducible and E does not have CM, so the hypotheses of Theorem 3.5 are satisfied. Next for each pair $(E,p) \in T$ except for $(722D, 3)$ and $(726F, 3)$, which we eliminated already, we find a K such that $p \nmid [E(K) : \mathbb{Z}y_K]$ and $\mathrm{disc}(K)$ is not divisible only be p. Theorem 3.5 implies that $p \nmid \#Ш(E)$, hence $\mathrm{BSD}(E,p)$ is true. □

3.6.3. *Two Descent.* In this section, we explain how descent computations imply that $\mathrm{BSD}(E,2)$ is true for curves of conductor $N \leq 1000$.

Theorem 3.31. *If E is an elliptic curve with $N \leq 1000$, then $\mathrm{BSD}(E,2)$ is true.*

Proof. According to Theorem 1.4, it suffices to prove the theorem for the set S of optimal elliptic curves with $N \leq 1000$. By doing an explicit 2-descent, Cremona computed $\mathrm{Sel}^{(2)}(E/\mathbb{Q})$ for every curve $E \in S$, as explained in [Cre97]. This implies that $Ш(E)[2]$ has order the predicted order of $Ш(E)[2^\infty]$ for all $E \in S$. Using MAGMA's `FourDescent` command, we compute $\mathrm{Sel}^{(4)}(E/\mathbb{Q})$ in the three cases in which $Ш(E)[2] \neq 0$, and find that $Ш(E)[4] = Ш(E)[2]$. By Theorem 1.7, it follows that $\mathrm{BSD}(E,2)$ is true for all $E \in S$. □

3.6.4. *Three Descent.* We sharpen Theorem 3.30 using Stoll's 3-descent package (see [Sto05]).

Proposition 3.32. *We have $3 \nmid \#Ш(E)$ for each of the curves listed in the Table in Proposition 3.28 with 3 in the second column and $\overline{\rho}_{E,3}$ irreducible, except for 681B where $\#Ш(E)[3^\infty] = 9$.*

Proof. We use Stoll's package [Sto05] to compute each of the Selmer groups

$$\mathrm{Sel}^{(3)}(E) \cong Ш(E)[3],$$

and obtain the claimed dimensions. When computing class groups in Stoll's package one must take care to not assume any conjectures (by slightly modifying the call to `ClassGroup` in `3descent.m`). Finally, that $Ш(E)[3^\infty] = 9$ follows by applying Theorem 3.2 with $K = \mathbb{Q}(\sqrt{-8})$, and noting that $\overline{\rho}_{E,3}$ is surjective and the index is exactly divisible by 3. □

4. The Kato Bound

Kato proved a theorem that bounds $Ш(E)$ from above when $L(E,1) \neq 0$.

Theorem 4.1 (Kato)**.** *Let E be an optimal elliptic curve over $\mathbb{Q}$ of conductor N, and let p be a prime such that $p \nmid 6N$ and $\rho_{E,p}$ is surjective. If $L(E,1) \neq 0$, then $Ш(E)$ is finite and*

$$\mathrm{ord}_p(\#Ш(E)) \leq \mathrm{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right).$$

This theorem follows from the existence of an "optimal" Kato Euler system (see [Kat04] and [MR04]) combined with a recent result of Matsuno [Mat03] on finite submodules of Selmer groups over $\mathbb{Z}_p$-extensions. For more details, look at the proof of [Rub98, Cor. 8.9] where one replaces an unknown module with the module Matsuno computes. See also [Gri05] for further discussion and recent results on lower bounds on Ш(E) that make use of optimal Kato Euler systems.

4.1. **Computations.** When $L(E,1) \neq 0$ the group Ш(E) is finite, so $\mathrm{ord}_p(\#Ш(E))$ is even. Thus if $\mathrm{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right)$ is odd, we conclude that

$$\mathrm{ord}_p(\#Ш(E)) \leq \mathrm{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right) - 1.$$

Lemma 4.2. *There are no pairs (E,p) that satisfy the conditions of Theorem 4.1 with $N \leq 1000$, such that*

$$\mathrm{ord}_p(\#Ш(E)_{\mathrm{an}}) < \mathrm{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right) - 1.$$

Proof. First we make a table of ratios $L(E,1)/\Omega_E$ for all curves of conductor $\leq$ 1000. For each of these with $L(E,1) \neq 0$, we factor the numerator of the rational number $L(E,1)/\Omega_E$. We then observe that the displayed inequality in the statement of the proposition does not occur. □

Theorem 4.3. *Suppose (E,p) is a pair such that $N \leq 1000$, $p \nmid 3N$, E is a non-CM elliptic curve of rank 0, and $\overline{\rho}_{E,p}$ is irreducible. Then* $\mathrm{BSD}(E,p)$ *is true.*

Proof. The statement for $p = 2$ follows from Theorem 3.31.

Let S be the set of pairs (E,p) as in the statement of Theorem 4.3 for which E is optimal and $p > 2$. By Theorem 1.7 it suffices to prove that $p \nmid \#Ш(E)$ for all $(E,p) \in S$. Using Proposition 2.5 with $A = 1000$, we compute for each rank 0 non-CM elliptic curve of conductor $N \leq 1000$, all primes $p \nmid 6N$ such that $\rho_{E,p}$ might not be surjective. This occurs for 53 pairs (E,p), with the E's all distinct. For these 53 pairs (E,p), we find that the representation $\overline{\rho}_{E,p}$ is reducible (since there is an explicit p isogeny listed in [Cre97]), except for the pair $(608B,5)$, for which $\overline{\rho}_{E,5}$ is irreducible.

Thus Theorem 4.1 implies that for each pair $(E,p) \in S$, except $(608B,5)$, we have the bound

$$\mathrm{ord}_p(\#Ш(E)) \leq \mathrm{ord}_p(L(E,1)/\Omega_E).$$

By Theorem 1.5, $\mathrm{ord}_p(\#Ш(E))$ is even, so Ш$(E)[p^\infty]$ is trivial whenever

$$\mathrm{ord}_p(L(E,1)/\Omega_E) \leq 1.$$

By Theorem 1.7, $\mathrm{ord}_p(\#Ш(E)_{\mathrm{an}}) = 0$ for all $p \geq 5$. Thus by Lemma 4.2, there are no pairs $(E,p) \in S$ with $\mathrm{ord}_p(L(E,1)/\Omega_E) > 1$ (since otherwise some $\mathrm{ord}_p(\#Ш(E)_{\mathrm{an}})$ would be nontrivial).

Finally, note that we dealt with $(608B,5)$ in Lemma 3.4 using Cha's theorem. This completes the proof. □

4.2. **Combining Kato and Kolyvagin.** In this section we bound Ш(E) for rank 0 curves by combining the Kato and Kolyvagin approaches.

Theorem 4.4. *Suppose E is a non-CM elliptic curve of rank 0 with conductor $N \leq 1000$, that $\overline{\rho}_{E,p}$ is irreducible, and that p does not divide any Tamagawa number of E. Then* $\mathrm{BSD}(E,p)$ *is true.*

Proof. Let (E,p) be as in the hypothesis to Theorem 4.4. By Theorem 4.3, $\mathrm{BSD}(E,p)$ is true, except possibly if $p \mid 3N$. Theorem 3.30 implies $\mathrm{BSD}(E,p)$, except if (E,p) appear in the Table of Proposition 3.28. Inspecting the table, we see that whenever a prime $p \geq 5$ is in the second column, then p does not divide the conductor N of E. This proves $\mathrm{BSD}(E,p)$ for $p \geq 5$.

Let E be the curve 681B. Then $\mathrm{BSD}(E,3)$ asserts that $\#\text{Ш}(E)[3^\infty] = 9$. It follows from [CM00] and [AS05, App.], or from the 3-descent of Section 3.6.4 that $\#\text{Ш}(E)[3] = 9$. Also, $\overline{\rho}_{E,3}$ is surjective and for $D = -8$ we have $\mathrm{ord}_3([E(K) : \mathbb{Z}y_K]) = 1$, so $\#\text{Ш}(E)[3^\infty] \mid 9$, which proves $\mathrm{BSD}(E,3)$.

Finally Proposition 3.32 implies $\mathrm{BSD}(E,3)$ for the remaining curves, which proves the theorem. □

5. Proof of Theorem 3.5

In this section we prove Theorem 3.5. Assume that E and K are as in the statement of the theorem, and assume that $\mathrm{ord}_{s=1} L(E/K,1) = 1$. Then the Heegner point y_K has infinite order. Kolyvagin ([Kol90]) shows that in this case the rank of $E(K)$ is 1 and $\text{Ш}(E/K)$ is finite.

5.1. **Gross's Account.**

Gross's account of Kolyvagin's work in [Gro91] contains a proof that if E does not have complex multiplication, then

$$\#\text{Ш}(E/K) \mid t \cdot [E(K) : \mathbb{Z}y_K]^2,$$

where t is an integer divisible only by primes p such that the representation $\overline{\rho}_{E,p} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(E[p])$ is not surjective. Gross makes no claim about the powers of primes that divide t (though Kolyvagin does in his papers). Our Theorem 3.5 provides a better bound, which removes the condition that E not have CM, and relaxes the surjectivity hypothesis on $\overline{\rho}_{E,p}$.

Gross uses surjectivity of $\overline{\rho}_{E,p}$ as a hypothesis only to prove the following two propositions. We will prove analogous propositions below, but under weaker hypotheses, which yields our claimed improvement to [Gro91].

Proposition 5.1 (Gross)**.** *Assume that $\overline{\rho}_{E,p}$ is surjective. For any integer n, let K_n be the ring class field of K of conductor n. The restriction map*

$$\mathrm{Res} : \mathrm{H}^1(K, E[p]) \to \mathrm{H}^1(K_n, E[p])^{\mathrm{Gal}(K_n/K)}$$

is an isomorphism.

Proof. That $\overline{\rho}_{E,p}$ is surjective implies that $E(K_n)[p] = 0$. The inflation-restriction-transgression sequence then implies that Res is an isomorphism. □

Gross also uses surjectivity of $\overline{\rho}_{E,p}$ when proving that the pairing

$$\mathrm{H}^1(K, E[p]) \otimes \mathrm{Gal}(K(E[p])/K) \to E[p]$$

is nondegenerate, as follows. Setting $L = K(E[p])$, we have that

$$\mathrm{H}^1(L/K, E(L)[p]) \to \mathrm{H}^1(K, E[p]) \to \mathrm{H}^1(L, E[p])^{\mathrm{Gal}(L/K)} \to \mathrm{H}^2(L/K, E(L)[p]).$$

To see that the pairing is nondegenerate, it suffices to know that the groups $\mathrm{H}^i(L/K, E[p])$ vanish for $i = 1, 2$. This is because we have

$$\mathrm{H}^1(L, E[p])^{\mathrm{Gal}(L/K)} = \mathrm{Hom}(G_L, E[p])^{\mathrm{Gal}(L/K)}$$

since $K(E[p]) \subset L$ and the pairing is $(c, \sigma) = \mathrm{res}_L(c)(\sigma)$. Thus nondegeneracy of the pairing then follows from the following proposition.

Proposition 5.2 (Gross)**.** *Let E be an elliptic curve over a number field K and let p be a prime. Assume that $\overline{\rho}_{E,p}$ is surjective. Then*

$$\mathrm{H}^i(K(E[p])/K, E[p]) = 0 \qquad \textit{for all} \quad i \geq 1.$$

Proof. As above set $L = K(E[p])$. The surjectivity of $\overline{\rho}_{E,p}$ implies that

$$G = \mathrm{Gal}(L/K) \cong \mathrm{Gal}(\mathbb{Q}(E[p])/\mathbb{Q}) \cong \mathrm{GL}_2(\mathbb{F}_p).$$

If $Z \subset G$ is the subgroup corresponding to the scalars in $\mathrm{GL}_2(\mathbb{F}_p)$, then the Hochschild-Serre spectral sequence implies that

$$\mathrm{H}^i(G/Z, \mathrm{H}^j(Z, E(L)[p])) \Longrightarrow \mathrm{H}^{i+j}(L/K, E(L)[p]).$$

Since $\#Z = p-1$, and $E(L)[p]$ is a p-group, and p is odd, we have $\mathrm{H}^j(Z, E(L)[p]) = 0$ for all $j \geq 1$. Also, since p is odd, and non-identity scalars have no nonzero fixed points, $\mathrm{H}^0(Z, E(L)[p]) = 0$. Thus for all i, j we have

$$\mathrm{H}^i(G/Z, \mathrm{H}^j(Z, E(L)[p])) = 0,$$

which implies that the groups $\mathrm{H}^{i+j}(L/K, E(L)[p])$ are all 0. □

Thus our goal is to prove analogues of Propositions 5.1–5.2 under hypotheses that are more amenable to computation.

5.2. **Preliminaries.**

Lemma 5.3. *The determinant of $\overline{\rho}_{E,p}$ is the cyclotomic character, hence $\det(\overline{\rho}_{E,p})$ is surjective.*

Proof. For the convenience of the reader, we give a proof here. The Weil pairing induces an isomorphism of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-modules $E[p] \wedge E[p] \cong \mu_p$. Fix a basis $\{e_1, e_2\}$ of $E[p]$, with respect to which $\rho_p(\sigma)$ has the form $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. Then

$$\sigma(e_1 \wedge e_2) = (ae_1 + ce_2) \wedge (be_1 + de_2) = \det(\rho_p(\sigma)) \cdot e_1 \wedge e_2.$$

It follows that composition with the determinant gives the cyclotomic character (i.e., the action of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on μ_p), which is surjective since no nontrivial roots of unity lie in $\mathbb{Q}$. □

We will choose the quadratic field K to be linearly disjoint from $\mathbb{Q}(E[p])$, so $\mathrm{Gal}(K(E[p])/K) \cong \mathrm{Gal}(\mathbb{Q}(E[p])/\mathbb{Q})$. Thus, for our application, it will suffice to show vanishing of $\mathrm{H}^i(\mathbb{Q}(E[p])/\mathbb{Q}, E[p])$, for $i > 0$.

Let $G \subseteq \mathrm{Gal}(\mathbb{Q}(E[p])/\mathbb{Q})$ be the image of $\overline{\rho}_{E,p}$. If $p \nmid \#G$, then for $i > 0$ we have $\mathrm{H}^i(G, E[p]) = 0$ since $E[p]$ is a p-group. Therefore we may assume that $p \mid \#G$. By [Ser72, Prop. 15], the image G either contains $\mathrm{SL}_2(\mathbb{F}_p)$ or is contained in a Borel subgroup of $\mathrm{GL}_2(\mathbb{F}_p)$. If G contains $\mathrm{SL}_2(\mathbb{F}_p)$ then properties of the Weil pairing imply that

$$\det : G \to \mathbb{F}_p^*$$

is surjective, so $G = \mathrm{GL}_2(\mathbb{F}_p)$. In this case, we already know Propositions 5.1–5.2.

Lemma 5.4. *Assume that G is contained in a Borel subgroup of $\mathrm{GL}_2(\mathbb{F}_p)$. Moreover, assume that there is a basis of $E[p]$ so that G acts as $\left(\begin{smallmatrix} \chi & * \\ 0 & \psi \end{smallmatrix}\right)$ where χ and ψ are nontrivial characters. Then $\mathrm{H}^i(G, E[p]) = 0$.*

Proof. Let $W = \left(\begin{smallmatrix} 1 & * \\ 0 & 1 \end{smallmatrix}\right)$ be the unique p-Sylow subgroup of $\left(\begin{smallmatrix} * & * \\ 0 & * \end{smallmatrix}\right) \subset \mathrm{GL}_2(\mathbb{F}_p)$. We may assume $W \subset G$, for otherwise G has order prime to p, and the cohomology vanishes.

We begin by explicitly computing $\mathrm{H}^j(W, E[p])$ using the fact that W is cyclic, generated by $w = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. Recall that for cyclic groups we can compute cohomology using the projective resolution

$$\cdots \to \mathbb{Z}[W] \to \mathbb{Z}[W] \to \mathbb{Z} \to 0$$

where the boundary maps alternate between multiplication by $w - 1$ and $\mathrm{Norm} = \sum_{i=0}^{p-1} w^i$.

Then we see that

$$\mathrm{H}^j(W, E[p]) = \begin{cases} \mathrm{Ker}(1-w)/\,\mathrm{Im}(\mathrm{Norm}(w)) = \langle \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right) \rangle\,, & \text{if } j \text{ is even,} \\ \mathrm{Ker}(\mathrm{Norm}(w))/\,\mathrm{Im}(1-w) = \mathbb{F}_p^2/\,\langle \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right) \rangle\,, & \text{if } j \text{ is odd.} \end{cases}$$

Since χ and ψ are nontrivial by assumption, the G/W-invariants for both of these groups are trivial. Thus $\mathrm{H}^j(W, E[p])^{G/W} = 0$ for $j \geq 0$. Consider the Hochschild-Serre spectral sequence

$$\mathrm{H}^i(G/W, \mathrm{H}^j(W, E[p])) \Rightarrow \mathrm{H}^{i+j}(G, E[p]).$$

For $i > 0$, since $\#(G/W)$ is prime to p, and $\mathrm{H}^j(W, E[p])$ is a p-group for all j, the group $\mathrm{H}^i(G/W, \mathrm{H}^j(W, E[p]))$ is trivial. But when $i = 0$ we have just computed that $\mathrm{H}^i(G/W, \mathrm{H}^j(W, E[p])) = \mathrm{H}^j(W, E[p])^{G/W} = 0$, so the entire spectral sequence is trivial, and we conclude that $\mathrm{H}^n(G, E[p]) = 0$ for all $n \geq 0$. □

5.3. Analogue of Proposition 5.1.

In this section we verify that $\mathrm{H}^i(K_n/K, E(K_n)[p]) = 0$ under a simple condition on p-torsion over K.

Proposition 5.5. *Let E be an elliptic curve over $\mathbb{Q}$ and K be a quadratic imaginary extension of $\mathbb{Q}$. Assume that p is a prime with $p \nmid \#E(K)_{\mathrm{tor}}$ and if $p = 3$ assume that $K \neq \mathbb{Q}(\zeta_3)$. Then for every finite abelian extension L of K we have*

$$\mathrm{H}^i(L/K, E(L)[p]) = 0 \qquad \textit{for all} \quad i \geq 1.$$

Proof. Write the abelian group $\mathrm{Gal}(L/K)$ as a direct sum $P \oplus P'$, where P is its Sylow p-subgroup, so $p \nmid \#P'$. First we show that the subgroup of $E(L)[p]$ invariant under P' is trivial. Let $G = \mathrm{Gal}(L/K)/H$, where H is the subgroup of $\mathrm{Gal}(L/K)$ that acts trivially on $E(L)[p]$. Thus $G \subset \mathrm{Aut}(E(L)[p])$.

Case 1. If $p \nmid \#G$, then $P \subseteq H$, so P' surjects onto G. There is no nonzero element of $E(L)[p]$ invariant under $\mathrm{Gal}(L/K)$ by our assumption that $p \nmid \#E(K)$, so the same holds for P'.

Case 2. If $p \mid \#G$, we cannot have $E(L)[p] = \mathbb{F}_p$, since $\mathbb{F}_p$ has automorphism group isomorphic to $\mathbb{F}_p^*$, of order $p - 1$, but $G \subset \mathrm{Aut}(E(L)[p])$ and $\#G > p - 1$. Thus, $E(L)[p]$ is the full p-torsion subgroup of E, and we identify G with a subgroup of $\mathrm{GL}_2(\mathbb{F}_p)$ acting on $E(L)[p] = \mathbb{F}_p^2$.

We can choose a basis of $\mathbb{F}_p^2$ so that G contains the subgroup generated by $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. Since G is abelian, it must be contained in the normalizer of this subgroup, so $G \subseteq \{\left(\begin{smallmatrix} a & b \\ 0 & a \end{smallmatrix}\right) : a \in \mathbb{F}_p^*, b \in \mathbb{F}_p\}$. We claim that G contains an element with $a \neq 1$. Since $E[p] = E(L)[p]$, the representation $\mathrm{Gal}(\overline{\mathbb{Q}}/K) \to \mathrm{Aut}(E[p])$ factors through $\mathrm{Gal}(L/K)$. The determinant of $\overline{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(E[p])$ is surjective onto $\mathbb{F}_p^*$, and $[K : \mathbb{Q}] = 2$, so the character $\mathrm{Gal}(\overline{K}/K) \to \mathbb{F}_p^*$ has image of index at most 2 in

F_p^*. That is, it contains at least $(p-1)/2$ elements, the squares in $\mathbb{F}_p^*$. Thus, for $p > 3$, the group G contains an element with non-trivial determinant having the form $\left(\begin{smallmatrix} a & b \\ 0 & a \end{smallmatrix}\right)$ with $a \neq 1$. Now, $\left(\begin{smallmatrix} a & b \\ 0 & a \end{smallmatrix}\right)^p = \left(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}\right)$ since $a, b \in \mathbb{F}_p$, so $\mathrm{Gal}(L/K)$ contains an element that acts as a nontrivial scalar. Since the group of scalars in $\mathrm{GL}_2(\mathbb{F}_p)$ has $p-1)$ elements, this nontrivial scalar must be in P', so $E(L)[p]^{P'} = 0$.

We have shown in each case that $E(L)[p]^{P'} = 0$. Because $p \nmid \#P'$ we have $\mathrm{H}^i(P', E(L)[p]) = 0$ for all $i \geq 1$, so for each $i \geq 1$ there is an exact inflation-restriction sequence

$$0 \to \mathrm{H}^i(P, E(L)[p]^{P'}) \to \mathrm{H}^i(L/K, E(L)[p]) \to \mathrm{H}^i(P', E(L)[p]).$$

The first group vanishes since $E(L)[p]^{P'} = 0$, and the third group vanishes as mentioned above. We conclude that $\mathrm{H}^i(L/K, E(L)[p]) = 0$, as claimed.

Finally we deal with the case $p = 3$. The only situation in the above argument where $p = 3$ is relevant is in Case 2, when $3 \mid \#G$. Our hypothesis that $K \neq \mathbb{Q}(\zeta_3)$ implies that $\det(\rho_{E,3}) : \mathrm{Gal}(\overline{K}/K) \to \mathbb{F}_3^*$ is surjective, since the fixed field of the kernel of the mod 3 cyclotomic character is $\mathbb{Q}(\zeta_3)$. If we are in Case 2, then the image of $\mathrm{Gal}(\overline{K}/K)$ in $\mathrm{GL}_2(\mathbb{F}_3)$ is contained in $\{\left(\begin{smallmatrix} a & b \\ 0 & a \end{smallmatrix}\right) : a \in \mathbb{F}_p^*, b \in \mathbb{F}_p\}$. Since no upper triangular matrix has determinant 2, this contradicts surjectivity of $\det(\rho_{E,3})$. Thus our hypothesis that $K \neq \mathbb{Q}(\zeta_3)$ implies that Case 2 does not occur. □

Corollary 5.6. *Let E be an elliptic curve with $p \nmid \#E(K)_{\mathrm{tor}}$, where $p > 3$ or, if $p = 3$, $K \neq \mathbb{Q}(\zeta_3)$. Let K_n be the ring class field of conductor n of K. Then $\mathrm{H}^i(K_n/K, E(K_n)[p]) = 0$ for all $i \geq 1$.*

Lemma 5.7. *Let E be an elliptic curve over $\mathbb{Q}$, let K be a quadratic imaginary extension, and let $p \mid \#E(K)_{\mathrm{tor}}$ an odd prime. If $p = 3$, assume $K \neq \mathbb{Q}(\zeta_3)$. Then $\overline{\rho}_{E,p}$ is reducible.*

Proof. Let $P \in E(K)[p]$ be nonzero, and let τ be a lift of the generator of $\mathrm{Gal}(K/\mathbb{Q})$ to $G_{\mathbb{Q}}$. If τP is a multiple of P, then the one-dimensional subspace of $E[p]$ generated by P is $G_{\mathbb{Q}}$-stable, so $\overline{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(E[p])$ is is reducible. If τP is not a multiple of P, then P and τP generate all of $E[p]$. Since $\tau P \in E(K)$, we have $E(K)[p] = E(\overline{\mathbb{Q}})[p]$. Because the Weil pairing in nondegenerate we have $\mu_p \subset K$. This is a contradiction by our hypothesis on K and p. Since $p > 3$, this is a contradiction. □

5.4. **Analogue of Proposition 5.2.** In this section we show how vanishing of $\mathrm{H}^i(\mathbb{Q}(E[p])/\mathbb{Q}, E[p])$ follows from a statement about torsion and rational isogenies.

Note that E has no $\mathbb{Q}$-rational p-isogeny if and only if $\overline{\rho}_{E,p}$ is irreducible.

Proposition 5.8. *If p is an odd prime and E has no $\mathbb{Q}$-rational p-isogeny, then $\mathrm{H}^i(\mathbb{Q}(E[p])/\mathbb{Q}, E[p]) = 0$ for all $i > 0$.*

Proof. Our hypothesis that E has no $\mathbb{Q}$-rational p-isogeny implies that $\overline{\rho}_{E,p}$ is irreducible. As we already noted, the problem reduces to the case when either G is contained in a Borel subgroup or $G = \mathrm{GL}_2(\mathbb{F}_p)$. The latter case follows from Proposition 5.2. The former case contradicts the hypothesis since the module $E[p]$ is reducible as a module over a Borel subgroup. □

For the above result, we used the irreducibility of the representation to deal with the case when G was contained in a Borel subgroup. The following proposition completes the proof of the general case:

Proposition 5.9. *Suppose p is an odd prime and that $E(\mathbb{Q})[p] = 0$ and for all elliptic curves E' that are p-isogenous to E over $\mathbb{Q}$ we have $E'(\mathbb{Q})[p] = 0$. Then*

$$\mathrm{H}^i(\mathbb{Q}(E[p])/\mathbb{Q}, E[p]) = 0 \qquad \text{for all} \qquad i > 0.$$

Proof. If E admits no p-isogeny, then Proposition 5.8 implies the required vanishing. Thus E admits a rational p-isogeny, so $E[p]$ is reducible, and $G = \mathrm{Im}(\overline{\rho}_{E,p})$ is contained in a Borel subgroup. In particular, for some basis of $E[p]$, the image G acts as $\left(\begin{smallmatrix} \chi & * \\ 0 & \psi \end{smallmatrix}\right)$ for characters χ and ψ. If both χ and ψ are nontrivial, then Lemma 5.4 implies the proposition and we are done. Thus assume that either χ or ψ is trivial.

First suppose that χ is trivial. Then all matrices of the above form fix $\left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$. Therefore there is a point of $E[p]$ fixed by the action of G, which contradicts the assumption that $E(\mathbb{Q})[p] = 0$.

Next suppose that ψ is trivial. Matrices of the above form preserve the line generated by $\left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$, so this line forms a $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-stable subspace of $E[p]$. In particular, there exists an isogeny over $\mathbb{Q}$ to a curve E' having this line as kernel. The image under this isogeny of the line generated by $\left(\begin{smallmatrix} 0 \\ 1 \end{smallmatrix}\right)$ is a 1-dimensional subspace of $E'[p]$, and since $\psi = 1$, $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts trivially on this subspace (we have an isomorphism of Galois modules $E/\left\langle \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right) \right\rangle \cong E'$). Thus, $E'(\mathbb{Q})[p]$ is nontrivial, contradicting our assumption.

The Manin Constant

Amod Agashe, Kenneth Ribet and William A. Stein

Abstract: The Manin constant of an elliptic curve is an invariant that arises in connection with the conjecture of Birch and Swinnerton-Dyer. One conjectures that this constant is 1; it is known to be an integer. After surveying what is known about the Manin constant, we establish a new sufficient condition that ensures that the Manin constant is an *odd* integer. Next, we generalize the notion of the Manin constant to certain abelian variety quotients of the Jacobians of modular curves; these quotients are attached to ideals of Hecke algebras. We also generalize many of the results for elliptic curves to quotients of the new part of $J_0(N)$, and conjecture that the generalized Manin constant is 1 for newform quotients. Finally an appendix by John Cremona discusses computation of the Manin constant for all elliptic curves of conductor up to 130000.

1. Introduction

Let E be an elliptic curve over $\mathbf{Q}$, and and let N be the conductor of E. By [BCDT01], we may view E as a quotient of the modular Jacobian $J_0(N)$. After possibly replacing E by an isogenous curve, we may assume that the kernel of the map $J_0(N) \to E$ is connected, i.e., that E is an *optimal* quotient of $J_0(N)$.

Let ω be the unique (up to sign) rational 1-form on a minimal Weierstrass model of E over $\mathbf{Z}$ that restricts to a nowhere-vanishing 1-form on the smooth locus. The pullback of ω is a rational multiple of the differential associated to the normalized new cuspidal eigenform $f_E \in S_2(\Gamma_0(N))$ associated to E. The Manin constant c_E of is E is the absolute value of this rational multiple. The Manin constant plays a role in the conjecture of Birch and Swinnerton-Dyer (see, e.g., [GZ86, p. 310]) and in work on modular parametrizations (see [Ste89, SW04, Vat05]). It is known that the Manin constant is an integer; this fact is important to Cremona's computations of elliptic curves (see [Cre97, pg. 45]), and algorithms

for computing special values of elliptic curve L-functions. Manin conjectured that $c_E = 1$. In Section 2, we summarize known results about c_E, and give the new result that $2 \nmid c_E$ if 2 is not a congruence prime and $4 \nmid N$.

In Section 3, we generalize the definition of the Manin constant and many of the results mentioned so far to optimal quotients of $J_0(N)$ and $J_1(N)$ of any dimension associated to ideals of the Hecke algebra. The generalized Manin constant comes up naturally in studying the conjecture of Birch and Swinnerton-Dyer for such quotients (see [AS05, §4]), which is our motivation for studying the generalization. We state what we can prove about the generalized Manin constant, and make a conjecture that the constant is also 1 for quotients associated to newforms. The proofs of the theorems stated in Section 3 are in Section 4. Section 5 is an appendix written by J. Cremona about computational verification that the Manin constant is 1 for many elliptic curves.

Acknowledgments. The authors are grateful to A. Abbes, K. Buzzard, R. Coleman, B. Conrad, B. Edixhoven, A. Joyce, L. Merel, and R. Taylor for discussions and advice regarding this paper. The authors wish to thank the referee for helpful comments and suggestions.

2. Optimal Elliptic Curve Quotients

Let N be a positive integer and let $X_0(N)$ be the modular curve over $\mathbf{Q}$ that classifies isomorphism classes of elliptic curves with a cyclic subgroup of order N. The Hecke algebra $\mathbf{T}$ of level N is the subring of the ring of endomorphisms of $J_0(N) = \mathrm{Jac}(X_0(N))$ generated by the Hecke operators T_n for all $n \geq 1$. Suppose f is a newform of weight 2 for $\Gamma_0(N)$ with integer Fourier coefficients, and let I_f be kernel of the homomorphism $\mathbf{T} \to \mathbf{Z}[\ldots, a_n(f), \ldots]$ that sends T_n to $a_n(f)$. Then the quotient $E = J_0(N)/I_f J_0(N)$ is an elliptic curve over $\mathbf{Q}$. We call E the *optimal quotient* associated to f. Composing the embedding $X_0(N) \hookrightarrow J_0(N)$ that sends x to $(\infty) - (x)$ with the quotient map $J_0(N) \to E$, we obtain a surjective morphism of curves $\phi_E : X_0(N) \to E$. The *modular degree* m_E of E is the degree of ϕ_E.

Let $E_{\mathbf{Z}}$ denote the Néron model of E over $\mathbf{Z}$. A general reference for Néron models is [BLR90]; for the special case of elliptic curves, see, e.g., [Sil92, App. C, §15], and [Sil94]. Let ω be a generator for the rank 1 $\mathbf{Z}$-module of invariant differential 1-forms on $E_{\mathbf{Z}}$. The pullback of ω to $X_0(N)$ is a differential $\phi_E^*\omega$ on $X_0(N)$. The newform f defines another differential $2\pi i f(z)dz = f(q)dq/q$ on $X_0(N)$. Because the action of Hecke operators is compatible with the map $X_0(N) \to E$, the differential $\phi_E^*\omega$ is a $\mathbf{T}$-eigenvector with the same eigenvalues as $f(z)$, so by [AL70] we have $\phi_E^*\omega = c \cdot 2\pi i f(z)dz$ for some $c \in \mathbf{Q}^*$ (see also

[Man72, §5]). The *Manin constant* c_E of E is the absolute value of the rational number c defined above.

The following conjecture is implicit in [Man72, §5].

Conjecture 2.1 (Manin)**.** *We have* $c_E = 1$*.*

Significant progress has been made towards this conjecture. In the following theorems, p denotes a prime and N denotes the conductor of E.

Theorem 2.2 (Edixhoven [Edi91, Prop. 2])**.** *The constant* c_E *is an integer.*

Edixhoven proved this using an integral q-expansion map, whose existence and properties follow from results in [KM85]. We generalize his theorem to quotients of arbitrary dimension in Theorem 3.4.

Theorem 2.3 (Mazur, [Maz78, Cor. 4.1])**.** *If* $p \mid c_E$*, then* $p^2 \mid 4N$*.*

Mazur proved this by applying theorems of Raynaud about exactness of sequences of differentials, then using the "q-expansion principle" in characteristic p and a property of the Atkin-Lehner involution. We generalize Mazur's theorem in Corollary 3.7.

The following two results refine the above results at $p = 2$.

Theorem 2.4 (Raynaud [AU96, Prop. 3.1])**.** *If* $4 \mid c_E$*, then* $4 \mid N$*.*

Theorem 2.5 (Abbes-Ullmo [AU96, Thm. A])**.** *If* $p \mid c_E$*, then* $p \mid N$*.*

We generalize Theorem 2.4 in Theorem 3.10. However, it is not clear if Theorem 2.5 generalizes to dimension greater than 1. It would be fantastic if the theorem could be generalized. It would imply that the Manin constant is 1 for newform quotients A_f of $J_0(N)$, with N odd and square free, which be useful for computations regarding the conjecture of Birch and Swinnerton-Dyer.

B. Edixhoven also has unpublished results (see [Edi89]) which assert that the only primes that can divide c_E are 2, 3, 5, and 7; he also gives bounds that are independent of E on the valuations of c_E at 2, 3, 5, and 7. His arguments rely on the construction of certain stable integral models for $X_0(p^2)$.

See Section 5 for more details about the following computation:

Theorem 2.6 (Cremona)**.** *If E is an optimal elliptic curve over* $\mathbf{Q}$ *with conductor at most* 130000*, then* $c_E = 1$*.*

To the above list of theorems we add the following:

Theorem 2.7. *If* $p \mid c_E$ *then* $p^2 \mid N$ *or* $p \mid m_E$*.*

This theorem is a special case of Theorem 3.11 below. In view of Theorem 2.3, our new contribution is that if m_E is odd and $\mathrm{ord}_2(N) = 1$, then c_E is odd. This hypothesis is *very stringent*—of the optimal elliptic curve quotients of conductor ≤ 120000, only 56 of them satisfy the hypothesis.

3. Quotients of arbitrary dimension

For $N \geq 4$, let Γ a subgroup of $\Gamma_1(N)$ that contains $\Gamma_0(N)$, let X be the modular curve over $\mathbf{Q}$ associated to Γ, and let J be the Jacobian of X. Let I be a *saturated* ideal of the corresponding Hecke algebra $\mathbf{T}$, so $\mathbf{T}/I$ is torsion free. Then $A = A_I = J/IJ$ is an optimal quotient of J.

For a newform $f = \sum a_n(f)q^n \in S_2(\Gamma)$, consider the ring homomorphism $\mathbf{T} \to \mathbf{Z}[\ldots, a_n(f), \ldots]$ that sends T_n to $a_n(f)$. The kernel $I_f \subset \mathbf{T}$ of this homomorphism is a saturated prime ideal of $\mathbf{T}$. The *newform quotient* A_f associated to f is the quotient J/I_fJ. Shimura introduced A_f in [Shi73] where he proved that A_f is an abelian variety over $\mathbf{Q}$ of dimension equal to the degree of the field $\mathbf{Q}(\ldots, a_n(f), \ldots)$. He also observed that there is a natural map $\mathbf{T} \to \mathrm{End}(A_f)$ with kernel I_f.

For the rest of this section, fix a quotient A associated to a saturated ideal I of $\mathbf{T}$; note that A may or may not be attached to a newform.

3.1. Generalization to quotients of arbitrary dimension.

If R is a subring of $\mathbf{C}$, let $S_2(R) = S_2(\Gamma; R)$ denote the $\mathbf{T}$-submodule of $S_2(\Gamma; \mathbf{C})$ of modular forms whose Fourier expansions have all coefficients in R.

Lemma 3.1. *The Hecke operators leave $S_2(R)$ stable.*

Proof. If $\Gamma = \Gamma_0(N)$, then by the explicit description of the Hecke operators on Fourier expansions (e.g., see [DI95, Prop. 3.4.3]), it is clear that the Hecke operators leave $S_2(R)$ stable. For a general Γ, by [DI95, (12.4.1)], one just has to check in addition that the diamond operators also leave $S_2(R)$ stable, which in turn follows from [DI95, Prop. 12.3.11]. □

Lemma 3.2. *We have $S_2(R) \cong S_2(\mathbf{Z}) \otimes R$.*

Proof. This is [DI95, Thm. 12.3.2] when our spaces $S_2(R)$ and $S_2(\mathbf{Z})$ are replaced by their algebraic analogues (see [DI95, pg. 111]). Our spaces and their algebraic analogues are identified by the natural q-expansion maps according to [DI95, Thm. 12.3.7]. □

If B is an abelian variety over $\mathbf{Q}$ and S is a Dedekind domain with field of fractions $\mathbf{Q}$, then we denote by B_S the Néron model of B over S; also, for ease of notation, we will abbreviate $H^0(B_S, \Omega^1_{B_S/S})$ by $H^0(B_S, \Omega^1_{B/S})$.

The inclusion $X \hookrightarrow J$ that sends the cusp ∞ to 0 induces an isomorphism

$$H^0(X, \Omega^1_{X/\mathbf{Q}}) \cong H^0(J, \Omega^1_{J/\mathbf{Q}}).$$

Let ϕ_2 be the optimal quotient map $J \to A$. Then ϕ_2^* induces an inclusion $\psi : H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}) \hookrightarrow H^0(J, \Omega^1_{J/\mathbf{Q}})[I] \cong S_2(\mathbf{Q})[I]$, and we have the following commutative diagram:

$$\begin{tikzcd}
H^0(A, \Omega^1_{A/\mathbf{Q}}) \arrow[r, hook, "\cong"] & H^0(J, \Omega^1_{J/\mathbf{Q}})[I] \arrow[r, "\cong"] & S_2(\mathbf{Q})[I] \\
H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}) \arrow[u, hook] \arrow[urr, hook, "\psi"'] & & S_2(\mathbf{Z})[I] \arrow[u, hook]
\end{tikzcd}$$

Definition 3.3. The *Manin constant* of A is the (lattice) index

$$c_A = [S_2(\mathbf{Z})[I] : \psi(H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}))].$$

Theorem 3.4 below asserts that $c_A \in \mathbf{Z}$, so we may also consider the Manin module of A, which is the quotient $M = S_2(\mathbf{Z})[I]/\psi(H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}))$, and the Manin ideal of A, which is the annihilator of M in $\mathbf{T}$.

If A is an elliptic curve, then c_A is the usual Manin constant. The constant c as defined above was also considered by Gross [Gro82, 2.5, p.222] and Lang [Lan91, III.5, p.95]. The constant c_A was defined for the winding quotient in [Aga99], where it was called the generalized Manin constant. A Manin constant is defined in the context of $\mathbf{Q}$-curves in [GL01].

3.2. **Motivation: connection with the conjecture of Birch and Swinnerton-Dyer.** On a Néron model, the global differentials are the same as the invariant differentials, so $H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}})$ is a free $\mathbf{Z}$-module of rank $d = \dim(A)$. The *real measure* Ω_A of A is the measure of $A(\mathbf{R})$ with respect to the volume given by a generator of $\bigwedge^d H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}) \simeq \mathrm{H}^0(A_{\mathbf{Z}}, \Omega^d_{A_{\mathbf{Z}}/\mathbf{Z}})$. This quantity is of interest because it appears in the conjecture of Birch and Swinnerton-Dyer, which expresses the ratio $L^{(r)}(A,1)/\Omega_A$, in terms of arithmetic invariants of A, where $r = \mathrm{ord}_{s=1} L(A,s)$ (see, e.g., [Lan91, Chap. III, §5] and [AS05, §2.3]).

If we take a $\mathbf{Z}$-basis of $S_2(\mathbf{Z})[I]$ and take the inverse image via the top chain of arrows in the commutative diagram above, we get a $\mathbf{Q}$-basis of $H^0(A, \Omega^1_{A/\mathbf{Q}})$; let Ω'_A denote the volume of $A(\mathbf{R})$ with respect to the wedge product of the elements in the latter basis (this is independent of the choice of the former basis). In doing calculations or proving formulas regarding the ratio in the Birch and Swinnerton-Dyer conjecture mentioned above, it is easier to work with the volume Ω'_A instead of working with Ω_A. If one works with the easier-to-compute volume Ω'_A instead of Ω_A, it is necessary to obtain information about c_A in order to make conclusions regarding the conjecture of Birch and Swinnerton-Dyer, since $\Omega_A = c_A \cdot \Omega'_A$. For example, see [AS05, §4.2] when $r = 0$ and [GZ86, p. 310–311] when $r = 1$; in each case, one gets a formula for computing the Birch and Swinnerton-Dyer conjectural order of the Shafarevich-Tate group, and the formula contains the Manin constant (see, e.g., [Mc91]).

The method of Section 5 for verifying that $c_A = 1$ for specific elliptic curves is of little use when applied to general abelian varieties, since there is no simple analogue of the minimal Weierstrass model (but see [GL01] for **Q**-curves). This emphasizes the need for general theorems regarding the Manin constant of quotients of dimension bigger than one.

3.3. **Results and a conjecture.** We start by giving several results regarding the Manin constant for quotients of arbitrary dimension. The proofs of most of the theorems are given in Section 4.

Let Γ be a subgroup of $\Gamma_0(N)$ that contains $\Gamma_1(N)$. We have the following generalization of Edixhoven's Theorem 2.2.

Theorem 3.4. *The Manin constant c_A is an integer. (In the notation of Section 3.1 we even have that $\psi(H^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}})) \subseteq S_2(\mathbf{Z})[I]$.)*

Proof. Let $J = \mathrm{Jac}(X_\Gamma)$ and $J' = J_1(N)$. Suppose A is an optimal quotient of J. We have natural maps $\mathrm{H}^0(J'_{\mathbf{Z}}, \Omega^1_{J'/\mathbf{Z}}) \hookrightarrow \mathrm{H}^0(J', \Omega^1_{J'/\mathbf{Q}}) \overset{\cong}{\to} S_2(\Gamma_1(N); \mathbf{Q})$; from the proof of Lemma 6.1.6 of [CES03], the image of the composite is contained in $S_2(\Gamma_1(N); \mathbf{Z})$. The maps $J' \to J \to A$ induce a chain of inclusions

$$\mathrm{H}^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}}) \hookrightarrow \mathrm{H}^0(J_{\mathbf{Z}}, \Omega^1_{J/\mathbf{Z}}) \hookrightarrow \mathrm{H}^0(J'_{\mathbf{Z}}, \Omega^1_{J'/\mathbf{Z}}) \hookrightarrow S_2(\Gamma_1(N); \mathbf{Z}) \hookrightarrow \mathbf{Z}[[q]].$$

Combining this chain of inclusions with commutativity of the diagram

$$\begin{tikzcd} & S_2(\Gamma_1(N)) \arrow[dr, "F\text{-exp}"] & \\ S_2(\Gamma) \arrow[ur, "f(q)\mapsto f(q)"] \arrow[rr, "F\text{-exp}"] & & \mathbf{C}[[q]], \end{tikzcd}$$

where F-exp is the Fourier expansion map, we see that the image of $\mathrm{H}^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}})$ lies in $S_2(\mathbf{Z})[I]$, as claimed. □

For the rest of the paper, we take $\Gamma = \Gamma_0(N)$. For each prime $\ell \mid N$ with $\mathrm{ord}_\ell(N) = 1$, let W_ℓ be the ℓth Atkin-Lehner operator. Let $J = J_0(N)$ and $A = A_I = J/IJ$ be an optimal quotient of J attached to a saturated ideal I. If ℓ is a prime, then as usual, $\mathbf{Z}_{(\ell)}$ will denote the localization of $\mathbf{Z}$ at ℓ.

Theorem 3.5. *Suppose that ℓ is an odd prime such that $\ell^2 \nmid N$, and that if $\ell \mid N$, then $A^\vee \subset J$ is stable under W_ℓ. Then $\ell \mid c_A$ if and only if $\ell \mid N$ and $S_2(\mathbf{Z}_{(\ell)})[I]$ is not stable under the action of W_ℓ.*

We will prove this theorem in Section 4.2.

Remark 3.6. The condition that $S_2(\mathbf{Z}_{(\ell)})[I]$ is stable under W_ℓ can be verified using standard algorithms. Thus in light of Theorem 3.5, if A is stable under all Atkin-Lehner operators and N is square free, then one can compute the set of odd primes that divide c_A. It would be interesting to refine the arguments of this paper to find an algorithm to compute c_A exactly.

Let J_{old} denote the abelian subvariety of J generated by the images of the degeneracy maps from levels that properly divide N (see, e.g., [Maz78, §2(b)]) and let J^{new} denote the quotient of J by J_{old}. A *new quotient* is a quotient $J \to A$ that factors through the map $J \to J^{\text{new}}$. The following corollary generalizes Mazur's Theorem 2.3:

Corollary 3.7. *If $A = A_f$ is an optimal newform quotient of $J_0(N)$ and $\ell \mid c_A$ is a prime, then $\ell = 2$ or $\ell^2 \mid N$.*

Proof. Since f is a newform, W_ℓ acts as either 1 or -1 on A hence on $S_2(\mathbf{Z}_{(\ell)})[I]$. Thus $S_2(\mathbf{Z}_{(\ell)})[I]$ is W_ℓ-stable. □

Corollary 3.8. *If $A = J_0(N)_{\text{new}}$ is the new subvariety of $J_0(N)$ and $\ell \mid c_A$ is a prime, then $\ell = 2$ or $\ell^2 \mid N$. (In particular, if N is prime then the Manin constant of $J_0(N)$ is a power of 2, since $A = J_0(N)[I]$ for $I = 0$.)*

Proof. We have $W_\ell = -T_\ell$ on A (e.g., see the end of [DI95, §6.3]). Also the new subspace $S_2(\mathbf{Z})_{\text{new}}$ of $S_2(\Gamma_0(N))$ is T_ℓ-stable. □

Remark 3.9. If $A = J_0(33)$, then

$$W_3 = \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{3} & \frac{1}{3} & -\frac{4}{3} \\ \frac{1}{3} & -\frac{2}{3} & -\frac{1}{3} \end{pmatrix}$$

with respect to the basis

$$\begin{aligned} f_1 &= q - q^5 - 2q^6 + 2q^7 + \cdots, \\ f_2 &= q^2 - q^4 - q^5 - q^6 + 2q^7 + \cdots, \\ f_3 &= q^3 - 2q^6 + \cdots \end{aligned}$$

for $S_2(\mathbf{Z})$. Thus W_3 does not preserve $S_2(\mathbf{Z}_{(3)})$. In fact, the Manin constant of $J_0(33)$ is not 1 in this case (see Section 3.4).

The hypothesis of Theorem 3.5 sometimes holds for non-new A. For example, take $J = J_0(33)$ and $\ell = 3$. Then W_3 acts as an endomorphism of J, and a computation shows that the characteristic polynomial of W_3 on $S_2(33)_{\mathrm{new}}$ is $x-1$ and on $S_2(33)_{\mathrm{old}}$ is $(x-1)(x+1)$, where $S_2(33)_{\mathrm{old}}$ is the old subspace of $S_2(33)$. Consider the optimal elliptic curve quotient $A = J/(W_3+1)J$, which is isogenous to $J_0(11)$. Then A is an optimal old quotient of J, and W_3 acts as -1 on A, so W_3 preserves the corresponding spaces of modular forms. Thus Theorem 3.5 implies that $3 \nmid c_A$.

The following theorem generalizes Raynaud's Theorem 2.4 (see also [GL01] for generalizations to **Q**-curves).

Theorem 3.10. *If $f \in S_2(\Gamma_0(N))$ is a newform and ℓ is a prime such that $\ell^2 \nmid N$, then* $\mathrm{ord}_\ell(c_{A_f}) \le \dim A_f$.

Note that in light of Theorem 3.5, this theorem gives new information only at $\ell = 2$, when $2 \parallel N$. We prove the theorem in Section 4.4

Let π denote the natural quotient map $J \to A$. When we compose π with its dual $A^\vee \to J^\vee$ (identifying $J^\vee$ with J using the inverse of the principal polarization of J), we get an isogeny $\phi : A^\vee \to A$. The *modular exponent* m_A of A is the exponent of the group $\ker(\phi)$. When A is an elliptic curve, the modular exponent is just the modular degree of A (see, e.g., [AU96, p. 278]).

Theorem 3.11. *If $f \in S_2(\Gamma_0(N))$ is a newform and $\ell \mid c_{A_f}$ is a prime, then $\ell^2 \mid N$ or $\ell \mid m_A$.*

Again, in view of Corollary 3.7, this theorem gives new information only at $\ell = 2$, when $\mathrm{ord}_2(N) \le 1$. We prove the theorem in Section 4.3.

The theorems above suggest that the Manin constant is 1 for quotients associated to newforms of square-free level. In the case when the level is not square free, computations of [FpS$^+$01] involving Jacobians of genus 2 curves that are quotients of $J_0(N)^{\mathrm{new}}$ show that $c_A = 1$ for 28 two-dimensional newform quotients. These include quotients having the following non-square-free levels:

$$3^2\cdot 7, \quad 3^2\cdot 13, \quad 5^3, \quad 3^3\cdot 5, \quad 3\cdot 7^2, \quad 5^2\cdot 7, \quad 2^2\cdot 47, \quad 3^3\cdot 7.$$

The above observations suggest the following conjecture, which generalizes Conjecture 2.1:

Conjecture 3.12. *If f is a newform on $\Gamma_0(N)$ then $c_{A_f} = 1$.*

It is plausible that $c_{A_f} = 1$ for any newform on any congruence subgroup between $\Gamma_0(N)$ and $\Gamma_1(N)$. However, we do not have enough data to justify making a conjecture in this context.

3.4. **Examples of nontrivial Manin constants.** We present two sets of examples in which the Manin constant is not 1.

Using results of [Kil02], Adam Joyce [Joy05] proves that there is a new optimal quotient of $J_0(431)$ with Manin constant 2. Joyce's methods also produce examples with Manin constant 2 at levels 503 and 2089. For the convenience of the reader, we breifly discuss his example at level 431. There are exactly two elliptic curves E_1 and E_2 of prime conductor 431, and $E_1 \cap E_2 = 0$ as subvarieties of $J_0(431)$, so $A = E_1 \times E_2$ is an optimal quotient of $J_0(431)$ attached to a saturated ideal I. If f_i is the newform corresponding to E_i, then one finds that $f_1 \equiv f_2 \pmod 2$, and so $g = (f_1 - f_2)/2 \in S_2(\mathbf{Z})[I]$. However g is not in the image of $\mathrm{H}^0(A_{\mathbf{Z}}, \Omega^1_{A/\mathbf{Z}})$. Thus the Manin constant of A is divisible by 2.

As another class of examples, one finds by computation for each prime $\ell \leq 100$ that W_ℓ does not leave $S_2(\Gamma_0(11\ell); \mathbf{Z}_{(\ell)})$ stable. Theorem 3.5 (with $I = 0$) then implies that the Manin constant of $J_0(11\ell)$ is divisible by ℓ for these values of ℓ.

4. Proofs of some of the Theorems

In Sections 4.2, 4.3, and 4.4, we prove Theorems 3.5, 3.11, and 3.10 respectively. In Section 4.1, we state two lemmas that will be used in these proofs. The proofs of the theorems may be read independently of each other, after reading Section 4.1.

4.1. **Two lemmas.** The following lemma is a standard fact; we state it as a lemma merely because it is used several times.

Lemma 4.1. *Suppose $i : A \hookrightarrow B$ is an injective homomorphism of torsion-free abelian groups. If p is a prime, then $B/i(A)$ has no nonzero p-torsion if and only if the induced map $A \otimes \mathbf{F}_p \to B \otimes \mathbf{F}_p$ is injective.*

Proof. Let Q denote the quotient $B/i(A)$. Tensor the exact sequence $0 \to A \to B \to Q \to 0$ with $\mathbf{F}_p$. The associated long exact sequences reveal that $\ker(A \otimes \mathbf{F}_p \to B \otimes \mathbf{F}_p) \cong Q_{\mathrm{tor}}[p]$. □

Suppose ℓ is a prime such that $\ell^2 \nmid N$. In what follows, we will be stating some standard facts taken from [Maz78, §2(e)] (which in turn relies on [DR73]). Let $\mathcal{X}_{\mathbf{Z}_{(\ell)}}$ be the minimal regular resolution of the coarse moduli scheme associated to $\Gamma_0(N)$ (as in [DR73, § VI.6.9]) over $\mathbf{Z}_{(\ell)}$, and let $\Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}$ denote the relative dualizing sheaf of $\mathcal{X}_{\mathbf{Z}_{(\ell)}}$ over $\mathbf{Z}_{(\ell)}$. The Tate curve over $\mathbf{Z}_{(\ell)}[[q]]$ gives rise to a morphism from Spec $\mathbf{Z}_{(\ell)}[[q]]$ to the smooth locus of $\mathcal{X}_{\mathbf{Z}_{(\ell)}} \to \operatorname{Spec} \mathbf{Z}_{(\ell)}$. Since the module of completed Kahler differentials for $\mathbf{Z}_{(\ell)}[[q]]$ over $\mathbf{Z}_{(\ell)}$ is free of rank 1 on the basis dq, we obtain a map q-exp $: H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}) \to \mathbf{Z}_{(\ell)}[[q]]$.

The natural morphism $\mathrm{Pic}^0_{\mathcal{X}/\mathbf{Z}_{(\ell)}} \to J_{\mathbf{Z}_{(\ell)}}$ identifies $\mathrm{Pic}^0_{\mathcal{X}/\mathbf{Z}_{(\ell)}}$ with the identity component of $J_{\mathbf{Z}_{(\ell)}}$ (see, e.g., [BLR90, §9.4–9.5]). Passing to tangent spaces along the identity section over $\mathbf{Z}_{(\ell)}$, we obtain an isomorphism $H^1(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \mathcal{O}_{\mathcal{X}_{\mathbf{Z}_{(\ell)}}}) \cong \mathrm{Tan}(J_{\mathbf{Z}_{(\ell)}})$. Using Grothendieck duality, one gets an isomorphism $\mathrm{Cot}(J_{\mathbf{Z}_{(\ell)}}) \overset{\cong}{\to} H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}})$, where $\mathrm{Cot}(J_{\mathbf{Z}_{(\ell)}})$ is the cotangent space at the identity section. On the Néron model $J_{\mathbf{Z}_{(\ell)}}$, the group of global differentials is the same as the group of invariant differentials, which in turn is naturally isomorphic to $\mathrm{Cot}(J_{\mathbf{Z}_{(\ell)}})$. Thus we obtain an isomorphism $H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \cong H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}})$.

Let G be a $\mathbf{T}$-module equipped with an injection $G \hookrightarrow H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}})$ of $\mathbf{T}$-modules such that G is annihilated by I. If $\ell \mid N$, assume moreover that G is a $\mathbf{T}[W_\ell]$-module and that the inclusion in the previous sentence is a homomorphism of $\mathbf{T}[W_\ell]$-modules. As a typical example, $G = H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$, with the injection $\pi^* : H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \hookrightarrow H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}})$. Let Φ be the composition of the inclusions

$$G \hookrightarrow H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \cong H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}) \xrightarrow{q\text{-exp}} \mathbf{Z}_{(\ell)}[[q]], \tag{1}$$

and let ψ' be the composition of

$$G \hookrightarrow H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}})[I] \hookrightarrow S_2(\mathbf{Z}_{(\ell)})[I],$$

where the last inclusion follows from a "local" version of Theorem 3.4. The maps Φ and ψ' are related by the commutative diagram

$$\begin{tikzcd}
 & S_2(\mathbf{Z}_{(\ell)})[I] \arrow[dr, "F\text{-exp}"] & \\
G \arrow[ur, "\psi'"] \arrow[rr, "\Phi"] & & \mathbf{Z}_{(\ell)}[[q]],
\end{tikzcd} \tag{2}$$

where F-exp is the Fourier expansion map (at infinity), as before.

We say that a subgroup B of an abelian group C is *saturated* (in C) if the quotient C/B is torsion free.

Lemma 4.2. *Recall that ℓ is a prime such that $\ell^2 \nmid N$. If ℓ divides N, suppose that $S_2(\mathbf{Z}_{(\ell)})[I]$ is stable under the action of W_ℓ; if $\ell = 2$ assume moreover that W_ℓ acts as a scalar on A. Consider the map*

$$G \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell,$$

which is obtained by tensoring the inclusion $G \hookrightarrow H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}})$ with $\mathbf{F}_\ell$. If this map is injective, then the image of G under the map Φ of (2) is saturated in $\mathbf{Z}_{(\ell)}[[q]]$.

Proof. By Lemma 4.1, it suffices to prove that the map

$$\Phi_\ell : G \otimes \mathbf{F}_\ell \to \mathbf{Z}_{(\ell)}[[q]] \otimes \mathbf{F}_\ell = \mathbf{F}_\ell[[q]]$$

obtained by tensoring (1) with $\mathbf{F}_\ell$ is injective. Let $\mathcal{X}_{\mathbf{F}_\ell}$ denote the special fiber of $\mathcal{X}_{\mathbf{Z}_{(\ell)}}$ and let $\Omega_{\mathcal{X}/\mathbf{F}_\ell}$ denote the relative dualizing sheaf of $\mathcal{X}_{\mathbf{F}_\ell}$ over $\mathbf{F}_\ell$.

First suppose that ℓ does not divide N. Then $\mathcal{X}_{\mathbf{Z}_{(\ell)}}$ is smooth and proper over $\mathbf{Z}_{(\ell)}$. Thus the formation of $\mathrm{H}^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}_{\mathbf{Z}_{(\ell)}}})$ is compatible with any base change on $\mathbf{Z}_{(\ell)}$ (such as reduction modulo ℓ). The injectivity of Φ_ℓ now follows since by hypothesis the induced map $G \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$ is injective, and

$$H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{X}_{\mathbf{F}_\ell}, \Omega_{\mathcal{X}/\mathbf{F}_\ell}) \to \mathbf{F}_\ell[[q]]$$

is injective by the q-expansion principle (which is easy in this setting, since $\mathcal{X}_{\mathbf{F}_\ell}$ is a smooth and geometrically connected curve).

Next suppose that ℓ divides N. First we verify that $\ker(\Phi_\ell)$ is stable under W_ℓ. Suppose $\omega \in \ker(\Phi_\ell)$. Choose $\omega' \in G$ such that the image of ω' in $G \otimes \mathbf{F}_\ell$ is ω, and let $f = \psi'(\omega')$. Because $\Phi_\ell(\omega) = 0$ in $\mathbf{F}_\ell[[q]]$, there exists $h \in \mathbf{Z}_{(\ell)}[[q]]$ such that $\ell h = F\text{-exp}(f)$. Let $f' = f/\ell \in S_2(\mathbf{Q})$; then f' is actually in $S_2(\mathbf{Z}_{(\ell)})$ (since $F\text{-exp}(f/\ell) = h \in \mathbf{Z}_{(\ell)}[[q]]$). Now $\ell f' = f$ is annihilated by every element of I, hence so is f'; thus $f' \in S_2(\mathbf{Z}_{(\ell)})[I]$. By hypothesis, $W_\ell(f') \in S_2(\mathbf{Z}_{(\ell)})[I]$. Then

$$\Phi(W_\ell \omega') = F\text{-exp}(W_\ell f) = \ell \cdot F\text{-exp}(W_\ell f') \in \ell \mathbf{Z}_{(\ell)}[[q]].$$

Reducing modulo ℓ, we get $\Phi_\ell(W_\ell \omega) = 0$ in $\mathbf{F}_\ell[[q]]$. Thus $W_\ell \omega \in \ker(\Phi_\ell)$, which proves that $\ker(\Phi_\ell)$ is stable under W_ℓ.

Since W_ℓ is an involution, and by hypothesis either ℓ is odd or W_ℓ is a scalar, the space $\ker(\Phi_\ell)$ breaks up into a direct sum of eigenspaces under W_ℓ with eigenvalues ± 1. It suffices to show that if $\omega \in \ker(\Phi_\ell)$ is an element of either eigenspace, then $\omega = 0$. For this, we use a standard argument that goes back to Mazur (see, e.g., the proof of Prop. 22 in [MR91]); we give some details to clarify the argument in our situation.

Following the proof of Prop. 3.3 on p. 68 of [Maz77], we have

$$H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{X}_{\mathbf{F}_\ell}, \Omega_{\mathcal{X}/\mathbf{F}_\ell}).$$

In the following, we shall think of $G \otimes \mathbf{F}_\ell$ as a subgroup of $H^0(\mathcal{X}_{\mathbf{F}_\ell}, \Omega_{\mathcal{X}/\mathbf{F}_\ell})$, which we can do by the hypothesis that the induced map $G \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$ is injective and that

$$H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{X}_{\mathbf{Z}_{(\ell)}}, \Omega_{\mathcal{X}/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{X}_{\mathbf{F}_\ell}, \Omega_{\mathcal{X}/\mathbf{F}_\ell}).$$

Suppose $\omega \in \ker(\Phi_\ell)$ is in the ± 1 eigenspace (we will treat the cases of $+1$ and -1 eigenspaces together). We will show that ω is trivial over $\mathcal{X}_{\overline{\mathbf{F}}_\ell}$, the base change of $\mathcal{X}_{\mathbf{F}_\ell}$ to an algebraic closure $\overline{\mathbf{F}}_\ell$, which suffices for our purposes. Since $\ell^2 \nmid N$, we have $\ell \mid\mid N$, and so the special fiber $\mathcal{X}_{\overline{\mathbf{F}}_\ell}$ is as depicted on p. 177 of [Maz77]: it consists of the union of two copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$ identified transversely at the supersingular points, and some copies of $\mathbf{P}^1$, each of which intersects exactly one of the two copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$ and perhaps another $\mathbf{P}^1$, all of them transversally. All the singular points are ordinary double points, and the cusp ∞ lies on one of the two copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$.

In particular, $\mathcal{X}_{\overline{\mathbf{F}}_\ell} \to \operatorname{Spec} \overline{\mathbf{F}}_\ell$ is locally a complete intersection, hence Gorenstein, and so by [DR73, § I.2.2, p. 162], the sheaf $\Omega_{\mathcal{X}/\overline{\mathbf{F}}_\ell} = \Omega_{\mathcal{X}/\mathbf{F}_\ell} \otimes \overline{\mathbf{F}}_\ell$ is invertible. Since $\omega \in \ker(\Phi_\ell)$, the differential ω vanishes on the copy of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$ containing the cusp ∞ by the q-expansion principle (which is easy in this case, since all that is being invoked here is that on an integral curve, the natural map from the group of global sections of an invertible sheaf into the completion of the sheaf's stalk at a point is injective). The two copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$ are swapped under the action of the Atkin-Lehner involution W_ℓ, and thus $W_\ell(\omega)$ vanishes on the other copy that does not contain the cusp ∞. Since $W_\ell(\omega) = \pm\omega$, we see that ω is zero on both copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$. Also, by the description of the relative dualizing sheaf in [DR73, § I.2.3, p. 162], if $\pi : \widetilde{\mathcal{X}}_{\overline{\mathbf{F}}_\ell} \to \mathcal{X}_{\overline{\mathbf{F}}_\ell}$ is a normalization, then ω correponds to a meromorphic differential $\widetilde{\omega}$ on $\widetilde{\mathcal{X}}_{\overline{\mathbf{F}}_\ell}$ which is regular outside the inverse images (under π) of the double points on $\mathcal{X}_{\overline{\mathbf{F}}_\ell}$ and has at worst a simple pole at any point that lies over a double point on $\mathcal{X}_{\overline{\mathbf{F}}_\ell}$. Moreover, on the inverse image of any double point on $\mathcal{X}_{\overline{\mathbf{F}}_\ell}$, the residues of $\widetilde{\omega}$ add to zero. For any of the $\mathbf{P}^1$'s, above a point of intersection of the $\mathbf{P}^1$ with a copy of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$, the residue of $\widetilde{\omega}$ on the inverse image of the copy of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$ is zero (since ω is trivial on both copies of $X_0(N/\ell)_{\overline{\mathbf{F}}_\ell}$), and thus the residue of $\widetilde{\omega}$ on the inverse image of $\mathbf{P}^1$ is zero. Thus $\widetilde{\omega}$ restricted to the inverse image of $\mathbf{P}^1$ is regular away from the inverse image of any point where the $\mathbf{P}^1$ meets another $\mathbf{P}^1$ (recall that there can be at most one such point). Hence the restriction of $\widetilde{\omega}$ to the inverse image of the $\mathbf{P}^1$ is either regular everywhere or is regular away from one point where it has at most a simple pole; in the latter case, the residue is zero by the residue theorem. Thus in either case, $\widetilde{\omega}$ restricted to the inverse image of the $\mathbf{P}^1$ is regular, and therefore is zero. Thus ω is trivial on all the copies of $\mathbf{P}^1$ as well. Hence $\omega = 0$, as was to be shown. □

4.2. **Proof of Theorem 3.5.** We continue to use the notation of Section 4.1.

First suppose that $\ell \mid N$ and $S_2(\mathbf{Z}_{(\ell)})[I]$ is not stable under the action of W_ℓ. Relative differentials and Néron models are functorial, so $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$ is W_ℓ-stable. Thus the map $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \to S_2(\mathbf{Z}_{(\ell)})[I]$ is not surjective. But c_A is the order of the cokernel, so $\ell \mid c_A$.

Next we prove the other implication, namely that if $\ell \mid c_A$, then $\ell \mid N$ and $S_2(\mathbf{Z}_{(\ell)})[I]$ is not stable under W_ℓ. We will prove this by proving the contrapositive, i.e., that if either $\ell \nmid N$ or $S_2(\mathbf{Z}_{(\ell)})[I]$ is stable under W_ℓ, then $\ell \nmid c_A$.

We now follow the discussion preceding Lemma 4.2, taking $G = H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$. To show that $\ell \nmid c_A$, we have to show that c_A is a unit in $\mathbf{Z}_{(\ell)}$. For this, it suffices to check that in diagram (2), the image of $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$ in $\mathbf{Z}_{(\ell)}[[q]]$ under Φ is saturated, since the image of $S_2(\Gamma_0(N); \mathbf{Z}_{(\ell)})[I]$ under F-exp is saturated in $\mathbf{Z}_{(\ell)}[[q]]$. In view of Lemma 4.2, it suffices to show that the map

$$H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$$

is injective.

Since A is an optimal quotient, $\ell \neq 2$, and J has good or semistable reduction at ℓ, [Maz78, Cor 1.1] yields an exact sequence

$$0 \to H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \to H^0(B_{\mathbf{Z}_{(\ell)}}, \Omega^1_{B/\mathbf{Z}_{(\ell)}}) \to 0$$

where $B = \ker(J \to A)$. Since $H^0(B_{\mathbf{Z}_{(\ell)}}, \Omega^1_{B/\mathbf{Z}_{(\ell)}})$ is torsion free, by Lemma 4.1 the map $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$ is injective, as was to be shown.

4.3. **Proof of Theorem 3.11.** We continue to use the notation and hypotheses of Section 4.1 (so $\ell^2 \nmid N$) and assume in addition that A is a newform quotient, and that $\ell \nmid m_A$. We have to show that then $\ell \nmid c_A$. Just as in the previous proof, it suffices to check that the image of $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$ in $\mathbf{Z}_{(\ell)}[[q]]$ is saturated. Since A is a newform quotient, if $\ell \mid N$, then W_ℓ acts as a scalar on A and on $S_2(\Gamma_0(N); \mathbf{Z}_{(\ell)})[I]$. So again, using Lemma 4.2, it suffices to show that the map $H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell \to H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$ is injective.

The composition of pullback and pushforward in the following diagram is multiplication by the modular exponent of A:

$$\begin{tikzcd} & H^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \arrow[dr, "\pi_*"] & \\ H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \arrow[ur, "\pi^*"] \arrow[rr, "m_A"] & & H^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \end{tikzcd}$$

Since $m_A \in {\mathbf{Z}_{(\ell)}}^\times$, the map π^* is a section to the map π_* up to a unit and hence its reduction modulo ℓ is injective, which is what was left to be shown.

4.4. **Proof of Theorem 3.10.** Theorem 3.10 asserts that if $A = A_f$ is a quotient of $J = J_0(N)$ attached to a newform f, and ℓ is a prime such that $\ell^2 \nmid N$, then $\mathrm{ord}_\ell(c_{\scriptscriptstyle A}) \leq \dim(A)$. Our proof follows [AU96], except at the end we argue using lattice indices instead of multiples.

Let B denote the kernel of the quotient map $J \to A$. Consider the exact sequence $0 \to B \to J \to A \to 0$, and the corresponding complex $B_{\mathbf{Z}_{(\ell)}} \to J_{\mathbf{Z}_{(\ell)}} \to A_{J_{\mathbf{Z}_{(\ell)}}}$ of Néron models. Because $J_{\mathbf{Z}_{(\ell)}}$ has semiabelian reduction (since $\ell^2 \nmid N$), Theorem A.1 of the appendix of [AU96, pg. 279–280], due to Raynaud, implies that there is an integer r and an exact sequence

$$0 \to \mathrm{Tan}(B_{\mathbf{Z}_{(\ell)}}) \to \mathrm{Tan}(J_{\mathbf{Z}_{(\ell)}}) \to \mathrm{Tan}(A_{\mathbf{Z}_{(\ell)}}) \to (\mathbf{Z}/\ell\mathbf{Z})^r \to 0.$$

Here Tan is the tangent space at the 0 section; it is a finite free $\mathbf{Z}_{(\ell)}$-module of rank equal to the dimension. In particular, we have $r \leq d = \dim(A)$. Note that Tan is $\mathbf{Z}_{(\ell)}$-dual to the cotangent space, and the cotangent space is isomorphic to the space of global differential 1-forms. The theorem of Raynaud mentioned above is the generalization to $e = \ell - 1$ of [Maz78, Cor. 1.1], which we used above in the proof of Theorem 3.5.

Let C be the cokernel of $\mathrm{Tan}(B_{\mathbf{Z}_{(\ell)}}) \to \mathrm{Tan}(J_{\mathbf{Z}_{(\ell)}})$. We have a diagram

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Tan}(B_{\mathbf{Z}_{(\ell)}}) \arrow[r] & \mathrm{Tan}(J_{\mathbf{Z}_{(\ell)}}) \arrow[rr] \arrow[dr] & & \mathrm{Tan}(A_{\mathbf{Z}_{(\ell)}}) \arrow[r] & (\mathbf{Z}/\ell\mathbf{Z})^r \arrow[r] & 0. \\
& & & C \arrow[ur, hook] & & &
\end{tikzcd} \tag{3}$$

Since $C \subset \mathrm{Tan}(A_{\mathbf{Z}_{(\ell)}})$, so C is torsion free, we see that C is a free $\mathbf{Z}_{(\ell)}$-module of rank d. Let $C^* = \mathrm{Hom}_{\mathbf{Z}_{(\ell)}}(C, \mathbf{Z}_{(\ell)})$ be the $\mathbf{Z}_{(\ell)}$-linear dual of C. Applying the $\mathrm{Hom}_{\mathbf{Z}_{(\ell)}}(-, \mathbf{Z}_{(\ell)})$ functor to the two short exact sequences in (3), we obtain exact sequences

$$0 \to C^* \to \mathrm{H}^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \to \mathrm{H}^0(B_{\mathbf{Z}_{(\ell)}}, \Omega^1_{B/\mathbf{Z}_{(\ell)}}) \to 0,$$

and

$$0 \to \mathrm{H}^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}}) \to C^* \to (\mathbf{Z}/\ell\mathbf{Z})^r \to 0. \tag{4}$$

The $(\mathbf{Z}/\ell\mathbf{Z})^r$ on the right in (4) occurs as $\mathrm{Ext}^1_{\mathbf{Z}_{(\ell)}}((\mathbf{Z}/\ell\mathbf{Z})^r, \mathbf{Z}_{(\ell)})$.

Since $\mathrm{H}^0(B_{\mathbf{Z}_{(\ell)}}, \Omega^1_{B/\mathbf{Z}_{(\ell)}})$ is torsion free, by Lemma 4.1, the induced map

$$C^* \otimes \mathbf{F}_\ell \to \mathrm{H}^0(J_{\mathbf{Z}_{(\ell)}}, \Omega^1_{J/\mathbf{Z}_{(\ell)}}) \otimes \mathbf{F}_\ell$$

is injective. Since A is a newform quotient, if $\ell \mid N$ then W_ℓ acts as a scalar on C^* and on $S_2(\Gamma_0(N); \mathbf{Z}_{(\ell)})[I]$. Using Lemma 4.2, with $G = C^*$, we see that the image of C^* in $\mathbf{Z}_{(\ell)}[[q]]$ under the composite of the maps in (1) is saturated. The Manin constant for A at ℓ is the index of the image via q-expansion of $\mathrm{H}^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$ in $\mathbf{Z}_{(\ell)}[[q]]$ in its saturation. Since the image of C^* in $\mathbf{Z}_{(\ell)}[[q]]$ is saturated, the image of C^* is the saturation of the image of $\mathrm{H}^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$, so the Manin constant at ℓ is the index of $\mathrm{H}^0(A_{\mathbf{Z}_{(\ell)}}, \Omega^1_{A/\mathbf{Z}_{(\ell)}})$ in C^*, which is ℓ^r by (4), hence is at most ℓ^d.

5. Appendix by J. Cremona: Verifying that $c = 1$

Let f be a normalised rational newform for $\Gamma_0(N)$. Let Λ_f be its period lattice; that is, the lattice of periods of $2\pi i f(z)dz$ over $H_1(X_0(N), \mathbf{Z})$.

We know that $E_f = \mathbf{C}/\Lambda_f$ is an elliptic curve E_f defined over $\mathbf{Q}$ and of conductor N. This is the optimal quotient of $J_0(N)$ associated to f. Our goal is two-fold: to identify E_f (by giving an explicit Weierstrass model for it with integer coeffients); and to show that the associated Manin constant for E_f is 1. In this section we will give an algorithm for this; our algorithm applies equally to optimal quotients of $J_1(N)$.

As input to our algorithm, we have the following data:

(1) a $\mathbf{Z}$-basis for Λ_f, known to a specific precision;
(2) the type of the lattice Λ_f (defined below); and
(3) a complete isogeny class of elliptic curves $\{E_1, \ldots, E_m\}$ of conductor N, given by minimal models, all with $L(E_j, s) = L(f, s)$.

So E_f is isomorphic over $\mathbf{Q}$ to E_{j_0} for a unique $j_0 \in \{1, \ldots, m\}$.

The justification for this uses the full force of the modularity of elliptic curves defined over $\mathbf{Q}$: we have computed a full set of newforms f at level N, and the same number of isogeny classes of elliptic curves, and the theory tells us that there is a bijection between these sets. Checking the first few terms of the L-series (i.e., comparing the Hecke eigenforms of the newforms with the traces of Frobenius for the curves) allows us to pair up each isogeny class with a newform.

We will assume that one of the E_j, which we always label E_1, is such that Λ_f and Λ_1 (the period lattice of E_1) are approximately equal. This is true in practice, because our method of finding the curves in the isogeny class is to compute the coefficients of a curve from numerical approximations to the c_4 and c_6 invariants of $\mathbf{C}/\Lambda_f$; in all cases these are very close to integers which are the invariants of the minimal model of an elliptic curve of conductor N, which we call E_1. The other curves in the isogeny class are then computed from E_1. For the algorithm described here, however, it is irrelevant how the curves E_j were obtained, provided that Λ_1 and Λ_f are close (in a precise sense defined below).

Normalisation of lattices: every lattice Λ in $\mathbf{C}$ which defined over $\mathbf{R}$ has a unique $\mathbf{Z}$-basis ω_1, ω_2 satisfying one of the following:

- **Type 1:** ω_1 and $(2\omega_2 - \omega_1)/i$ are real and positive; or

- **Type 2:** ω_1 and ω_2/i are real and positive.

For Λ_f we know the type from modular symbol calculations, and we know ω_1, ω_2 to a certain precision by numerical integration; modular symbols provide us with cycles $\gamma_1, \gamma_2 \in H_1(X_0(N), \mathbf{Z})$ such that the integral of $2\pi i f(z)dz$ over γ_1, γ_2 give ω_1, ω_2.

For each curve E_j we compute (to a specific precision) a $\mathbf{Z}$-basis for its period lattice Λ_j using the standard AGM method. Here, Λ_j is the lattice of periods of the Néron differential on E_j. The type of Λ_j is determined by the sign of the discriminant of E_j: type 1 for negative discriminant, and type 2 for positive discriminant.

For our algorithm we will need to know that Λ_1 and Λ_f are approximately equal. To be precise, we know that they have the same type, and also we verify, for a specific positive ε, that

$$(*) \qquad \left|\frac{\omega_{1,1}}{\omega_{1,f}} - 1\right| < \varepsilon \qquad \text{and} \qquad \left|\frac{\mathrm{im}(\omega_{2,1})}{\mathrm{im}(\omega_{2,f})} - 1\right| < \varepsilon.$$

Here $\omega_{1,j}$, $\omega_{2,j}$ denote the normalised generators of Λ_j, and $\omega_{1,f}$, $\omega_{2,f}$ those of Λ_f.

Pulling back the Néron differential on E_{j_0} to $X_0(N)$ gives $c \cdot 2\pi i f(z)dz$ where $c \in \mathbf{Z}$ is the Manin constant for f. Hence

$$c\Lambda_f = \Lambda_{j_0}.$$

Our task is now to

(1) identify j_0, to find which of the E_j is (isomorphic to) the "optimal" curve E_f; and
(2) determine the value of c.

Our main result is that $j_0 = 1$ and $c = 1$, provided that the precision bound ε in (*) is sufficiently small (in most cases, $\varepsilon < 1$ suffices). In order to state this precisely, we need some further definitions.

A result of Stevens says that in the isogeny class there is a curve, say E_{j_1}, whose period lattice Λ_{j_1} is contained in every Λ_j; this is the unique curve in the class with minimal Faltings height. (It is conjectured that E_{j_1} is the $\Gamma_1(N)$-optimal curve, but we do not need or use this fact. In many cases, the $\Gamma_0(N)$- and $\Gamma_1(N)$-optimal curves are the same, so we expect that $j_0 = j_1$ often; indeed, this holds for the vast majority of cases.)

For each j, we know therefore that $a_j = \omega_{1,j_1}/\omega_{1,j} \in \mathbf{N}$ and also $b_j = \mathrm{im}(\omega_{2,j_1})/\mathrm{im}(\omega_{2,j}) \in \mathbf{N}$. Let B be the maximum of a_1 and b_1.

Proposition 5.1. *Suppose that (*) holds with $\epsilon = B^{-1}$; then $j_0 = 1$ and $c = 1$. That is, the curve E_1 is the optimal quotient and its Manin constant is* 1.

Proof. Let $\varepsilon = B^{-1}$ and $\lambda = \frac{\omega_{1,1}}{\omega_{1,f}}$, so $|\lambda - 1| < \varepsilon$. For some j we have $c\Lambda_f = \Lambda_j$. The idea is that $\operatorname{lcm}(a_1, b_1)\Lambda_1 \subseteq \Lambda_{j_1} \subseteq \Lambda_j = c\Lambda_f$; if $a_1 = b_1 = 1$, then the closeness of Λ_1 and Λ_f forces $c = 1$ and equality throughout. To cover the general case it is simpler to work with the real and imaginary periods separately.

Firstly,

$$\frac{\omega_{1,j}}{\omega_{1,f}} = c \in \mathbf{Z}.$$

Then

$$c = \frac{\omega_{1,1}}{\omega_{1,f}} \frac{\omega_{1,j}}{\omega_{1,1}} = \frac{a_1}{a_j}\lambda.$$

Hence

$$0 \le |\lambda - 1| = \frac{|a_j c - a_1|}{a_1} < \varepsilon.$$

If $\lambda \neq 1$, then $\varepsilon > |\lambda - 1| \ge a_1^{-1} \ge B^{-1} = \varepsilon$, contradiction. Hence $\lambda = 1$, so $\omega_{1,1} = \omega_{1,f}$. Similarly, we have

$$\frac{\operatorname{im}(\omega_{2,j})}{\operatorname{im}(\omega_{2,f})} = c \in \mathbf{Z}$$

and again we can conclude that $\operatorname{im}(\omega_{2,1}) = \operatorname{im}(\omega_{2,f})$, and hence $\omega_{2,1} = \omega_{2,f}$.

Thus $\Lambda_1 = \Lambda_f$, from which the result follows. □

Theorem 5.2. *For all $N < 60000$, every optimal elliptic quotient of $J_0(N)$ has Manin constant equal to* 1. *Moreover, the optimal curve in each class is the one whose identifying number on the tables* [Cre] *is* 1 *(except for class* 990h *where the optimal curve is* 990h3*).*

Proof. For all $N < 60000$ we used modular symbols to find all newforms f and their period lattices, and also the corresponding isogeny classes of curves. In all cases we verified that (*) held with the appropriate value of ε. (The case of 990h is only exceptional on account of an error in labelling the curves several years ago, and is not significant.) □

Remark 5.3. In the vast majority of cases, the value of B is 1, so the precision needed for the computation of the periods is very low. For $N < 60000$, out of 258502 isogeny classes, only 136 have $B > 1$: we found $a_1 = 2$ in 13 cases, $a_1 = 3$ in 29 cases, and $a_1 = 4$ and $a_1 = 5$ once each (for $N = 15$ and $N = 11$ respectively); $b_1 = 2$ in 93 cases; and no larger values. Class 17a is the only one for which both a_1 and b_1 are greater than 1 (both are 2).

Finally, we give a slightly weaker result for $60000 < N < 130000$; in this range we do not know Λ_f precisely, but only its projection onto the real line. (The reason for this is that we can find the newforms using modular symbols for $H_1^+(X_0(N), \mathbf{Z})$, which has half the dimension of $H_1(X_0(N), \mathbf{Z})$; but to find the exact period lattice requires working in $H_1(X_0(N), \mathbf{Z})$.) The argument is similar to the one given above, using $B = a_1$.

Theorem 5.4. *For all N in the range $60000 < N < 130000$, every optimal elliptic quotient of $J_0(N)$ has Manin constant equal to 1.*

Proof. We continue to use the notation above. We do not know the lattice Λ_f but only (to a certain precision) a positive real number $\omega_{1,f}^{+}$ such that either Λ_f has type 1 and $\omega_{1,f} = 2\omega_{1,f}^{+}$, or Λ_f has type 2 and $\omega_{1,f} = \omega_{1,f}^{+}$. Curve E_1 has lattice Λ_1, and the ratio $\lambda = \omega_{1,1}^{+}/\omega_{1,f}^{+}$ satisfies $|\lambda - 1| < \varepsilon$. In all cases this holds with $\varepsilon = \frac{1}{3}$, which will suffice.

First assume that $a_1 = 1$.

If the type of Λ_f is the same as that of Λ_1 (for example, this must be the case if all the Λ_j have the same type, which will hold whenever all the isogenies between the E_j have odd degree) then from $c\Lambda_f = \Lambda_j$ we deduce as before that $\lambda = 1$ exactly, and $c = a_1/a_j = 1/a_j$, hence $c = a_j = 1$. So in this case we have that $c = 1$, though there might be some ambiguity in which curve is optimal if $a_j = 1$ for more than one value of j.

Assume next that Λ_1 has type 1 but Λ_f has type 2. Now $\lambda = \omega_{1,1}/2\omega_{1,f}$. The usual argument now gives $ca_j = 2$. Hence either $c = 1$ and $a_j = 2$, or $c = 2$ and $a_j = 1$. To see if the latter case could occur, we look for classes in which $a_1 = 1$ and Λ_1 has type 1, while for some $j > 1$ we also have $a_j = 1$ and Λ_j of type 2. This occurs 28 times for $60000 < N < 130000$, but for 15 of these the level N is odd, so we know that c must be odd. The remaining 13 cases are

$$62516a, 67664a, 71888e, 72916a, 75092a, 85328d, 86452a, 96116a,$$
$$106292b, 111572a, 115664a, 121168e, 125332a;$$

we have been able to eliminate these by carrying out the extra computations necessary as in the proof of Theorem 5.2. We note that in all of these 13 cases, the isogeny class consists of two curves, E_1 of type 1 and E_2 of type 2, with $[\Lambda_1 : \Lambda_2] = 2$, so that E_2 rather than E_1 has minimal Faltings height.

Next suppose that Λ_1 has type 2 but Λ_f has type 1. Now $\lambda = 2\omega_{1,1}/\omega_{1,f}$. The usual argument now gives $2ca_j = 1$, which is impossible; so this case cannot occur.

Finally we consider the cases where $a_1 > 1$. There are only three of these for $60000 < N < 130000$: namely, $91270a$, $117622a$ and $124973b$, where $a_1 = 3$. In each case the Λ_j all have the same type (they are linked via 3-isogenies) and the usual argument shows that $ca_j = 3$. But none of these levels is divisible by 3, so $c = 1$ in each case. □

28 Average Ranks Of Elliptic Curves: Tension Between Data And Conjecture, with B. Bektemirov, B. Mazur, and M. Watkins

AVERAGE RANKS OF ELLIPTIC CURVES: TENSION BETWEEN DATA AND CONJECTURE

BAUR BEKTEMIROV, BARRY MAZUR, WILLIAM STEIN AND MARK WATKINS

Abstract. Rational points on elliptic curves are the gems of arithmetic: they are, to diophantine geometry, what units in rings of integers are to algebraic number theory, what algebraic cycles are to algebraic geometry. A rational point in just the right context, at one place in the theory, can inhibit and control—thanks to ideas of Kolyvagin [Kol88]—the existence of rational points and other mathematical structures elsewhere. Despite all that we know about these objects, the initial mystery and excitement that drew mathematicians to this arena in the first place remains in full force today.

We have a network of heuristics and conjectures regarding rational points, and we have massive data accumulated to exhibit instances of the phenomena. Generally, we would expect that our data support our conjectures; and if not, we lose faith in our conjectures. But here there is a somewhat more surprising interrelation between data and conjecture: they are not exactly in open conflict one with the other, but they are no great comfort to each other either. We discuss various aspects of this story, including recent heuristics and data that attempt to resolve this mystery. We shall try to convince the reader that, despite seeming discrepancy, data and conjecture are, in fact, in harmony.

1. Introduction

Suppose you are given an algebraic curve C defined, let us say, as the locus of zeroes of a polynomial $f(x, y)$ in two variables with rational coefficients. Suppose you are told that C has at least one rational point, i.e., there is a pair of rational numbers (a, b) such that $f(a, b) = 0$. How likely is it that C will have infinitely many rational points?

Such a question, on the one hand, clearly touches on a fundamental issue in diophantine geometry, and on the other, is somewhat meaningless until it is made more precise and appropriately organized. The question we have just asked has distinctly different features when considered for each of the three basic "types" of algebraic curves: curves of (geometric) genus 0, 1, and > 1. Curves of genus 0 possessing a rational point *always* have infinitely many rational points (an easy fact; indeed, even known to the ancient Greeks, since our curve can be written as a conic in this case); curves of genus > 1 never do (a hard fact; indeed a theorem of Faltings [Fal86], for which he received the Fields Medal).

This leaves curves of genus 1 as the unresolved, and thus most interesting, case of the problem we posed, since some elliptic curves, like

$$x^3 + y^3 = 1,$$

only have finitely many rational points (two, in this instance) and others, like

$$y^2 + y = x^3 - x,$$

have infinitely many, starting with $(0,0)$, $(1,0)$, $(-1,-1)$, $(2,-3)$, $(1/4,-5/8)$, $(6,14)$, $(-5/9,8/27)$, $(21/25,-69/125)$, $(-20/49,-435/343)$, ...

If we are to try to extract an actual number between 0 and 1 that will describe "the" probability that a curve of genus 1 possessing at least one rational point has infinitely many, we have to be precise about exactly which curves we want to count, and how we propose to "sort" them. Let us agree, then (with details later):

- to deal only with the smooth projective models of the curves of genus 1 possessing a rational point (these being precisely the *elliptic curves* defined over $\mathbb{Q}$),
- to count their isomorphism classes over $\mathbb{Q}$, and
- to list them in order of increasing conductor, banking on the theorem that tells us that there are only finitely many isomorphism classes of elliptic curves over $\mathbb{Q}$ with any given conductor.

We can now pose our question. Does

$$P(X) = \frac{\#\{\text{elliptic curves of conductor } \leq X \text{ with infinitely many rational points}\}}{\#\{\text{elliptic curves of conductor} \leq X\}}$$

converge as X tends to infinity, and if so, what is the limit

$$P = \lim_{X\to\infty} P(X)?$$

In this way we have made our initial question precise:

What is the probability P that an elliptic curve has infinitely many rational points?

It is extraordinary how much vacillation there has been in the past three decades, in the various guesses about the answer to this—clearly basic—question. The subject of this paper is to discuss aspects of this drama. Its see-saw history, involving a network of heuristics and conjectures and massive data that seemed not to offer much comfort to the conjecturers, comes in four parts.

(1) **The minimalist conjecture.** The "classical" Birch and Swinnerton-Dyer conjecture (see Section 2) suggests that the probability P described by our question is at least $1/2$. The reason for this is the (heuristic) phenomenon of *parity*: elliptic curves can be sorted into two classes, those of **even parity**, where the "sign in the functional equation of the L-function" is $+1$, and those of **odd parity**, where the "sign" is -1. The (conjectural) probability that an elliptic curve is of even parity is $1/2$, and the same—of course—for odd parity. A consequence of the Birch and Swinnerton-Dyer conjecture is that *all* elliptic curves of odd parity have infinitely many rational points. This is why no one doubts that the probability P described above is $\geq 1/2$.

It has long been a folk conjecture that P is *exactly* $1/2$—let us call this the **minimalist conjecture**. Given the Birch and Swinnerton-Dyer conjecture and the Parity Principle, an equivalent, and cleaner, way of stating it is as follows:

Conjecture 1.1. *An elliptic curve of even parity has probability zero of having infinitely many rational points.*

This minimalist conjecture might seem appealing purely on the grounds that rational points of elliptic curves are accidental gems of mathematics, and it is hard to imagine that there could be bulk occurrence of these precious accidents—or at least substantially more bulk than is already predicted.

It seems that one cannot find such a minimalist conjecture explicitly in the literature until very recently (see [Wat06] and Conjecture 3.4). Nevertheless, for some particular families of elliptic curves (the "quadratic twist" families—see Section 3.3 below) the conjecture is much older. Over a quarter of a century ago, Dorian Goldfeld conjectured that for any elliptic curve E, the probability

$$G(D) = \frac{\#\{\text{quadratic twists up to } D \text{ of } E \text{ with infinitely many rational points}\}}{\#\{\text{quadratic twists up to } D \text{ of } E\}}$$

has $G = 1/2$ as its limit as $D \to \infty$.

(2) **Contrary numerical data.** The next phase of our story involves the accumulation of numerical data regarding this probability P taken over the entirety of elliptic curves, and also over various selected families of elliptic curves. The short description of this data (but see the detailed discussion in the body of our article) is the following. Over every data set accumulated so far, about 2/3 (or sometimes more) of the curves in the families being considered have had infinitely many rational points, and rather flatly so over the range of conductors involved in the computations; these now include a large set (over 100 million curves) of elliptic curves of conductor $< 10^8$.

(3) **A gross heuristic, for special families.** To get the most precise results we change the data set, and restrict attention to the probability that a member of even parity of a *quadratic twist family* of elliptic curves has infinitely many rational points. As a refinement to Goldfeld's conjecture, Peter Sarnak gave a heuristic that predicts that among the first D members of such a quadratic twist family (essentially arranged in order of increasing conductor) the number of those with even parity and infinitely many rational points is caught between $D^{3/4-\epsilon}$ and $D^{3/4+\epsilon}$ for any positive ϵ and D sufficiently large. This guess, based on consideration of the size of Fourier coefficients of modular forms of half-integral weight, revived the minimalist conjecture: if Sarnak's estimate is correct, we would indeed have $G = 1/2$ in Goldfeld's conjecture, and even-parity members of a quadratic twist family would have probability zero of having infinitely many rational points.

At this point in our story, there is decided friction between accumulated data which suggests something like 2/3 as the probability for the general member to have infinitely many rational points, and a reasoned theoretical expectation, which suggests exactly 1/2 for that probability. Generally, the least we would expect of our data is that they either support our conjectures, or overthrow them. Here there was a somewhat more surprising interrelation between data and conjecture: a kind of truce between them: we believed our guesses, we believed the data, and acknowledged the apparent gap between them.

(4) **A refined heuristic, for special families.** More recently, another twist to this story has developed. The work of Katz and Sarnak [KaSa99] regarding symmetry groups of the analogous families of curves over function

fields[1] gave impetus to the random matrix theory calculations of Keating and Snaith [KeSn00] regarding moments of L-functions and their value distribution. This was then combined with a discretization process by Conrey, Keating, Rubinstein, and Snaith in [CKRS02] to give a more precise guess for the (asymptotic) number of even parity curves with infinitely many rational points in a given quadratic twist family. For example, for the quadratic twist family $y^2 = x^3 - d^2x$, the prediction is that among the first D members of this family, the number of those with even parity and infinitely many rational points is asymptotic to

$$F(D) = c \cdot D^{3/4} \log(D)^{11/8} \tag{1}$$

for some (positive) constant c.

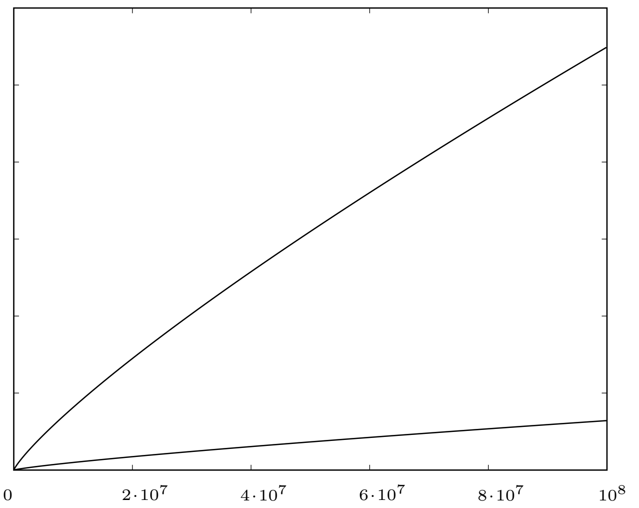

FIGURE 1. Plots of $D^{3/4}\log(D)^{11/8}$ (upper) and $\Delta^{19/24}(\log\Delta)^{3/8}$ (lower) up to 10^8

On the one hand, this is a sharpening of the prior heuristic, for $F(D)$ is comfortably sandwiched between $D^{3/4\pm\epsilon}$. On the other hand, we may be in for a surprise when we actually plot the graph of the function $F(D)$. See Figure 1. The striking aspect of the graph in Figure 1 is how "linear" it looks. Indeed, if $F(D)$ were replaced by a linear function with roughly the slope that appears in Figure 1, it would predict something closer to 2/3 than 1/2 for the proportion of curves in the family with infinitely many rational points.

Similarly—cf. Section 3.5 below—if we order all elliptic curves by discriminant, one of us (see [Wat06]) has conjectured that the number of even

[1] More recently, Kowalski [KowB] has used monodromy results of Katz to prove upper bounds for average ranks in the function field analogues.

parity elliptic curves with infinitely many rational points and absolute discriminant less than X is asymptotically given by

$$\Phi(X) \;=\; cX^{19/24}(\log X)^{3/8}.$$

See Figure 1.

Here, roughly speaking, is where the story is at present, as we will explain in detail in the body of this article. The curious last phase of it, focussing on *special families*, makes it seem now that data for these families is (a) more closely adhering to the refined guess than one might expect, even for relatively small values of the conductor, and (b) a refined guess predicts an asymptotic behavior that is far from linear, but within the currently attainable range is so close to linear, that the numerical evidence elucidating these phenomena (even the very large data sets that computers have amassed) seem indecisive when it comes to distinguishing convincingly between such gross questions as: is the probability closer to 1/2 or to 2/3?

It may very well be that until we actually prove our conjectures, no data that we can accumulate, however massive it may appear, will give even lukewarm comfort to the conjecturers.[2] This conflict raises the question of whether we as mathematicians may, at times, face a situation where the substance we study has one shape asymptotically, and yet all computational evidence elucidating this substance, even up to the very large numbers that computers today, or in our lifetime, can compute, seems consistent with the possibility that the data have a different asymptotic shape.

But, of course, our story will continue. We would hope for

- a refined heuristic that covers the full set of elliptic curves, and not just quadratic twist families,
- an extension of the numerical computation to conductors $< 10^{10}$, which is a range where we may begin to see some significant differences between the graph of $F(D)$ and a linear function,
- a conceptual understanding of how to obtain—by more unified means—this impressive bulk of rational points that we see occurring for even parity elliptic curves, at least for curves of "small" conductor.

We find it useful to compare our question *what is the probability that an elliptic curve has infinitely many points* with some of the other counting problems of current interest. Specifically, consider the problem of *counting quartic fields* and sorting them into classes corresponding to the isomorphy type of the Galois group of their Galois closure. We have to be exceedingly careful when choosing the coefficients of a degree 4 polynomial if we want a root of that polynomial to generate anything other than a field whose Galois group is S_4. Hilbert's irreducibility theorem provides corroboration of this with a proof that if you rank algebraic numbers of degree 4 by the size of the coefficients of their minimal polynomial (monic, over $\mathbb{Q}$) then 100% of them have Galois group S_4. But consider the problem of counting quartic

[2] We are reminded of the challenge of Shanks [Sha85, §69] regarding Carmichael numbers; with respect to the conjecture of Erdős that, for every $\epsilon > 0$, there are, for sufficiently large X, at least $X^{1-\epsilon}$ Carmichael numbers up to X, Shanks (essentially) noted that the data for small X did not remotely conform to this, and proposed giving an explicit X for which there were at least (say) $\sqrt{X}$ Carmichael numbers up to X, suspecting that exhibiting such an X would be much beyond the capabilities of computers.

fields (rather than the algebraic numbers that generate them) listed by the size (absolute value) of their discriminant. Counting field extensions of a given field whose Galois closure has its Galois group of a particular isomorphy type has been the subject of a number of precise conjectures (initially [CDO], and then successively refined in [Mal02, Mal04]). Bhargava's remarkable paper [Bha05], which is further evidence for these conjectures, proves that when we count quartic fields, nested by absolute discriminant, we do *not* get that 100% of them have Galois group S_4.

Bhargava regards the problem of counting quartic fields as a problem purely in the Geometry of Numbers, and *proves* the following theorem:

Theorem 1.2. *[Bhargava]. When ordered by absolute discriminant,* a positive proportion *(approximately 0.17111) of quartic fields have associated Galois group D_4 (the dihedral group). The remaining approximately 0.82889 of quartic fields have Galois group S_4, and the other three transitive subgroups occur with probability 0 asymptotically.*

It should be noted that these are Bhargava's percentages when counting fields up to isomorphism; when working in a fixed algebraic closure of the rationals, the percentages are not the same.

We would be more than delighted to see unconditional results of this precision established for questions such as the one motivating this survey article.

Acknowledgment. We thank Armand Brumer, Frank Calegari, Noam Elkies and Oisin McGuinness for stimulating conversations. We used PARI [ABCRZ] and SAGE [SJ05] to compute and analyze the data, and matplotlib [Mpl05] to draw the graphs. We thank Bob Guralnik for references to work about distributions of Galois groups. Similar surveys to this are those of Rubin and Silverberg [RS02] and Kowalski [KowA], the latter of which also relates random matrix theory to the theory of elliptic curves, and then discusses questions related to the inability of reconciling experimental data with theoretical asymptotics, particularly with respect to the work of Heath-Brown [HB93] on the 2-Selmer rank of the congruent number curves.

2. Elliptic Curves

An *elliptic curve* E over $\mathbb{Q}$ is a projective nonsingular curve defined as the projective closure of the zero locus of an equation of the form

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \tag{2}$$

with the a_i in $\mathbb{Q}$. The set $E(\mathbb{Q})$ of rational points on E is equipped with an abelian group structure (see [Sil92]).

Via completing the square in the y-variable, translating to eliminate the quadratic x-term, and then re-scaling, we find that the equation (2) is rationally equivalent to exactly one of the form

$$y^2 = x^3 - 27c_4x - 54c_6, \tag{3}$$

with $c_4, c_6, \Delta = (c_4^3 - c_6^2)/1728 \in \mathbb{Z}$ and for which there is no prime p with $p^4 \mid c_4$ and $p^{12} \mid \Delta$. We call Δ the *minimal discriminant* of E. (For example, the minimal discriminant of the curve $y^2 + y = x^3 - x$ mentioned in Section 1 is $\Delta = 37$; also $c_4 = 48$ and $c_6 = -216$ for this curve.)

The *conductor* of an elliptic curve E over $\mathbb{Q}$ is a positive integer $N = N_E$ that is a measure of the nature of the reduction of the elliptic curve modulo the prime divisors of Δ. For example, a prime $p \geq 5$ divides the conductor N only if there is no way of finding another defining equation (2) of E so that when reduced modulo p we obtain an equation over the field $\mathbb{F}_p$ without multiple roots; the maximal power of such a prime p dividing N is 2 and whether it is 1 or 2 is determined by the nature of the *best* reduction of E modulo p, i.e., whether its defining cubic polynomial has a double or a triple root modulo p. There is a slightly more involved, but elementary, recipe to give the power of the primes 2 and 3 dividing the conductor (see [Tat75]).

Mordell proved in 1922 (see [Mor22]) that the *Mordell-Weil group* $E(\mathbb{Q})$ of rational points on E is a finitely generated abelian group, so $E(\mathbb{Q}) \approx \mathbb{Z}^r \oplus E(\mathbb{Q})_{\mathrm{tor}}$. The integer r is the *rank* of E, and is the main statistic that we will discuss below; in contrast, the torsion group is rather well-understood, and is thus of less interest.

Let Δ be the minimal discriminant of E. The *L-function* $L(E,s)$ of E is a Dirichlet series given by a simple recipe in terms of the number of points N_p of the reduction of E over $\mathbb{F}_p$ for all primes p. Specifically,

(4)
$$L(E,s) = \prod_{p \nmid \Delta} \frac{1}{1-(1+p-N_p)p^{-s}+p^{1-2s}} \cdot \prod_{p \mid \Delta} \frac{1}{1-(1+p-N_p)p^{-s}} = \sum_{n=1}^{\infty} \frac{a_n}{n^s}.$$

The integers a_n are defined by expanding the Euler product; e.g., $a_p = p+1-N_p$ and $a_{p^2} = a_p^2 - p$ when $p \nmid \Delta$, etc. As an example, if E is $y^2 + y = x^3 - x$ then

$$L(E,s) = 1 - \frac{2}{2^s} - \frac{3}{3^s} + \frac{2}{4^s} - \frac{2}{5^s} + \frac{6}{6^s} - \frac{1}{7^s} + \frac{6}{9^s} + \frac{4}{10^s} - \frac{5}{11^s} + \cdots .$$

For any elliptic curve E, the celebrated papers of Wiles [Wil95] and others [BCDT01] imply that $L(E,s)$ extends to an entire analytic function on the complex plane. Moreover these results imply that the completed L-function $\Lambda(E,s) = N^{s/2} \cdot (2\pi)^{-s} \cdot \Gamma(s) \cdot L(E,s)$ satisfies the functional equation

$$\Lambda(E,s) = u_E \cdot \Lambda(E, 2-s),$$

where u_E is either -1 or 1, and is called the *sign in the functional equation for E*. Note that $u_E = 1$ if and only if $L(E,s)$ vanishes to even order at $s=1$.

The classical Birch and Swinnerton-Dyer Conjecture [BSD] asserts that the order of vanishing of $\Lambda(E,s)$ at the point $s=1$ is equal to the rank of the Mordell-Weil group $E(\mathbf{Q})$. In the data regarding *rank* that we will be reporting below, at times the Mordell-Weil rank r has been computed directly by finding r rational points of E that are linearly independent and span a subgroup of finite index in $E(\mathbf{Q})$ and we will refer to this r as the *arithmetic rank* of E. At times, however, what is computed is the apparent order of vanishing of $L(E,s)$ at $s=1$; we refer to this order of vanishing as the *analytic rank* of E. The BSD conjecture asserts that the ranks are in fact equal. We say a curve has *even parity* if the analytic rank is even, and *odd parity* if it is odd.

We now state the refined BSD conjecture for curves of rank 0. When E is given by (3), the real period Ω_{re} is, up to easily determined factors of 2 and 3, equal to the integral $\int_{E(\mathbb{R})} dx/y$. For a prime p, the Tamagawa number Ω_p is the index in $E(\mathbb{Q}_p)$ of the subgroup of p-adic points that reduce to a nonsingular point in $E(\mathbb{F}_p)$.

Conjecture 2.1. *[Birch and Swinnerton-Dyer]. If $L(E,1) \neq 0$, then*

$$L(E,1) = \frac{\Omega(E) \cdot \#\text{Ш}(E)}{\#E(\mathbb{Q})^2_{\text{tor}}}, \tag{5}$$

where Ш(E)*, the* Shafarevich-Tate group of E*, is a certain (mysterious) group associated to* E *(it measures the failure of a local-global principle), and*

$$\Omega(E) = \Omega_{\text{re}} \cdot \prod_p \Omega_p.$$

Since $L(E,1) \neq 0$, the group Ш(E) is known to be finite [Kol88] of order a perfect square [Cas62].

For any $r = 0, 1, 2, \ldots$ the question we now may ask is: what percentage of elliptic curves (nested according to size of conductor) have rank r? More correctly, we should ask: do these percentages exist, and if so what are they?

3. Conjectures

One fairly firm anchor in the study of elliptic curves is a principle that goes under the heading of parity. This principle is still only conjectural, but is amply confirmed numerically in our accumulated data, and we also have theoretical reasons to believe it.[3] The parity principle is that 50% of the members of any of the sets of elliptic curves we will be considering have even parity, and 50% have odd parity (under reasonable orderings). So by BSD, 50% should have even rank, and 50% should have odd rank.

In general terms, the minimalist principle proclaims that from the rough viewpoint of percentages, there are as few rational points on elliptic curves as is possible, given the constraint of the parity principle. That is, 50% of the members of any of the families of elliptic curves we will be considering have rank $r = 0$, and 50% have rank $r = 1$, and the remaining ranks $r \geq 2$ account for 0% of the family.

As one thing or another things comes to light in the subject, the minimalist position is sometimes favored, and sometimes not. For certain special families of elliptic curves this minimalist conjecture has long been in print, and has had a wild ride in terms of its being believed, and doubted.

3.1. The form of the conjectures.

There are two types of asymptotic conjectures that we encounter in discussions regarding rank statistics. The first we might call a *rough conjecture* where it is asserted, or conjectured, for a certain collection $\mathcal{F}(x)$ of items indexed by a variable x that there is an *exponent* a and a function $x(\epsilon)$ such that the cardinality of $\mathcal{F}(x)$ is bounded above by $x^{a+\epsilon}$ and below by $x^{a-\epsilon}$ for any positive ϵ and any $x \geq x(\epsilon)$.

We also will be discussing *fine conjectures* where such collections $\mathcal{F}(x)$ will be conjectured to have asymptotic estimates of the form

$$\#\mathcal{F}(x) \sim x^a \cdot (\log x)^b \cdot c,$$

for constants a, b, c; the delicacy, of course, of these constants is inversely related to their alphabetical order.

What seems to be a pattern is that the exponent a, appearing in both rough and fine versions, in specific contexts under discussion, can usually be guessed by more

[3] In particular, the sign of the functional equation is a product of local signs for primes $p|\Delta$, each of which is ±1 with equal proportion. See the work of Helfgott [Hel04] for the latest results.

old-fashioned heuristics. But—at present, at least—the on-going work regarding random matrix eigenvalues is the only source of heuristics that lead us to formulate specific "fine conjectures" regarding ranks, and specifically for guesses regarding the exponent b of the $\log x$ term. The fact that the graphs of some of the specific concoctions of the form $x^a \cdot (\log x)^b \cdot c$ predicted by random matrix statistics can look deceivingly like x^1 even though $a < 1$ (and for a significant range of the variable x) is one of the curiosities of our story.

3.2. **Random matrix statistics.** Originally developed in mathematical physics, random matrix theory [Meh04] has now found many applications in number theory, the first being the oft-told story [Dy] of Dyson's remark to Montgomery regarding the pair-correlation of zeros of the Riemann ζ-function. Based on substantial numerical evidence, random matrix theory appears to give reasonable models for the distribution of L-values in families, though the issue of what constitutes a proper "family" can be delicate. The work of Katz and Sarnak [KaSa99] regarding families of curves over function fields implies that for quadratic twists of even parity, we should expect orthogonal symmetry with even parity. Though we have no function field analogue when considering all curves of even parity, we still brazenly assume (largely from looking at the sign in the functional equation) that the symmetry is orthogonal with even parity. What this means is that we want to model properties of the L-function via random matrices taken from $\mathrm{SO}(2M)$ with respect to Haar measure, for an appropriate value of M.[4] We suspect that the L-value distribution is approximately given by the distribution of the evaluations at 1 of the characteristic polynomials of our random matrices. In the large, this distribution is determined entirely by the symmetry type, while finer considerations are distinguished via arithmetic considerations.

Via the moment conjectures [KeSn00] of random matrix theory and then using Mellin inversion, we expect that (for some constant $c > 0$)

$$\mathrm{Prob}[L(E,1) < t] \sim ct^{1/2}(\log N)^{3/8} \qquad \text{as} \qquad t \to 0, \tag{6}$$

when the curves E are taken from a suitable family.

3.3. **Conjectures about twist families.** Let E be an elliptic curve over $\mathbb{Q}$ defined by an equation $y^2 = x^3 + ax + b$. The *quadratic twist* E_d of E by a nonzero integer d is the elliptic curve defined by $y^2 = x^3 + ad^2x + bd^3$. The twist E_d is isomorphic to E over the field $\mathbb{Q}(\sqrt{d})$, and (when d is a fundamental discriminant relatively prime to N_E) the conductor of E_d is $d^2 \cdot N_E$.

Conjecture 3.1. *[Goldfeld,* [Gol79]*]. The average rank of the curves E_d is $\frac{1}{2}$, in the sense that*

$$\lim_{D\to\infty} \frac{\sum_{|d|<D} \mathrm{rank}(E_d)}{\#\{d : |d| < D\}} = \frac{1}{2}.$$

(Here the integers d are fundamental discriminants.)

There are many conditional and unconditional results regarding Goldfeld's conjecture. For a survey, see the papers of Rubin and Silverberg [RS02, Sil01].

The values $L(E_d, 1)$ of quadratic twists E_d of a given curve E essentially appear in a single object, as the coefficients (weighted by the real period and Tamagawa

[4] Here we wish the mean density of zeros of the L-functions to match the mean density of eigenvalues of our matrices, and so, as in [KeSn00], we should take $2M \approx 2 \log N$.

numbers) of an integral modular form g_E of weight $3/2$ (this follows from work of Waldspurger, see [Wal81]). In particular, for many d, we have that $L(E_d, 1) = 0$ precisely when the dth (or $-d$th, depending on the case) coefficient of g_E is zero. This object g_E does not give us values of $L(E_d, 1)$ for all d, but does provide a large proportion of them. The Ramunajan conjecture for modular forms implies that the coefficients of g_E should be bounded by about $|d|^{1/4}$, and so if we assume a coefficient distribution that is somewhat uniform, we approximate the count $F(D)$ of quadratic twists up to D with even parity that have $L(E_d, 1) = 0$ by $\sum_{|d|<D} 1/|d|^{1/4}$. Sarnak's rough heuristic asserts that this count lies between $D^{3/4-\varepsilon}$ and $D^{3/4+\varepsilon}$. Using random matrix theory, the paper [CKRS06] gets the refined heuristic that

$$F(D) \sim D^{3/4} \cdot (\log D)^b \cdot c,$$

where there are four possibilities for b (depending on the Galois group of the cubic polynomial $x^3 - 27c_4x - 54c_6$), and c is still mysterious.

In [CKRS06], Rubinstein used weight 3/2 forms to give data about $L(E_d, 1)$ for over 2000 elliptic curves E. For each of these he computed $L(E_d, 1)$ for a substantial subset of the quadratic twists by fundamental discriminants d with $|d| < 10^8$. (For example, for the curve E given by $y^2 + y = x^3 - x^2$ of conductor 11, the only twist E_{-d} of even parity with $L(E_{-d}, 1) = 0$ for $3 < d < 91$ is $d = 47$.) The data of Rubinstein agree fairly well with predictions such as (1).

It is possible, however, to ameliorate the effects of b and c (and the 3/4-exponent for that matter) via the ratio conjecture of [CKRS02]. Fix an elliptic curve E and a modulus q, prime for simplicity. Consider the d with $\gcd(q, d) = 1$ for which E_d has even parity and $L(E_d, 1) = 0$, and divide these into two classes depending on whether d is a square modulo q. The ratio conjecture asserts that the (asymptotic) ratio of the sizes of these two classes is $\left(\frac{q+1+a_q}{q+1-a_q}\right)^{-1/2}$, where the exponent $-1/2$ comes from the arguments leading to (6). In essence, the d's that are squares should give $c_S X^{3/4}(\log X)^{b_E}$ while those that are not should yield $c_N X^{3/4}(\log X)^{b_E}$, and [CKRS02] predicts c_S/c_N via a clever methodology. The data match this prediction fairly well,[5] especially for $a_q = 0$, when the convergence is quite rapid.

We can also consider other twist families. For example, Kramarz and Zagier [ZK87] considered cubic twists $x^3 + y^3 = m$ of the Fermat cubic[6] $x^3 + y^3 = 1$ and found in their data that 23.3% of the curves with even parity have rank at least 2, and 2.2% of those with odd parity have rank at least 3. One of the authors of the present article [Wat04] and independently Fermigier (unpublished) have followed up on these computations. Also, Patricia Quattrini (Universidad de Buenos Aires) as part of her thesis work (to appear in Experimental Mathematics) did some extensive calculations of the analytic rank for the curves $y^2 = x^3 - nx$. As in the Kramarz-Zagier case, the percentage of curves with analytic rank ≥ 2 was in the 20% range but did seem to be going down. Similar computations [DFK04] have also been undertaken for twists by other (complex) Dirichlet characters, which are related to ranks over number fields. Finally, Fermigier [Fer96] investigated specializations of various (about 100) elliptic curves defined over $\mathbb{Q}(t)$, and found that

[5] In [CPRW] a secondary term is computed, and the fit to the data becomes even better. The paper [Wat04] notes similar data for cubic twists, while [CRSW] analyses the data of Elkies for the congruent number curve in the odd parity case.

[6] Note that this is rationally isomorphic to the elliptic curve in the form (3) given by the equation $Y^2 = X^3 - 54 \cdot 5832$ via the map $(X, Y) = \big(108/(x + y), 972(y - x)/(y + x)\big)$.

typically 10-20% of the specializations had excess rank that could not be explained simply from parity.

3.4. **Conjectures when counting all elliptic curves.** Before we can count curves with even parity and infinitely many points, we might first take a step back, and just try to count curves. Though before we ordered curves by conductor, when deriving heuristics it is often easier to sort by discriminant. Indeed, Brumer and McGuinness [BM90, §5] state a heuristic estimate for the number of minimal discriminants of elliptic curves up to a given bound:

Conjecture 3.2. *[Brumer-McGuinness]. We have the following estimates for the number of positive or negative minimal discriminants of elliptic curves of absolute value at most X (respectively):*

$$A_{\pm}(X) \sim \frac{\alpha_{\pm}}{\zeta(10)} X^{5/6}$$

where $\alpha_+ = 0.4206\ldots$ and $\alpha_- = \sqrt{3}\alpha_+ = 0.7285\ldots$ are given by

$$\alpha_{\pm} = \frac{\sqrt{3}}{10} \int_{\pm 1}^{\infty} \frac{du}{\sqrt{u^3 \mp 1}}.$$

Brumer and McGuinness say little about their derivation of this heuristic, but remark that it suggests a heuristic for prime discriminants that matches very well with their data. We can derive their heuristic by counting lattice points in the (c_4, c_6)-plane, restricting to congruence classes modulo powers of 2 and 3 to ensure that Δ is integral. Because $\Delta = (c_4^3 - c_6^2)/1728$, we heuristically have that $A_+(X)$ is proportional to the area of the region $0 < c_4^3 - c_6^2 < 1728X$, and similarly with $A_-(X)$. This gives $\alpha_{\pm} X^{5/6}$; the extra factor of $\zeta(10)$ comes about since we need (for $p \geq 5$, and similarly for $p = 2, 3$) to eliminate (c_4, c_6) pairs with $p^4 | c_4$ and $p^6 | c_6$. For a more complete derivation of the value of $\alpha_{\pm}$ see [Wat06].

We expect that half of these curves have even parity. Now we wish to estimate how many of the curves with even parity have $L(E, 1) = 0$.

3.5. **Rank conjectures for all curves.** To make use of the heuristic (6), we introduce a discretization process. We want to connect $L(E, 1)$ with the *winding number* $W = W(E) = |L(E, 1)/\Omega_{\mathrm{re}}|$ (see [MSD74, §2.2]),[7] and measure the likelihood that W is 0. Ignoring torsion (so that W is an integer) we are trying to estimate the probability that $L(E, 1) < \Omega(E)$. If we consider *only* elliptic curves for which $\Omega(E)$ lies in a fixed interval $c_1 < \Omega(E) < c_2$ then we get a neat estimate of this probability. So this line of reasoning leads one to try to deal with the statistics of the invariant $\Omega(E)$ for varying E.

Next, we simplify matters by restricting to curves with prime positive discriminant (and even parity). Three nice things about these curves are that (except for a sparse subset): all have trivial torsion; all have $\Omega_p = 1$ for all (finite) primes p; and all have that $N = \Delta$. The idea of our discretization is that W can only take on integral values (note that when $W \neq 0$, Conjecture 2.1 implies that $W = \#Ш(E)$, which is a perfect square, but we will not use this). Thus, in terms of our probability distribution of L-values, we get that $L(E, 1) < \Omega_{\mathrm{re}}$ if and only if $L(E, 1) = 0$;

[7] We could relate W to the Birch and Swinnerton-Dyer conjecture, but the (topological) winding number interpretation is rigorous and sufficient for our needs.

this is because

$$0 \leq W = \left| \frac{L(E,1)}{\Omega_{\mathrm{re}}} \right| < 1$$

and W is an integer.

Putting $t = \Omega_{\mathrm{re}}$ and $N = \Delta$ in (6) we get:

Heuristic 3.3. *A curve with positive prime discriminant and even parity has infinitely many points with probability* $c\Omega_{\mathrm{re}}^{1/2}(\log \Delta)^{3/8}$.

Using the above, the number $B(X)$ of such curves up to X with even parity and infinitely many points is estimated by integrating $\int\int c\Omega_{\mathrm{re}}^{1/2}(\log\Delta)^{3/8-1}du_4du_6$ over the region $|u_4^3 - u_6^2| < 1728X$, where the "-1" in the exponent of $\log\Delta$ comes about from the prime number theorem. Also, the integral makes sense because Ω_{re} and Δ are smooth functions of c_4 and c_6, that is, we can define Ω_{re} and Δ for c_4 and c_6 that are not necessarily integral (or even rational). So, similar to the above discussion of the Brumer-McGuinness heuristic, we have replaced a (weighted) lattice-point problem with the area of a region in a plane, weighted by a factor depending on the real period and the discriminant (and congruence restrictions as before).

We expect that the typical size[8] of the real period Ω_{re} is $1/|\Delta|^{1/12}$, and so, from the above heuristic,[9] we thus get a crude estimate that $B(X)$ is of size $X^{19/24}$.

The preprint [Wat06] handles more of the details, and considers all curves, not only those with prime discriminant. Indeed, if $F(X)$ is the number of elliptic curves E with even parity and $L(E,1) = 0$ and $|\Delta| \leq X$ then [Wat06] predicts

$$F(X) \sim c_1 X^{19/24}(\log X)^{3/8},$$

with a computable[10] positive constant c_1.

In any case, since we expect $cX^{5/6}$ curves with $|\Delta| \leq X$, this heuristic says that 100% of the even parity curves have rank 0.

The best known results (conditional on a Generalized Riemann Hypothesis and a Parity Principle analogue) on nonvanishing of even parity L-functions appear in the work of Young [YouB], and results about average (analytic) ranks and their relation to random matrix theory appear in [YouA].

3.6. **Ordering by conductor.** The predictions become more difficult to derive when we order by conductor instead of discriminant, as this introduces arithmetic considerations related to the ABC-conjecture (see [GT02]) in the accounting. Even giving a heuristic for the number $C(X)$ of curves of conductor less than X is nontrivial. The preprint [Wat06] asserts heuristic asymptotics of $c_2 X^{5/6}$ for $C(X)$ and similarly $c_3 X^{19/24}(\log X)^{3/8}$ for the number of rank 2 curves with conductor less than X. However, Cremona's data (see below) might suggest linear growth

[8] This is also an upper bound; the ABC conjecture says Ω_{re} is never much smaller than $1/|\Delta|^{1/2}$.

[9] Note that random matrix theory is largely used to determine the power of logarithm in this heuristic. The cruder estimate of $X^{19/24}$ can alternatively be obtained by assuming that the winding number is a random square integer of size up to $1/\Omega_{\mathrm{re}}$ (this is similar to Sarnak's heuristic); indeed this was probably known to Brumer and McGuinness, as they conclude their paper with

> *While our data may seem massive,* $N = 10^8$ *is not sufficient to distinguish growth laws of* $\log\log N$, $N^{1/12}$ *or* $N^{1/24}$ *from constants. So we have to be cautious in formulating conjectures based on the numerical evidence.*

[10] Our imprecise discretization might make the computed value of c_1 not too relevant.

for $C(X)$. In any event, in all cases we expect that 100% of the even parity curves have rank 0. Despite our lack of numerical confirmation, we label these guesses as "conjectures":

Conjecture 3.4. *The number of even parity elliptic curves with infinitely many rational points and absolute discriminant less than X is asymptotically given by $c_1 X^{19/24}(\log X)^{3/8}$ for some positive computable constant c_1 as $X \to \infty$. If we replace absolute discriminant by conductor, we get an asymptotic of $c_3 X^{19/24}(\log X)^{3/8}$. In particular, asymptotically almost all elliptic curves with even parity have finitely many rational points.*

See [Wat06] for more details.

4. Data

> The opinion had been expressed that, in general, an elliptic curve might tend to have the smallest possible rank, namely 0 or 1, compatible with the rank parity predictions of Birch and Swinnerton-Dyer. We present evidence that this may not be the case. [...] This proportion of rank 2 curves seemed too large to conform to the conventional wisdom. – Brumer and McGuinness [BM90]

In [BM90], Brumer and McGuinness considered over 310000 curves of prime conductor $\leq 10^8$. In this section we discuss extensions of their data, and answer in the affirmative that there is a similar large proportion of rank 2 curves for composite conductor $\leq 10^8$, and for prime conductor $\leq 10^{10}$. More precisely, we consider 136832795 curves of all conductors $\leq 10^8$, and 11378911 curves of prime conductor $\leq 10^{10}$. The results of the rank computation we describe are similar to those of Brumer and McGuinness, which appear to suggest that if one orders all elliptic curves over $\mathbb{Q}$ by conductor, then the average rank is bigger than 0.5. However, as discussed above, we conjecture that the average rank is 0.5.

4.1. Brumer-McGuinness.

In [BM90], Brumer and McGuinness found, by thousands of hours of computer search, 311219 curves of prime conductor $\leq 10^8$. For 310716 of these curves they computed the probable rank by a combination of point searches and computation of apparent order of vanishing of L-functions. Table 1 (expanded from [BM90]) summarizes the rank distribution that they found.[11]

Table 1. Brumer-McGuinness Rank Distribution

Rank	0	1	2	3	4	5
$\Delta > 0$	31748	51871	24706	5267	377	0
$\Delta < 0$	61589	91321	36811	6594	427	5
Total # Curves	93337	143192	61517	11861	804	5
Proportion	0.300	0.461	0.198	0.038	0.0026	0.00002
Proportion $\Delta > 0$	0.279	0.455	0.217	0.046	0.0033	0.00000
Proportion $\Delta < 0$	0.313	0.464	0.187	0.034	0.0022	0.00003

[11] Some of their counts were computed incorrectly (for instance, they only used 4000 terms of the L-series, and thus mis-identified 11 curves of rank 0 as having rank 2), but this has little influence on the overall statistics.

In Table 1, note that curves with $\Delta > 0$ are more likely to have large rank. Let $r_\varepsilon(X)$ be the average rank of elliptic curves in [BM90] with conductor at most X and discriminant sign ε. They observe that in their data, r_+ climbs to 1.04 and r_- climbs to 0.94, and they remark that *"An interesting phenomenon was the systematic influence of the discriminant sign on all aspects of the arithmetic of the curve."* The more extensive computations do *not* always find this to be the case; see, in particular, Figure 3 below, where the graphs split by discriminant cross.

4.2. **The Stein-Watkins Database.** Brumer and McGuinness fixed the a_1, a_2, a_3 invariants (12 total possibilities, as (2) can be modified first to be integral, and then to ensure that $a_1, a_3 \in \{0, 1\}$ and $|a_2| \leq 1$) and then searched for a_4 and a_6 that made $|\Delta|$ small. Stein and Watkins [SW02] broke the c_4 and c_6 invariants into congruence classes, and then found small solutions to $c_4^3 - c_6^2 = 1728\Delta$, with c_4, c_6 minimal in the sense of (3). There is little theoretical advantage in this approach; more computing power and disk space were the main advances in [SW02]. Stein and Watkins searched for curves with prime conductor up to 10^{10}, and for composite conductor chose $|\Delta| < 10^{12}$ and $N \leq 10^8$ as search bounds, and then included isogenous curves and twists (with $N \leq 10^8$) of the curves they found.

4.3. **Completeness of the Databases.** Note that neither the method of Brumer-McGuinness nor Stein-Watkins is guaranteed to find all curves of prime (absolute) discriminant up to a given bound (indeed, it is more likely that they miss a few curves), but we think that their data sets are reasonable surrogates, and should exhibit validity when compared to the predictions of the theoretical model.

For curves of composite conductor, the Stein-Watkins database is much more likely to miss curves. Here the comparison is to the data set of Cremona [Cre], who used the algorithms of [Cre97] and the modularity theorem of [BCDT01] to find *every* elliptic curve of conductor up to 120000. Cremona found 782493 curves up to conductor 120000. In the Stein-Watkins computation, they found 614442 curves of conductor up to 120000, so they found over 78.5% of the curves. The first case in which Cremona has a curve and Stein-Watkins do not is the curve $y^2 + xy + y = x^3 - 7705x + 1226492$ of conductor 174, which has discriminant $-621261297432576 = -2^{11} \cdot 3^{21} \cdot 29$, whose absolute value is substantially larger than 10^{12}. The conductors up to 500 where they miss curves are

$$174, 222, 273, 291, 330, 354, 357, 390, 420, 442, 462, 493.$$

Figure 2 shows the proportion of the number of curves in the Stein-Watkins database to the number of curves in Cremona's database, as a function of the conductor.

The rank distribution of Cremona's curves is given in Table 2. The average rank for Cremona's curves is about 0.688. This is smaller than the average rank in other data sets we consider (and is probably explainable via the real period considerations of the last section), but we prefer to highlight the results from other data sets.

Table 2. Rank Distribution of All Curves of Conductor $\leq$ 120000

Rank	0	1	2	3
Proportion	0.404	0.505	0.090	0.001
Proportion $\Delta > 0$	0.408	0.503	0.087	0.001
Proportion $\Delta < 0$	0.401	0.506	0.092	0.001

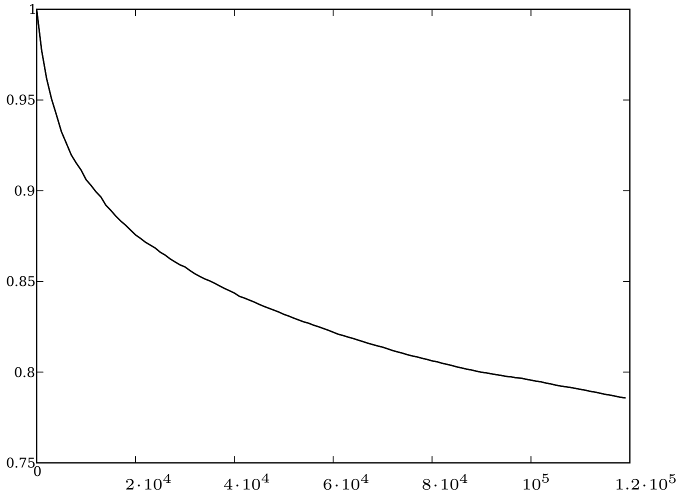

Figure 2. Proportion of Cremona's Curves obtained by Stein and Watkins for $N \leq 120000$

As noted above, when ordering by conductor there is presently no consensus guesstimate for the number of curves up to X. Cremona has commented that there is approximately linear growth in the number of curves of conductor less than 120000, and extrapolating this gives a prediction close to 650 million for the number of curves with $N \leq 10^8$.

D. J. Bernstein suggested that we try to quantify the completeness of the Stein-Watkins database by considering what percentage of Cremona's curves would be obtained by using their search methods with a smaller discriminant bound. That is, for a parameter B, if we find all curves with $N \leq B^2$, $|\Delta| \leq B^3$, and $c_4 \leq 100 \cdot (12B)^2$, and then take all isogenous curves and twists of these with conductor less than B^2, what percentage of Cremona's curves do we obtain? With $B = 300$, we get 246532 curves, while Cremona has 592519 curves of conductor $\leq 90000 = 300^2$, so we get about 42%. Applying this percentage to the Stein-Watkins database with $B = 10^4$, this would suggest that there are about 325 million elliptic curves with conductor less than 10^8. So the two guesses differ by a factor of two, exemplifying our ignorance on so basic an issue.

5. Average Ranks: Graphs of Data

This section contains graphs that at a glance suggest that the minimalist principle is contradicted by the data for curves of conductor $\leq 10^8$; indeed, particularly in Figure 3, we see that *the average rank is increasing!* However, for prime conductor $\leq 10^{10}$ the average rank drops, though only slightly from 0.978 to 0.964. With some imagination, the distribution of rank for prime conductor might appear to support the minimalist conjecture that the average rank is 0.5. Table 3 gives the average rank for various collections of curves that are described in more detail elsewhere in this paper and section.

TABLE 3. Average Ranks

Cremona's curves of conductor ≤ 120000	0.688
All Stein-Watkins curves of conductor $\leq 10^8$	0.865
Brumer-McGuinness curves of prime conductor $\leq 10^8$	0.982
Stein-Watkins curves of prime conductor $\leq 10^{10}$	0.964
Selected curves of prime conductor near 10^{14} with $\Delta < 0$	0.869
Selected curves of prime conductor near 10^{14} with $\Delta > 0$	0.938

In this section when we write elliptic curves with property P, we mean elliptic curves in the Stein-Watkins database with property P.

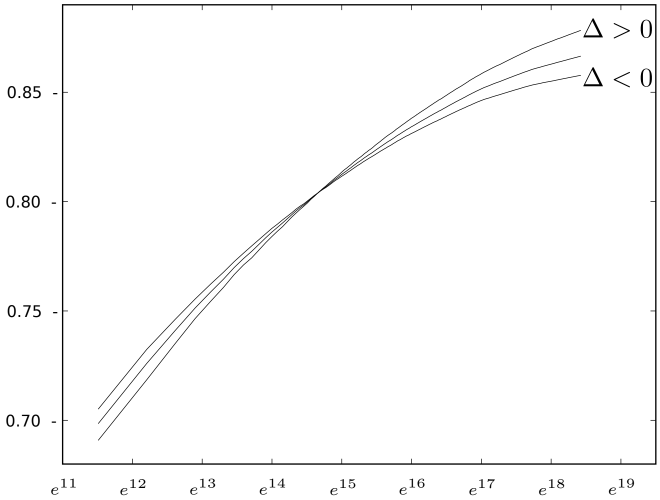

FIGURE 3. Average Rank of Stein-Watkins Curves of Conductor $\leq 10^8$

5.1. **Curves Ordered By Conductor.** The average rank of all Stein-Watkins curves with conductor $\leq 10^8$ is about 0.87. Figure 3 gives the average rank as a function of log of the conductor, and also the average rank for curves of positive and negative discriminant. We created this graph by computing the average rank of curves of conductor up to $n \cdot 10^5$ for $1 \leq n \leq 1000$. Figure 4 graphs the proportion of curves with each rank 0, 1, 2, and 3, as a function of log of the conductor, all on a single graph. The overall rank proportions are in Table 4.

TABLE 4. Rank Distribution for Stein-Watkins Curves with $N \leq 10^8$

Rank	0	1	2	3	≥ 4
Proportion	0.336	0.482	0.163	0.019	0.000
Proportion $\Delta > 0$	0.331	0.480	0.168	0.020	0.000
Proportion $\Delta < 0$	0.339	0.482	0.160	0.018	0.000

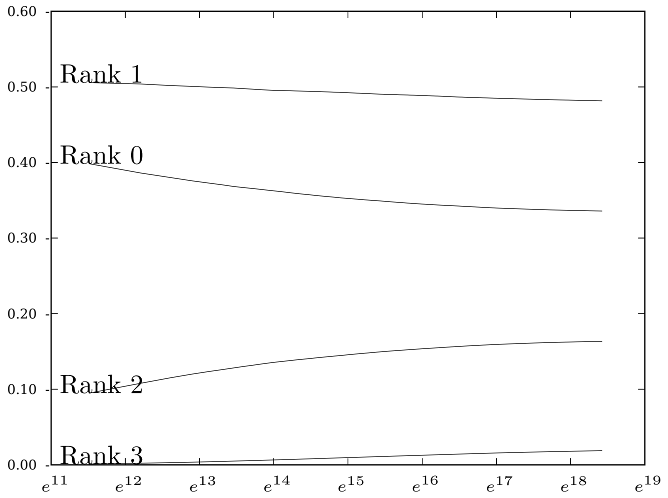

FIGURE 4. Rank Distribution of Stein-Watkins Curves with $N \leq 10^8$

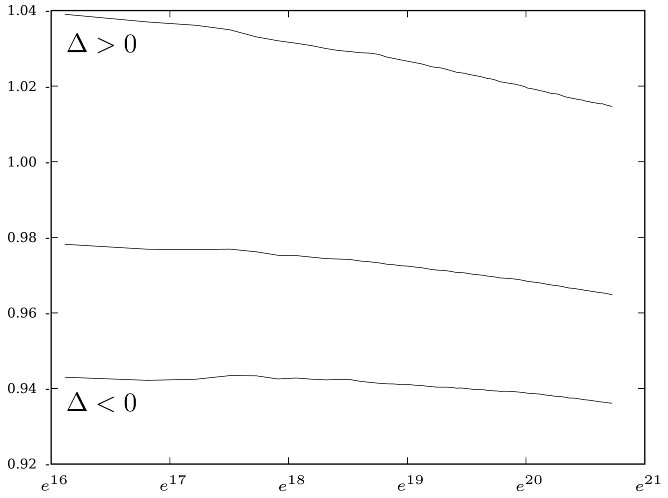

FIGURE 5. Average Rank of Curves with prime $N \leq 10^{10}$

5.2. **Prime Conductor Curves.** The average rank for the curves of prime conductor $\leq 10^{10}$ is about 0.964; see Table 5 for the rank distribution. Figure 5 plots the average rank of curves of prime conductor $\leq 10^{10}$ as a function of log of the conductor. Note that here the average ranks are decreasing, unlike in Figure 3.

5.2.1. *An experiment.* The data of [BM90] and [SW02] for curves of prime conductor up to 10^8 and 10^{10} show very little drop in the observed average rank.

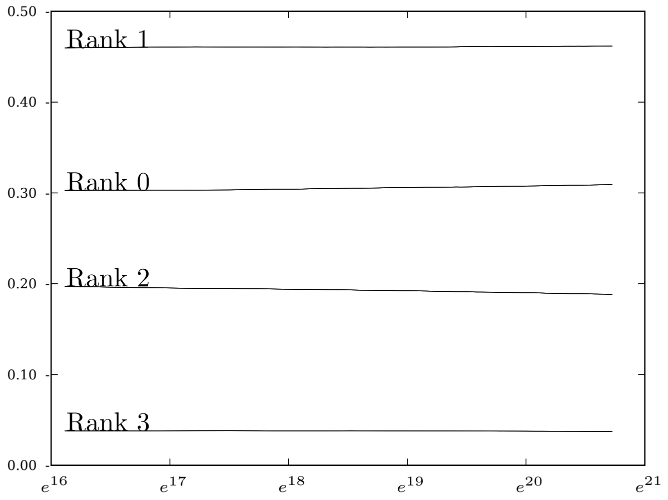

FIGURE 6. Rank Distribution of Curves with prime $N \leq 10^{10}$

TABLE 5. Rank Distribution for Prime Conductor $\leq 10^{10}$

Rank	0	1	2	3	≥ 4
Proportion	0.309	0.462	0.188	0.037	0.004
Proportion $\Delta > 0$	0.291	0.457	0.204	0.044	0.004
Proportion $\Delta < 0$	0.320	0.465	0.179	0.033	0.003

To investigate the possibility that the average rank might not decrease much below 0.964 we chose a selection of curves with prime conductor of size 10^{14}. It is non-trivial to get a good data set, since we must take congruence conditions on the elliptic curve coefficients and the variation of the size of the real period into account; see [Wat06] for more details on how to account for this.

Our data sets contained 89913 curves of positive prime discriminant, and 89749 similar curves with negative discriminant, with $|\Delta|$ near 10^{14} for all the curves. It then took a few months to compute the analytic rank for these curves. We found that for positive discriminant the average analytic rank is approximately 0.937 and for negative discriminant it is approximately 0.869 (see Table 6 for more details). Note that this is significantly less than the average rank found in [BM90] and [SW02]. It could be said that this is the strongest numerical evidence yet for the Minimalist Conjecture, though, it is still very weak. Incidentally, the largest rank found in any of these data sets is 6.

Let $f(\Delta)$ be the "probability" that $L(E, 1) = 0$ for an even parity curve of discriminant near Δ for Δ positive. For example, Tables 5 and 6 suggests that

$$f(10^{10}) \sim \frac{0.204 + 0.004}{0.291 + 0.204 + 0.004} = 0.417\ldots$$

$$f(10^{14}) \sim \frac{0.176 + 0.004}{0.319 + 0.176 + 0.004} = 0.361\ldots$$

Table 6. Rank Distribution For a Selection of Curves With Prime Conductor Near 10^{14}

Rank	0	1	2	3	≥ 4
Proportion $\Delta > 0$	0.319	0.467	0.176	0.034	0.004
Proportion $\Delta < 0$	0.343	0.475	0.154	0.025	0.002

(Note that we approximated $f(10^{10})$ using data for all $|\Delta| < 10^{10}$.) Motivated by the discussion in Section 3, we might heuristically approximate this probability function by $\hat{f}(\Delta) = c \cdot (\log \Delta)^{3/8}/\Delta^{1/24}$, where $\Delta^{1/24}$ comes about as the square root of the "typical" real period. The value of $\hat{f}(10^{10})/\hat{f}(10^{14})$ is about 1.29, which is not ridiculously far from the observed ratio of

$$\frac{f(10^{10})}{f(10^{14})} \sim \frac{0.417}{0.361} \sim 1.16.$$

5.3. **Variants.** We also carried out computations similar to the ones described above when counting isogeny classes instead of isomorphism classes of curves (isogeny is a coarser equivalence relation than isomorphism, grouping together curves between which there is a finite degree morphism). In our data the average size of isogeny classes for all curves of conductor up to X converges reasonably quickly to 1 (Duke has shown [Duk97] that this is indeed the case under a different ordering). Thus the data and graphs look almost identical to those presented above. Table 7 gives rank data for other subsets of the Stein-Watkins database of curves of conductor $\leq 10^8$. In the table, "has CM" refers to curves that have complex multiplication, i.e., whose endomorphism ring (over $\mathbb{C}$) is bigger than $\mathbb{Z}$.

Table 7. Distribution of Rank in Various Subsets of the Stein-Watkins Database with Conductor $N < 10^8$

Description	**Number**	**Rank 0**	**Rank 1**	**Rank 2**	**Rank** ≥ 3
All Curves	136832795	0.336	0.482	0.163	0.019
All Isogeny Classes	115821258	0.328	0.480	0.171	0.021
Has Isogeny	38599162	0.375	0.492	0.125	0.008
Has nontrivial torsion	35249448	0.373	0.492	0.127	0.008
N squarefree	21841534	0.296	0.467	0.202	0.034
Has Full 2-torsion	1674285	0.392	0.496	0.107	0.005
N is square	538558	0.416	0.496	0.084	0.004
N is prime	312435	0.303	0.460	0.197	0.041
Has 3-torsion	184590	0.422	0.498	0.078	0.002
Has CM	135226	0.411	0.498	0.087	0.005
N is prime squared	517	0.439	0.480	0.072	0.010

6. How can we *systematically* account for the Mordell-Weil rank we have already computed?

Forget all questions of asymptotics. Consider only the curves of prime conductor up to 10^{10} in our data. Is there an argument other than just computing ranks for each of the elliptic curves in the databases—is there a pure thought heuristic—that explains why we are witnessing so much Mordell-Weil rank? In a sense, these rational points are both analogous, and not analogous, to the physicist's dark matter.[12] This large mass of rational points for elliptic curves of prime conductor $\leq 10^{10}$ is palpably there. We aren't in the dark about that. We are merely in the dark about how to give a satisfactory account of it being there, other than computing instances, one after another.

We are, in a word, just at the very beginning of this story.

Abstract. This is a textbook about algorithms for computing with modular forms. It is nontraditional in that the primary focus is not on underlying theory; instead, it answers the question *"how do you explicitly compute spaces of modular forms?"*

To my grandmother, Annette Maurer.

Contents

Preface

This is a graduate-level textbook about algorithms for computing with modular forms. It is nontraditional in that the primary focus is not on underlying theory; instead, it answers the question *"how do you use a computer to explicitly compute spaces of modular forms?"*

This book emerged from notes for a course the author taught at Harvard University in 2004, a course at UC San Diego in 2005, and a course at the University of Washington in 2006.

The author has spent years trying to find good practical ways to compute with classical modular forms for congruence subgroups of $\mathrm{SL}_2(\mathbb{Z})$ and has implemented most of these algorithms several times, first in C++ [**Ste99b**], then in MAGMA [**BCP97**], and as part of the free open source computer algebra system SAGE (see [**Ste06**]). Much of this work has involved turning formulas and constructions buried in obscure research papers into precise computational recipes then testing these and eliminating inaccuracies.

The author is aware of no other textbooks on computing with modular forms, the closest work being Cremona's book [**Cre97a**], which is about computing with elliptic curves, and Cohen's book [**Coh93**] about algebraic number theory.

In this book we focus on how to compute *in practice* the spaces $M_k(N, \varepsilon)$ of modular forms, where $k \geq 2$ is an integer and ε is a Dirichlet character of modulus N (the appendix treats modular forms for higher rank groups). We spend the most effort explaining the general algorithms that appear so far to be the best (in practice!) for such computations. We will not discuss in any detail computing with quaternion algebras, half-integral weight forms, weight 1 forms, forms for noncongruence subgroups or groups other than GL_2, Hilbert and Siegel modular forms, trace formulas, p-adic modular forms, and modular abelian varieties, all of which are topics for additional books. We also rarely analyze the complexity of the algorithms, but instead settle for occasional remarks about their practical efficiency.

For most of this book we assume the reader has some prior exposure to modular forms (e.g., [**DS05**]), though we recall many of the basic definitions. We cite standard books for proofs of the fundamental results about modular forms that we will use. The reader should also be familiar with basic algebraic number theory, linear algebra, complex analysis (at the level of [**Ahl78**]), and algorithms (e.g., know what an algorithm is and what big oh notation means). In some of the examples and applications we assume that the reader knows about elliptic curves at the level of [**Sil92**].

Chapter 1 is foundational for the rest of this book. It introduces congruence subgroups of $\mathrm{SL}_2(\mathbb{Z})$ and modular forms as functions on the complex upper half plane. We discuss q-expansions, which provide an important computational handle on modular forms. We also study an algorithm for computing with congruence subgroups. The chapter ends with a list of applications of modular forms throughout mathematics.

In Chapter 2 we discuss level 1 modular forms in much more detail. In particular, we introduce Eisenstein series and the cusp form Δ and describe their q-expansions and basic properties. Then we prove a structure theorem for level 1 modular forms and use it to deduce dimension formulas and give an algorithm for explicitly computing a basis. We next introduce Hecke operators on level 1 modular forms, prove several results about them, and deduce multiplicativity of the Ramanujan τ function as an application. We also discuss explicit computation of Hecke operators. In Section 2.6 we make some brief remarks on recent work on asymptotically fast computation of values of τ. Finally, we describe computation of constant terms of Eisenstein series using an analytic algorithm. We generalize many of the constructions in this chapter to higher level in subsequent chapters.

In Chapter 3 we turn to modular forms of higher level but restrict for simplicity to weight 2 since much is clearer in this case. (We remove the weight restriction later in Chapter 8.) We describe a geometric way of viewing cuspidal modular forms as differentials on modular curves, which leads to modular symbols, which are an explicit way to present a certain homology group. This chapter closes with methods for explicitly computing cusp forms of weight 2 using modular symbols, which we generalize in Chapter 9.

In Chapter 4 we introduce Dirichlet characters, which are important both in explicit construction of Eisenstein series (in Chapter 5) and in decomposing spaces of modular forms as direct sums of simpler spaces. The main focus of this chapter is a detailed study of how to explicitly represent and compute with Dirichlet characters.

Chapter 5 is about how to explicitly construct the Eisenstein subspace of modular forms. First we define generalized Bernoulli numbers attached to a Dirichlet character and an integer then explain a new analytic algorithm for computing them (which generalizes the algorithm in Chapter 2). Finally we give without proof an explicit description of a basis of Eisenstein series, explain how to compute it, and give some examples.

Chapter 6 records a wide range of dimension formulas for spaces of modular forms, along with a few remarks about where they come from and how to compute them.

Chapter 7 is about linear algebra over exact fields, mainly the rational numbers. This chapter can be read independently of the others and does not require any background in modular forms. Nonetheless, this chapter occupies a central position in this book, because the algorithms in this chapter are of crucial importance to any actual implementation of algorithms for computing with modular forms.

Chapter 8 is the most important chapter in this book; it generalizes Chapter 3 to higher weight and general level. The modular symbols formulation described here is central to general algorithms for computing with modular forms.

Chapter 9 applies the algorithms from Chapter 8 to the problem of computing with modular forms. First we discuss decomposing spaces of modular forms using Dirichlet characters, and then explain how to compute a basis of Hecke eigenforms for each subspace using several approaches. We also discuss congruences between modular forms and bounds needed to provably generate the Hecke algebra.

Chapter 10 is about computing analytic invariants of modular forms. It discusses tricks for speeding convergence of certain infinite series and sketches how to compute every elliptic curve over $\mathbb{Q}$ with given conductor.

Chapter 11 contains detailed solutions to most of the exercises in this book. (Many of these were written by students in a course taught at the University of Washington.)

Appendix A deals with computational techniques for working with generalizations of modular forms to more general groups than $\mathrm{SL}_2(\mathbb{Z})$, such as $\mathrm{SL}_n(\mathbb{Z})$ for $n \geq 3$. Some of this material requires more prerequisites than the rest of the book. Nonetheless, seeing a natural generalization of the material in the rest of this book helps to clarify the key ideas. The topics in the appendix are directly related to the main themes of this book: modular symbols, Manin symbols, cohomology of subgroups of $\mathrm{SL}_2(\mathbb{Z})$ with various coefficients, explicit computation of modular forms, etc.

Software. We use SAGE, Software for Algebra and Geometry Experimentation (see [**Ste06**]), to illustrate how to do many of the examples. SAGE is completely free and packages together a wide range of open source mathematics software for doing much more than just computing with modular forms. SAGE can be downloaded and run on your computer or can be used via a web browser over the Internet. The reader is encouraged to experiment with many of the objects in this book using SAGE. We do not describe the basics of using SAGE in this book; the reader should read the SAGE tutorial (and other documentation) available at the SAGE website [**Ste06**]. All examples in this book have been automatically tested and should work exactly as indicated in SAGE version at least 1.5.

Acknowledgements. David Joyner and Gabor Wiese carefully read the book and provided a huge number of helpful comments.

John Cremona and Kevin Buzzard both made many helpful remarks that were important in the development of the algorithms in this book. Much of the mathematics (and some of the writing) in Chapter 10 is joint work with Helena Verrill.

Noam Elkies made remarks about Chapters 1 and 2. Sándor Kovács provided interesting comments on Chapter 1. Allan Steel provided helpful feedback on Chapter 7. Jordi Quer made useful remarks about Chapter 4 and Chapter 6.

The students in the courses that I taught on this material at Harvard, San Diego, and Washington provided substantial feedback: in particular, Abhinav Kumar made numerous observations about computing widths of cusps (see Section 1.4.1) and Thomas James Barnet-Lamb made helpful remarks about how to represent Dirichlet characters. James Merryfield made helpful remarks about complex analytic issues and about convergence in Stirling's formula. Robert Bradshaw, Andrew Crites (who wrote Exercise 7.5), Michael Goff, Dustin Moody, and Koopa Koo wrote most of the solutions included in Chapter 11 and found numerous typos throughout the book. Dustin Moody also carefully read through the book and provided feedback.

H. Stark suggested using Stirling's formula in Section 2.7.1, and Mark Watkins and Lynn Walling made comments on Chapter 3.

Justin Walker found typos in the first published version of the book.

Parts of Chapter 1 follow Serre's beautiful introduction to modular forms [**Ser73**, Ch. VII] closely, though we adjust the notation, definitions, and order of presentation to be consistent with the rest of this book.

I would like to acknowledge the partial support of NSF Grant DMS 05-55776. Gunnells was supported in part by NSF Grants DMS 02-45580 and DMS 04-01525.

Notation and Conventions. We denote canonical isomorphisms by $\cong$ and noncanonical isomorphisms by $\approx$. If V is a vector space and s denotes some sort of construction involving V, we let V_s denote the corresponding subspace and V^s the quotient space. E.g., if ι is an involution of V, then V_+ is $\mathrm{Ker}(\iota - 1)$ and $V^+ = V/\mathrm{Im}(\iota - 1)$. If A is a finite abelian group, then A_{tor} denotes the torsion subgroup and A/tor denotes the quotient A/A_{tor}. We denote right group actions using exponential notation. Everywhere in this book, N is a positive integer and k is an integer.

If N is an integer, a *divisor* t of N is a *positive* integer such that N/t is an integer.

Chapter 1

Modular Forms

This chapter introduces modular forms and congruence subgroups, which are central objects in this book. We first introduce the upper half plane and the group $\mathrm{SL}_2(\mathbb{Z})$ then recall some definitions from complex analysis. Next we define modular forms of level 1 followed by modular forms of general level. In Section 1.4 we discuss congruence subgroups and explain a simple way to compute generators for them and determine element membership. Section 1.5 lists applications of modular forms.

We assume familiarity with basic number theory, group theory, and complex analysis. For a deeper understanding of modular forms, the reader is urged to consult the standard books in the field, e.g., [**Lan95, Ser73, DI95, Miy89, Shi94, Kob84**]. See also [**DS05**], which is an excellent first introduction to the theoretical foundations of modular forms.

1.1. Basic Definitions

The group

$$\mathrm{SL}_2(\mathbb{R}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : ad - bc = 1 \text{ and } a, b, c, d \in \mathbb{R} \right\}$$

acts on the *complex upper half plane*

$$\mathfrak{h} = \{z \in \mathbb{C} : \mathrm{Im}(z) > 0\}$$

by *linear fractional transformations*, as follows. If $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{R})$, then for any $z \in \mathfrak{h}$ we let

$$\gamma(z) = \frac{az + b}{cz + d} \in \mathfrak{h}. \tag{1.1.1}$$

Since the determinant of γ is 1, we have

$$\left(\frac{d}{dz}\gamma\right)(z) = \frac{1}{(cz+d)^2}.$$

Definition 1.1 (Modular Group)**.** The *modular group* is the group of all matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with $a, b, c, d \in \mathbb{Z}$ and $ad - bc = 1$.

For example, the matrices

$$S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \qquad \text{and} \qquad T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \tag{1.1.2}$$

are both elements of $\mathrm{SL}_2(\mathbb{Z})$; the matrix S induces the function $z \mapsto -1/z$ on $\mathfrak{h}$, and T induces the function $z \mapsto z + 1$.

Theorem 1.2. *The group* $\mathrm{SL}_2(\mathbb{Z})$ *is generated by* S *and* T*.*

Proof. See e.g. [**Ser73**, §VII.1]. □

In SAGE we compute the group $\mathrm{SL}_2(\mathbb{Z})$ and its generators as follows:

```
sage: G = SL(2,ZZ); G
Modular Group SL(2,Z)
sage: S, T = G.gens()
sage: S
[ 0 -1]
[ 1  0]
sage: T
[1 1]
[0 1]
```

Definition 1.3 (Holomorphic and Meromorphic)**.** Let R be an open subset of $\mathbb{C}$. A function $f : R \to \mathbb{C}$ is *holomorphic* if f is complex differentiable at every point $z \in R$, i.e., for each $z \in R$ the limit

$$f'(z) = \lim_{h \to 0} \frac{f(z+h) - f(z)}{h}$$

exists, where h may approach 0 along any path. A function $f : R \to \mathbb{C} \cup \{\infty\}$ is *meromorphic* if it is holomorphic except (possibly) at a discrete set S of points in R, and at each $\alpha \in S$ there is a positive integer n such that $(z - \alpha)^n f(z)$ is holomorphic at α.

The function $f(z) = e^z$ is a holomorphic function on $\mathbb{C}$; in contrast, $1/(z - i)$ is meromorphic on $\mathbb{C}$ but not holomorphic since it has a pole at i. The function $e^{-1/z}$ is not even meromorphic on $\mathbb{C}$.

Modular forms are holomorphic functions on $\mathfrak{h}$ that transform in a particular way under a certain subgroup of $\mathrm{SL}_2(\mathbb{Z})$. Before defining general modular forms, we define modular forms of level 1.

1.2. Modular Forms of Level 1

Definition 1.4 (Weakly Modular Function)**.** A *weakly modular function* of *weight* $k \in \mathbb{Z}$ is a meromorphic function f on $\mathfrak{h}$ such that for all $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ and all $z \in \mathfrak{h}$ we have

$$f(z) = (cz+d)^{-k} f(\gamma(z)). \tag{1.2.1}$$

The constant functions are weakly modular of weight 0. There are no nonzero weakly modular functions of odd weight (see Exercise 1.4), and it is not obvious that there are any weakly modular functions of even weight $k \geq 2$ (but there are, as we will see!). The product of two weakly modular functions of weights k_1 and k_2 is a weakly modular function of weight $k_1 + k_2$ (see Exercise 1.3).

When k is even, (1.2.1) has a possibly more conceptual interpretation; namely (1.2.1) is the same as

$$f(\gamma(z))(d(\gamma(z)))^{k/2} = f(z)(dz)^{k/2}.$$

Thus (1.2.1) simply says that the weight k "differential form" $f(z)(dz)^{k/2}$ is fixed under the action of every element of $\mathrm{SL}_2(\mathbb{Z})$.

By Theorem 1.2, the group $\mathrm{SL}_2(\mathbb{Z})$ is generated by the matrices S and T of (1.1.2), so to show that a meromorphic function f on $\mathfrak{h}$ is a weakly modular function, all we have to do is show that for all $z \in \mathfrak{h}$ we have

$$f(z+1) = f(z) \qquad \text{and} \qquad f(-1/z) = z^k f(z). \tag{1.2.2}$$

Suppose f is a weakly modular function of weight k. A *Fourier expansion* of f, if it exists, is a representation of f as $f(z) = \sum_{n=m}^{\infty} a_n e^{2\pi i n z}$, for all $z \in \mathfrak{h}$. Let $q = q(z) = e^{2\pi i z}$, which we view as a holomorphic function on $\mathbb{C}$. Let D' be the open unit disk with the origin removed, and note that q defines a map $\mathfrak{h} \to D'$. By (1.2.2) we have $f(z+1) = f(z)$, so there is a function $F : D' \to \mathbb{C}$ such that $F(q(z)) = f(z)$. This function F is a complex-valued function on D', but it may or may not be well behaved at 0.

Suppose that F is well behaved at 0, in the sense that for some $m \in \mathbb{Z}$ and all q in a neighborhood of 0 we have the equality

$$F(q) = \sum_{n=m}^{\infty} a_n q^n. \tag{1.2.3}$$

If this is the case, we say that f is *meromorphic at* ∞. If, moreover, $m \geq 0$, we say that f is *holomorphic at* ∞. We also call (1.2.3) the *q-expansion* of f about ∞.

Definition 1.5 (Modular Function)**.** A *modular function* of *weight k* is a weakly modular function of weight k that is meromorphic at ∞.

Definition 1.6 (Modular Form)**.** A *modular form* of *weight k* (and *level* 1) is a modular function of weight k that is holomorphic on $\mathfrak{h}$ and at ∞.

If f is a modular form, then there are numbers a_n such that for all $z \in \mathfrak{h}$,

$$f(z) = \sum_{n=0}^{\infty} a_n q^n. \tag{1.2.4}$$

Proposition 1.7. *The above series converges for all $z \in \mathfrak{h}$.*

Proof. The function $f(q)$ is holomorphic on D, so its Taylor series converges absolutely in D. □

Since $e^{2\pi i z} \to 0$ as $z \to i\infty$, we set $f(\infty) = a_0$.

Definition 1.8 (Cusp Form)**.** A *cusp form* of *weight k* (and *level* 1) is a modular form of weight k such that $f(\infty) = 0$, i.e., $a_0 = 0$.

Let $\mathbb{C}[[q]]$ be the ring of all *formal power series* in q. If $k = 2$, then $dq = 2\pi i q dz$, so $dz = \frac{1}{2\pi i}\frac{dq}{q}$. If $f(q)$ is a cusp form of weight 2, then

$$2\pi i f(z) dz = f(q)\frac{dq}{q} = \frac{f(q)}{q} dq \in \mathbb{C}[[q]]dq.$$

Thus the differential $2\pi i f(z)dz$ is holomorphic at ∞, since q is a local parameter at ∞.

1.3. Modular Forms of Any Level

In this section we define spaces of modular forms of arbitrary level.

Definition 1.9 (Congruence Subgroup)**.** A *congruence subgroup* of $\mathrm{SL}_2(\mathbb{Z})$ is any subgroup of $\mathrm{SL}_2(\mathbb{Z})$ that contains

$$\Gamma(N) = \mathrm{Ker}(\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z}))$$

for some positive integer N. The smallest such N is the *level of* Γ.

The most important congruence subgroups in this book are

$$\Gamma_1(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \pmod{N} \right\}$$

and

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{N} \right\},$$

where $*$ means any element. Both groups have level N (see Exercise 1.6).

Let k be an integer. Define the *weight k right action* of $\mathrm{GL}_2(\mathbb{Q})$ on the set of all functions $f : \mathfrak{h} \to \mathbb{C}$ as follows. If $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$, let

$$(f^{[\gamma]_k})(z) = \det(\gamma)^{k-1}(cz+d)^{-k} f(\gamma(z)). \tag{1.3.1}$$

Proposition 1.10. *Formula* (1.3.1) *defines a right action of* $\mathrm{GL}_2(\mathbb{Z})$ *on the set of all functions* $f : \mathfrak{h} \to \mathbb{C}$*; in particular,*

$$f^{[\gamma_1\gamma_2]_k} = (f^{[\gamma_1]_k})^{[\gamma_2]_k}.$$

Proof. See Exercise 1.7. □

Definition 1.11 (Weakly Modular Function)**.** A *weakly modular function* of weight k for a congruence subgroup Γ is a meromorphic function $f : \mathfrak{h} \to \mathbb{C}$ such that $f^{[\gamma]_k} = f$ for all $\gamma \in \Gamma$.

A central object in the theory of modular forms is the *set of cusps*

$$\mathbb{P}^1(\mathbb{Q}) = \mathbb{Q} \cup \{\infty\}.$$

An element $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ acts on $\mathbb{P}^1(\mathbb{Q})$ by

$$\gamma(z) = \begin{cases} \frac{az+b}{cz+d} & \text{if } z \neq \infty, \\ \frac{a}{c} & \text{if } z = \infty. \end{cases}$$

Also, note that if the denominator c or $cz+d$ is 0 above, then

$$\gamma(z) = \infty \in \mathbb{P}^1(\mathbb{Q}).$$

The set of *cusps for a congruence subgroup* Γ is the set $C(\Gamma)$ of Γ-orbits of $\mathbb{P}^1(\mathbb{Q})$. (We will often identify elements of $C(\Gamma)$ with a representative element from the orbit.) For example, the lemma below asserts that if $\Gamma = \mathrm{SL}_2(\mathbb{Z})$, then there is exactly one orbit, so $C(\mathrm{SL}_2(\mathbb{Z})) = \{[\infty]\}$.

Lemma 1.12. *For any cusps* $\alpha, \beta \in \mathbb{P}^1(\mathbb{Q})$ *there exists* $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ *such that* $\gamma(\alpha) = \beta$.

Proof. This is Exercise 1.8. □

Proposition 1.13. *For any congruence subgroup* Γ*, the set* $C(\Gamma)$ *of cusps is finite.*

Proof. This is Exercise 1.9. □

See [**DS05**, §3.8] and Algorithm 8.12 below for more discussion of cusps and results relevant to their enumeration.

In order to define modular forms for general congruence subgroups, we next explain what it means for a function to be holomorphic on the *extended upper half plane*

$$\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q}).$$

See [**Shi94**, §1.3–1.5] for a detailed description of the correct topology to consider on $\mathfrak{h}^*$. In particular, a basis of neighborhoods for $\alpha \in \mathbb{Q}$ is given by the sets $\{\alpha\} \cup D$, where D is an open disc in $\mathfrak{h}$ that is tangent to the real line at α.

Recall from Section 1.2 that a weakly modular function f on $\mathrm{SL}_2(\mathbb{Z})$ is holomorphic at ∞ if its q-expansion is of the form $\sum_{n=0}^{\infty} a_n q^n$.

In order to make sense of holomorphicity of a weakly modular function f for an arbitrary congruence subgroup Γ at any $\alpha \in \mathbb{Q}$, we first prove a lemma.

Lemma 1.14. *If $f : \mathfrak{h} \to \mathbb{C}$ is a weakly modular function of weight k for a congruence subgroup Γ and if $\delta \in \mathrm{SL}_2(\mathbb{Z})$, then $f^{[\delta]_k}$ is a weakly modular function for $\delta^{-1}\Gamma\delta$.*

Proof. If $s = \delta^{-1}\gamma\delta \in \delta^{-1}\Gamma\delta$, then

$$(f^{[\delta]_k})^{[s]_k} = f^{[\delta s]_k} = f^{[\delta\delta^{-1}\gamma\delta]_k} = f^{[\gamma\delta]_k} = f^{[\delta]_k}.$$

□

Fix a weakly modular function f of weight k for a congruence subgroup Γ, and suppose $\alpha \in \mathbb{Q}$. In Section 1.2 we constructed the q-expansion of f by using that $f(z) = f(z+1)$, which held since $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$. There are congruence subgroups Γ such that $T \not\in \Gamma$. Moreover, even if we are interested only in modular forms for $\Gamma_1(N)$, where we have $T \in \Gamma_1(N)$ for all N, we will still have to consider q-expansions at infinity for modular forms on groups $\delta^{-1}\Gamma_1(N)\delta$, and these need not contain T. Fortunately, $T^N = \left(\begin{smallmatrix} 1 & N \\ 0 & 1 \end{smallmatrix}\right) \in \Gamma(N)$, so a congruence subgroup of level N contains T^N. Thus we have $f(z+H) = f(H)$ for some positive integer H, e.g., $H = N$ always works, but there may be a smaller choice of H. The minimal choice of $H > 0$ such that $\left(\begin{smallmatrix} 1 & H \\ 0 & 1 \end{smallmatrix}\right) \in \delta^{-1}\Gamma\delta$, where $\delta(\infty) = \alpha$, is called the *width of the cusp* α relative to the group Γ (see Section 1.4.1). When f is meromorphic at infinity, we obtain a Fourier expansion

$$f(z) = \sum_{n=m}^{\infty} a_n q^{n/H} \tag{1.3.2}$$

in powers of the function $q^{1/H} = e^{2\pi i z/H}$. We say that f is holomorphic at ∞ if in (1.3.2) we have $m \geq 0$.

What about the other cusps $\alpha \in \mathbb{P}^1(\mathbb{Q})$? By Lemma 1.12 there is a $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ such that $\gamma(\infty) = \alpha$. We declare f to be *holomorphic at the cusp* α if the weakly modular function $f^{[\gamma]_k}$ is holomorphic at ∞.

Definition 1.15 (Modular Form)**.** A *modular form* of integer *weight* k for a congruence subgroup Γ is a weakly modular function $f : \mathfrak{h} \to \mathbb{C}$ that is holomorphic on $\mathfrak{h}^*$. We let $M_k(\Gamma)$ denote the space of weight k modular forms of weight k for Γ.

Proposition 1.16. *If a weakly modular function f is holomorphic at a set of representative elements for $C(\Gamma)$, then it is holomorphic at every element of $\mathbb{P}^1(\mathbb{Q})$.*

Proof. Let $c_1, \ldots, c_n \in \mathbb{P}^1(\mathbb{Q})$ be representatives for the set of cusps for Γ. If $\alpha \in \mathbb{P}^1(\mathbb{Q})$, then there is $\gamma \in \Gamma$ such that $\alpha = \gamma(c_i)$ for some i. By hypothesis f is holomorphic at c_i, so if $\delta \in \mathrm{SL}_2(\mathbb{Z})$ is such that $\delta(\infty) = c_i$, then $f^{[\delta]_k}$ is holomorphic at ∞. Since f is a weakly modular function for Γ,

$$f^{[\delta]_k} = (f^{[\gamma]_k})^{[\delta]_k} = f^{[\gamma\delta]_k}. \tag{1.3.3}$$

But $\gamma(\delta(\infty)) = \gamma(c_i) = \alpha$, so (1.3.3) implies that f is holomorphic at α. $\square$

1.4. Remarks on Congruence Subgroups

Recall that a congruence subgroup is a subgroup of $\mathrm{SL}_2(\mathbb{Z})$ that contains $\Gamma(N)$ for some N. Any congruence subgroup has finite index in $\mathrm{SL}_2(\mathbb{Z})$, since $\Gamma(N)$ does. What about the converse: is every finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$ a congruence subgroup? This is the *congruence subgroup problem.* One can ask about the congruence subgroup problem with $\mathrm{SL}_2(\mathbb{Z})$ replaced by many similar groups. If p is a prime, then one can prove that every finite index subgroup of $\mathrm{SL}_2(\mathbb{Z}[1/p])$ is a congruence subgroup (i.e., contains the kernel of reduction modulo some integer coprime to p), and for any $n > 2$, all finite index subgroups of $\mathrm{SL}_n(\mathbb{Z})$ are congruence subgroups (see [**Hum80**]). However, there are numerous finite index subgroups of $\mathrm{SL}_2(\mathbb{Z})$ that are not congruence subgroups. The paper [**Hsu96**] contains an *algorithm* to decide if certain finite index subgroups are congruence subgroups and gives an example of a subgroup of index 12 that is not a congruence subgroup.

One can consider modular forms even for noncongruence subgroups. See, e.g., [**Tho89**] and the papers it references for work on this topic. We will not consider such modular forms further in this book. Note that modular symbols (which we define later in this book) *are* computable for noncongruence subgroups.

Finding coset representatives for $\Gamma_0(N)$, $\Gamma_1(N)$ and $\Gamma(N)$ in $\mathrm{SL}_2(\mathbb{Z})$ is straightforward and will be discussed at length later in this book. To make the problem more explicit, note that you can quotient out by $\Gamma(N)$ first. Then the question amounts to finding coset representatives for a subgroup of $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ (and lifting), which is reasonably straightforward.

Given coset representatives for a finite index subgroup G of $\mathrm{SL}_2(\mathbb{Z})$, we can compute generators for G as follows. Let R be a set of coset representatives for G. Let $\sigma, \tau \in \mathrm{SL}_2(\mathbb{Z})$ be the matrices denoted by S and T in (1.1.2). Define maps $s, t : R \to G$ as follows. If $r \in R$, then there exists a unique $\alpha_r \in R$ such that $Gr\sigma = G\alpha_r$. Let $s(r) = r\sigma\alpha_r^{-1}$. Likewise, there is a unique β_r such that $Gr\tau = G\beta_r$ and we let $t(r) = r\tau\beta_r^{-1}$. Note that $s(r)$ and $t(r)$ are in G for all r. Then G is generated by $s(R) \cup t(R)$.

Proposition 1.17. *The above procedure computes generators for G.*

Proof. Without loss of generality, assume that $I = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ represents the coset of G. Let g be an element of G. Since σ and τ generate $\mathrm{SL}_2(\mathbb{Z})$, it is possible to write g as a product of powers of σ and τ. There is a procedure, which we explain below with an example in order to avoid cumbersome notation, which writes g as a product of elements of $s(R) \cup t(R)$ times a right coset representative $r \in R$. For example, if

$$g = \sigma\tau^2\sigma\tau,$$

then $g = I\sigma\tau^2\sigma\tau = s(I)y\tau^2\sigma\tau$ for some $y \in R$. Continuing,

$$s(I)y\tau^2\sigma\tau = s(I)(y\tau)\tau\sigma\tau = s(I)(t(y)z)\tau\sigma\tau$$

for some $z \in R$. Again,

$$s(I)(t(y)z)\tau\sigma\tau = s(I)t(y)(z\tau)\sigma\tau = \cdots .$$

The procedure illustrated above (with an example) makes sense for arbitrary g and, after carrying it out, writes g as a product of elements of $s(R) \cup t(R)$ times a right coset representative $r \in R$. But $g \in G$ and I is the right coset representative for G, so this right coset representative must be I. □

Remark 1.18. We could also apply the proof of Proposition 1.17 to write any element of G in terms of the given generators. Moreover, we could use it to write any element $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ in the form gr, where $g \in G$ and $r \in R$, so we can decide whether or not $\gamma \in G$.

1.4.1. Computing Widths of Cusps. Let Γ be a congruence subgroup of level N. Suppose $\alpha \in C(\Gamma)$ is a cusp, and choose $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ such that $\gamma(\infty) = \alpha$. Recall that the minimal h such that $\left(\begin{smallmatrix} 1 & h \\ 0 & 1 \end{smallmatrix}\right) \in \gamma^{-1}\Gamma\gamma$ is called the *width of the cusp* α for the group Γ. In this section we discuss how to compute h.

Algorithm 1.19 (Width of Cusp)**.** *Given a congruence subgroup Γ of level N and a cusp α for Γ, this algorithm computes the width h of α. We assume that Γ is given by congruence conditions, e.g., $\Gamma = \Gamma_0(N)$ or $\Gamma_1(N)$.*

(1) [Find γ] Use the extended Euclidean algorithm to find $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ such that $\gamma(\infty) = \alpha$, as follows. If $\alpha = \infty$, set $\gamma = 1$; otherwise, write $\alpha = a/b$, find c, d such that $ad - bc = 1$, and set $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$.

(2) [Compute Conjugate Matrix] Compute the following element of $\mathrm{Mat}_2(\mathbb{Z}[x])$:

$$\delta(x) = \gamma \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \gamma^{-1}.$$

Note that the entries of $\delta(x)$ are constant or linear in x.

(3) [Solve] The congruence conditions that define Γ give rise to four linear congruence conditions on x. Use techniques from elementary number theory (or enumeration) to find the smallest simultaneous positive solution h to these four equations.

Example 1.20. (1) Suppose $\alpha = 0$ and $\Gamma = \Gamma_0(N)$ or $\Gamma_1(N)$. Then $\gamma = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ has the property that $\gamma(\infty) = \alpha$. Next, the congruence condition is

$$\delta(x) = \gamma \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \gamma^{-1} = \begin{pmatrix} 1 & 0 \\ -x & 1 \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \pmod{N}.$$

Thus the smallest positive solution is $h = N$, so the width of 0 is N.

(2) Suppose $N = pq$ where p, q are distinct primes, and let $\alpha = 1/p$. Then $\gamma = \left(\begin{smallmatrix} 1 & 0 \\ p & 1 \end{smallmatrix}\right)$ sends ∞ to α. The congruence condition for $\Gamma_0(pq)$ is

$$\delta(x) = \gamma \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \gamma^{-1} = \begin{pmatrix} 1 - px & x \\ -p^2 x & px + 1 \end{pmatrix} \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{pq}.$$

Since $p^2 x \equiv 0 \pmod{pq}$, we see that $x = q$ is the smallest solution. Thus $1/p$ has width q, and symmetrically $1/q$ has width p.

Remark 1.21. For $\Gamma_0(N)$, once we enforce that the bottom left entry is 0 (mod N) and use that the determinant is 1, the coprimality from the other two congruences is automatic. So there is one congruence to solve in the $\Gamma_0(N)$ case. There are two congruences in the $\Gamma_1(N)$ case.

1.5. Applications of Modular Forms

The above definition of modular forms might leave the impression that modular forms occupy an obscure corner of complex analysis. This is *not* the case! Modular forms are highly geometric, arithmetic, and topological objects that are of extreme interest all over mathematics:

(1) **Fermat's last theorem:** Wiles' proof [**Wil95**] of Fermat's last theorem uses modular forms extensively. The work of Wiles et al. on modularity also massively extends computational methods for elliptic curves over $\mathbb{Q}$, because many elliptic curve algorithms, e.g., for computing L-functions, modular degrees, Heegner points, etc., require that the elliptic curve be modular.

(2) **Diophantine equations:** Wiles' proof of Fermat's last theorem has made available a wide array of new techniques for solving certain diophantine equations. Such work relies crucially on having access to tables or software for computing modular forms. See, e.g., [**Dar97, Mer99, Che05, SC03**]. (Wiles did not need a computer, because the relevant spaces of modular forms that arise in his proof have dimension 0!) Also, according to Siksek (personal communication) the paper [**BMS06**] would "have been entirely impossible to write without [the algorithms described in this book]."

(3) **Congruent number problem:** This ancient open problem is to determine which integers are the area of a right triangle with rational side lengths. There is a potential solution that uses modular forms (of weight 3/2) extensively (the solution is conditional on truth of the Birch and Swinnerton-Dyer conjecture, which is not yet known). See [**Kob84**].

(4) **Topology:** Topological modular forms are a major area of current research.

(5) **Construction of Ramanujan graphs:** Modular forms can be used to construct almost optimal expander graphs, which play a role in communications network theory.

(6) **Cryptography and Coding Theory:** Point counting on elliptic curves over finite fields is crucial to the construction of elliptic curve cryptosystems, and modular forms are relevant to efficient algorithms for point counting (see [**Elk98**]). Algebraic curves that are associated to modular forms are useful in constructing and studying certain error-correcting codes (see [**Ebe02**]).

(7) **The Birch and Swinnerton-Dyer conjecture:** This central open problem in arithmetic geometry relates arithmetic properties of elliptic curves (and abelian varieties) to special values of L-functions. Most deep results toward this conjecture use modular forms extensively (e.g., work of Kolyvagin, Gross-Zagier, and Kato). Also, modular forms are used to compute and prove results about special values of these L-functions. See [**Wil00**].

(8) **Serre's Conjecture on modularity of Galois representation:** Let $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ be the Galois group of an algebraic closure of $\mathbb{Q}$. Serre conjectured and many people have (nearly!) proved that every continuous homomorphism $\rho : G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{F}_q)$, where $\mathbb{F}_q$ is a finite field and $\det(\rho(\text{complex conjugation})) = -1$, "arises" from a modular form. More precisely, for almost all primes p the coefficients a_p of a modular (eigen-)form $\sum a_n q^n$ are congruent to the traces of elements $\rho(\mathrm{Frob}_p)$, where Frob_p are certain special elements of $G_{\mathbb{Q}}$ called Frobenius elements. See [**RS01**] and [**DS05**, Ch. 9].

(9) **Generating functions for partitions:** The generating functions for various kinds of partitions of an integer can often be related to modular forms. Deep theorems about modular forms then translate into results about partitions. See work of Ramanujan, Gordon, Andrews, and Ahlgren and Ono (e.g., [**AO01**]).

(10) **Lattices:** If $L \subset \mathbb{R}^n$ is an even unimodular lattice (the basis matrix has determinant ± 1 and $\lambda \cdot \lambda \in 2\mathbb{Z}$ for all $\lambda \in L$), then the theta series

$$\theta_L(q) = \sum_{\lambda \in L} q^{\lambda\cdot\lambda}$$

is a modular form of weight $n/2$. The coefficient of q^m is the number of lattice vectors with squared length m. Theorems and computational methods for modular forms translate into theorems and computational methods for lattices. For example, the 290 theorem of M. Bharghava and J. Hanke is a theorem about lattices, which asserts that an integer-valued quadratic form represents all positive integers if and only if it represents the integers up to 290; it is proved by doing many calculations with modular forms (both theoretical and with a computer).

1.6. Exercises

1.1 Suppose $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{R})$ has positive determinant. Prove that if $z \in \mathbb{C}$ is a complex number with positive imaginary part, then the imaginary part of $\gamma(z) = (az+b)/(cz+d)$ is also positive.

1.2 Prove that every rational function (quotient of two polynomials) is a meromorphic function on $\mathbb{C}$.

1.3 Suppose f and g are weakly modular functions for a congruence subgroup Γ with $f \neq 0$.

(a) Prove that the product fg is a weakly modular function for Γ.

(b) Prove that $1/f$ is a weakly modular function for Γ.

(c) If f and g are modular functions, show that fg is a modular function for Γ.

(d) If f and g are modular forms, show that fg is a modular form for Γ.

1.4 Suppose f is a weakly modular function of odd weight k and level $\Gamma_0(N)$ for some N. Show that $f = 0$.

1.5 Prove that $\mathrm{SL}_2(\mathbb{Z}) = \Gamma_0(1) = \Gamma_1(1) = \Gamma(1)$.

1.6 (a) Prove that $\Gamma_1(N)$ is a group.

(b) Prove that $\Gamma_1(N)$ has finite index in $\mathrm{SL}_2(\mathbb{Z})$ (Hint: It contains the kernel of the homomorphism $\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$.)

(c) Prove that $\Gamma_0(N)$ has finite index in $\mathrm{SL}_2(\mathbb{Z})$.

(d) Prove that $\Gamma_0(N)$ and $\Gamma_1(N)$ have level N.

1.7 Let k be an integer, and for any function $f : \mathfrak{h}^* \to \mathbb{C}$ and $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$, set $f^{[\gamma]_k}(z) = \det(\gamma)^{k-1} \cdot (cz+d)^{-k} \cdot f(\gamma(z))$. Prove that if $\gamma_1, \gamma_2 \in \mathrm{GL}_2(\mathbb{Z})$, then for all $z \in \mathfrak{h}^*$ we have

$$f^{[\gamma_1\gamma_2]_k}(z) = ((f^{[\gamma_1]_k})^{[\gamma_2]_k})(z).$$

1.8 Prove that for any $\alpha, \beta \in \mathbb{P}^1(\mathbb{Q})$, there exists $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ such that $\gamma(\alpha) = \beta$.

1.9 Prove Proposition 1.13, which asserts that the set of cusps $C(\Gamma)$, for any congruence subgroup Γ, is finite.

1.10 Use Algorithm 1.19 to give an example of a group Γ and cusp α with width 2.

Chapter 2

Modular Forms of Level 1

In this chapter we study in detail the structure of level 1 modular forms, i.e., modular forms on $\mathrm{SL}_2(\mathbb{Z}) = \Gamma_0(1) = \Gamma_1(1)$. We assume some complex analysis (e.g., the residue theorem), linear algebra, and that the reader has read Chapter 1.

2.1. Examples of Modular Forms of Level 1

In this section we will finally see some examples of modular forms of level 1! We first introduce the Eisenstein series and then define Δ, which is a cusp form of weight 12. In Section 2.2 we prove the structure theorem, which says that all modular forms of level 1 are polynomials in Eisenstein series.

For an even integer $k \geq 4$, the *nonnormalized weight k Eisenstein series* is the function on the extended upper half plane $\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q})$ given by

$$G_k(z) = \sideset{}{^*}\sum_{m,n \in \mathbb{Z}} \frac{1}{(mz+n)^k}. \tag{2.1.1}$$

The star on top of the sum symbol means that for each z the sum is over all $m, n \in \mathbb{Z}$ such that $mz + n \neq 0$.

Proposition 2.1. *The function $G_k(z)$ is a modular form of weight k, i.e., $G_k \in M_k(\mathrm{SL}_2(\mathbb{Z}))$.*

Proof. See [**Ser73**, § VII.2.3] for a proof that $G_k(z)$ defines a holomorphic function on $\mathfrak{h}^*$. To see that G_k is modular, observe that

$$G_k(z+1) = \sum^{*} \frac{1}{(m(z+1)+n)^k} = \sum^{*} \frac{1}{(mz+(n+m))^k} = \sum^{*} \frac{1}{(mz+n)^k},$$

where for the last equality we use that the map $(m, n+m) \mapsto (m,n)$ on $\mathbb{Z} \times \mathbb{Z}$ is invertible. Also,

$$\begin{aligned} G_k(-1/z) &= \sum^{*} \frac{1}{(-m/z+n)^k} \\ &= \sum^{*} \frac{z^k}{(-m+nz)^k} \\ &= z^k \sum^{*} \frac{1}{(mz+n)^k} = z^k G_k(z), \end{aligned}$$

where we use that $(n,-m) \mapsto (m,n)$ is invertible. □

Proposition 2.2. $G_k(\infty) = 2\zeta(k)$, *where* ζ *is the Riemann zeta function.*

Proof. As $z \to \infty$ (along the imaginary axis) in (2.1.1), the terms that involve z with $m \neq 0$ go to 0. Thus

$$G_k(\infty) = \sum_{n \in \mathbb{Z}}^{*} \frac{1}{n^k}.$$

This sum is twice $\zeta(k) = \sum_{n \geq 1} \frac{1}{n^k}$, as claimed. □

2.1.1. The Cusp Form Δ. Suppose $E = \mathbb{C}/\Lambda$ is an elliptic curve over $\mathbb{C}$, viewed as a quotient of $\mathbb{C}$ by a lattice $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$, with $\omega_1/\omega_2 \in \mathfrak{h}$ (see [**DS05**, §1.4]). The *Weierstrass $\wp$-function* of the lattice Λ is

$$\wp = \wp_\Lambda(u) = \frac{1}{u^2} + \sum_{k=4,6,8,\ldots} (k-1)G_k(\omega_1/\omega_2)u^{k-2},$$

where the sum is over even integers $k \geq 4$. It satisfies the differential equation

$$(\wp')^2 = 4\wp^3 - 60G_4(\omega_1/\omega_2)\wp - 140G_6(\omega_1/\omega_2).$$

If we set $x = \wp$ and $y = \wp'$, the above is an (affine) equation of the form $y^2 = ax^3+bx+c$ for an elliptic curve that is complex analytically isomorphic to $\mathbb{C}/\Lambda$ (see [**Ahl78**, pg. 277] for why the cubic has distinct roots).

The discriminant of the cubic

$$4x^3 - 60G_4(\omega_1/\omega_2)x - 140G_6(\omega_1/\omega_2)$$

is $16D(\omega_1/\omega_2)$, where

$$D(z) = (60G_4(z))^3 - 27(140G_6(z))^2.$$

Since $D(z)$ is the difference of two modular forms of weight 12 it has weight 12. Moreover,

$$\begin{aligned} D(\infty) &= (60G_4(\infty))^3 - 27\,(140G_6(\infty))^2 \\ &= \left(\frac{60}{3^2\cdot 5}\pi^4\right)^3 - 27\left(\frac{140\cdot 2}{3^3\cdot 5\cdot 7}\pi^6\right)^2 \\ &= 0, \end{aligned}$$

so D is a cusp form of weight 12. Let

$$\Delta = \frac{D}{(2\pi)^{12}}.$$

Lemma 2.3. *If $z \in \mathfrak{h}$, then $\Delta(z) \neq 0$.*

Proof. Let $\omega_1 = z$ and $\omega_2 = 1$. Since $E = \mathbb{C}/(\mathbb{Z}\omega_1 + \mathbb{Z}\omega_2)$ is an elliptic curve, it has nonzero discriminant $\Delta(z) = \Delta(\omega_1/\omega_2) \neq 0$. □

Proposition 2.4. *We have $\Delta = q \cdot \prod_{n=1}^{\infty}(1-q^n)^{24}$.*

Proof. See [**Ser73**, Thm. 6, pg. 95]. □

Remark 2.5. SAGE computes the q-expansion of Δ efficiently to high precision using the command `delta_qexp`:

```
sage: delta_qexp(6)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
```

2.1.2. Fourier Expansions of Eisenstein Series. Recall from (1.2.4) that elements f of $M_k(\mathrm{SL}_2(\mathbb{Z}))$ can be expressed as formal power series in terms of $q(z) = e^{2\pi i z}$ and that this expansion is called the Fourier expansion of f. The following proposition gives the Fourier expansion of the Eisenstein series $G_k(z)$.

Definition 2.6 (Sigma)**.** For any integer $t \geq 0$ and any positive integer n, the *sigma function*

$$\sigma_t(n) = \sum_{1 \leq d | n} d^t$$

is the sum of the tth powers of the positive divisors of n. Also, let $d(n) = \sigma_0(n)$, which is the number of divisors of n, and let $\sigma(n) = \sigma_1(n)$. For example, if p is prime, then $\sigma_t(p) = 1 + p^t$.

Proposition 2.7. *For every even integer $k \geq 4$, we have*

$$G_k(z) = 2\zeta(k) + 2\cdot\frac{(2\pi i)^k}{(k-1)!}\cdot\sum_{n=1}^{\infty}\sigma_{k-1}(n)q^n.$$

Proof. See [**Ser73**, Section VII.4], which uses clever manipulations of series, starting with the identity

$$\pi\cot(\pi z) = \frac{1}{z} + \sum_{m=1}^{\infty}\left(\frac{1}{z+m} + \frac{1}{z-m}\right).$$

□

From a computational point of view, the q-expansion of Proposition 2.7 is unsatisfactory because it involves transcendental numbers. To understand these numbers, we introduce the *Bernoulli numbers* B_n for $n \geq 0$ *defined* by the following equality of formal power series:

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} B_n \frac{x^n}{n!}. \tag{2.1.2}$$

Expanding the power series, we have

$$\frac{x}{e^x-1} = 1 - \frac{x}{2} + \frac{x^2}{12} - \frac{x^4}{720} + \frac{x^6}{30240} - \frac{x^8}{1209600} + \cdots .$$

As this expansion suggests, the Bernoulli numbers B_n with $n > 1$ odd are 0 (see Exercise 1.2). Expanding the series further, we obtain the following table:

$$B_0 = 1, \quad B_1 = -\frac{1}{2}, \quad B_2 = \frac{1}{6}, \quad B_4 = -\frac{1}{30}, \quad B_6 = \frac{1}{42}, \quad B_8 = -\frac{1}{30},$$

$$B_{10} = \frac{5}{66}, \quad B_{12} = -\frac{691}{2730}, \quad B_{14} = \frac{7}{6}, \quad B_{16} = -\frac{3617}{510}, \quad B_{18} = \frac{43867}{798},$$

$$B_{20} = -\frac{174611}{330}, \quad B_{22} = \frac{854513}{138}, \quad B_{24} = -\frac{236364091}{2730}, \quad B_{26} = \frac{8553103}{6}.$$

See Section 2.7 for a discussion of fast (analytic) methods for computing Bernoulli numbers.

We compute some Bernoulli numbers in SAGE:

```
sage: bernoulli(12)
-691/2730
sage: bernoulli(50)
495057205241079648212477525/66
sage: len(str(bernoulli(10000)))
27706
```

A key fact is that Bernoulli numbers are rational numbers and they are connected to values of ζ at positive even integers.

Proposition 2.8. *If $k \geq 2$ is an even integer, then*

$$\zeta(k) = -\frac{(2\pi i)^k}{2 \cdot k!} \cdot B_k.$$

Proof. This is proved by manipulating a series expansion of $z\cot(z)$ (see [**Ser73**, Section VII.4]). □

Definition 2.9 (Normalized Eisenstein Series)**.** The *normalized Eisenstein series* of even weight $k \geq 4$ is

$$E_k = \frac{(k-1)!}{2 \cdot (2\pi i)^k} \cdot G_k.$$

Combining Propositions 2.7 and 2.8, we see that

$$E_k = -\frac{B_k}{2k} + q + \sum_{n=2}^{\infty} \sigma_{k-1}(n) q^n. \tag{2.1.3}$$

Warning 2.10. Our series E_k is normalized so that the coefficient of q is 1, but often in the literature E_k is normalized so that the constant coefficient is 1. We use the normalization with the coefficient of q equal to 1, because then the eigenvalue of the nth Hecke operator (see Section 2.4) is the coefficient of q^n. Our normalization is also convenient when considering congruences between cusp forms and Eisenstein series.

2.2. Structure Theorem for Level 1 Modular Forms

In this section we describe a structure theorem for modular forms of level 1. If f is a nonzero meromorphic function on $\mathfrak{h}$ and $w \in \mathfrak{h}$, let $\mathrm{ord}_w(f)$ be the largest integer n such that $f(z)/(w-z)^n$ is holomorphic at w. If $f = \sum_{n=m}^{\infty} a_n q^n$ with $a_m \neq 0$, we set $\mathrm{ord}_\infty(f) = m$. We will use the following theorem to give a presentation for the vector space of modular forms of weight k; this presentation yields an algorithm to compute this space.

Let $M_k = M_k(\mathrm{SL}_2(\mathbb{Z}))$ denote the complex vector space of modular forms of weight k for $\mathrm{SL}_2(\mathbb{Z})$. The *standard fundamental domain* $\mathcal{F}$ for $\mathrm{SL}_2(\mathbb{Z})$ is the set of $z \in \mathfrak{h}$ with $|z| \geq 1$ and $|\mathrm{Re}(z)| \leq 1/2$. Let $\rho = e^{2\pi i/3}$.

Theorem 2.11 (Valence Formula)**.** *Let k be any integer and suppose $f \in M_k(\mathrm{SL}_2(\mathbb{Z}))$ is nonzero. Then*

$$\mathrm{ord}_\infty(f) + \frac{1}{2}\mathrm{ord}_i(f) + \frac{1}{3}\mathrm{ord}_\rho(f) + \sum_{w \in \mathcal{F}}^{*} \mathrm{ord}_w(f) = \frac{k}{12},$$

where $\displaystyle\sum_{w \in \mathcal{F}}^{*}$ is the sum over elements of $\mathcal{F}$ other than i and ρ.

Proof. The proof in [**Ser73**, §VII.3] uses the residue theorem. □

Let $S_k = S_k(\mathrm{SL}_2(\mathbb{Z}))$ denote the subspace of weight k cusp forms for $\mathrm{SL}_2(\mathbb{Z})$. We have an exact sequence

$$0 \to S_k \to M_k \xrightarrow{\iota_\infty} \mathbb{C}$$

that sends $f \in M_k$ to $f(\infty)$. When $k \geq 4$ is even, the space M_k contains the Eisenstein series G_k, and $G_k(\infty) = 2\zeta(k) \neq 0$, so the map $M_k \to \mathbb{C}$ is surjective. This proves the following lemma.

Lemma 2.12. *If $k \geq 4$ is even, then $M_k = S_k \oplus \mathbb{C}G_k$ and the following sequence is exact:*

$$0 \to S_k \to M_k \xrightarrow{\iota_\infty} \mathbb{C} \to 0.$$

Proposition 2.13. *For $k < 0$ and $k = 2$, we have $M_k = 0$.*

Proof. Suppose $f \in M_k$ is nonzero yet $k = 2$ or $k < 0$. By Theorem 2.11,

$$\mathrm{ord}_\infty(f) + \frac{1}{2}\mathrm{ord}_i(f) + \frac{1}{3}\mathrm{ord}_\rho(f) + \sum_{w\in D}^{*} \mathrm{ord}_w(f) = \frac{k}{12} \leq \frac{1}{6}.$$

This is not possible because each quantity on the left is nonnegative so whatever the sum is, it is too big (or 0, in which case $k = 0$). □

Theorem 2.14. *Multiplication by Δ defines an isomorphism $M_{k-12} \to S_k$.*

Proof. By Lemma 2.3, Δ is not identically 0, so because Δ is holomorphic, multiplication by Δ defines an injective map $M_{k-12} \hookrightarrow S_k$. To see that this map is surjective, we show that if $f \in S_k$, then $f/\Delta \in M_{k-12}$. Since Δ has weight 12 and $\mathrm{ord}_\infty(\Delta) \geq 1$, Theorem 2.11 implies that Δ has a simple zero at ∞ and does not vanish on $\mathfrak{h}$. Thus if $f \in S_k$ and if we let $g = f/\Delta$, then g is holomorphic and satisfies the appropriate transformation formula, so $g \in M_{k-12}$. □

Corollary 2.15. *For $k = 0, 4, 6, 8, 10, 14$, the space M_k has dimension 1, with basis 1, G_4, G_6, G_8, G_{10}, and G_{14}, respectively, and $S_k = 0$.*

Proof. Combining Proposition 2.13 with Theorem 2.14, we see that the spaces M_k for $k \leq 10$ cannot have dimension greater than 1, since otherwise $M_{k'} \neq 0$ for some $k' < 0$. Also M_{14} has dimension at most 1, since M_2 has dimension 0. Each of the indicated spaces of weight ≥ 4 contains the indicated Eisenstein series and so has dimension 1, as claimed. □

Corollary 2.16. $\dim M_k = \begin{cases} 0 & \textit{if } k \textit{ is odd or negative,} \\ \lfloor k/12 \rfloor & \textit{if } k \equiv 2 \pmod{12}, \\ \lfloor k/12 \rfloor + 1 & \textit{if } k \not\equiv 2 \pmod{12}. \end{cases}$

Here $\lfloor x \rfloor$ is the biggest integer $\leq x$.

Proof. As we have already seen above, the formula is true when $k \leq 12$. By Theorem 2.14, the dimension increases by 1 when k is replaced by $k+12$. □

Theorem 2.17. *The space M_k has as basis the modular forms $G_4^a G_6^b$, where a, b run over all pairs of nonnegative integers such that $4a + 6b = k$.*

Proof. Fix an even integer k. We first prove by induction that the modular forms $G_4^a G_6^b$ generate M_k; the cases $k \leq 10$ and $k = 14$ follow from the above arguments (e.g., when $k = 0$, we have $a = b = 0$ and basis 1). Choose some pair of nonnegative integers a, b such that $4a + 6b = k$. The form $g = G_4^a G_6^b$ is not a cusp form, since it is nonzero at ∞. Now suppose $f \in M_k$ is arbitrary. Since $g(\infty) \neq 0$, there exists $\alpha \in \mathbb{C}$ such that $f - \alpha g \in S_k$. Then by Theorem 2.14, there is $h \in M_{k-12}$ such that $f - \alpha g = \Delta \cdot h$. By induction, h is a polynomial in G_4 and G_6 of the required type, and so is Δ, so f is as well. Thus

$$\{G_4^a G_6^b \mid a \geq 0,\ b \geq 0,\ 4a + 6b = k\}$$

spans M_k.

Suppose there is a nontrivial linear relation between the $G_4^a G_6^b$ for a given k. By multiplying the linear relation by a suitable power of G_4 and G_6, we may assume that we have such a nontrivial relation with $k \equiv 0 \pmod{12}$. Now divide the linear relation by the weight k form $G_6^{k/6}$ to see that G_4^3/G_6^2 satisfies a polynomial with coefficients in $\mathbb{C}$ (see Exercise 2.4). Hence G_4^3/G_6^2 is a root of a polynomial, hence a constant, which is a contradiction since the q-expansion of G_4^3/G_6^2 is not constant. □

Algorithm 2.18 (Basis for M_k)**.** *Given integers n and k, this algorithm computes a basis of q-expansions for the complex vector space M_k mod q^n. The q-expansions output by this algorithm have coefficients in $\mathbb{Q}$.*

(1) [Simple Case] If $k = 0$, output the basis with just 1 in it and terminate; otherwise if $k < 4$ or k is odd, output the empty basis and terminate.
(2) [Power Series] Compute E_4 and E_6 mod q^n using the formula from (2.1.3) and Section 2.7.
(3) [Initialize] Set $b = 0$.
(4) [Enumerate Basis] For each integer b between 0 and $\lfloor k/6 \rfloor$, compute $a = (k - 6b)/4$. If a is an integer, compute and output the basis element $E_4^a E_6^b \mod q^n$. When computing E_4^a, find $E_4^m \pmod{q^n}$ for each $m \leq a$, and save these intermediate powers, so they can be reused later, and likewise for powers of E_6.

Proof. This is simply a translation of Theorem 2.17 into an algorithm, since E_k is a nonzero scalar multiple of G_k. That the q-expansions have coefficients in $\mathbb{Q}$ follows from (2.1.3). □

Example 2.19. We compute a basis for M_{24}, which is the space with smallest weight whose dimension is greater than 1. It has as basis E_4^6, $E_4^3E_6^2$, and E_6^4, whose explicit expansions are

$$\begin{aligned} E_4^6 &= \frac{1}{191102976000000} + \frac{1}{132710400000}q + \frac{203}{44236800000}q^2 + \cdots, \\ E_4^3E_6^2 &= \frac{1}{3511517184000} - \frac{1}{12192768000}q - \frac{377}{4064256000}q^2 + \cdots, \\ E_6^4 &= \frac{1}{64524128256} - \frac{1}{32006016}q + \frac{241}{10668672}q^2 + \cdots. \end{aligned}$$

We compute this basis in SAGE as follows:

```
sage: E4 = eisenstein_series_qexp(4, 3)
sage: E6 = eisenstein_series_qexp(6, 3)
sage: E4^6
1/191102976000000 + 1/132710400000*q
                  + 203/44236800000*q^2 + O(q^3)
sage: E4^3*E6^2
1/3511517184000 - 1/12192768000*q
                - 377/4064256000*q^2 + O(q^3)
sage: E6^4
1/64524128256 - 1/32006016*q + 241/10668672*q^2 + O(q^3)
```

In Section 2.3, we will discuss the reduced echelon form basis for M_k.

2.3. The Miller Basis

Lemma 2.20 (V. Miller). *The space S_k has a basis $f_1, \ldots, f_d$ such that if $a_i(f_j)$ is the ith coefficient of f_j, then $a_i(f_j) = \delta_{i,j}$ for $i = 1, \ldots, d$. Moreover the f_j all lie in $\mathbb{Z}[[q]]$. We call this basis the* Miller basis *for S_k.*

This is a straightforward construction involving E_4, E_6 and Δ. The following proof very closely follows [**Lan95**, Ch. X, Thm. 4.4], which in turn follows the first lemma of V. Miller's thesis.

Proof. Let $d = \dim S_k$. Since $B_4 = -1/30$ and $B_6 = 1/42$, we note that

$$F_4 = -\frac{8}{B_4} \cdot E_4 = 1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \cdots$$

and

$$F_6 = -\frac{12}{B_6} \cdot E_6 = 1 - 504q - 16632q^2 - 122976q^3 - 532728q^4 + \cdots$$

have q-expansions in $\mathbb{Z}[[q]]$ with leading coefficient 1. Choose integers $a, b \geq 0$ such that

$$4a + 6b \leq 14 \qquad \text{and} \qquad 4a + 6b \equiv k \pmod{12},$$

with $a = b = 0$ when $k \equiv 0 \pmod{12}$, and let

$$g_j = \Delta^j F_6^{2(d-j)+b} F_4^a = \left(\frac{\Delta}{F_6^2}\right)^j F_6^{2d+b} F_4^a, \qquad\qquad \text{for } j = 1, \ldots, d.$$

Then it is elementary to check that g_j has weight k

$$a_j(g_j) = 1 \qquad \text{and} \qquad a_i(g_j) = 0 \qquad \text{when} \qquad i < j.$$

Hence the g_j are linearly independent over $\mathbb{C}$, so form a basis for S_k. Since F_4, F_6, and Δ are all in $\mathbb{Z}[[q]]$, so are the g_j. The f_i may then be constructed from the g_j by Gauss elimination. The coefficients of the resulting power series lie in $\mathbb{Z}$ because each time we clear a column we use the power series g_j whose leading coefficient is 1 (so no denominators are introduced). □

Remark 2.21. The basis coming from Miller's lemma is "canonical", since it is just the reduced row echelon form of any basis. Also the set of all *integral* linear combinations of the elements of the Miller basis are precisely the modular forms of level 1 with integral q-expansion.

We extend the Miller basis to all M_k by taking a multiple of G_k with constant term 1 and subtracting off the f_i from the Miller basis so that the coefficients of $q, q^2, \ldots q^d$ of the resulting expansion are 0. We call the extra basis element f_0.

Example 2.22. If $k = 24$, then $d = 2$. Choose $a = b = 0$, since $k \equiv 0 \pmod{12}$. Then

$$g_1 = \Delta F_6^2 = q - 1032q^2 + 245196q^3 + 10965568q^4 + 60177390q^5 - \cdots$$

and

$$g_2 = \Delta^2 = q^2 - 48q^3 + 1080q^4 - 15040q^5 + \cdots.$$

We let $f_2 = g_2$ and

$$f_1 = g_1 + 1032g_2 = q + 195660q^3 + 12080128q^4 + 44656110q^5 - \cdots.$$

Example 2.23. When $k = 36$, the Miller basis including f_0 is

$$\begin{aligned}
f_0 &= 1 + \quad 6218175600q^4 + 15281788354560q^5 + \cdots ,\\
f_1 &= \quad q + \quad 57093088q^4 + \quad 37927345230q^5 + \cdots ,\\
f_2 &= \qquad q^2 + \quad 194184q^4 + \qquad 7442432q^5 + \cdots ,\\
f_3 &= \qquad\quad q^3 - \quad 72q^4 + \qquad\quad 2484q^5 + \cdots .
\end{aligned}$$

Example 2.24. The SAGE command `victor_miller_basis` computes the Miller basis to any desired precision for a given k.

```
sage: victor_miller_basis(28,5)
[
1 + 15590400*q^3 + 36957286800*q^4 + O(q^5),
q + 151740*q^3 + 61032448*q^4 + O(q^5),
q^2 + 192*q^3 - 8280*q^4 + O(q^5)
]
```

Remark 2.25. To write $f \in M_k$ as a polynomial in E_4 and E_6, it is wasteful to compute the Miller basis. Instead, use the upper triangular (but not echelon!) basis $\Delta^j F_6^{2(d-j)+a} F_4^b$, and match coefficients from q^0 to q^d.

2.4. Hecke Operators

In this section we define Hecke operators on level 1 modular forms and derive their basic properties. We will not give proofs of the analogous properties for Hecke operators on higher level modular forms, since the proofs are clearest in the level 1 case, and the general case is similar (see, e.g., [**Lan95**]).

For any positive integer n, let

$$X_n = \left\{ \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \in \mathrm{Mat}_2(\mathbb{Z}) \;:\; a \geq 1,\ ad = n,\ \text{and } 0 \leq b < d \right\}.$$

Note that the set X_n is in bijection with the set of subgroups of $\mathbb{Z}^2$ of index n, where $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ corresponds to $L = \mathbb{Z} \cdot (a, b) + \mathbb{Z} \cdot (0, d)$, as one can see using Hermite normal form, which is the analogue over $\mathbb{Z}$ of echelon form (see Exercise 7.5).

Recall from (1.3.1) that if $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$, then

$$f^{[\gamma]_k} = \det(\gamma)^{k-1}(cz + d)^{-k} f(\gamma(z)).$$

Definition 2.26 (Hecke Operator $T_{n,k}$)**.** The nth Hecke operator $T_{n,k}$ of weight k is the operator on the set of functions on $\mathfrak{h}$ defined by

$$T_{n,k}(f) = \sum_{\gamma \in X_n} f^{[\gamma]_k}.$$

Remark 2.27. It would make more sense to write $T_{n,k}$ on the right, e.g., $f|T_{n,k}$, since $T_{n,k}$ is defined using a right group action. However, if n, m are integers, then the action of $T_{n,k}$ and $T_{m,k}$ on weakly modular functions commutes (by Proposition 2.29 below), so it makes no difference whether we view the Hecke operators of given weight k as acting on the right or left.

Proposition 2.28. *If f is a weakly modular function of weight k, then so is $T_{n,k}(f)$; if f is a modular function, then so is $T_{n,k}(f)$.*

Proof. Suppose $\gamma \in \mathrm{SL}_2(\mathbb{Z})$. Since γ induces an automorphism of $\mathbb{Z}^2$,

$$X_n \cdot \gamma = \{\delta\gamma : \delta \in X_n\}$$

is also in bijection with the subgroups of $\mathbb{Z}^2$ of index n. For each element $\delta\gamma \in X_n \cdot \gamma$, there is $\sigma \in \mathrm{SL}_2(\mathbb{Z})$ such that $\sigma\delta\gamma \in X_n$ (the element σ transforms $\delta\gamma$ to Hermite normal form), and the set of elements $\sigma\delta\gamma$ is thus equal to X_n. Thus

$$T_{n,k}(f) = \sum_{\sigma\delta\gamma \in X_n} f^{[\sigma\delta\gamma]_k} = \sum_{\delta \in X_n} f^{[\delta\gamma]_k} = T_{n,k}(f)^{[\gamma]_k}.$$

A finite sum of meromorphic function is meromorphic, so $T_{n,k}(f)$ is weakly modular. If f is holomorphic on $\mathfrak{h}$, then each $f^{[\delta]_k}$ is holomorphic on $\mathfrak{h}$ for $\delta \in X_n$. A finite sum of holomorphic functions is holomorphic, so $T_{n,k}(f)$ is holomorphic.

□

We will frequently drop k from the notation in $T_{n,k}$, since the weight k is implicit in the modular function to which we apply the Hecke operator. Henceforth we make the convention that if we write $T_n(f)$ and if f is modular, then we mean $T_{n,k}(f)$, where k is the weight of f.

Proposition 2.29. *On weight k modular functions we have*

$$T_{mn} = T_m T_n \qquad \text{if } (m,n) = 1, \tag{2.4.1}$$

and

$$T_{p^n} = T_{p^{n-1}} T_p - p^{k-1} T_{p^{n-2}} \qquad \text{if } p \text{ is prime.} \tag{2.4.2}$$

Proof. Let L be a subgroup of index mn. The quotient $\mathbb{Z}^2/L$ is an abelian group of order mn, and $(m,n) = 1$, so $\mathbb{Z}^2/L$ decomposes uniquely as a direct sum of a subgroup of order m with a subgroup of order n. Thus there exists a unique subgroup L' such that $L \subset L' \subset \mathbb{Z}^2$, and L' has index m in $\mathbb{Z}^2$. The subgroup L' corresponds to an element of X_m, and the index n subgroup $L \subset L'$ corresponds to multiplying that element on the right by some uniquely determined element of X_n. We thus have

$$\mathrm{SL}_2(\mathbb{Z}) \cdot X_m \cdot X_n = \mathrm{SL}_2(\mathbb{Z}) \cdot X_{mn},$$

i.e., the set products of elements in X_m with elements of X_n equal the elements of X_{mn}, up to $\mathrm{SL}_2(\mathbb{Z})$-equivalence. Thus for any f, we have $T_{mn}(f) = T_n(T_m(f))$. Applying this formula with m and n swapped yields the equality $T_{mn} = T_m T_n$.

We will show that $T_{p^n} + p^{k-1}T_{p^{n-2}} = T_p T_{p^{n-1}}$. Suppose f is a weight k weakly modular function. Using that $f^{[\left(\begin{smallmatrix} p & 0 \\ 0 & p \end{smallmatrix}\right)]_k} = (p^2)^{k-1}p^{-k}f = p^{k-2}f$, we have

$$\sum_{x \in X_{p^n}} f^{[x]_k} \; + \; p^{k-1} \sum_{x \in X_{p^{n-2}}} f^{[x]_k} = \sum_{x \in X_{p^n}} f^{[x]_k} \; + p \sum_{x \in pX_{p^{n-2}}} f^{[x]_k}.$$

Also

$$T_p T_{p^{n-1}}(f) = \sum_{y \in X_p} \sum_{x \in X_{p^{n-1}}} (f^{[x]_k})^{[y]_k} = \sum_{x \in X_{p^{n-1}} \cdot X_p} f^{[x]_k}.$$

Thus it suffices to show that X_{p^n} disjoint union p copies of $pX_{p^{n-2}}$ is equal to $X_{p^{n-1}} \cdot X_p$, where we consider elements with multiplicities and up to left $\mathrm{SL}_2(\mathbb{Z})$-equivalence (i.e., the left action of $\mathrm{SL}_2(\mathbb{Z})$).

Suppose L is a subgroup of $\mathbb{Z}^2$ of index p^n, so L corresponds to an element of X_{p^n}. First suppose L is not contained in $p\mathbb{Z}^2$. Then the image of L in $\mathbb{Z}^2/p\mathbb{Z}^2 = (\mathbb{Z}/p\mathbb{Z})^2$ is of order p, so if $L' = p\mathbb{Z}^2 + L$, then $[\mathbb{Z}^2 : L'] = p$ and $[L : L'] = p^{n-1}$, and L' is the only subgroup with this property. Second, suppose that $L \subset p\mathbb{Z}^2$ if of index p^n and that $x \in X_{p^n}$ corresponds to L. Then every one of the $p+1$ subgroups $L' \subset \mathbb{Z}^2$ of index p contains L. Thus there are $p+1$ chains $L \subset L' \subset \mathbb{Z}^2$ with $[\mathbb{Z}^2 : L'] = p$.

The chains $L \subset L' \subset \mathbb{Z}^2$ with $[\mathbb{Z}^2 : L'] = p$ and $[\mathbb{Z}^2 : L] = p^{n-1}$ are in bijection with the elements of $X_{p^{n-1}} \cdot X_p$. On the other hand the union of X_{p^n} with p copies of $pX_{p^{n-2}}$ corresponds to the subgroups L of index p^n, but with those that contain $p\mathbb{Z}^2$ counted $p+1$ times. The structure of the set of chains $L \subset L' \subset \mathbb{Z}^2$ that we derived in the previous paragraph gives the result. □

Corollary 2.30. *The Hecke operator T_{p^n}, for prime p, is a polynomial in T_p with integer coefficients, i.e., $T_{p^n} \in \mathbb{Z}[T_p]$. If n, m are any integers, then $T_n T_m = T_m T_n$.*

Proof. The first statement follows from (2.4.2) of Proposition 2.29. It then follows that $T_n T_m = T_m T_n$ when m and n are both powers of a single prime p. Combining this with (2.4.1) gives the second statement in general. □

Proposition 2.31. *Let $f = \sum_{n \in \mathbb{Z}} a_n q^n$ be a modular function of weight k. Then*

$$T_n(f) = \sum_{m \in \mathbb{Z}} \left(\sum_{1 \leq d \,|\, \gcd(n,m)} d^{k-1} a_{mn/d^2} \right) q^m.$$

In particular, if $n = p$ is prime, then

$$T_p(f) = \sum_{m\in\mathbb{Z}} \left(a_{mp} + p^{k-1}a_{m/p}\right) q^m,$$

where $a_{m/p} = 0$ if $m/p \notin \mathbb{Z}$.

Proof. This is proved in [**Ser73**, §VII.5.3] by writing out $T_n(f)$ explicitly and using that $\sum_{0\leq b<d} e^{2\pi ibm/d}$ is d if $d \mid m$ and 0 otherwise. □

Corollary 2.32. *The Hecke operators preserve M_k and S_k.*

Remark 2.33. Alternatively, for M_k the above corollary is Proposition 2.28, and for S_k we see from the definitions that if $f(\infty) = 0$, then $T_n f$ also vanishes at ∞.

Example 2.34. Recall from (2.1.3) that

$$E_4 = \frac{1}{240} + q + 9q^2 + 28q^3 + 73q^4 + 126q^5 + 252q^6 + 344q^7 + \cdots .$$

Using the formula of Proposition 2.31, we see that

$$T_2(E_4) = (1/240 + 2^3 \cdot (1/240)) + 9q + (73 + 2^3 \cdot 1)q^2 + \cdots .$$

Since M_4 has dimension 1 and since we have proved that T_2 preserves M_4, we know that T_2 acts as a scalar. Thus we know just from the constant coefficient of $T_2(E_4)$ that

$$T_2(E_4) = 9E_4.$$

More generally, for p prime we see by inspection of the constant coefficient of $T_p(E_4)$ that

$$T_p(E_4) = (1 + p^3)E_4.$$

In fact $T_n(E_k) = \sigma_{k-1}(n)E_k$, for any integer $n \geq 1$ and even weight $k \geq 4$.

Example 2.35. By Corollary 2.32, the Hecke operators T_n also preserve the subspace S_k of M_k. Since S_{12} has dimension 1 (spanned by Δ), we see that Δ is an eigenvector for every T_n. Since the coefficient of q in the q-expansion of Δ is 1, the eigenvalue of T_n on Δ is the nth coefficient of Δ. Since $T_{nm} = T_n T_m$ for $\gcd(n, m) = 1$, we have proved the nonobvious fact that the *Ramanujan function* $\tau(n)$ that gives the nth coefficient of Δ is a multiplicative function, i.e., if $\gcd(n, m) = 1$, then $\tau(nm) = \tau(n)\tau(m)$.

Remark 2.36. The Hecke operators respect the decomposition $M_k = S_k \oplus \mathbb{C}E_k$, i.e., for all k the series E_k are eigenvectors for all T_n.

2.5. Computing Hecke Operators

This section is about how to compute matrices of Hecke operators on M_k.

Algorithm 2.37 (Hecke Operator)**.** *This algorithm computes the matrix of the Hecke operator T_n on the Miller basis for M_k.*

(1) [Dimension] Compute $d = \dim(M_k) - 1$ using Corollary 2.16.
(2) [Basis] Using Lemma 2.20, compute the echelon basis $f_0, \dots, f_d$ for $M_k \pmod{q^{dn+1}}$.
(3) [Hecke operator] Using Proposition 2.31, compute for each i the image $T_n(f_i) \pmod{q^{d+1}}$.
(4) [Write in terms of basis] The elements $T_n(f_i) \pmod{q^{d+1}}$ determine linear combinations of
$$f_0, f_1, \dots, f_d \pmod{q^d}.$$
These linear combinations are easy to find once we compute $T_n(f_i)$ (mod q^{d+1}), since our basis of f_i is in echelon form. The linear combinations are just the coefficients of the power series $T_n(f_i)$ up to and including q^d.
(5) [Write down matrix] The matrix of T_n acting from the right relative to the basis $f_0, \dots, f_d$ is the matrix whose rows are the linear combinations found in the previous step, i.e., whose rows are the coefficients of $T_n(f_i)$.

Proof. By Proposition 2.31, the dth coefficient of $T_n(f)$ involves only a_{dn} and smaller-indexed coefficients of f. We need only compute a modular form f modulo q^{dn+1} in order to compute $T_n(f)$ modulo q^{d+1}. Uniqueness in step (4) follows from Lemma 2.20 above. □

Example 2.38. We compute the Hecke operator T_2 on M_{12} using the above algorithm.

(1) [Compute dimension] We have $d = 2 - 1 = 1$.
(2) [Compute basis] Compute up to (but not including) the coefficient of $q^{dn+1} = q^{1\cdot 2+1} = q^3$. As given in the proof of Lemma 2.20, we have
$$F_4 = 1 + 240q + 2160q^2 + \cdots \quad \text{and} \quad F_6 = 1 - 504q - 16632q^2 + \cdots .$$
Thus M_{12} has basis
$$F_4^3 = 1+720q+179280q^2+\cdots \quad \text{and} \quad \Delta = (F_4^3 - F_6^2)/1728 = q - 24q^2 + \cdots .$$
Subtracting 720Δ from F_4^3 yields the echelon basis, which is
$$f_0 = 1 + 196560q^2 + \cdots \quad \text{and} \quad f_1 = q - 24q^2 + \cdots .$$
SAGE does the arithmetic in the above calculation as follows:

```
sage: R.<q> = QQ[['q']]
sage: F4 =  240 * eisenstein_series_qexp(4,3)
sage: F6 = -504 * eisenstein_series_qexp(6,3)
sage: F4^3
1 + 720*q + 179280*q^2 + O(q^3)
sage: Delta = (F4^3 - F6^2)/1728; Delta
q - 24*q^2 + O(q^3)
sage: F4^3 - 720*Delta
1 + 196560*q^2 + O(q^3)
```

(3) [Compute Hecke operator] In each case letting a_n denote the nth coefficient of f_0 or f_1, respectively, we have

$$\begin{aligned} T_2(f_0) &= T_2(1 + 196560q^2 + \cdots) \\ &= (a_0 + 2^{11}a_0)q^0 + (a_2 + 2^{11}a_{1/2})q^1 + \cdots \\ &= 2049 + 196560q + \cdots, \end{aligned}$$

and

$$\begin{aligned} T_2(f_1) &= T_2(q - 24q^2 + \cdots) \\ &= (a_0 + 2^{11}a_0)q^0 + (a_2 + 2^{11}a_{1/2})q^1 + \cdots \\ &= 0 - 24q + \cdots. \end{aligned}$$

(Note that $a_{1/2} = 0$.)

(4) [Write in terms of basis] We read off at once that

$$T_2(f_0) = 2049 f_0 + 196560 f_1 \quad \text{and} \quad T_2(f_1) = 0 f_0 + (-24) f_1.$$

(5) [Write down matrix] Thus the matrix of T_2, acting from the right on the basis f_0, f_1, is

$$T_2 = \begin{pmatrix} 2049 & 196560 \\ 0 & -24 \end{pmatrix}.$$

As a check note that the characteristic polynomial of T_2 is $(x-2049)(x+24)$ and that $2049 = 1 + 2^{11}$ is the sum of the 11th powers of the divisors of 2.

Example 2.39. The Hecke operator T_2 on M_{36} with respect to the echelon basis is

$$\begin{pmatrix} 34359738369 & 0 & 6218175600 & 9026867482214400 \\ 0 & 0 & 34416831456 & 5681332472832 \\ 0 & 1 & 194184 & -197264484 \\ 0 & 0 & -72 & -54528 \end{pmatrix}.$$

It has characteristic polynomial

$$(x - 34359738369) \cdot (x^3 - 139656x^2 - 59208339456x - 1467625047588864),$$

where the cubic factor is irreducible.

The `echelon_form()` command creates the space of modular forms but with basis in echelon form (which is not the default).

```
sage: M = ModularForms(1,36, prec=6).echelon_form()
sage: M.basis()
[
1 + 6218175600*q^4 + 15281788354560*q^5 + O(q^6),
q + 57093088*q^4 + 37927345230*q^5 + O(q^6),
q^2 + 194184*q^4 + 7442432*q^5 + O(q^6),
q^3 - 72*q^4 + 2484*q^5 + O(q^6)
]
```

Next we compute the matrix of the Hecke operator T_2.

```
sage: T2 = M.hecke_matrix(2); T2
[34359738369   0       6218175600 9026867482214400]
[          0   0      34416831456    5681332472832]
[          0   1           194184       -197264484]
[          0   0              -72           -54528]
```

Finally we compute and factor its characteristic polynomial.

```
sage: T2.charpoly().factor()
(x - 34359738369) *
   (x^3 - 139656*x^2 - 59208339456*x - 1467625047588864)
```

The following is a famous open problem about Hecke operators on modular forms of level 1. It generalizes our above observation that the characteristic polynomial of T_2 on M_k, for $k = 12, 36$, factors as a product of a linear factor and an irreducible factor.

Conjecture 2.40 (Maeda)**.** *The characteristic polynomial of T_2 on S_k is irreducible for any k.*

Kevin Buzzard observed that in several specific cases the Galois group of the characteristic polynomial of T_2 is the full symmetric group (see [**Buz96**]). See also [**FJ02**] for more evidence for the following conjecture:

Conjecture 2.41. *For all primes p and all even $k \geq 2$ the characteristic polynomial of $T_{p,k}$ acting on S_k is irreducible.*

2.6. Fast Computation of Fourier Coefficients

How difficult is it to compute prime-indexed coefficients of

$$\Delta = \sum_{n=1}^{\infty} \tau(n) q^n = q - 24q^2 + 252q^3 - 1472q^4 + 4830q^5 - 6048q^6 + \cdots ?$$

Theorem 2.42 (Bosman, Couveignes, Edixhoven, de Jong, Merkl)**.** *Let p be a prime. There is a probabilistic algorithm to compute $\tau(p)$, for prime p, that has expected running time polynomial in* $\log(p)$*.*

Proof. See [**ECdJ$^+$06**]. □

More generally, if $f = \sum a_n q^n$ is an eigenform in some space $M_k(\Gamma_1(N))$, where $k \geq 2$, then one expects that there is an algorithm to compute a_p in time polynomial in $\log(p)$. Bas Edixhoven, Jean-Marc Couveignes and Robin de Jong have proved that $\tau(p)$ can be computed in polynomial time; their approach involves sophisticated techniques from arithmetic geometry (e.g., étale cohomology, motives, Arakelov theory). The ideas they use are inspired by the ones introduced by Schoof, Elkies and Atkin for quickly counting points on elliptic curves over finite fields (see [**Sch95**]).

Edixhoven describes (in an email to the author) the strategy as follows:

(1) We compute the mod ℓ Galois representation ρ associated to Δ. In particular, we produce a polynomial f such that $\mathbb{Q}[x]/(f)$ is the fixed field of $\ker(\rho)$. This is then used to obtain $\tau(p) \pmod{\ell}$ and to do a Schoof-like algorithm for computing $\tau(p)$.

(2) We compute the field of definition of suitable points of order ℓ on the modular Jacobian $J_1(\ell)$ to do part (1) (see [**DS05**, Ch. 6] for the definition of $J_1(\ell)$).

(3) The method is to approximate the polynomial f in some sense (e.g., over the complex numbers or modulo many small primes r) and to use an estimate from Arakelov theory to determine a precision that will suffice.

2.7. Fast Computation of Bernoulli Numbers

This section, which was written jointly with Kevin McGown, is about computing the Bernoulli numbers B_n, for $n \geq 0$, defined in Section 2.1.2 by

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} B_n \frac{x^n}{n!}. \tag{2.7.1}$$

One way to compute B_n is to multiply both sides of (2.7.1) by $e^x - 1$ and equate coefficients of x^{n+1} to obtain the recurrence

$$B_0 = 1, \qquad B_n = -\frac{1}{n+1} \cdot \sum_{k=0}^{n-1} \binom{n+1}{k} B_k.$$

This recurrence provides a straightforward and easy-to-implement method for calculating B_n if one is interested in computing B_n for all n up to some bound. For example,

$$B_1 = -\frac{1}{2} \cdot \left(\binom{2}{0} B_0 \right) = -\frac{1}{2}$$

and

$$B_2 = -\frac{1}{3} \cdot \left(\binom{3}{0} B_0 + \binom{3}{1} B_1 \right) = -\frac{1}{3} \cdot \left(1 - \frac{3}{2} \right) = \frac{1}{6}.$$

However, computing B_n via the recurrence is slow; it requires summing over many large terms, it requires storing the numbers $B_0, \ldots, B_{n-1}$, and it takes only limited advantage of asymptotically fast arithmetic algorithms. There is also an inductive procedure to compute Bernoulli numbers that resembles Pascal's triangle called the Akiyama-Tanigawa algorithm (see [**Kan00**]).

Another approach to computing B_n is to use Newton iteration and asymptotically fast polynomial arithmetic to approximate $1/(e^x - 1)$. This method yields a very fast algorithm to compute $B_0, B_2, \ldots, B_{p-3}$ modulo p. See [**BCS92**] for an application of this method modulo a prime p to the verification of Fermat's last theorem for irregular primes up to one million.

Example 2.43. David Harvey implemented the algorithm of [**BCS92**] in SAGE as the command `bernoulli_mod_p`:

```
sage: bernoulli_mod_p(23)
[1, 4, 13, 17, 13, 6, 10, 5, 10, 9, 15]
```

A third way to compute B_n uses an algorithm based on Proposition 2.8, which we explain below (Algorithm 2.45). This algorithm appears to have been independently invented by several people: by Bernd C. Kellner (see [**Kel06**]); by Bill Dayl; and by H. Cohen and K. Belabas.

We compute B_n as an exact rational number by approximating $\zeta(n)$ to very high precision using Proposition 2.8, the Euler product

$$\zeta(s) = \sum_{m=1}^{\infty} m^{-s} = \prod_{p \text{ prime}} (1 - p^{-s})^{-1},$$

and the following theorem:

Theorem 2.44 (Clausen, von Staudt)**.** *For even $n \geq 2$,*

$$\mathrm{denom}(B_n) = \prod_{p-1\,|\,n} p.$$

Proof. See [**Lan95**, Ch. X, Thm. 2.1]. □

2.7.1. The Number of Digits of B_n. The following is a new quick way to compute the number of digits of the numerator of B_n. For example, using it we can compute the number of digits of $B_{10^{50}}$ in less than a second.

By Theorem 2.44 we have $d_n = \mathrm{denom}(B_n) = \prod_{p-1|n} p$. The number of digits of the numerator is thus

$$\lceil \log_{10}(d_n \cdot |B_n|) \rceil.$$

But

$$\begin{aligned}\log(|B_n|) &= \log\left(\frac{2\cdot n!}{(2\pi)^n}\,\zeta(n)\right)\\ &= \log(2) + \log(n!) - n\log(2) - n\log(\pi) + \log(\zeta(n)),\end{aligned}$$

and $\zeta(n) \sim 1$ so $\log(\zeta(n)) \sim 0$. Finally, Stirling's formula (see [**Ahl78**, pg. 198–206]) gives a fast way to compute $\log(n!) = \log(\Gamma(n+1))$:
(2.7.2)

$$\log(\Gamma(z))\text{``}=\text{''}\,\frac{\log(2\pi)}{2} + \left(z - \frac{1}{2}\right)\log(z) - z + \sum_{m=1}^{\infty} \frac{B_{2m}}{2m(2m-1)z^{2m-1}}.$$

We put quotes around the equality sign because $\log(\Gamma(z))$ does not converge to its Laurent series. Indeed, note that for any fixed value of z the summands on the right side go to ∞ as $m \to \infty$! Nonetheless, we can use this formula to very efficiently compute $\log(\Gamma(z))$, since if we truncate the sum, then the error is smaller than the next term in the infinite sum.

2.7.2. Computing B_n Exactly. We return to the problem of computing B_n. Let

$$K = \frac{2\cdot n!}{(2\pi)^n}$$

so that $|B_n| = K\zeta(n)$. Write

$$B_n = \frac{a}{d},$$

with $a, d \in \mathbb{Z}$, $d \geq 1$, and $\gcd(a, d) = 1$. It is elementary to show that $a = (-1)^{n/2+1}\,|a|$ for even $n \geq 2$. Suppose that using the Euler product we approximate $\zeta(n)$ from below by a number z such that

$$0 \leq \zeta(m) - z < \frac{1}{Kd}.$$

Then $0 \leq |B_n| - zK < d^{-1}$; hence $0 \leq |a| - zKd < 1$. It follows that $|a| = \lceil zKd \rceil$ and hence $a = (-1)^{n/2+1} \lceil zKd \rceil$.

It remains to compute z. Consider the following problem: given $s > 1$ and $\varepsilon > 0$, find $M \in \mathbb{Z}_+$ so that

$$z = \prod_{p \leq M} (1 - p^{-s})^{-1}$$

satisfies $0 \leq \zeta(s) - z < \varepsilon$. We always have $0 \leq \zeta(s) - z$. Also,

$$\sum_{n \leq M} n^{-s} \leq \prod_{p \leq M} (1 - p^{-s})^{-1},$$

so

$$\zeta(s) - z \leq \sum_{n=M+1}^{\infty} n^{-s} \leq \int_M^{\infty} x^{-s}\, dx = \frac{1}{(s-1)M^{s-1}}.$$

Thus if $M > \varepsilon^{-1/(s-1)}$, then

$$\frac{1}{(s-1)M^{s-1}} \leq \frac{1}{M^{s-1}} < \varepsilon\,,$$

so $\zeta(s) - z < \varepsilon$, as required. For our purposes, we have $s = n$ and $\varepsilon = (Kd)^{-1}$, so it suffices to take $M > (Kd)^{1/(n-1)}$.

Algorithm 2.45 (Bernoulli Number B_n)**.** *Given an integer $n \geq 0$, this algorithm computes the Bernoulli number B_n as an exact rational number.*

```
(1) [Special cases] If $n = 0$, return 1; if $n = 1$, return $-1/2$; if $n \geq 3$ is odd, return 0.
(2) [Factorial factor] Compute $K = \frac{2 \cdot n!}{(2\pi)^n}$ to sufficiently many digits of precision so the ceiling in step (6) is uniquely determined (this precision can be determined using Section 2.7.1).
(3) [Denominator] Compute $d = \prod_{p-1|n} p$.
(4) [Bound] Compute $M = \left\lceil (Kd)^{1/(n-1)} \right\rceil$.
(5) [Approximate $\zeta(n)$] Compute $z = \prod_{p \leq M} (1 - p^{-n})^{-1}$.
(6) [Numerator] Compute $a = (-1)^{n/2+1} \lceil dKz \rceil$.
(7) [Output $B_n$] Return $\frac{a}{d}$.
```

In step (5) use a sieve to compute all primes $p \leq M$ efficiently (which is fast, since M is so small). In step (4) we may replace M by any integer greater than the one specified by the formula, so we do not have to compute $(Kd)^{1/(n-1)}$ to very high precision.

In Section 5.2.2 below we will generalize the above algorithm.

Example 2.46. We illustrate Algorithm 2.45 by computing B_{50}. Using 135 binary digits of precision, we compute

$$K = 7500866746076957704747736.71552473164563479.$$

The divisors of n are $1, 2, 5, 10, 25, 50$, so

$$d = 2 \cdot 3 \cdot 11 = 66.$$

We find $M = 4$ and compute

$$z = 1.000000000000000888178421093081590298350 12.$$

Finally we compute

$$dKz = 4950572052410796482124775 24.999999994425778,$$

so

$$B_{50} = \frac{495057205241079648212477525}{66}.$$

2.8. Exercises

2.1 Using Proposition 2.8 and the table on page 16, compute $\sum_{n=1}^{\infty} \frac{1}{n^{26}}$ explicitly.

2.2 Prove that if $n > 1$ is odd, then the Bernoulli number B_n is 0.

2.3 Use (2.1.3) to write down the coefficients of 1, q, q^2, and q^3 of the Eisenstein series E_8.

2.4 Suppose k is a positive integer with $k \equiv 0 \pmod{12}$. Suppose $a, b \geq 0$ are integers with $4a + 6b = k$.
 (a) Prove $3 \mid a$.
 (b) Show that $G_4^a \cdot G_6^b \,/\, G_6^{\frac{k}{6}} = \left(G_4^3/G_6^2\right)^{\frac{a}{3}}$.

2.5 Compute the Miller basis for $M_{28}(\mathrm{SL}_2(\mathbb{Z}))$ with precision $O(q^8)$. Your answer will look like Example 2.23.

2.6 Consider the cusp form $f = q^2+192q^3-8280q^4+\cdots$ in $S_{28}(\mathrm{SL}_2(\mathbb{Z}))$. Write f as a polynomial in E_4 and E_6 (see Remark 2.25).

2.7 Let G_k be the weight k Eisenstein series from equation (2.1.1). Let c be the complex number so that the constant coefficient of the q-expansion of $g = c \cdot G_k$ is 1. Is it always the case that the q-expansion of g lies in $\mathbb{Z}[[q]]$?

2.8 Compute the matrix of the Hecke operator T_2 on the Miller basis for $M_{32}(\mathrm{SL}_2(\mathbb{Z}))$. Then compute its characteristic polynomial and verify it factors as a product of two irreducible polynomials.

What Next? Much of the rest of this book is about methods for computing subspaces of $M_k(\Gamma_1(N))$ for general N and k. These general methods are more complicated than the methods presented in this chapter, since there are many more modular forms of small weight and it can be difficult to obtain them. Forms of level $N > 1$ have subtle connections with elliptic curves, abelian varieties, and motives. Read on for more!

Chapter 3

Modular Forms of Weight 2

We saw in Chapter 2 (especially Section 2.2) that we can compute each space $M_k(\mathrm{SL}_2(\mathbb{Z}))$ explicitly. This involves computing Eisenstein series E_4 and E_6 to some precision, then forming the basis $\{E_4^a E_6^b : 4a + 6b = k, 0 \leq a, b \in \mathbb{Z}\}$ for $M_k(\mathrm{SL}_2(\mathbb{Z}))$. In this chapter we consider the more general problem of computing $S_2(\Gamma_0(N))$, for any positive integer N. Again we have a decomposition

$$M_2(\Gamma_0(N)) = S_2(\Gamma_0(N)) \oplus E_2(\Gamma_0(N)),$$

where $E_2(\Gamma_0(N))$ is spanned by generalized Eisenstein series and $S_2(\Gamma_0(N))$ is the space of cusp forms, i.e., elements of $M_2(\Gamma_0(N))$ that vanish at *all* cusps.

In Chapter 5 we compute the space $E_2(\Gamma_0(N))$ in a similar way to how we computed $M_k(\mathrm{SL}_2(\mathbb{Z}))$. On the other hand, elements of $S_2(\Gamma_0(N))$ often cannot be written as sums or products of generalized Eisenstein series. In fact, the structure of $M_2(\Gamma_0(N))$ is, in general, much more complicated than that of $M_k(\mathrm{SL}_2(\mathbb{Z}))$. For example, when p is a prime, $E_2(\Gamma_0(p))$ has dimension 1, whereas $S_2(\Gamma_0(p))$ has dimension about $p/12$.

Fortunately an idea of Birch, which he called modular symbols, provides a method for computing $S_2(\Gamma_0(N))$ and indeed for much more that is relevant to understanding special values of L-functions. Modular symbols are also a powerful theoretical tool. In this chapter, we explain how $S_2(\Gamma_0(N))$ is related to modular symbols and how to use this relationship to explicitly compute a basis for $S_2(\Gamma_0(N))$. In Chapter 8 we will introduce more general modular symbols and explain how to use them to compute $S_k(\Gamma_0(N))$, $S_k(\Gamma_1(N))$ and $S_k(N, \varepsilon)$ for any integers $k \geq 2$ and N and character ε.

Section 3.1 contains a very brief summary of basic facts about modular forms of weight 2, modular curves, Hecke operators, and integral homology. Section 3.2 introduces modular symbols and describes how to compute with them. In Section 3.5 we talk about how to cut out the subspace of modular symbols corresponding to cusp forms using the boundary map. Section 3.6 is about a straightforward method to compute a basis for $S_2(\Gamma_0(N))$ using modular symbols, and Section 3.7 outlines a more sophisticated algorithm for computing newforms that uses Atkin-Lehner theory.

Before reading this chapter, you should have read Chapter 1 and Chapter 2. We also assume familiarity with algebraic curves, Riemann surfaces, and homology groups of compact Riemann surfaces.

3.1. Hecke Operators

Recall from Chapter 1 that the group $\Gamma_0(N)$ acts on $\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q})$ by linear fractional transformations. The quotient $\Gamma_0(N)\backslash\mathfrak{h}^*$ is a Riemann surface, which we denote by $X_0(N)$. See [**DS05**, Ch. 2] for a detailed description of the topology on $X_0(N)$. The Riemann surface $X_0(N)$ also has a canonical structure of algebraic curve over $\mathbb{Q}$, as is explained in [**DS05**, Ch. 7] (see also [**Shi94**, §6.7]).

Recall from Section 1.3 that a cusp form of weight 2 for $\Gamma_0(N)$ is a function f on $\mathfrak{h}$ such that $f(z)dz$ defines a holomorphic differential on $X_0(N)$. Equivalently, a cusp form is a holomorphic function f on $\mathfrak{h}$ such that

(a) the expression $f(z)dz$ is invariant under replacing z by $\gamma(z)$ for each $\gamma \in \Gamma_0(N)$ and

(b) $f(z)$ vanishes at every cusp for $\Gamma_0(N)$.

The space $S_2(\Gamma_0(N))$ of weight 2 cusp forms on $\Gamma_0(N)$ is a finite-dimensional complex vector space, of dimension equal to the genus g of $X_0(N)$. The space $X_0(N)(\mathbb{C})$ is a compact oriented Riemann surface, so it is a 2-dimensional oriented real manifold, i.e., $X_0(N)(\mathbb{C})$ is a g-holed torus (see Figure 3.1.1 on page 38).

Condition (b) in the definition of f means that f has a Fourier expansion about each element of $\mathbb{P}^1(\mathbb{Q})$. Thus, at ∞ we have

$$\begin{aligned} f(z) &= a_1 e^{2\pi i z} + a_2 e^{2\pi i 2z} + a_3 e^{2\pi i 3z} + \cdots \\ &= a_1 q + a_2 q^2 + a_3 q^3 + \cdots, \end{aligned}$$

where, for brevity, we write $q = q(z) = e^{2\pi i z}$.

Example 3.1. Let E be the elliptic curve defined by the equation $y^2+xy = x^3+x^2-4x-5$. Let $a_p = p+1-\#\tilde{E}(\mathbb{F}_p)$, where $\tilde{E}$ is the reduction of E mod p (note that for the primes that divide the conductor of E we have $a_3 = -1$, $a_{13} = 1$). For n composite, define a_n using the relations at the end of Section 3.7. Then the Shimura-Taniyama conjecture asserts that

$$\begin{aligned} f &= q + a_2q^2 + a_3q^3 + a_4q^4 + a_5q^5 + \cdots \\ &= q + q^2 - q^3 - q^4 + 2q^5 + \cdots \end{aligned}$$

is the q-expansion of an element of $S_2(\Gamma_0(39))$. This conjecture, which is now a theorem (see [**BCDT01**]), asserts that any q-expansion constructed as above from an elliptic curve over $\mathbb{Q}$ is a modular form. This conjecture was mostly proved first by Wiles [**Wil95**] as a key step in the proof of Fermat's last theorem.

Just as is the case for level 1 modular forms (see Section 2.4) there are commuting Hecke operators $T_1, T_2, T_3, \ldots$ that act on $S_2(\Gamma_0(N))$. To define them conceptually, we introduce an interpretation of the modular curve $X_0(N)$ as an object whose points *parameterize* elliptic curves with extra structure.

Proposition 3.2. *The complex points of* $Y_0(N) = \Gamma_0(N)\backslash\mathfrak{h}$ *are in natural bijection with isomorphism classes of pairs* (E, C)*, where* E *is an elliptic curve over* $\mathbb{C}$ *and* C *is a cyclic subgroup of* $E(\mathbb{C})$ *of order* N*. The class of the point* $\lambda \in \mathfrak{h}$ *corresponds to the pair*

$$\left(\mathbb{C}/(\mathbb{Z}+\mathbb{Z}\lambda), \quad \left(\frac{1}{N}\mathbb{Z}+\mathbb{Z}\lambda\right)/(\mathbb{Z}+\mathbb{Z}\lambda)\right).$$

Proof. See Exercise 3.1. □

Suppose n and N are coprime positive integers. There are two natural maps π_1 and π_2 from $Y_0(n\cdot N)$ to $Y_0(N)$; the first, π_1, sends $(E, C) \in Y_0(n\cdot N)(\mathbb{C})$ to (E, C'), where C' is the unique cyclic subgroup of C of order N, and the second, π_2, sends (E, C) to $(E/D, C/D)$, where D is the unique cyclic subgroup of C of order n. These maps extend in a unique way to algebraic maps from $X_0(n\cdot N)$ to $X_0(N)$:

(3.1.1)

$$\begin{tikzcd} & X_0(n\cdot N) \arrow[dl, "\pi_2"'] \arrow[dr, "\pi_1"] & \\ X_0(N) & & X_0(N). \end{tikzcd}$$

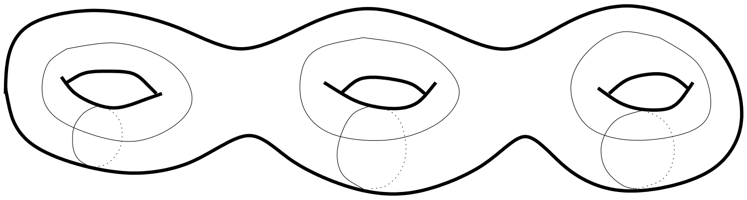
The nth *Hecke operator* T_n is $\pi_{1*}\circ\pi_2^*$, where π_2^* and π_{1*} denote pullback and pushforward of differentials, respectively. (There is a similar definition of T_n when $\gcd(n, N) \neq 1$.) Using our interpretation of $S_2(\Gamma_0(N))$ as differentials on $X_0(N)$, this gives an action of Hecke operators on $S_2(\Gamma_0(N))$. One can show that these induce the maps of Proposition 2.31 on q-expansions.

Example 3.3. There is a basis of $S_2(39)$ so that

$$T_2 = \begin{pmatrix} 1 & 1 & 0 \\ -2 & -3 & -2 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad T_5 = \begin{pmatrix} -4 & -2 & -6 \\ 4 & 4 & 4 \\ 0 & 0 & 2 \end{pmatrix}.$$

Notice that these matrices commute. Also, the characteristic polynomial of T_2 is $(x-1)\cdot(x^2+2x-1)$.

3.1.1. Homology. The first homology group $\mathrm{H}_1(X_0(N),\mathbb{Z})$ is the group of closed 1-cycles modulo boundaries of 2-cycles (formal sums of images of 2-simplexes). Topologically $X_0(N)$ is a g-holed torus, where g is the genus of $X_0(N)$. Thus $\mathrm{H}_1(X_0(N),\mathbb{Z})$ is a free abelian group of rank $2g$ (see, e.g., [**GH81**, Ex. 19.30] and [**DS05**, §6.1]), with two generators corresponding to each hole, as illustrated in the case $N = 39$ in Figure 3.1.1.



$$\mathrm{H}_1(X_0(39),\mathbb{Z}) \cong \mathbb{Z}\times\mathbb{Z}\times\mathbb{Z}\times\mathbb{Z}\times\mathbb{Z}\times\mathbb{Z}$$

Figure 3.1.1. The homology of $X_0(39)$.

The homology of $X_0(N)$ is closely related to modular forms, since the Hecke operators T_n also act on $\mathrm{H}_1(X_0(N),\mathbb{Z})$. The action is by pullback of homology classes by π_2 followed by taking the image under π_1, where π_1 and π_2 are as in (3.1.1).

Integration defines a pairing

$$\langle\, ,\, \rangle : S_2(\Gamma_0(N)) \times \mathrm{H}_1(X_0(N),\mathbb{Z}) \to \mathbb{C}. \tag{3.1.2}$$

Explicitly, for a path x,

$$\langle f, x\rangle = 2\pi i \cdot \int_x f(z)dz.$$

Theorem 3.4. *The pairing* (3.1.2) *is nondegenerate and Hecke equivariant in the sense that for every Hecke operator T_n, we have $\langle fT_n, x\rangle = \langle f, T_n x\rangle$. Moreover, it induces a perfect pairing*

$$\langle\, ,\, \rangle : S_2(\Gamma_0(N)) \times \mathrm{H}_1(X_0(N),\mathbb{R}) \to \mathbb{C}. \tag{3.1.3}$$

This is a special case of the results in Section 8.5.

As we will see, modular symbols allow us to make explicit the action of the Hecke operators on $\mathrm{H}_1(X_0(N), \mathbb{Z})$; the above pairing then translates this into a wealth of information about cusp forms.

We will also consider the relative homology group $\mathrm{H}_1(X_0(N), \mathbb{Z}; \{\text{cusps}\})$ of $X_0(N)$ *relative to the cusps*; it is the same as usual homology, but in addition we allow paths with endpoints in the cusps instead of restricting to closed loops. Modular symbols provide a "combinatorial" presentation of $\mathrm{H}_1(X_0(N), \mathbb{Z})$ in terms of paths between elements of $\mathbb{P}^1(\mathbb{Q})$.

3.2. Modular Symbols

Let $\mathbb{M}_2$ be the free abelian group with basis the set of symbols $\{\alpha, \beta\}$ with $\alpha, \beta \in \mathbb{P}^1(\mathbb{Q})$ modulo the 3-term relations

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0$$

above and modulo any torsion. Since $\mathbb{M}_2$ is torsion-free, we have

$$\{\alpha, \alpha\} = 0 \qquad \text{and} \qquad \{\alpha, \beta\} = -\{\beta, \alpha\}.$$

Remark 3.5 (Warning)**.** The symbols $\{\alpha, \beta\}$ satisfy the relations $\{\alpha, \beta\} = -\{\beta, \alpha\}$, so order matters. The notation $\{\alpha, \beta\}$ looks like the set containing two elements, which strongly (and incorrectly) suggests that the order does not matter. This is the standard notation in the literature.

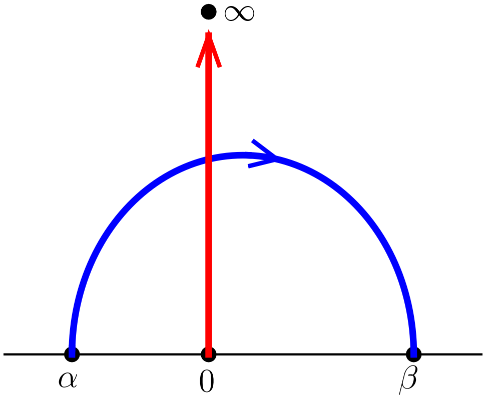


Figure 3.2.1. The modular symbols $\{\alpha, \beta\}$ and $\{0, \infty\}$.

As illustrated in Figure 3.2.1, we "think of" this modular symbol as the homology class, relative to the cusps, of a path from α to β in $\mathfrak{h}^*$.

Define a *left action of* $\mathrm{GL}_2(\mathbb{Q})$ on $\mathbb{M}_2$ by letting $g \in \mathrm{GL}_2(\mathbb{Q})$ act by

$$g\{\alpha, \beta\} = \{g(\alpha), g(\beta)\},$$

and g acts on α and β via the corresponding linear fractional transformation. The space $\mathbb{M}_2(\Gamma_0(N))$ of *modular symbols for* $\Gamma_0(N)$ is the quotient of $\mathbb{M}_2$ by the submodule generated by the infinitely many elements of the form $x - g(x)$, for x in $\mathbb{M}_2$ and g in $\Gamma_0(N)$, and modulo any torsion. A modular symbol for $\Gamma_0(N)$ is an element of this space. We frequently denote the equivalence class of a modular symbol by giving a representative element.

Example 3.6. Some modular symbols are 0 no matter what the level N is! For example, since $\gamma = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right) \in \Gamma_0(N)$, we have

$$\{\infty, 0\} = \{\gamma(\infty), \gamma(0)\} = \{\infty, 1\},$$

so

$$0 = \{\infty, 1\} - \{\infty, 0\} = \{\infty, 1\} + \{0, \infty\} = \{0, \infty\} + \{\infty, 1\} = \{0, 1\}.$$

See Exercise 3.2 for a generalization of this observation.

There is a natural homomorphism

$$\varphi : \mathbb{M}_2(\Gamma_0(N)) \to \mathrm{H}_1(X_0(N), \{\text{cusps}\}, \mathbb{Z}) \tag{3.2.1}$$

that sends a formal linear combination of geodesic paths in the upper half plane to their image as paths on $X_0(N)$. In [**Man72**] Manin proved that (3.2.1) is an isomorphism (this is a fairly involved topological argument).

Manin identified the subspace of $\mathbb{M}_2(\Gamma_0(N))$ that is sent isomorphically onto $\mathrm{H}_1(X_0(N), \mathbb{Z})$. Let $\mathbb{B}_2(\Gamma_0(N))$ denote the free abelian group whose basis is the finite set $C(\Gamma_0(N)) = \Gamma_0(N)\backslash\mathbb{P}^1(\mathbb{Q})$ of cusps for $\Gamma_0(N)$. The *boundary map*

$$\delta : \mathbb{M}_2(\Gamma_0(N)) \to \mathbb{B}_2(\Gamma_0(N))$$

sends $\{\alpha, \beta\}$ to $\{\beta\} - \{\alpha\}$, where $\{\beta\}$ denotes the basis element of $\mathbb{B}_2(\Gamma_0(N))$ corresponding to $\beta \in \mathbb{P}^1(\mathbb{Q})$. The kernel $\mathbb{S}_2(\Gamma_0(N))$ of δ is the subspace of *cuspidal modular symbols*. Thus an element of $\mathbb{S}_2(\Gamma_0(N))$ can be thought of as a linear combination of paths in $\mathfrak{h}^*$ whose endpoints are cusps and whose images in $X_0(N)$ are homologous to a $\mathbb{Z}$-linear combination of closed paths.

Theorem 3.7 (Manin)**.** *The map φ above induces a canonical isomorphism*

$$\mathbb{S}_2(\Gamma_0(N)) \cong \mathrm{H}_1(X_0(N), \mathbb{Z}).$$

Proof. This is [**Man72**, Thm. 1.9]. □

For any (commutative) ring R let

$$\mathbb{M}_2(\Gamma_0(N), R) = \mathbb{M}_2(\Gamma_0(N)) \otimes_{\mathbb{Z}} R$$

and

$$\mathbb{S}_2(\Gamma_0(N), R) = \mathbb{S}_2(\Gamma_0(N)) \otimes_{\mathbb{Z}} R.$$

Proposition 3.8. *We have*

$$\dim_{\mathbb{C}} \mathbb{S}_2(\Gamma_0(N), \mathbb{C}) = 2 \dim_{\mathbb{C}} S_2(\Gamma_0(N)).$$

Proof. We have

$$\dim_{\mathbb{C}} \mathbb{S}_2(\Gamma_0(N), \mathbb{C}) = \operatorname{rank}_{\mathbb{Z}} \mathbb{S}_2(\Gamma_0(N)) = \operatorname{rank}_{\mathbb{Z}} \mathrm{H}_1(X_0(N), \mathbb{Z}) = 2g.$$

□

Example 3.9. We illustrate modular symbols in the case when $N = 11$. Using SAGE (below), which implements the algorithm that we describe below over $\mathbb{Q}$, we find that $\mathbb{M}_2(\Gamma_0(11); \mathbb{Q})$ has basis $\{\infty, 0\}$, $\{-1/8, 0\}$, $\{-1/9, 0\}$. A basis for the integral homology $\mathrm{H}_1(X_0(11), \mathbb{Z})$ is the subgroup generated by $\{-1/8, 0\}$ and $\{-1/9, 0\}$.

```
sage: set_modsym_print_mode ('modular')
sage: M = ModularSymbols(11, 2)
sage: M.basis()
({Infinity,0}, {-1/8,0}, {-1/9,0})
sage: S = M.cuspidal_submodule()
sage: S.integral_basis()     # basis over ZZ.
({-1/8,0}, {-1/9,0})
sage: set_modsym_print_mode ('manin')    # set it back
```

3.3. Computing with Modular Symbols

3.3.1. Manin's Trick. In this section, we describe a trick of Manin that we will use to prove that spaces of modular symbols are computable.

By Exercise 1.6 the group $\Gamma_0(N)$ has finite index in $\mathrm{SL}_2(\mathbb{Z})$. Fix right coset representatives $r_0, r_1, \ldots, r_m$ for $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbb{Z})$, so that

$$\mathrm{SL}_2(\mathbb{Z}) = \Gamma_0(N) r_0 \cup \Gamma_0(N) r_1 \cup \cdots \cup \Gamma_0(N) r_m,$$

where the union is disjoint. For example, when N is prime, a list of coset representatives is

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 3 & 1 \end{pmatrix}, \ldots, \begin{pmatrix} 1 & 0 \\ N-1 & 1 \end{pmatrix}, \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Let

$$\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z}) = \{(a : b) \, : \, a, b \in \mathbb{Z}/N\mathbb{Z}, \ \gcd(a, b, N) = 1\}/\sim \tag{3.3.1}$$

where $(a : b) \sim (a' : b')$ if there is $u \in (\mathbb{Z}/N\mathbb{Z})^*$ such that $a = ua', b = ub'$.

Proposition 3.10. *There is a bijection between* $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$ *and the right cosets of* $\Gamma_0(N)$ *in* $\mathrm{SL}_2(\mathbb{Z})$*, which sends a coset representative* $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ *to the class of* $(c : d)$ *in* $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$*.*

Proof. See Exercise 3.3. □

See Proposition 8.6 for the analogous statement for $\Gamma_1(N)$.

We now describe an observation of Manin (see [**Man72**, §1.5]) that is crucial to making $\mathbb{M}_2(\Gamma_0(N))$ computable. It allows us to write any modular symbol $\{\alpha, \beta\}$ as a $\mathbb{Z}$-linear combination of symbols of the form $r_i\{0, \infty\}$, where the $r_i \in \mathrm{SL}_2(\mathbb{Z})$ are coset representatives as above. In particular, the finitely many symbols $r_0\{0,\infty\}, \ldots, r_m\{0,\infty\}$ generate $\mathbb{M}_2(\Gamma_0(N))$.

Proposition 3.11 (Manin)**.** *Let* N *be a positive integer and* $r_0, \ldots, r_m$ *a set of right coset representatives for* $\Gamma_0(N)$ *in* $\mathrm{SL}_2(\mathbb{Z})$*. Every* $\{\alpha, \beta\} \in \mathbb{M}_2(\Gamma_0(N))$ *is a* $\mathbb{Z}$*-linear combination of* $r_0\{0,\infty\}, \ldots, r_m\{0,\infty\}$*.*

We give two proofs of the proposition. The first is useful for computation (see [**Cre97a**, §2.1.6]); the second (see [**MTT86**, §2]) is easier to understand conceptually since it does not require any knowledge of continued fractions.

Continued Fractions Proof of Proposition 3.11. Since

$$\{\alpha, \beta\} = \{0, \beta\} - \{0, \alpha\},$$

it suffices to consider modular symbols of the form $\{0, b/a\}$, where the rational number b/a is in lowest terms. Expand b/a as a continued fraction and consider the successive convergents in lowest terms:

$$\frac{b_{-2}}{a_{-2}} = \frac{0}{1}, \quad \frac{b_{-1}}{a_{-1}} = \frac{1}{0}, \quad \frac{b_0}{a_0} = \frac{b_0}{1}, \ldots, \quad \frac{b_{n-1}}{a_{n-1}}, \quad \frac{b_n}{a_n} = \frac{b}{a}$$

where the first two are included formally. Then

$$b_k a_{k-1} - b_{k-1} a_k = (-1)^{k-1},$$

so that

$$g_k = \begin{pmatrix} b_k & (-1)^{k-1} b_{k-1} \\ a_k & (-1)^{k-1} a_{k-1} \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}).$$

Hence

$$\left\{ \frac{b_{k-1}}{a_{k-1}}, \frac{b_k}{a_k} \right\} = g_k\{0, \infty\} = r_i\{0, \infty\},$$

for some i, is of the required special form. Since

$$\{0, b/a\} = \{0, \infty\} + \{\infty, b_0\} + \left\{ \frac{b_0}{1}, \frac{b_1}{a_1} \right\} + \cdots + \left\{ \frac{b_{n-1}}{a_{n-1}}, \frac{b_n}{a_n} \right\},$$

this completes the proof. □

Inductive Proof of Proposition 3.11. As in the first proof it suffices to prove the proposition for any symbol $\{0, b/a\}$, where b/a is in lowest terms. We will induct on $a \in \mathbb{Z}_{\geq 0}$. If $a = 0$, then the symbol is $\{0, \infty\}$, which corresponds to the identity coset, so assume that $a > 0$. Find $a' \in \mathbb{Z}$ such that

$$ba' \equiv 1 \pmod{a};$$

then $b' = (ba' - 1)/a \in \mathbb{Z}$ so the matrix

$$\delta = \begin{pmatrix} b & b' \\ a & a' \end{pmatrix}$$

is an element of $\mathrm{SL}_2(\mathbb{Z})$. Thus $\delta = \gamma \cdot r_j$ for some right coset representative r_j and $\gamma \in \Gamma_0(N)$. Then

$$\{0, b/a\} - \{0, b'/a'\} = \{b'/a', b/a\} = \begin{pmatrix} b & b' \\ a & a' \end{pmatrix} \cdot \{0, \infty\} = r_j\{0, \infty\},$$

as elements of $\mathbb{M}_2(\Gamma_0(N))$. By induction, $\{0, b'/a'\}$ is a linear combination of symbols of the form $r_k\{0, \infty\}$, which completes the proof. □

Example 3.12. Let $N = 11$, and consider the modular symbol $\{0, 4/7\}$. We have

$$\frac{4}{7} = 0 + \frac{1}{1 + \frac{1}{1+\frac{1}{3}}},$$

so the partial convergents are

$$\frac{b_{-2}}{a_{-2}} = \frac{0}{1}, \quad \frac{b_{-1}}{a_{-1}} = \frac{1}{0}, \quad \frac{b_0}{a_0} = \frac{0}{1}, \quad \frac{b_1}{a_1} = \frac{1}{1}, \quad \frac{b_2}{a_2} = \frac{1}{2}, \quad \frac{b_3}{a_3} = \frac{4}{7}.$$

Thus, noting as in Example 3.6 that $\{0, 1\} = 0$, we have

$$\begin{aligned} \{0, 4/7\} &= \{0, \infty\} + \{\infty, 0\} + \{0, 1\} + \{1, 1/2\} + \{1/2, 4/7\} \\ &= \begin{pmatrix} 1 & -1 \\ 2 & -1 \end{pmatrix} \{0, \infty\} + \begin{pmatrix} 4 & 1 \\ 7 & 2 \end{pmatrix} \{0, \infty\} \\ &= \begin{pmatrix} 1 & 0 \\ 9 & 1 \end{pmatrix} \{0, \infty\} + \begin{pmatrix} 1 & 0 \\ 9 & 1 \end{pmatrix} \{0, \infty\} \\ &= 2 \cdot \left[\begin{pmatrix} 1 & 0 \\ 9 & 1 \end{pmatrix} \{0, \infty\} \right]. \end{aligned}$$

We compute the convergents of $4/7$ in SAGE as follows (note that 0 and ∞ are excluded):

```
sage: convergents(4/7)
[0, 1, 1/2, 4/7]
```

3.3.2. Manin Symbols. As above, fix coset representatives $r_0, \ldots, r_m$ for $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbb{Z})$. Consider formal symbols $[r_i]'$ for $i = 0, \ldots, m$. Let $[r_i]$ be the modular symbol $r_i\{0, \infty\} = \{r_i(0), r_i(\infty)\}$. We equip the symbols $[r_0]', \ldots, [r_m]'$ with a *right action of* $\mathrm{SL}_2(\mathbb{Z})$, which is given by $[r_i]'.g = [r_j]'$, where $\Gamma_0(N)r_j = \Gamma_0(N)r_i g$. We extend the notation by writing $[\gamma]' = [\Gamma_0(N)\gamma]' = [r_i]'$, where $\gamma \in \Gamma_0(N)r_i$. Then the right action of $\Gamma_0(N)$ is simply $[\gamma]'.g = [\gamma g]'$.

Theorem 1.2 implies that $\mathrm{SL}_2(\mathbb{Z})$ is generated by the two matrices $\sigma = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ and $\tau = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Note that $\sigma = S$ from Theorem 1.2 and $\tau = TS$, so $T = \tau\sigma \in \langle \sigma, \tau \rangle$.

The following theorem provides us with a finite presentation for the space $\mathbb{M}_2(\Gamma_0(N))$ of modular symbols.

Theorem 3.13 (Manin)**.** *Consider the quotient M of the free abelian group on Manin symbols $[r_0]', \ldots, [r_m]'$ by the subgroup generated by the elements (for all i):*

$$[r_i]' + [r_i]'\sigma \qquad \textit{and} \qquad [r_i]' + [r_i]'\tau + [r_i]'\tau^2,$$

and modulo any torsion. Then there is an isomorphism

$$\Psi : M \xrightarrow{\sim} \mathbb{M}_2(\Gamma_0(N))$$

given by $[r_i]' \mapsto [r_i] = r_i\{0, \infty\}$.

Proof. We will only prove that Ψ is surjective; the proof that Ψ is injective requires much more work and will be omitted from this book (see [**Man72**, §1.7] for a complete proof).

Proposition 3.11 implies that Ψ is surjective, assuming that Ψ is well defined. We next verify that Ψ is well defined, i.e., that the listed 2-term and 3-term relations hold in the image. To see that the first relation holds, note that

$$\begin{aligned}
[r_i] + [r_i]\sigma &= \{r_i(0), r_i(\infty)\} + \{r_i\sigma(0), r_i\sigma(\infty)\} \\
&= \{r_i(0), r_i(\infty)\} + \{r_i(\infty), r_i(0)\} \\
&= 0.
\end{aligned}$$

For the second relation we have

$$\begin{aligned}
[r_i] + [r_i]\tau + [r_i]\tau^2 &= \{r_i(0), r_i(\infty)\} + \{r_i\tau(0), r_i\tau(\infty)\} + \{r_i\tau^2(0), r_i\tau^2(\infty)\} \\
&= \{r_i(0), r_i(\infty)\} + \{r_i(\infty), r_i(1)\} + \{r_i(1), r_i(0)\} \\
&= 0.
\end{aligned}$$

□

Example 3.14. By default SAGE computes modular symbols spaces over $\mathbb{Q}$, i.e., $\mathbb{M}_2(\Gamma_0(N);\mathbb{Q}) \cong \mathbb{M}_2(\Gamma_0(N))\otimes\mathbb{Q}$. SAGE represents (weight 2) Manin symbols as pairs (c,d). Here c, d are integers that satisfy $0 \leq c, d < N$; they define a point $(c:d) \in \mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$, hence a right coset of $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbb{Z})$ (see Proposition 3.10).

Create $\mathbb{M}_2(\Gamma_0(N);\mathbb{Q})$ in SAGE by typing `ModularSymbols(N, 2)`. We then use the SAGE command `manin_generators` to enumerate a list of generators $[r_0], \ldots, [r_n]$ as in Theorem 3.13 for several spaces of modular symbols.

```
sage: M = ModularSymbols(2,2)
sage: M
Modular Symbols space of dimension 1 for Gamma_0(2)
of weight 2 with sign 0 over Rational Field
sage: M.manin_generators()
[(0,1), (1,0), (1,1)]

sage: M = ModularSymbols(3,2)
sage: M.manin_generators()
[(0,1), (1,0), (1,1), (1,2)]

sage: M = ModularSymbols(6,2)
sage: M.manin_generators()
[(0,1), (1,0), (1,1), (1,2), (1,3), (1,4), (1,5), (2,1),
 (2,3), (2,5), (3,1), (3,2)]
```

Given `x=(c,d)`, the command `x.lift_to_sl2z(N)` computes an element of $\mathrm{SL}_2(\mathbb{Z})$ whose lower two entries are congruent to (c,d) modulo N.

```
sage: M = ModularSymbols(2,2)
sage: [x.lift_to_sl2z(2) for x in M.manin_generators()]
[[1, 0, 0, 1], [0, -1, 1, 0], [0, -1, 1, 1]]
sage: M = ModularSymbols(6,2)
sage: x = M.manin_generators()[9]
sage: x
(2,5)
sage: x.lift_to_sl2z(6)
[1, 2, 2, 5]
```

The `manin_basis` command returns a list of indices into the Manin generator list such that the corresponding symbols form a basis for the quotient of the $\mathbb{Q}$-vector space spanned by Manin symbols modulo the 2-term and 3-term relations of Theorem 3.13.

```
sage: M = ModularSymbols(2,2)
sage: M.manin_basis()
[1]
sage: [M.manin_generators()[i] for i in M.manin_basis()]
[(1,0)]
sage: M = ModularSymbols(6,2)
sage: M.manin_basis()
[1, 10, 11]
sage: [M.manin_generators()[i] for i in M.manin_basis()]
[(1,0), (3,1), (3,2)]
```

Thus, e.g., every element of $\mathbb{M}_2(\Gamma_0(6))$ is a $\mathbb{Q}$-linear combination of the three symbols $[(1,0)]$, $[(3,1)]$, and $[(3,2)]$. We can write each of these as a modular symbol using the `modular_symbol_rep` function.

```
sage: M.basis()
((1,0), (3,1), (3,2))
sage: [x.modular_symbol_rep() for x in M.basis()]
[{Infinity,0}, {0,1/3}, {-1/2,-1/3}]
```

The `manin_gens_to_basis` function returns a matrix whose rows express each Manin symbol generator in terms of the subset of Manin symbols that forms a basis (as returned by `manin_basis`).

```
sage: M = ModularSymbols(2,2)
sage: M.manin_gens_to_basis()
[-1]
[ 1]
[ 0]
```

Since the basis is $(1,0)$, this means that in $\mathbb{M}_2(\Gamma_0(2);\mathbb{Q})$, we have $[(0,1)] = -[(1,0)]$ and $[(1,1)] = 0$. (Since no denominators are involved, we have in fact computed a presentation of $\mathbb{M}_2(\Gamma_0(2);\mathbb{Z})$.)

To convert a Manin symbol $x = (c,d)$ to an element of a modular symbols space M, use `M(x)`:

```
sage: M = ModularSymbols(2,2)
sage: x = (1,0); M(x)
(1,0)
```

Next consider $\mathbb{M}_2(\Gamma_0(6);\mathbb{Q})$:

```
sage: M = ModularSymbols(6,2)
sage: M.manin_gens_to_basis()
[-1  0  0]
[ 1  0  0]
[ 0  0  0]
[ 0 -1  1]
[ 0 -1  0]
[ 0 -1  1]
[ 0  0  0]
[ 0  1 -1]
[ 0  0 -1]
[ 0  1 -1]
[ 0  1  0]
[ 0  0  1]
```

Recall that our choice of basis for $\mathbb{M}_2(\Gamma_0(6);\mathbb{Q})$ is $[(1,0)], [(3,1)], [(3,2)]$. Thus, e.g., the first row of this matrix says that $[(0,1)] = -[(1,0)]$, and the fourth row asserts that $[(1,2)] = -[(3,1)] + [(3,2)]$.

```
sage: M = ModularSymbols(6,2)
sage: M((0,1))
-(1,0)
sage: M((1,2))
-(3,1) + (3,2)
```

3.4. Hecke Operators

3.4.1. Hecke Operators on Modular Symbols. When p is a prime not dividing N, define

$$T_p(\{\alpha,\beta\}) = \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \{\alpha,\beta\} + \sum_{r \bmod p} \begin{pmatrix} 1 & r \\ 0 & p \end{pmatrix} \{\alpha,\beta\}.$$

The Hecke operators are compatible with the integration pairing $\langle\, ,\, \rangle$ of Section 3.1, in the sense that $\langle fT_p, x\rangle = \langle f, T_p x\rangle$. When $p \mid N$, the definition is the same, except that the matrix $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ is not included in the sum (see Theorem 8.23). There is a similar definition of T_n for n composite (see Section 8.3.1).

Example 3.15. For example, when $N = 11$, we have

$$\begin{aligned} T_2\{0, 1/5\} &= \{0, 2/5\} + \{0, 1/10\} + \{1/2, 3/5\} \\ &= -2\{0, 1/5\}. \end{aligned}$$

See Figure 3.4.1.

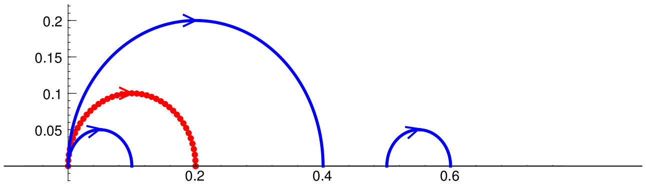

Figure 3.4.1. Image of $\{0, 1/5\}$ under T_2

3.4.2. Hecke Operators on Manin Symbols. In [**Mer94**], L. Merel gives a description of the action of T_p directly on Manin symbols $[r_i]$ (see Section 8.3.2 for details). For example, when $p = 2$ and N is odd, we have

$$T_2([r_i]) = [r_i]\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} + [r_i]\begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} + [r_i]\begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix} + [r_i]\begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix}. \tag{3.4.1}$$

For any prime, let C_p be the set of matrices constructed using the following algorithm (see [**Cre97a**, §2.4]):

Algorithm 3.16 (Cremona's Heilbronn Matrices)**.** *Given a prime p, this algorithm outputs a list of 2×2 matrices of determinant p that can be used to compute the Hecke operator T_p.*

```
(1) Output $\begin{pmatrix} 1 & 0 \\ 0 & p \end{pmatrix}$.
(2) For $r = \left\lceil -\frac{p}{2} \right\rceil, \ldots, \left\lfloor \frac{p}{2} \right\rfloor$:
    (a) Let $x_1 = p$, $x_2 = -r$, $y_1 = 0$, $y_2 = 1$, $a = -p$, $b = r$.
    (b) Output $\begin{pmatrix} x_1 & x_2 \\ y_1 & y_2 \end{pmatrix}$.
    (c) As long as $b \neq 0$, do the following:
        (i) Let $q$ be the integer closest to $a/b$ (if $a/b$ is a half integer,
            round away from 0).
        (ii) Let $c = a - bq$, $a = -b$, $b = c$.
```

(iii) Set $x_3 = qx_2 - x_1$, $x_1 = x_2$, $x_2 = x_3$, and
$y_3 = qy_2 - y_1$, $y_1 = y_2$, $y_2 = y_3$.

(iv) Output $\begin{pmatrix} x_1 & x_2 \\ y_1 & y_2 \end{pmatrix}$.

Proposition 3.17 (Cremona, Merel). *Let C_p be as above. Then for $p \nmid N$ and $[x] \in \mathbb{M}_2(\Gamma_0(N))$ a Manin symbol, we have*

$$T_p([x]) = \sum_{g \in C_p} [xg].$$

Proof. See Proposition 2.4.1 of [**Cre97a**]. □

There are other lists of matrices, due to Merel, that work even when $p \mid N$ (see Section 8.3.2).

The command `HeilbronnCremonaList(p)`, for p prime, outputs the list of matrices from Algorithm 3.16.

```
sage: HeilbronnCremonaList(2)
[[1, 0, 0, 2], [2, 0, 0, 1], [2, 1, 0, 1], [1, 0, 1, 2]]
sage: HeilbronnCremonaList(3)
[[1, 0, 0, 3], [3, 1, 0, 1], [1, 0, 1, 3], [3, 0, 0, 1],
 [3, -1, 0, 1], [-1, 0, 1, -3]]
sage: HeilbronnCremonaList(5)
[[1, 0, 0, 5], [5, 2, 0, 1], [2, 1, 1, 3], [1, 0, 3, 5],
 [5, 1, 0, 1], [1, 0, 1, 5], [5, 0, 0, 1], [5, -1, 0, 1],
 [-1, 0, 1, -5], [5, -2, 0, 1], [-2, 1, 1, -3],
 [1, 0, -3, 5]]
sage: len(HeilbronnCremonaList(37))
128
sage: len(HeilbronnCremonaList(389))
1892
sage: len(HeilbronnCremonaList(2003))
11662
```

Example 3.18. We compute the matrix of T_2 on $\mathbb{M}_2(\Gamma_0(2))$:

```
sage: M = ModularSymbols(2,2)
sage: M.T(2).matrix()
[1]
```

Example 3.19. We compute some Hecke operators on $\mathbb{M}_2(\Gamma_0(6))$:

```
sage: M = ModularSymbols(6, 2)
sage: M.T(2).matrix()
[ 2  1 -1]
[-1  0  1]
[-1 -1  2]
sage: M.T(3).matrix()
[3 2 0]
[0 1 0]
[2 2 1]
sage: M.T(3).fcp()  # factored characteristic polynomial
(x - 3) * (x - 1)^2
```

For $p \geq 5$ we have $T_p = p + 1$, since $M_2(\Gamma_0(6))$ is spanned by generalized Eisenstein series (see Chapter 5).

Example 3.20. We compute the Hecke operators on $\mathbb{M}_2(\Gamma_0(39))$:

```
sage: M = ModularSymbols(39, 2)
sage: T2 = M.T(2)
sage: T2.matrix()
[ 3  0 -1  0  0  1  1 -1  0]
[ 0  0  2  0 -1  1  0  1 -1]
[ 0  1  0 -1  1  1  0  1 -1]
[ 0  0  1  0  0  1  0  1 -1]
[ 0 -1  2  0  0  1  0  1 -1]
[ 0  0  1  1  0  1  1 -1  0]
[ 0  0  0 -1  0  1  1  2  0]
[ 0  0  0  1  0  0  2  0  1]
[ 0  0 -1  0  0  0  1  0  2]
sage: T2.fcp()     # factored characteristic polynomial
(x - 3)^3 * (x - 1)^2 * (x^2 + 2*x - 1)^2
```

The Hecke operators commute, so their eigenspace structures are related.

```
sage: T2 = M.T(2).matrix()
sage: T5 = M.T(5).matrix()
sage: T2*T5 - T5*T2 == 0
True
sage: T5.charpoly().factor()
(x^2 - 8)^2 * (x - 6)^3 * (x - 2)^2
```

The decomposition of T_2 is a list of the kernels of $(f^e)(T_2)$, where f runs through the irreducible factors of the characteristic polynomial of T_2 and f^e exactly divides this characteristic polynomial. Using SAGE, we find them:

```
sage: M = ModularSymbols(39, 2)
sage: M.T(2).decomposition()
[
Modular Symbols subspace of dimension 3 of Modular
Symbols space of dimension 9 for Gamma_0(39) of weight
2 with sign 0 over Rational Field,
Modular Symbols subspace of dimension 2 of Modular
Symbols space of dimension 9 for Gamma_0(39) of weight
2 with sign 0 over Rational Field,
Modular Symbols subspace of dimension 4 of Modular
Symbols space of dimension 9 for Gamma_0(39) of weight
2 with sign 0 over Rational Field
]
```

3.5. Computing the Boundary Map

In Section 3.2 we defined a map $\delta : \mathbb{M}_2(\Gamma_0(N)) \to \mathbb{B}_2(\Gamma_0(N))$. The kernel of this map is the space $\mathbb{S}_2(\Gamma_0(N))$ of cuspidal modular symbols. This kernel will be important in computing cusp forms in Section 3.7 below.

To compute the boundary map on $[\gamma]$, note that $[\gamma] = \{\gamma(0), \gamma(\infty)\}$, so if $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then

$$\delta([\gamma]) = \{\gamma(\infty)\} - \{\gamma(0)\} = \{a/c\} - \{b/d\}.$$

Computing this boundary map would appear to first require an algorithm to compute the set $C(\Gamma_0(N)) = \Gamma_0(N)\backslash\mathbb{P}^1(\mathbb{Q})$ of cusps for $\Gamma_0(N)$. In fact, there is a trick that computes the set of cusps in the course of running the algorithm. First, give an algorithm for deciding whether or not two elements of $\mathbb{P}^1(\mathbb{Q})$ are equivalent modulo the action of $\Gamma_0(N)$. Then simply construct $C(\Gamma_0(N))$ in the course of computing the boundary map, i.e., keep a list of cusps found so far, and whenever a new cusp class is discovered, add it to the list. The following proposition, which is proved in [**Cre97a**, Prop. 2.2.3], explains how to determine whether two cusps are equivalent.

Proposition 3.21 (Cremona)**.** *Let (c_i, d_i), $i = 1, 2$, be pairs of integers with $\gcd(c_i, d_i) = 1$ and possibly $d_i = 0$. There is $g \in \Gamma_0(N)$ such that $g(c_1/d_1) = c_2/d_2$ in $\mathbb{P}^1(\mathbb{Q})$ if and only if*

$$s_1 d_2 \equiv s_2 d_1 \pmod{\gcd(d_1 d_2, N)}$$

where s_j satisfies $c_j s_j \equiv 1 \pmod{d_j}$.

In SAGE the command `boundary_map()` computes the boundary map from $\mathbb{M}_2(\Gamma_0(N))$ to $\mathbb{B}_2(\Gamma_0(N))$, and the `cuspidal_submodule()` command computes its kernel. For example, for level 2 the boundary map is given by the matrix $[1\ \ -1]$, and its kernel is the 0 space:

```
sage: M = ModularSymbols(2, 2)
sage: M.boundary_map()
Hecke module morphism boundary map defined by the matrix
[ 1 -1]
Domain: Modular Symbols space of dimension 1 for
Gamma_0(2) of weight ...
Codomain: Space of Boundary Modular Symbols for
Congruence Subgroup Gamma0(2) ...
sage: M.cuspidal_submodule()
Modular Symbols subspace of dimension 0 of Modular
Symbols space of dimension 1 for Gamma_0(2) of weight
2 with sign 0 over Rational Field
```

The smallest level for which the boundary map has nontrivial kernel, i.e., for which $\mathbb{S}_2(\Gamma_0(N)) \neq 0$, is $N = 11$.

```
sage: M = ModularSymbols(11, 2)
sage: M.boundary_map().matrix()
[ 1 -1]
[ 0  0]
[ 0  0]
sage: M.cuspidal_submodule()
Modular Symbols subspace of dimension 2 of Modular
Symbols space of dimension 3 for Gamma_0(11) of weight
2 with sign 0 over Rational Field
sage: S = M.cuspidal_submodule(); S
Modular Symbols subspace of dimension 2 of Modular
Symbols space of dimension 3 for Gamma_0(11) of weight
2 with sign 0 over Rational Field
sage: S.basis()
((1,8), (1,9))
```

The following illustrates that the Hecke operators preserve $\mathbb{S}_2(\Gamma_0(N))$:

```
sage: S.T(2).matrix()
[-2  0]
[ 0 -2]
sage: S.T(3).matrix()
[-1  0]
[ 0 -1]
sage: S.T(5).matrix()
[1 0]
[0 1]
```

A nontrivial fact is that for p prime the eigenvalue of each of these matrices is $p+1-\#E(\mathbb{F}_p)$, where E is the elliptic curve $X_0(11)$ defined by the (affine) equation $y^2+y=x^3-x^2-10x-20$. For example, we have

```
sage: E = EllipticCurve([0,-1,1,-10,-20])
sage: 2 + 1 - E.Np(2)
-2
sage: 3 + 1 - E.Np(3)
-1
sage: 5 + 1 - E.Np(5)
1
sage: 7 + 1 - E.Np(7)
-2
```

The same numbers appear as the eigenvalues of Hecke operators:

```
sage: [S.T(p).matrix()[0,0] for p in [2,3,5,7]]
[-2, -1, 1, -2]
```

In fact, something similar happens for every elliptic curve over $\mathbb{Q}$. The book [**DS05**] (especially Chapter 8) is about this striking numerical relationship between the number of points on elliptic curves modulo p and coefficients of modular forms.

3.6. Computing a Basis for $S_2(\Gamma_0(N))$

This section is about a method for using modular symbols to compute a basis for $S_2(\Gamma_0(N))$. It is not the most efficient for certain applications, but it is easy to explain and understand. See Section 3.7 for a method that takes advantage of additional structure of $S_2(\Gamma_0(N))$.

Let $\mathbb{M}_2(\Gamma_0(N);\mathbb{Q})$ and $\mathbb{S}_2(\Gamma_0(N);\mathbb{Q})$ be the spaces of modular symbols and cuspidal modular symbols over $\mathbb{Q}$. Before we begin, we describe a simple but crucial fact about the relation between cusp forms and Hecke operators.

If $f = \sum b_n q^n \in \mathbb{C}[[q]]$ is a power series, let $a_n(f) = b_n$ be the n coefficient of f. Notice that a_n is a $\mathbb{C}$-linear map $\mathbb{C}[[q]] \to \mathbb{C}$.

As explained in [**DS05**, Prop. 5.3.1] and [**Lan95**, §VII.3] (recall also Proposition 2.31), the Hecke operators T_n act on elements of $M_2(\Gamma_0(N))$ as follows (where $k = 2$ below):

$$T_n\left(\sum_{m=0}^{\infty} a_m q^m\right) = \sum_{m=0}^{\infty}\left(\sum_{1\leq d\,|\,\gcd(n,m)} \varepsilon(d)\cdot d^{k-1}\cdot a_{mn/d^2}\right) q^m, \tag{3.6.1}$$

where $\varepsilon(d) = 1$ if $\gcd(d, N) = 1$ and $\varepsilon(d) = 0$ if $\gcd(d, N) \neq 1$. (Note: More generally, if $f \in M_k(\Gamma_1(N))$ is a modular form with Dirichlet character ε, then the above formula holds; above we are considering this formula in the special case when ε is the trivial character and $k = 2$.)

Lemma 3.22. *Suppose $f \in \mathbb{C}[[q]]$ and n is a positive integer. Let T_n be the operator on q-expansions (formal power series) defined by* (3.6.1). *Then*

$$a_1(T_n(f)) = a_n(f).$$

Proof. The coefficient of q in (3.6.1) is $\varepsilon(1)\cdot 1\cdot a_{1\cdot n/1^2} = a_n$. □

The *Hecke algebra* $\mathbb{T}$ is the ring generated by all Hecke operators T_n acting on $M_k(\Gamma_1(N))$. Let $\mathbb{T}'$ denote the image of the Hecke algebra in $\mathrm{End}(S_2(\Gamma_0(N)))$, and let $\mathbb{T}'_{\mathbb{C}} = \mathbb{T}'\otimes_{\mathbb{Z}}\mathbb{C}$ be the $\mathbb{C}$-span of the Hecke operators. Let $\tilde{\mathbb{T}}_{\mathbb{C}}$ denote the subring of $\mathrm{End}(\mathbb{C}[[q]])$ generated over $\mathbb{C}$ by all Hecke operators acting on formal power series via definition (3.6.1).

Proposition 3.23. *There is a bilinear pairing of complex vector spaces*

$$\mathbb{C}[[q]] \times \tilde{\mathbb{T}}_{\mathbb{C}} \to \mathbb{C}$$

given by

$$\langle f, t\rangle = a_1(t(f)).$$

If f is such that $\langle f, t\rangle = 0$ for all $t \in \tilde{\mathbb{T}}_{\mathbb{C}}$, then $f = 0$.

Proof. The pairing is bilinear since both t and a_1 are linear.

Suppose $f \in \mathbb{C}[[q]]$ is such that $\langle f, t\rangle = 0$ for all $t \in \tilde{\mathbb{T}}_{\mathbb{C}}$. Then $\langle f, T_n\rangle = 0$ for each positive integer n. But by Lemma 3.22 we have

$$a_n(f) = a_1(T_n(f)) = 0$$

for all n; thus $f = 0$. □

Proposition 3.24. *There is a perfect bilinear pairing of complex vector spaces*

$$S_2(\Gamma_0(N)) \times \mathbb{T}'_{\mathbb{C}} \to \mathbb{C}$$

given by

$$\langle f, t\rangle = a_1(t(f)).$$

Proof. The pairing has 0 kernel on the left by Proposition 3.23. Suppose that $t \in \mathbb{T}'_{\mathbb{C}}$ is such that $\langle f, t\rangle = 0$ for all $f \in S_2(\Gamma_0(N))$. Then $a_1(t(f)) = 0$ for all f. For any n, the image $T_n(f)$ is also a cusp form, so $a_1(t(T_n(f))) = 0$ for all n and f. Finally the fact that $\mathbb{T}'$ is commutative and Lemma 3.22 together imply that for all n and f,

$$0 = a_1(t(T_n(f))) = a_1(T_n(t(f))) = a_n(t(f)),$$

so $t(f) = 0$ for all f. Thus t is the 0 operator.

Since $S_2(\Gamma_0(N))$ has finite dimension and the kernel on each side of the pairing is 0, it follows that the pairing is perfect, i.e., defines an *isomorphism*

$$\mathbb{T}'_{\mathbb{C}} \cong \mathrm{Hom}_{\mathbb{C}}(S_2(\Gamma_0(N)); \mathbb{C}).$$

□

By Proposition 3.24 there is an isomorphism of vector spaces

$$\Psi : S_2(\Gamma_0(N)) \xrightarrow{\cong} \mathrm{Hom}(\mathbb{T}'_{\mathbb{C}}, \mathbb{C}) \tag{3.6.2}$$

that sends $f \in S_2(\Gamma_0(N))$ to the homomorphism

$$t \mapsto a_1(t(f)).$$

For any $\mathbb{C}$-linear map $\varphi : \mathbb{T}'_{\mathbb{C}} \to \mathbb{C}$, let

$$f_\varphi = \sum_{n=1}^{\infty} \varphi(T_n) q^n \in \mathbb{C}[[q]].$$

Lemma 3.25. *The series f_φ is the q-expansion of $\Psi^{-1}(\varphi) \in S_2(\Gamma_0(N))$.*

Proof. Note that it is not even *a priori* obvious that f_φ is the q-expansion of a modular form. Let $g = \Psi^{-1}(\varphi)$, which is by definition the unique element of $S_2(\Gamma_0(N))$ such that $\langle g, T_n\rangle = \varphi(T_n)$ for all n. By Lemma 3.22, we have

$$\langle f_\varphi, T_n\rangle = a_1(T_n(f_\varphi)) = a_n(f_\varphi) = \varphi(T_n),$$

so $\langle f_\varphi - g, T_n\rangle = 0$ for all n. Proposition 3.23 implies that $f_\varphi - g = 0$, so $f_\varphi = g = \Psi^{-1}(\varphi)$, as claimed. □

Conclusion: The cusp forms f_φ, as φ varies through a basis of $\mathrm{Hom}(\mathbb{T}'_{\mathbb{C}}, \mathbb{C})$, form a basis for $S_2(\Gamma_0(N))$. In particular, we can compute $S_2(\Gamma_0(N))$ by computing $\mathrm{Hom}(\mathbb{T}'_{\mathbb{C}}, \mathbb{C})$, where we compute $\mathbb{T}'$ in any way we want, e.g., using a space that contains an isomorphic copy of $S_2(\Gamma_0(N))$.

Algorithm 3.26 (Basis of Cusp Forms)**.** *Given positive integers N and B, this algorithm computes a basis for $S_2(\Gamma_0(N))$ to precision $O(q^B)$.*

(1) Compute $\mathbb{M}_2(\Gamma_0(N);\mathbb{Q})$ via the presentation of Section 3.3.2.
(2) Compute the subspace $\mathbb{S}_2(\Gamma_0(N);\mathbb{Q})$ of cuspidal modular symbols as in Section 3.5.
(3) Let $d = \frac{1}{2}\cdot\dim \mathbb{S}_2(\Gamma_0(N);\mathbb{Q})$. By Proposition 3.8, d is the dimension of $S_2(\Gamma_0(N))$.
(4) Let $[T_n]$ denote the matrix of T_n acting on a basis of $\mathbb{S}_2(\Gamma_0(N);\mathbb{Q})$. For a matrix A, let $a_{ij}(A)$ denote the ijth entry of A. For various integers i, j with $0 \leq i, j \leq d-1$, compute formal q-expansions

$$f_{ij}(q) = \sum_{n=1}^{B-1} a_{ij}([T_n])q^n + O(q^B) \in \mathbb{Q}[[q]]$$

until we find enough to span a space of dimension d (or exhaust all of them). These f_{ij} are a basis for $S_2(\Gamma_0(N))$ to precision $O(q^B)$.

3.6.1. Examples.

We use SAGE to demonstrate Algorithm 3.26.

Example 3.27. The smallest N with $S_2(\Gamma_0(N)) \neq 0$ is $N = 11$.

```
sage: M = ModularSymbols(11); M.basis()
((1,0), (1,8), (1,9))
sage: S = M.cuspidal_submodule(); S
Modular Symbols subspace of dimension 2 of Modular
Symbols space of dimension 3 for Gamma_0(11) of weight
2 with sign 0 over Rational Field
```

We compute a few Hecke operators, and then read off a nonzero cusp form, which forms a basis for $S_2(\Gamma_0(11))$:

```
sage: S.T(2).matrix()
[-2  0]
[ 0 -2]
sage: S.T(3).matrix()
[-1  0]
[ 0 -1]
```

Thus

$$f_{0,0} = q - 2q^2 - q^3 + \cdots \in S_2(\Gamma_0(11))$$

forms a basis for $S_2(\Gamma_0(11))$.

Example 3.28. We compute a basis for $S_2(\Gamma_0(33))$ to precision $O(q^6)$.

```
sage: M = ModularSymbols(33)
sage: S = M.cuspidal_submodule(); S
Modular Symbols subspace of dimension 6 of Modular
Symbols space of dimension 9 for Gamma_0(33) of weight
2 with sign 0 over Rational Field
```

Thus $\dim S_2(\Gamma_0(33)) = 3$.

```
sage: R.<q> = PowerSeriesRing(QQ)
sage: v = [S.T(n).matrix()[0,0] for n in range(1,6)]
sage: f00 = sum(v[n-1]*q^n for n in range(1,6)) + O(q^6)
sage: f00
q - q^2 - q^3 + q^4 + O(q^6)
```

This gives us one basis element of $S_2(\Gamma_0(33))$. It remains to find two others. We find

```
sage: v = [S.T(n).matrix()[0,1] for n in range(1,6)]
sage: f01 = sum(v[n-1]*q^n for n in range(1,6)) + O(q^6)
sage: f01
-2*q^3 + O(q^6)
```

and

```
sage: v = [S.T(n).matrix()[1,0] for n in range(1,6)]
sage: f10 = sum(v[n-1]*q^n for n in range(1,6)) + O(q^6)
sage: f10
q^3 + O(q^6)
```

This third one is (to our precision) a scalar multiple of the second, so we look further.

```
sage: v = [S.T(n).matrix()[1,1] for n in range(1,6)]
sage: f11 = sum(v[n-1]*q^n for n in range(1,6)) + O(q^6)
sage: f11
q - 2*q^2 + 2*q^4 + q^5 + O(q^6)
```

This latter form is clearly not in the span of the first two. Thus we have the following basis for $S_2(\Gamma_0(33))$ (to precision $O(q^6)$):

$$\begin{aligned} f_{00} &= q - q^2 - q^3 + q^4 + \cdots, \\ f_{11} &= q - 2q^2 + 2q^4 + q^5 + \cdots, \\ f_{10} &= q^3 + \cdots. \end{aligned}$$

Example 3.29. Next consider $N = 23$, where we have

$$d = \dim S_2(\Gamma_0(23)) = 2.$$

The command q_expansion_cuspforms computes matrices T_n and returns a function f such that $f(i,j)$ is the q-expansion of $f_{i,j}$ to some precision. (For efficiency reasons, $f(i,j)$ in SAGE actually computes matrices of T_n acting on a basis for the linear dual of $\mathbb{S}_2(\Gamma_0(N))$.)

```
sage: M = ModularSymbols(23)
sage: S = M.cuspidal_submodule()
sage: S
Modular Symbols subspace of dimension 4 of Modular
Symbols space of dimension 5 for Gamma_0(23) of weight
2 with sign 0 over Rational Field
sage: f = S.q_expansion_cuspforms(6)
sage: f(0,0)
q - 2/3*q^2 + 1/3*q^3 - 1/3*q^4 - 4/3*q^5 + O(q^6)
sage: f(0,1)
O(q^6)
sage: f(1,0)
-1/3*q^2 + 2/3*q^3 + 1/3*q^4 - 2/3*q^5 + O(q^6)
```

Thus a basis for $S_2(\Gamma_0(23))$ is

$$f_{0,0} = q - \frac{2}{3}q^2 + \frac{1}{3}q^3 - \frac{1}{3}q^4 - \frac{4}{3}q^5 + \cdots,$$
$$f_{1,0} = -\frac{1}{3}q^2 + \frac{2}{3}q^3 + \frac{1}{3}q^4 - \frac{2}{3}q^5 + \cdots.$$

Or, in echelon form,

$$q - q^3 - q^4 + \cdots$$
$$q^2 - 2q^3 - q^4 + 2q^5 + \cdots$$

which we computed using

```
sage: S.q_expansion_basis(6)
[
q - q^3 - q^4 + O(q^6),
q^2 - 2*q^3 - q^4 + 2*q^5 + O(q^6)
]
```

3.7. Computing $S_2(\Gamma_0(N))$ Using Eigenvectors

In this section we describe how to use modular symbols to construct a basis of $S_2(\Gamma_0(N))$ consisting of modular forms that are eigenvectors for every element of the ring $\mathbb{T}^{(N)}$ generated by the Hecke operator T_p, with $p \nmid N$. Such eigenvectors are called *eigenforms*.

Suppose M is a positive integer that divides N. As explained in [**Lan95**, VIII.1–2], for each divisor d of N/M there is a natural *degeneracy map* $\alpha_{M,d}$: $S_2(\Gamma_0(M)) \to S_2(\Gamma_0(N))$ given by $\alpha_{M,d}(f(q)) = f(q^d)$. The *new subspace* of $S_2(\Gamma_0(N))$, denoted $S_2(\Gamma_0(N))_{\text{new}}$, is the complementary $\mathbb{T}$-submodule of the $\mathbb{T}$-module generated by the images of all maps $\alpha_{M,d}$, with M and d as above. It is a nontrivial fact that this complement is well defined; one possible proof uses the Petersson inner product (see [**Lan95**, §VII.5]).

The theory of Atkin and Lehner [**AL70**] (see Theorem 9.4 below) asserts that, as a $\mathbb{T}^{(N)}$-module, $S_2(\Gamma_0(N))$ decomposes as follows:

$$S_2(\Gamma_0(N)) \quad = \bigoplus_{M|N,\ d|N/M} \beta_{M,d}(S_2(\Gamma_0(M))_{\text{new}}).$$

To compute $S_2(\Gamma_0(N))$ it suffices to compute $S_2(\Gamma_0(M))_{\text{new}}$ for each $M \mid N$.

We now turn to the problem of computing $S_2(\Gamma_0(N))_{\text{new}}$. Atkin and Lehner [**AL70**] proved that $S_2(\Gamma_0(N))_{\text{new}}$ is spanned by eigenforms for all T_p with $p \nmid N$ and that the common eigenspaces of all the T_p with $p \nmid N$ each have dimension 1. Moreover, if $f \in S_2(\Gamma_0(N))_{\text{new}}$ is an eigenform then the coefficient of q in the q-expansion of f is nonzero, so it is possible to normalize f so the coefficient of q is 1 (such a *normalized* eigenform in the new subspace is called a *newform*). With f so normalized, if $T_p(f) = a_p f$, then the pth Fourier coefficient of f is a_p. If $f = \sum_{n=1}^{\infty} a_n q^n$ is a normalized eigenvector for all T_p, then the a_n, with n composite, are determined by the a_p, with p prime, by the following formulas: $a_{nm} = a_n a_m$ when n and m are relatively prime and $a_{p^r} = a_{p^{r-1}} a_p - p a_{p^{r-2}}$ for $p \nmid N$ prime. When $p \mid N$, $a_{p^r} = a_p^r$. We conclude that in order to compute $S_2(\Gamma_0(N))_{\text{new}}$, it suffices to compute all systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$ of the prime-indexed Hecke operators $T_2, T_3, T_5, \ldots$ acting on $S_2(\Gamma_0(N))_{\text{new}}$. Given a system of eigenvalues, the corresponding eigenform is $f = \sum_{n=1}^{\infty} a_n q^n$, where the a_n, for n composite, are determined by the recurrence given above.

In light of the pairing $\langle\ ,\ \rangle$ introduced in Section 3.1, computing the above systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$ amounts to computing the systems of eigenvalues of the Hecke operators T_p on the subspace V of $\mathbb{S}_2(\Gamma_0(N))$ that corresponds to the new subspace of $S_2(\Gamma_0(N))$. For each proper divisor M of N and each divisor d of N/M, let $\phi_{M,d} : \mathbb{S}_2(\Gamma_0(N)) \to \mathbb{S}_2(\Gamma_0(M))$ be the map sending x to $\left(\begin{smallmatrix} d & 0 \\ 0 & 1 \end{smallmatrix}\right) x$. Then V is the intersection of the kernels of all maps $\phi_{M,d}$.

Computing the systems of eigenvalues of a collection of commuting diagonalizable endomorphisms is a problem in linear algebra (see Chapter 7).

Example 3.30. All forms in $S_2(\Gamma_0(39))$ are new. Up to Galois conjugacy, the eigenvalues of the Hecke operators T_2, T_3, T_5, and T_7 on $\mathbb{S}_2(\Gamma_0(39))$ are $\{1, -1, 2, -4\}$ and $\{a, 1, -2a-2, 2a+2\}$, where $a^2+2a-1=0$. Each of these eigenvalues occur in $\mathbb{S}_2(\Gamma_0(39))$ with multiplicity two; for example, the characteristic polynomial of T_2 on $\mathbb{S}_2(\Gamma_0(39))$ is $(x-1)^2 \cdot (x^2+2x-1)^2$. Thus $S_2(\Gamma_0(39))$ is spanned by

$$\begin{aligned}
f_1 &= q + q^2 - q^3 - q^4 + 2q^5 - q^6 - 4q^7 + \cdots,\\
f_2 &= q + aq^2 + q^3 + (-2a-1)q^4 + (-2a-2)q^5 + aq^6 + (2a+2)q^7 + \cdots,\\
f_3 &= q + \sigma(a)q^2 + q^3 + (-2\sigma(a)-1)q^4 + (-2\sigma(a)-2)q^5 + \sigma(a)q^6 + \cdots,
\end{aligned}$$

where $\sigma(a)$ is the other $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugate of a.

3.7.1. Summary. To compute the q-expansion of a basis for $S_2(\Gamma_0(N))$, we use the degeneracy maps so that we only have to solve the problem for $S_2(\Gamma_0(M))_{\mathrm{new}}$, for all integers $M \mid N$. Using modular symbols, we compute all systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$, and then write down the corresponding eigenforms $\sum a_n q^n$.

3.8. Exercises

3.1 Suppose that $\lambda, \lambda' \in \mathfrak{h}$ are in the same orbit for the action of $\Gamma_0(N)$, i.e., that there exists $g \in \Gamma_0(N)$ such that $g(\lambda) = \lambda'$. Let $\Lambda = \mathbb{Z} + \mathbb{Z}\lambda$ and $\Lambda' = \mathbb{Z} + \mathbb{Z}\lambda'$. Prove that the pairs $(\mathbb{C}/\Lambda, (\frac{1}{N}\mathbb{Z} + \Lambda)/\Lambda)$ and $(\mathbb{C}/\Lambda', (\frac{1}{N}\mathbb{Z} + \Lambda')/\Lambda')$ are isomorphic. (By an isomorphism $(E, C) \to (F, D)$ of pairs, we mean an isomorphism $\phi : E \to F$ of elliptic curves that sends C to D. You may use the fact that an isomorphism of elliptic curves over $\mathbb{C}$ is a $\mathbb{C}$-linear map $\mathbb{C} \to \mathbb{C}$ that sends the lattice corresponding to one curve onto the lattice corresponding to the other.)

3.2 Let n, m be integers and N a positive integer. Prove that the modular symbol $\{n, m\}$ is 0 as an element of $\mathbb{M}_2(\Gamma_0(N))$. [Hint: See Example 3.6.]

3.3 Let p be a prime.
(a) List representative elements of $\mathbb{P}^1(\mathbb{Z}/p\mathbb{Z})$.
(b) What is the cardinality of $\mathbb{P}^1(\mathbb{Z}/p\mathbb{Z})$ as a function of p?
(c) Prove that there is a bijection between the right cosets of $\Gamma_0(p)$ in $\mathrm{SL}_2(\mathbb{Z})$ and the elements of $\mathbb{P}^1(\mathbb{Z}/p\mathbb{Z})$ that sends $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ to $(c : d)$. (As mentioned in this chapter, the analogous statement is also true when the level is composite; see [**Cre97a**, §2.2] for complete details.)

3.4 Use the inductive proof of Proposition 3.11 to write $\{0, 4/7\}$ in terms of Manin symbols for $\Gamma_0(7)$.

3.5 Show that the Hecke operator T_2 acts as multiplication by 3 on the space $\mathbb{M}_2(\Gamma_0(3))$ as follows:

(a) Write down right coset representatives for $\Gamma_0(3)$ in $\mathrm{SL}_2(\mathbb{Z})$.

(b) List all eight relations coming from Theorem 3.13.

(c) Find a single Manin symbols $[r_i]$ so that the three other Manin symbols are a nonzero multiple of $[r_i]$ modulo the relations found in the previous step.

(d) Use formula (3.4.1) to compute $T_2([r_i])$. You will obtain a sum of four symbols. Using the relations above, write this sum as a multiple of $[r_i]$. (The multiple must be 3 or you made a mistake.)

Chapter 4

Dirichlet Characters

In this chapter we develop a theory for computing with Dirichlet characters, which are extremely important to computations with modular forms for (at least) two reasons:

(1) To compute the Eisenstein subspace $E_k(\Gamma_1(N))$ of $M_k(\Gamma_1(N))$, we write down Eisenstein series attached to pairs of Dirichlet characters (the space $E_k(\Gamma_1(N))$ will be defined in Chapter 5).

(2) To compute $S_k(\Gamma_1(N))$, we instead compute a decomposition

$$M_k(\Gamma_1(N)) = \bigoplus M_k(\Gamma_1(N), \varepsilon)$$

and then compute each factor (see Section 9.1). Here the sum is over all Dirichlet characters ε of modulus N.

Dirichlet characters appear frequently in many other areas of number theory. For example, by the Kronecker-Weber theorem, Dirichlet characters correspond to the 1-dimensional representations of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$.

After defining Dirichlet characters in Section 4.1, in Section 4.2 we describe a good way to represent Dirichlet characters using a computer. Section 4.3 is about how to evaluate Dirichlet characters and leads naturally to a discussion of the baby-step giant-step algorithm for solving the discrete log problem and methods for efficiently computing the Kronecker symbol. In Section 4.4 we explain how to factor Dirichlet characters into their prime power constituents and apply this to the computations of conductors. We describe how to carry out a number of standard operations with Dirichlet characters in Section 4.6 and discuss alternative ways to represent them in Section 4.7. Finally, in Section 4.8 we give a very short tutorial about how to compute with Dirichlet characters using SAGE.

4.1. The Definition

Fix an integral domain R and a root ζ of unity in R.

Definition 4.1 (Dirichlet Character)**.** A *Dirichlet character* of modulus N over R is a map $\varepsilon : \mathbb{Z} \to R$ such that there is a homomorphism $f : (\mathbb{Z}/N\mathbb{Z})^* \to \langle\zeta\rangle$ for which

$$\varepsilon(a) = \begin{cases} 0 & \text{if } \gcd(a, N) > 1, \\ f\,(a \bmod N) & \text{if } \gcd(a, N) = 1. \end{cases}$$

We denote the group of such Dirichlet characters by $D(N, R)$. Note that elements of $D(N, R)$ are in bijection with homomorphisms $(\mathbb{Z}/N\mathbb{Z})^* \to \langle\zeta\rangle$.

A familiar Dirichlet character is the Legendre symbol $\left(\frac{a}{p}\right)$, with p an odd prime, that appears in quadratic reciprocity theory. It is a Dirichlet character of modulus p that takes the value 1 on integers that are congruent to a nonzero square modulo p, the value -1 on integers that are congruent to a nonzero nonsquare modulo p, and 0 on integers divisible by p.

4.2. Representing Dirichlet Characters

Lemma 4.2. *The groups $(\mathbb{Z}/N\mathbb{Z})^*$ and $D(N, \mathbb{C})$ are isomorphic.*

Proof. We prove the more general fact that for any finite abelian group G, we have that $G \approx \mathrm{Hom}(G, \mathbb{C}^*)$. To deduce this latter isomorphism, first reduce to the case when G is cyclic by writing G as a product of cyclic groups. The cyclic case follows because if G is cyclic of order n, then $\mathbb{C}^*$ contains an nth root of unity, so $\mathrm{Hom}(G, \mathbb{C}^*)$ is also cyclic of order n. Any two cyclic groups of the same order are isomorphic, so G and $\mathrm{Hom}(G, \mathbb{C}^*)$ are isomorphic. □

Corollary 4.3. *We have $\#D(N, R) \mid \varphi(N)$, with equality if and only if the order of our choice of $\zeta \in R$ is a multiple of the exponent of the group $(\mathbb{Z}/N\mathbb{Z})^*$.*

Proof. This is because $\#(\mathbb{Z}/N\mathbb{Z})^* = \varphi(N)$. □

Fix a positive integer N. To find the set of "canonical" generators for the group $(Z/NZ)^*$, write $N = \prod_{i=0}^{n} p_i^{e_i}$ where $p_0 < p_1 < \cdots < p_n$ are the prime divisors of N. By Exercise 4.2, each factor $(\mathbb{Z}/p_i^{e_i}\mathbb{Z})^*$ is a cyclic group $C_i = \langle g_i \rangle$, except if $p_0 = 2$ and $e_0 \geq 3$, in which case $(\mathbb{Z}/p_0^{e_0}\mathbb{Z})^*$ is a product of the cyclic subgroup $C_0 = \langle -1 \rangle$ of order 2 with the cyclic subgroup $C_1 = \langle 5 \rangle$. In all cases we have

$$(\mathbb{Z}/N\mathbb{Z})^* \cong \prod_{0 \leq i \leq n} C_i = \prod_{0 \leq i \leq n} \langle g_i \rangle.$$

For i such that $p_i > 2$, choose the generator g_i of C_i to be the element of $\{2, 3, \ldots, p_i^{e_i} - 1\}$ that is smallest and generates. Finally, use the Chinese Remainder Theorem (see [**Coh93**, §1.3.3]) to lift each g_i to an element in $(\mathbb{Z}/N\mathbb{Z})^*$, also denoted g_i, that is 1 modulo each $p_j^{e_j}$ for $j \neq i$.

Algorithm 4.4 (Minimal Generator for $(\mathbb{Z}/p^r\mathbb{Z})^*$)**.** *Given a prime power p^r with p odd, this algorithm computes the minimal generator of $(\mathbb{Z}/p^r\mathbb{Z})^*$.*

(1) [Factor Group Order] Factor $n = \phi(p^r) = p^{r-1} \cdot 2 \cdot ((p-1)/2)$ as a product $\prod p_i^{e_i}$ of primes. This is equivalent in difficulty to factoring $(p-1)/2$. (See, e.g., [**Coh93**, Ch.8, Ch. 10] for an excellent discussion of factorization algorithms, though of course much progress has been made since then.)
(2) [Initialize] Set $g = 2$.
(3) [Generator?] Using the binary powering algorithm (see [**Coh93**, §1.2]), compute $g^{n/p_i} \pmod{p^r}$, for each prime divisor p_i of n. If any of these powers are 1, then g is not a generator, so set $g = g+1$ and go to step (2). If no powers are 1, output g and terminate.

See Exercise 4.3 for a proof that this algorithm is correct.

Example 4.5. A minimal generator for $(\mathbb{Z}/49\mathbb{Z})^*$ is 3. We have $n = \varphi(49) = 42 = 2 \cdot 3 \cdot 7$ and

$$2^{n/2} \equiv 1, \qquad 2^{n/3} \equiv 18, \qquad 2^{n/7} \equiv 15 \pmod{49},$$

so 2 is not a generator for $(\mathbb{Z}/49\mathbb{Z})^*$. (We see this just from $2^{n/2} \equiv 1 \pmod{49}$.) However 3 is a generator since

$$3^{n/2} \equiv 48, \qquad 3^{n/3} \equiv 30, \qquad 3^{n/7} \equiv 43 \pmod{49}.$$

Example 4.6. In this example we compute minimal generators for $N = 25$, 100, and 200:

(1) The minimal generator for $(\mathbb{Z}/25\mathbb{Z})^*$ is 2.
(2) The minimal generators for $(\mathbb{Z}/100\mathbb{Z})^*$, lifted to numbers modulo 100, are $g_0 = 51$ and $g_1 = 77$. Notice that $g_0 \equiv -1 \pmod 4$ and $g_0 \equiv 1 \pmod{25}$ and that $g_1 \equiv 2 \pmod{25}$ is the minimal generator modulo 25.
(3) The minimal generators for $(\mathbb{Z}/200\mathbb{Z})^*$, lifted to numbers modulo 200, are $g_0 = 151$, $g_1 = 101$, and $g_2 = 177$. Note that $g_0 \equiv -1 \pmod 4$, that $g_1 \equiv 5 \pmod 8$ and $g_2 \equiv 2 \pmod{25}$.

In SAGE, the command `Integers(N)` creates $\mathbb{Z}/N\mathbb{Z}$.

```
sage: R = Integers(49)
sage: R
Ring of integers modulo 49
```

The unit_gens command computes the minimal generators for $(\mathbb{Z}/N\mathbb{Z})^*$, as defined above.

```
sage: R.unit_gens()
[3]
sage: Integers(25).unit_gens()
[2]
sage: Integers(100).unit_gens()
[51, 77]
sage: Integers(200).unit_gens()
[151, 101, 177]
sage: Integers(2005).unit_gens()
[402, 1206]
sage: Integers(200000000).unit_gens()
[174218751, 51562501, 187109377]
```

Fix an element ζ of finite multiplicative order in a ring R, and let $D(N,R)$ denote the group of Dirichlet characters of modulus N over R, with image in $\langle\zeta\rangle \cup \{0\}$. In most of this chapter, we specify an element $\varepsilon \in D(N,R)$ by giving the list

$$[\varepsilon(g_0), \varepsilon(g_1), \ldots, \varepsilon(g_n)] \tag{4.2.1}$$

of images of the generators of $(\mathbb{Z}/N\mathbb{Z})^*$. (Note that if N is even, the number of elements of the list (4.2.1) *does* depend on whether or not $8 \mid N$—there are two factors corresponding to 2 if $8 \mid N$, but only one if $8 \nmid N$.) This representation completely determines ε and is convenient for arithmetic operations. It is analogous to representing a linear transformation by a matrix.

Remark 4.7. In any actual implementation (e.g., the one in SAGE), it is better to represent the $\varepsilon(g_i)$ by recording an integer j such that $\varepsilon(g_i) = \zeta^j$, where $\zeta \in R$ is a fixed root of unity. Then (4.2.1) is internally represented as an element of $(\mathbb{Z}/m\mathbb{Z})^{n+1}$, where m is the multiplicative order of ζ. When the representation of (4.2.1) is needed for an algorithm, it can be quickly computed on the fly using a table of the powers of ζ. See Section 4.7 for further discussion about ways to represent characters.

Example 4.8. The group $D(5,\mathbb{C})$ has elements $\{[1],[i],[-1],[-i]\}$, so it is cyclic of order $\varphi(5) = 4$. In contrast, the group $D(5,\mathbb{Q})$ has only the two elements [1] and $[-1]$ and order 2. The command `DirichletGroup(N)` with no second argument creates the group of Dirichlet characters with values in the cyclotomic field $\mathbb{Q}(\zeta_n)$, where n is the exponent of the group $(\mathbb{Z}/N\mathbb{Z})^*$. Every element in $D(N, \mathbb{C})$ takes values in $\mathbb{Q}(\zeta_n)$, so $D(N, \mathbb{Q}(\zeta_n)) \approx D(N, \mathbb{C})$.

```
sage: list(DirichletGroup(5))
[[1], [zeta4], [-1], [-zeta4]]
sage: list(DirichletGroup(5, QQ))
[[1], [-1]]
```

4.3. Evaluation of Dirichlet Characters

This section is about how to compute $\varepsilon(n)$, where ε is a Dirichlet character and n is an integer. We begin with an example.

Example 4.9. If $N = 200$, then $g_0 = 151$, $g_1 = 101$ and $g_2 = 177$, as we saw in Example 4.6. The exponent of $(\mathbb{Z}/200\mathbb{Z})^*$ is 20, since that is the least common multiple of the exponents of $4 = \#(\mathbb{Z}/8\mathbb{Z})^*$ and $20 = \#(\mathbb{Z}/25\mathbb{Z})^*$. The orders of g_0, g_1, and g_2 are 2, 2, and 20. Let $\zeta = \zeta_{20}$ be a primitive 20th root of unity in $\mathbb{C}$. Then the following are generators for $D(200, \mathbb{C})$:

$$\varepsilon_0 = [-1, 1, 1], \qquad \varepsilon_1 = [1, -1, 1], \qquad \varepsilon_2 = [1, 1, \zeta],$$

and $\varepsilon = [1, -1, \zeta^5]$ is an example element of order 4. To evaluate $\varepsilon(3)$, we write 3 in terms of g_0, g_1, and g_2. First, reducing 3 modulo 8, we see that $3 \equiv g_0 \cdot g_1 \pmod{8}$. Next reducing 3 modulo 25 and trying powers of $g_2 = 2$, we find that $e \equiv g_2^7 \pmod{25}$. Thus

$$\begin{aligned}
\varepsilon(3) &= \varepsilon(g_0 \cdot g_1 \cdot g_2^7) \\
&= \varepsilon(g_0)\varepsilon(g_1)\varepsilon(g_2)^7 \\
&= 1 \cdot (-1) \cdot (\zeta^5)^7 \\
&= -\zeta^{35} = -\zeta^{15}.
\end{aligned}$$

We next illustrate the above computation of $\varepsilon(3)$ in SAGE. First we make the group $D(200, \mathbb{Q}(\zeta_8))$ and list its generators.

```
sage: G = DirichletGroup(200)
sage: G
Group of Dirichlet characters of modulus 200 over
Cyclotomic Field of order 20 and degree 8
sage: G.exponent()
20
sage: G.gens()
([-1, 1, 1], [1, -1, 1], [1, 1, zeta20])
```

We construct ε.

```
sage: K = G.base_ring()
sage: zeta = K.0
sage: eps = G([1,-1,zeta^5])
sage: eps
[1, -1, zeta20^5]
```

Finally, we evaluate ε at 3.

```
sage: eps(3)
zeta20^5
sage: -zeta^15
zeta20^5
```

Example 4.9 illustrates that if ε is represented using a list as described above, evaluation of ε is inefficient without extra information; it requires solving the discrete log problem in $(\mathbb{Z}/N\mathbb{Z})^*$.

Remark 4.10. For a general character ε, is calculation of ε at least as hard as finding discrete logarithms? Quadratic characters are easier—see Algorithm 4.23.

Algorithm 4.11 (Evaluate ε)**.** *Given a Dirichlet character ε of modulus N, represented by a list $[\varepsilon(g_0), \varepsilon(g_1), \ldots, \varepsilon(g_n)]$, and an integer a, this algorithm computes $\varepsilon(a)$.*

(1) [GCD] Compute $g = \gcd(a, N)$. If $g > 1$, output 0 and terminate.
(2) [Discrete Log] For each i, write $a \pmod{p_i^{e_i}}$ as a power m_i of g_i using some algorithm for solving the discrete log problem (see below). If $p_i = 2$, write $a \pmod{p_i^{e_i}}$ as $(-1)^{m_0} \cdot 5^{m_1}$. (This step is analogous to writing a vector in terms of a basis.)

(3) [Multiply] Output $\prod \varepsilon(g_i)^{m_i}$ as an element of R, and terminate. (This is analogous to multiplying a matrix times a vector.)

4.3.1. The Discrete Log Problem.

Exercise 4.4 gives an isomorphism of groups

$$(1 + p^{n-1}(\mathbb{Z}/p^n\mathbb{Z}), \times) \cong (\mathbb{Z}/p\mathbb{Z}, +),$$

so one sees by induction that step (2) is "about as difficult" as finding a discrete log in $(\mathbb{Z}/p\mathbb{Z})^*$. There is an algorithm called "baby-step giant-step", which solves the discrete log problem in $(\mathbb{Z}/p\mathbb{Z})^*$ in time $O(\sqrt{\ell})$, where ℓ is the largest prime factor of $p - 1 = \#(\mathbb{Z}/p\mathbb{Z})^*$ (note that the discrete log problem in $(\mathbb{Z}/p\mathbb{Z})^*$ reduces to a series of discrete log problems in each prime-order cyclic factor). This is unfortunately still exponential in the number of digits of ℓ; it also uses $O(\sqrt{\ell})$ memory. We now describe this algorithm without any specific optimizations.

Algorithm 4.12 (Baby-step Giant-step Discrete Log)**.** *Given a prime p, a generator g of $(\mathbb{Z}/p\mathbb{Z})^*$, and an element $a \in (\mathbb{Z}/p\mathbb{Z})^*$, this algorithm finds an n such that $g^n = a$. (Note that this algorithm works in any cyclic group, not just $(\mathbb{Z}/p\mathbb{Z})^*$.)*

(1) [Make Lists] Let $m = \lceil \sqrt{p} \rceil$ be the ceiling of $\sqrt{p}$, and construct two lists

$$1,\, g^m,\, \ldots,\, g^{(m-1)m} \qquad \text{(giant steps)}$$

and

$$a, ag,\, ag^2,\, \ldots,\, ag^{m-1} \qquad \text{(baby steps).}$$

(2) [Find Match] Sort the two lists and find a match $g^{im} = ag^j$. Then $a = g^{im-j}$.

Proof. We prove that there will always be a match. Since we know that $a = g^k$ for some k with $0 \leq k \leq p - 1$ and any such k can be written in the form $im - j$ for $0 \leq i, j \leq m - 1$, we will find such a match. □

Algorithm 4.12 uses nothing special about $(\mathbb{Z}/p\mathbb{Z})^*$, so it works in a generic group. It is a theorem that there is no faster algorithm to find discrete logs in a "generic group" (see [**Sho97, Nec94**]). There are much better subexponential algorithms for solving the discrete log problem in $(\mathbb{Z}/p\mathbb{Z})^*$, which use the special structure of this group. They use the number field sieve (see, e.g., [**Gor93**]), which is also the best-known algorithm for factoring integers. This class of algorithms has been very well studied by cryptographers; though sub-exponential, solving discrete log problems when p is large is still extremely difficult. For a more in-depth survey see [**Gor04**]. For computing Dirichlet characters in our context, p is not too large, so Algorithm 4.12 works well.

4.3.2. Enumeration of All Values. For many applications of Dirichlet characters to computing modular forms, N is fairly small, e.g., $N < 10^6$, and we evaluate ε on a *huge* number of random elements, inside inner loops of algorithms. Thus for such purposes it will often be better to make a table of all values of ε, so that evaluation of ε is extremely fast. The following algorithm computes a table of all values of ε, and it does not require computing any discrete logs since we are computing *all* values.

Algorithm 4.13 (Values of ε)**.** *Given a Dirichlet character ε represented by the list of values of ε on the minimal generators g_i of $(\mathbb{Z}/N\mathbb{Z})^*$, this algorithm creates a list of all the values of ε.*

(1) [Initialize] For each minimal generator g_i, set $a_i = 0$. Let $n = \prod g_i^{a_i}$, and set $z = 1$. Create a list v of N values, all initially set equal to 0. When this algorithm terminates, the list v will have the property that

$$v\ [x \pmod N] = \varepsilon(x).$$

Notice that we index v starting at 0.

(2) [Add Value to Table] Set $v[n] = z$.

(3) [Finished?] If each a_i is one less than the order of g_i, output v and terminate.

(4) [Increment] Set $a_0 = a_0 + 1$, $n = n \cdot g_0 \pmod N$, and $z = z \cdot \varepsilon(g_0)$. If $a_0 \geq \mathrm{ord}(g_0)$, set $a_0 \to 0$, and then set $a_1 = a_1 + 1$, $n = n \cdot g_1 \pmod N$, and $z = z \cdot \varepsilon(g_1)$. If $a_1 \geq \mathrm{ord}(g_1)$, do what you just did with a_0 but with all subscripts replaced by 1. Etc. (Imagine a car odometer.) Go to step (2).

4.4. Conductors of Dirichlet Characters

The following algorithm for computing the order of ε reduces the problem to computing the orders of powers of ζ in R.

Algorithm 4.14 (Order of Character)**.** *This algorithm computes the order of a Dirichlet character $\varepsilon \in D(N, R)$.*

(1) Compute the order r_i of each $\varepsilon(g_i)$, for each minimal generator g_i of $(\mathbb{Z}/N\mathbb{Z})^*$. The order of $\varepsilon(g_i)$ is a divisor of $n = \#(\mathbb{Z}/p_i^{e_i}\mathbb{Z})^*$ so we can compute its order by considering the divisors of n.

(2) Compute and output the least common multiple of the integers r_i.

Remark 4.15. Computing the order of $\varepsilon(g_i) \in R$ is potentially difficult. Simultaneously using a different representation of Dirichlet characters avoids having to compute the order of elements of R (see Section 4.7).

The next algorithm factors ε as a product of "local" characters, one for each prime divisor of N. It is useful for other algorithms, e.g., for explicit computations with trace formulas (see [**Hij74**]). This factorization is easy to compute because of how we represent ε.

Algorithm 4.16 (Factorization of Character)**.** *Given a Dirichlet character $\varepsilon \in D(N,R)$, with $N = \prod p_i^{e_i}$, this algorithm finds Dirichlet characters ε_i modulo $p_i^{e_i}$, such that for all $a \in (\mathbb{Z}/N\mathbb{Z})^*$, we have $\varepsilon(a) = \prod \varepsilon_i(a \pmod{p_i^{e_i}})$. If $2 \mid N$, the steps are as follows:*

(1) Let g_i be the minimal generators of $(\mathbb{Z}/N\mathbb{Z})^*$, so ε is given by a list
$$[\varepsilon(g_0), \ldots, \varepsilon(g_n)].$$
(2) For $i = 2, \ldots, n$, let ε_i be the element of $D(p_i^{e_i}, R)$ defined by the singleton list $[\varepsilon(g_i)]$.
(3) Let ε_1 be the element of $D(2^{e_1}, R)$ defined by the list $[\varepsilon(g_0), \varepsilon(g_1)]$ of length 2. Output the ε_i and terminate.

If $2 \nmid N$, then omit step (3), and include all i in step (2).

The factorization of Algorithm 4.16 is unique since each ε_i is determined by the image of the canonical map $(\mathbb{Z}/p_i^{e_i}\mathbb{Z})^*$ in $(\mathbb{Z}/N\mathbb{Z})^*$, which sends $a \pmod{p_i^{e_i}}$ to the element of $(\mathbb{Z}/N\mathbb{Z})^*$ that is $a \pmod{p_i^{e_i}}$ and $1 \pmod{p_j^{e_j}}$ for $j \neq i$.

Example 4.17. If $\varepsilon = [1, -1, \zeta^5] \in D(200, \mathbb{C})$, then $\varepsilon_1 = [1, -1] \in D(8, \mathbb{C})$ and $\varepsilon_2 = [\zeta^5] \in D(25, \mathbb{C})$.

Definition 4.18 (Conductor)**.** The *conductor* of a Dirichlet character $\varepsilon \in D(N,R)$ is the smallest positive divisor $c \mid N$ such that there is a character $\varepsilon' \in D(c, R)$ for which $\varepsilon(a) = \varepsilon'(a)$ for all $a \in \mathbb{Z}$ with $(a, N) = 1$. A Dirichlet character is *primitive* if its modulus equals its conductor. The character ε' associated to ε with modulus equal to the conductor of ε is called the *primitive character associated to* ε.

We will be interested in conductors later, when computing new subspaces of spaces of modular forms with character. Also certain formulas for special values of L functions are only valid for primitive characters.

Algorithm 4.19 (Conductor)**.** *This algorithm computes the conductor of a Dirichlet character $\varepsilon \in D(N, R)$.*

(1) [Factor Character] Using Algorithm 4.16, find characters ε_i whose product is ε.
(2) [Compute Orders] Using Algorithm 4.14, compute the orders r_i of each ε_i.
(3) [Conductors of Factors] For each i, either set $c_i \to 1$ if ε_i is the trivial character (i.e., of order 1) or set $c_i = p_i^{\mathrm{ord}_{p_i}(r_i)+1}$, where $\mathrm{ord}_p(n)$ is the largest power of p that divides n.

(4) [Adjust at 2?] If $p_1 = 2$ and $\varepsilon_1(5) \neq 1$, set $c_1 = 2c_1$.
(5) [Finished] Output $c = \prod c_i$ and terminate.

Proof. Let ε_i be the local factors of ε, as in step (1). We first show that the product of the conductors f_i of the ε_i is the conductor f of ε. Since ε_i factors through $(\mathbb{Z}/f_i\mathbb{Z})^*$, the product ε of the ε_i factors through $(\mathbb{Z}/\prod f_i\mathbb{Z})^*$, so the conductor of ε divides $\prod f_i$. Conversely, if $\mathrm{ord}_{p_i}(f) < \mathrm{ord}_{p_i}(f_i)$ for some i, then we could factor ε as a product of local (prime power) characters differently, which contradicts that this factorization is unique.

It remains to prove that if ε is a nontrivial character of modulus p^n, where p is a prime, and if r is the order of ε, then the conductor of ε is $p^{\mathrm{ord}_p(r)+1}$, except possibly if $8 \mid p^n$. Since the order and conductor of ε and of the associated primitive character ε' are the same, we may assume ε is primitive, i.e., that p^n is the conductor of ε; note that $n > 0$, since ε is nontrivial.

First suppose p is odd. Then the abelian group $D(p^n, R)$ splits as a direct sum $D(p, R) \oplus D(p^n, R)'$, where $D(p^n, R)'$ is the p-power torsion subgroup of $D(p^n, R)$. Also ε has order $u \cdot p^m$, where u, which is coprime to p, is the order of the image of ε in $D(p, R)$ and p^m is the order of the image in $D(p^n, R)'$. If $m = 0$, then the order of ε is coprime to p, so ε is in $D(p, R)$, which means that $n = 1$, so $n = m + 1$, as required. If $m > 0$, then $\zeta \in R$ must have order divisible by p, so R has characteristic not equal to p. The conductor of ε does not change if we adjoin roots of unity to R, so in light of Lemma 4.2 we may assume that $D(N, R) \approx (\mathbb{Z}/N\mathbb{Z})^*$. It follows that for each $n' \leq n$, the p-power subgroup $D(p^{n'}, R)'$ of $D(p^{n'}, R)$ is the $p^{n'-1}$-torsion subgroup of $D(p^n, R)'$. Thus $m = n - 1$, since $D(p^n, R)'$ is by assumption the smallest such group that contains the projection of ε. This proves the formula of step (3). We leave the argument when $p = 2$ as an exercise (see Exercise 4.5). □

Example 4.20. If $\varepsilon = [1, -1, \zeta^5] \in D(200, \mathbb{C})$, then as in Example 4.17, ε is the product of $\varepsilon_1 = [1, -1]$ and $\varepsilon_2 = [\zeta^5]$. Because $\varepsilon_1(5) = -1$, the conductor of ε_1 is 8. The order of ε_2 is 4 (since ζ is a 20th root of unity), so the conductor of ε_2 is 5. Thus the conductor of ε is $40 = 8 \cdot 5$.

4.5. The Kronecker Symbol

In this section all characters have values in $\mathbb{C}$.

Frequently quadratic characters are described in terms of the Kronecker symbol $\left(\frac{a}{n}\right)$, which we define for any integer a and positive integer n as follows. First, if $n = p$ is an odd prime, then for any integer a,

$$\left(\frac{a}{p}\right) = \begin{cases} 0 & \text{if } \gcd(a,p) \neq 1, \\ 1 & \text{if } a \text{ is a square mod } p, \\ -1 & \text{if } a \text{ is not a square mod } p. \end{cases}$$

If $p = 2$, then

$$\left(\frac{a}{2}\right) = \begin{cases} 0 & \text{if } a \text{ is even}, \\ 1 & \text{if } a \equiv \pm 1 \pmod 8, \\ -1 & \text{if } a \equiv \pm 3 \pmod 8. \end{cases}$$

More generally, if $n = \prod p_i^{e_i}$ with the p_i prime, then

$$\left(\frac{a}{n}\right) = \prod \left(\frac{a}{p_i}\right)^{e_i}.$$

Remark 4.21. One can also extend $\left(\frac{a}{n}\right)$ to $n < 0$, but we will not need this. The extension is to set $\left(\frac{a}{-1}\right) = -1$ and $\left(\frac{a}{1}\right) = 1$, for $a \neq 0$, and to extend multiplicatively (in the denominator). Note that the map $\left(\frac{\bullet}{-1}\right)$ is not a Dirichlet character (see Exercise 4.1).

Let M be the product of the primes p such that $\mathrm{ord}_p(n)$ is odd. If M is odd, let $N = M$; otherwise, let $N = 8M$.

Lemma 4.22. *The function*

$$\varepsilon(a) = \begin{cases} \left(\frac{a}{n}\right) & \text{if } \gcd(a,N) = 1, \\ 0 & \text{otherwise} \end{cases}$$

is a Dirichlet character of modulus N. The function

$$\varepsilon(a) = \begin{cases} \left(\frac{-1}{a}\right) & \text{if } a \text{ is odd}, \\ 0 & \text{if } a \text{ is even} \end{cases}$$

is a Dirichlet character of modulus N.

Proof. When restricted to $(\mathbb{Z}/N\mathbb{Z})^*$, each map $\left(\frac{\bullet}{p}\right)$, for p prime, is a homomorphism, so ε a product of homomorphisms. The second statement follows from the definition and the fact that -1 is a square modulo an odd prime p if and only if $p \equiv 1 \pmod 4$. □

This section is about going between representing quadratic characters as row matrices and via Kronecker symbols. This is valuable because the algorithms in [**Coh93**, §1.1.4] for computing Kronecker symbols run in time quadratic in the number of digits of the input. They do not require computing discrete logarithms; instead, they use, e.g., that $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod{p}$, when p is an odd prime.

Algorithm 4.23 (Kronecker Symbol as Dirichlet Character)**.** *Given $n > 0$, this algorithm computes a representation of the Kronecker symbol $\left(\frac{\bullet}{n}\right)$ as a Dirichlet character.*

(1) [Modulus] Compute N as in Lemma 4.22.
(2) [Minimal Generators] Compute minimal generators g_i of $(\mathbb{Z}/N\mathbb{Z})^*$ using Algorithm 4.4.
(3) [Images] Compute $\left(\frac{g_i}{N}\right)$ for each g_i using one of the algorithms of [**Coh93**, §1.1.4].

Example 4.24. We compute the Dirichlet character associated to $\left(\frac{\bullet}{200}\right)$. Using SAGE, we compute the $\left(\frac{g_i}{200}\right)$, for $i = 0, 1, 2$, where the g_i are as in Example 4.9:

```
sage: kronecker(151,200)
1
sage: kronecker(101,200)
-1
sage: kronecker(177,200)
1
```

Thus the corresponding character is defined by $[1, -1, 1]$.

Example 4.25. We compute the character associated to $\left(\frac{\bullet}{420}\right)$. We have $420 = 4 \cdot 3 \cdot 5 \cdot 7$, and minimal generators are

$$g_0 = 211, \quad g_1 = 1, \quad g_2 = 281, \quad g_3 = 337, \quad g_4 = 241.$$

We have $g_0 \equiv -1 \pmod{4}$, $g_2 \equiv 2 \pmod{3}$, $g_3 \equiv 2 \pmod{5}$ and $g_4 \equiv 3 \pmod{7}$. We find $\left(\frac{g_0}{420}\right) = \left(\frac{g_1}{420}\right) = 1$ and $\left(\frac{g_2}{420}\right) = \left(\frac{g_3}{420}\right) = \left(\frac{g_4}{420}\right) = -1$. The corresponding character is $[1, 1, -1, -1, -1]$.

Using the following algorithm, we can go in the other direction, i.e., write any quadratic Dirichlet character as a Kronecker symbol.

Algorithm 4.26 (Dirichlet Character as Kronecker Symbol)**.** *Given ε of order 2 with modulus N, this algorithm writes ε as a Kronecker symbol.*

(1) [Conductor] Use Algorithm 4.19 to compute the conductor f of ε.
(2) [Odd] If f is odd, output $\left(\frac{\bullet}{f}\right)$.
(3) [Even] If $\varepsilon(-1) = 1$, output $\left(\frac{\bullet}{f}\right)$; if $\varepsilon(-1) = -1$, output $\left(\frac{\bullet}{f}\right) \cdot \left(\frac{-1}{\bullet}\right)$.

Proof. Since f is the conductor of a quadratic Dirichlet character, it is a square-free product g of odd primes times either 4 or 8, so the group $(\mathbb{Z}/f\mathbb{Z})^*$ does not inject into $(\mathbb{Z}/g\mathbb{Z})^*$ for any proper divisor g of f (see this by reducing to the prime power case). Since g is odd and square-free, the character $\left(\frac{\bullet}{g}\right)$ has conductor g. For each odd prime p, by step (3) of Algorithm 4.19 the factor at p of both ε and $\left(\frac{\bullet}{g}\right)$ is a quadratic character with modulus p. By Exercise 4.2 and Lemma 4.2 the group $D(p, \mathbb{C})$ is cyclic, so it has a unique element of order 2, so the factors of ε and $\left(\frac{\bullet}{g}\right)$ at p are equal.

The quadratic characters with conductor a power of 2 are $[-1]$, $[1, -1]$, and $[-1, -1]$. The character $[1, -1]$ is $\left(\frac{\bullet}{2}\right)$ and the character $[-1]$ is $\left(\frac{-1}{\bullet}\right)$. □

Example 4.27. Consider $\varepsilon = [-1, -1, -1, -1, -1]$ with modulus $840 = 8 \cdot 3 \cdot 5 \cdot 7$. It has conductor 840, and $\varepsilon(-1) = -1$, so for all a with $\gcd(a, 840) = 1$, we have $\varepsilon(a) = \left(\frac{a}{840}\right) \cdot \left(\frac{-1}{a}\right)$.

4.6. Restriction, Extension, and Galois Orbits

The following two algorithms restrict and extend characters to a compatible modulus. Using them, it is easy to define multiplication of two characters $\varepsilon \in D(N, R)$ and $\varepsilon' \in D(N', R')$, as long as R and R' are subrings of a common ring. To carry out the multiplication, extend both characters to a common base ring, and then extend them to characters modulo $\mathrm{lcm}(N, N')$ and multiply.

Algorithm 4.28 (Restriction of Character)**.** *Given a Dirichlet character $\varepsilon \in D(N, R)$ and a divisor N' of N that is a multiple of the conductor of ε, this algorithm finds a characters $\varepsilon' \in D(N', R)$, such that $\varepsilon'(a) = \varepsilon(a)$, for all $a \in \mathbb{Z}$ with $(a, N) = 1$.*

(1) [Conductor] Compute the conductor of ε using Algorithm 4.19, and verify that N' is divisible by the conductor and divides N.
(2) [Minimal Generators] Compute minimal generators g_i for $(\mathbb{Z}/N'\mathbb{Z})^*$.
(3) [Values of Restriction] For each i, compute $\varepsilon'(g_i)$ as follows. Find a multiple aN' of N' such that $(g_i + aN',\, N) = 1$; then $\varepsilon'(g_i) = \varepsilon(g_i + aN')$.
(4) [Output Character] Output the Dirichlet character of modulus N' defined by $[\varepsilon'(g_0), \ldots, \varepsilon'(g_n)]$.

Proof. The only part that is not clear is that in step (3) there is an a such that $(g_i + aN', N) = 1$. If we write $N = N_1 \cdot N_2$, with $(N_1, N_2) = 1$ and N_1 divisible by all primes that divide N', then $(g_i, N_1) = 1$ since $(g_i, N') = 1$. By the Chinese Remainder Theorem, there is an $x \in \mathbb{Z}$ such that $x \equiv g_i$

(mod N_1) and $x \equiv 1 \pmod{N_2}$. Then $x = g_i + bN_1 = g_i + (bN_1/N') \cdot N'$ and $(x, N) = 1$, which completes the proof. □

Algorithm 4.29 (Extension of Character)**.** *Given a Dirichlet character $\varepsilon \in D(N, R)$ and a multiple N' of N, this algorithm finds a character $\varepsilon' \in D(N', R)$, such that $\varepsilon'(a) = \varepsilon(a)$, for all $a \in \mathbb{Z}$ with $(a, N') = 1$.*

(1) [Minimal Generators] Compute minimal generators g_i for $(\mathbb{Z}/N'\mathbb{Z})^*$.
(2) [Evaluate] Compute $\varepsilon(g_i)$ for each i. Since $(g_i, N') = 1$, we also have $(g_i, N) = 1$.
(3) [Output Character] Output the character $[\varepsilon(g_0), \ldots, \varepsilon(g_n)]$.

Let F be the prime subfield of R, and assume that $R \subset \overline{F}$, where $\overline{F}$ is a separable closure of F. If $\sigma \in \mathrm{Gal}(\overline{F}/F)$ and $\varepsilon \in D(N, R)$, let $(\sigma\varepsilon)(n) = \sigma(\varepsilon(n))$; this defines an action of $\mathrm{Gal}(\overline{F}/F)$ on $D(N, R)$. Our next algorithm computes the orbits for the action of $\mathrm{Gal}(\overline{F}/F)$ on $D(N, R)$. This algorithm can provide huge savings for modular forms computations because the spaces $M_k(N, \varepsilon)$ and $M_k(N, \varepsilon')$ are canonically isomorphic if ε and ε' are conjugate.

Algorithm 4.30 (Galois Orbit)**.** *Given a Dirichlet character $\varepsilon \in D(N, R)$, this algorithm computes the orbit of ε under the action of $G = \mathrm{Gal}(\overline{F}/F)$, where F is the prime subfield of $\mathrm{Frac}(R)$, so $F = \mathbb{F}_p$ or $\mathbb{Q}$.*

(1) [Order of ζ] Let n be the order of the chosen root $\zeta \in R$.
(2) [Nontrivial Automorphisms] If $\mathrm{char}(R) = 0$, let

$$A = \{a : 2 \le a < n \text{ and } (a, n) = 1\}.$$

If $\mathrm{char}(R) = p > 0$, compute the multiplicative order r of $p \pmod{n}$, and let

$$A = \{p^m : 1 \le m < r\}.$$

(3) [Compute Orbit] Compute and output the *set* of unique elements ε^a for each $a \in A$ (there could be repeats, so we output unique elements only).

Proof. We prove that the nontrivial automorphisms of $\langle\zeta\rangle$ in characteristic p are as in step (2). It is well known that every automorphism in characteristic p on $\zeta \in \overline{\mathbb{F}}_p$ is of the form $x \mapsto x^{p^s}$, for some s. The images of ζ under such automorphisms are

$$\zeta, \zeta^p, \zeta^{p^2}, \ldots.$$

Suppose $r > 0$ is minimal such that $\zeta = \zeta^{p^r}$. Then the orbit of ζ is $\zeta, \ldots, \zeta^{p^{r-1}}$. Also $p^r \equiv 1 \pmod{n}$, where n is the multiplicative order of ζ, so r is the multiplicative order of p modulo n, which completes the proof. □

Example 4.31. The Galois orbits of characters in $D(20, \mathbb{C}^*)$ are as follows:

$$\begin{aligned} G_0 &= \{[1, 1, 1]\}, \\ G_1 &= \{[-1, 1, 1]\}, \\ G_2 &= \{[1, 1, \zeta_4],\ [1, 1, -\zeta_4]\} \\ G_3 &= \{[-1, 1, \zeta_4],\ [-1, 1, -\zeta_4]\} \\ G_4 &= \{[1, 1, -1]\}, \\ G_5 &= \{[-1, 1, -1]\}. \end{aligned}$$

The conductors of the characters in orbit G_0 are 1, in orbit G_1 they are 4, in orbit G_2 they are 5, in G_3 they are 20, in G_4 the conductor is 5, and in G_5 the conductor is 20. (You should verify this.)

SAGE computes Galois orbits as follows:

```
sage: G = DirichletGroup(20)
sage: G.galois_orbits()
[
[[1, 1]],
[[1, zeta4], [1, -zeta4]],
[[1, -1]],
[[-1, 1]],
[[-1, zeta4], [-1, -zeta4]],
[[-1, -1]]
]
```

4.7. Alternative Representations of Characters

Let N be a positive integer and R an integral domain, with fixed root of unity ζ of order n, and let $D(N, R) = D(N, R, \zeta)$. As in the rest of this chapter, write $N = \prod p_i^{e_i}$, and let $C_i = \langle g_i \rangle$ be the corresponding cyclic factors of $(\mathbb{Z}/N\mathbb{Z})^*$. In this section we discuss other ways to represent elements $\varepsilon \in D(N, R)$. Each representation has advantages and disadvantages, and no single representation is best. It is easy to convert between them, and some algorithms are much easier using one representation than when using another. In this section we present two other representations, each having advantages and disadvantages. There is no reason to restrict to only one representation; for example, SAGE internally uses both.

We could represent ε by giving a list $[b_0, \ldots, b_r]$, where each $b_i \in \mathbb{Z}/n\mathbb{Z}$ and $\varepsilon(g_i) = \zeta^{b_i}$. Then arithmetic in $D(N, R)$ is arithmetic in $(\mathbb{Z}/n\mathbb{Z})^{r+1}$, which is very efficient. A drawback to this approach (in practice) is that it is easy to accidentally consider sequences that do not actually correspond to elements of $D(N, R)$. Also the choice of ζ is less clear, which can cause confusion. Finally, the orders of the local factors is more opaque, e.g., compare $[-1, \zeta_{40}]$ with $[20, 1]$. Overall this representation is not too bad and is more like representing a linear transformation by a matrix. It has the *advantage* over the representation discussed earlier in this chapter that arithmetic in $D(N, R)$ is very efficient and does not require any operations in the ring R.

Another way to represent ε would be to give a list $[b_0, \ldots, b_r]$ of integers, but this time with $b_i \in \mathbb{Z}/\gcd(s_i, n)\mathbb{Z}$, where s_i is the order of g_i. Then

$$\varepsilon(g_i) = \zeta^{b_i \cdot n/(\gcd(s_i,n))},$$

which is already pretty complicated. With this representation we set up an identification

$$D(N, R) \cong \bigoplus_i \mathbb{Z}/\gcd(s_i, n)\mathbb{Z},$$

and arithmetic is efficient. This approach is seductive because every sequence of integers determines a character, and the sizes of the integers in the sequence nicely indicate the local orders of the character. However, giving analogues of many of the algorithms discussed in this chapter that operate on characters represented this way is tricky. For example, the representation depends very much on the order of ζ, so it is difficult to correctly compute natural maps $D(N, R) \to D(N, S)$, for $R \subset S$ rings.

4.8. Dirichlet Characters in SAGE

To create a Dirichlet character in SAGE, first create the group $D(N, R)$ of Dirichlet characters then construct elements of that group. First we make $D(11, \mathbb{Q})$:

```
sage: G = DirichletGroup(11, QQ); G
Group of Dirichlet characters of modulus 11 over
Rational Field
```

A Dirichlet character prints as a matrix that gives the values of the character on canonical generators of $(\mathbb{Z}/N\mathbb{Z})^*$ (as discussed below).

```
sage: list(G)
[[1], [-1]]
sage: eps = G.0      # 0th generator for Dirichlet group
sage: eps
[-1]
```

The character ε takes the value -1 on the unit generator.

```
sage: G.unit_gens()
[2]
sage: eps(2)
-1
sage: eps(3)
1
```

It is 0 on any integer not coprime to 11:

```
sage: [eps(11*n) for n in range(10)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

We can also create groups of Dirichlet characters taking values in other rings or fields. For example, we create the cyclotomic field $\mathbb{Q}(\zeta_4)$.

```
sage: R = CyclotomicField(4)
sage: CyclotomicField(4)
Cyclotomic Field of order 4 and degree 2
```

Then we define $G = D(15, \mathbb{Q}(\zeta_4))$.

```
sage: G = DirichletGroup(15, R)
sage: G
Group of Dirichlet characters of modulus 15 over
Cyclotomic Field of order 4 and degree 2
```

Next we list each of its elements.

```
sage: list(G)
[[1, 1], [-1, 1], [1, zeta4], [-1, zeta4], [1, -1],
[-1, -1], [1, -zeta4], [-1, -zeta4]]
```

Now we evaluate the second generator of G on various integers:

```
sage: e = G.1
sage: e(4)
-1
sage: e(-1)
-1
sage: e(5)
0
```

Finally we list all the values of e.

```
sage: [e(n) for n in range(15)]
[0, 1, zeta4, 0, -1, 0, 0, zeta4, -zeta4,
    0, 0, 1, 0, -zeta4, -1]
```

We can also compute with groups of Dirichlet characters with values in a finite field.

```
sage: G = DirichletGroup(15, GF(5)); G
Group of Dirichlet characters of modulus 15
      over Finite Field of size 5
```

We list all the elements of G, again represented by lists that give the images of each unit generator, as an element of $\mathbb{F}_5$.

```
sage: list(G)
  [[1, 1], [4, 1], [1, 2], [4, 2], [1, 4], [4, 4],
   [1, 3], [4, 3]]
```

We evaluate the second generator of G on several integers.

```
sage: e = G.1
sage: e(-1)
4
sage: e(2)
2
sage: e(5)
0
sage: print [e(n) for n in range(15)]
[0, 1, 2, 0, 4, 0, 0, 2, 3, 0, 0, 1, 0, 3, 4]
```

4.9. Exercises

4.1 Let $f : \mathbb{Z} \to \mathbb{C}$ be the map given by

$$f(a) = \begin{cases} 0 & \text{if } a = 0, \\ -1 & \text{if } a < 0, \\ 1 & \text{if } a > 0. \end{cases}$$

Prove that f is not a Dirichlet character of any modulus N.

4.2 This exercise is about the structure of the units of $\mathbb{Z}/p^n\mathbb{Z}$.

(a) If p is odd and n is a positive integer, prove that $(\mathbb{Z}/p^n\mathbb{Z})^*$ is cyclic.

(b) For $n \geq 3$, prove that $(\mathbb{Z}/2^n\mathbb{Z})^*$ is a direct sum of the cyclic subgroups $\langle -1 \rangle$ and $\langle 5 \rangle$, of orders 2 and 2^{n-2}, respectively.

4.3 Prove that Algorithm 4.4 works, i.e., that if $g \in (\mathbb{Z}/p^r\mathbb{Z})^*$ and $g^{n/p_i} \neq 1$ for all $p_i \mid n = \varphi(p^r)$, then g is a generator of $(\mathbb{Z}/p^r\mathbb{Z})^*$.

4.4 (a) Let p be an odd prime and $n \geq 2$ an integer, and prove that

$$\big((1 + p^{n-1}\mathbb{Z}/p^n\mathbb{Z}),\, \times\big) \cong (\mathbb{Z}/p\mathbb{Z},\, +).$$

(b) Use the first part to show that solving the discrete log problem in $(\mathbb{Z}/p^n\mathbb{Z})^*$ is "not much harder" than solving the discrete log problem in $(\mathbb{Z}/p\mathbb{Z})^*$.

4.5 Suppose ε is a nontrivial Dirichlet character of modulus 2^n of order r over the complex numbers $\mathbb{C}$. Prove that the conductor of ε is

$$c = \begin{cases} 2^{\mathrm{ord}_2(r)+1} & \text{if } \varepsilon(5) = 1, \\ 2^{\mathrm{ord}_2(r)+2} & \text{if } \varepsilon(5) \neq 1. \end{cases}$$

4.6 (a) Find an irreducible quadratic polynomial f over $\mathbb{F}_5$.

(b) Then $\mathbb{F}_{25} = \mathbb{F}_5[x]/(f)$. Find an element with multiplicative order 4 in $\mathbb{F}_{25}$.

(c) Make a list of all Dirichlet characters in $D(25, \mathbb{F}_{25}, \zeta)$.

(d) Divide these characters into orbits for the action of $\mathrm{Gal}(\overline{\mathbb{F}}_5/\mathbb{F}_5)$.

Chapter 5

Eisenstein Series and Bernoulli Numbers

We introduce generalized Bernoulli numbers attached to Dirichlet characters and give an algorithm to enumerate the Eisenstein series in $M_k(N, \varepsilon)$.

5.1. The Eisenstein Subspace

Let $M_k(\Gamma_1(N))$ be the space of modular forms of weight k for $\Gamma_1(N)$, and let $\mathbb{T}$ be the *Hecke algebra* acting on $M_k(\Gamma_1(N))$, which is the subring of $\mathrm{End}(M_k(\Gamma_1(N)))$ generated by all Hecke operators. Then there is a $\mathbb{T}$-module decomposition

$$M_k(\Gamma_1(N)) = E_k(\Gamma_1(N)) \oplus S_k(\Gamma_1(N)),$$

where $S_k(\Gamma_1(N))$ is the subspace of modular forms that vanish at all cusps and $E_k(\Gamma_1(N))$ is the *Eisenstein subspace*, which is uniquely determined by this decomposition. The above decomposition induces a decomposition of $M_k(\Gamma_0(N))$ and of $M_k(N, \varepsilon)$, for any Dirichlet character ε of modulus N.

5.2. Generalized Bernoulli Numbers

Suppose ε is a Dirichlet character of modulus N over $\mathbb{C}$. Leopoldt [**Leo58**] defined generalized Bernoulli numbers attached to ε.

Definition 5.1 (Generalized Bernoulli Number)**.** We define the *generalized Bernoulli numbers $B_{k,\varepsilon}$* attached to ε by the following identity of infinite series:

$$\sum_{a=1}^{N} \frac{\varepsilon(a) \cdot x \cdot e^{ax}}{e^{Nx} - 1} = \sum_{k=0}^{\infty} B_{k,\varepsilon} \cdot \frac{x^k}{k!}.$$

If ε is the trivial character of modulus 1 and B_k are as in Section 2.1, then $B_{k,\varepsilon} = B_k$, except when $k = 1$, in which case $B_{1,\varepsilon} = -B_1 = 1/2$ (see Exercise 5.2).

5.2.1. Algebraically Computing Generalized Bernoulli Numbers.

Let $\mathbb{Q}(\varepsilon)$ denote the field generated by the image of the character ε; thus $\mathbb{Q}(\varepsilon)$ is the cyclotomic extension $\mathbb{Q}(\zeta_n)$, where n is the order of ε.

Algorithm 5.2 (Generalized Bernoulli Numbers)**.** *Given an integer $k \geq 0$ and any Dirichlet character ε with modulus N, this algorithm computes the generalized Bernoulli numbers $B_{j,\varepsilon}$, for $j \leq k$.*

(1) Compute $g = x/(e^{Nx}-1) \in \mathbb{Q}[[x]]$ to precision $O(x^{k+1})$ by computing $e^{Nx} - 1 = \sum_{n\geq 1} N^n x^n/n!$ to precision $O(x^{k+2})$ and computing the inverse $1/(e^{Nx} - 1)$, then multiplying by x.

(2) For each $a = 1, \ldots, N$, compute $f_a = g \cdot e^{ax} \in \mathbb{Q}[[x]]$, to precision $O(x^{k+1})$. This requires computing $e^{ax} = \sum_{n\geq 0} a^n x^n/n!$ to precision $O(x^{k+1})$. (Omit computation of e^{Nx} if $N > 1$ since then $\varepsilon(N) = 0$.)

(3) Then for $j \leq k$, we have

$$B_{j,\varepsilon} = j! \cdot \sum_{a=1}^{N} \varepsilon(a) \cdot c_j(f_a),$$

where $c_j(f_a)$ is the coefficient of x^j in f_a.

Note that in steps (1) and (2) we compute the power series doing arithmetic only in $\mathbb{Q}[[x]]$, not in $\mathbb{Q}(\varepsilon)[[x]]$, which could be much less efficient if ε has large order. In step (1) if k is huge, we could compute the inverse $1/(e^{Nx} - 1)$ using asymptotically fast arithmetic and Newton iteration.

Example 5.3. The nontrivial character ε with modulus 4 has order 2 and takes values in $\mathbb{Q}$. The Bernoulli numbers $B_{k,\varepsilon}$ for k even are all 0 and for

k odd they are

$$\begin{aligned}
B_{1,\varepsilon} &= -1/2,\\
B_{3,\varepsilon} &= 3/2,\\
B_{5,\varepsilon} &= -25/2,\\
B_{7,\varepsilon} &= 427/2,\\
B_{9,\varepsilon} &= -12465/2,\\
B_{11,\varepsilon} &= 555731/2,\\
B_{13,\varepsilon} &= -35135945/2,\\
B_{15,\varepsilon} &= 2990414715/2,\\
B_{17,\varepsilon} &= -329655706465/2,\\
B_{19,\varepsilon} &= 45692713833379/2.
\end{aligned}$$

Example 5.4. The generalized Bernoulli numbers need not be in $\mathbb{Q}$. Suppose ε is the mod 5 character such that $\varepsilon(2) = i = \sqrt{-1}$. Then $B_{k,\varepsilon} = 0$ for k even and

$$\begin{aligned}
B_{1,\varepsilon} &= \frac{-i-3}{5},\\
B_{3,\varepsilon} &= \frac{6i+12}{5},\\
B_{5,\varepsilon} &= \frac{-86i-148}{5},\\
B_{7,\varepsilon} &= \frac{2366i+3892}{5},\\
B_{9,\varepsilon} &= \frac{-108846i-176868}{5},\\
B_{11,\varepsilon} &= \frac{7599526i+12309572}{5},\\
B_{13,\varepsilon} &= \frac{-751182406i-1215768788}{5},\\
B_{15,\varepsilon} &= \frac{99909993486i+161668772052}{5},\\
B_{17,\varepsilon} &= \frac{-17209733596766i-27846408467908}{5}.
\end{aligned}$$

Example 5.5. We use SAGE to compute some of the above generalized Bernoulli numbers. First we define the character and verify that $\varepsilon(2) = i$ (note that in SAGE `zeta4` is $\sqrt{-1}$).

```
sage: G = DirichletGroup(5)
sage: e = G.0
sage: e(2)
zeta4
```

We compute the Bernoulli number $B_{1,\varepsilon}$.

```
sage: e.bernoulli(1)
-1/5*zeta4 - 3/5
```

We compute $B_{9,\varepsilon}$.

```
sage: e.bernoulli(9)
-108846/5*zeta4 - 176868/5
```

Proposition 5.6. *If $\varepsilon(-1) \neq (-1)^k$ and $k \geq 2$, then $B_{k,\varepsilon} = 0$.*

Proof. See Exercise 5.3. □

5.2.2. Computing Generalized Bernoulli Numbers Analytically.

This section, which was written jointly with Kevin McGown, is about a way to compute generalized Bernoulli numbers, which is similar to the algorithm in Section 2.7.

Let χ be a primitive Dirichlet character modulo its conductor f. Note from the definition of Bernoulli numbers that if $\sigma \in \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, then

$$\sigma(B_{n,\chi}) = B_{n,\sigma(\chi)}. \tag{5.2.1}$$

For any character χ, we define the Gauss sum $\tau(\chi)$ as

$$\tau(\chi) = \sum_{r=1}^{f-1} \chi(r)\,\zeta^r\,,$$

where $\zeta = \exp(2\pi i/f)$ is the principal fth root of unity. The Dirichlet L-function for χ for $\mathrm{Re}(s) > 1$ is

$$L(s,\chi) = \sum_{n=1}^{\infty} \chi(n)\,n^{-s}\,.$$

In the right half plane $\{s \in \mathbb{C} \mid \mathrm{Re}(s) > 1\}$ this function is analytic, and because χ is multiplicative, we have the Euler product representation

$$L(s,\chi) = \prod_{p \text{ prime}} \left(1 - \chi(p)p^{-s}\right)^{-1}\,. \tag{5.2.2}$$

We note (but will not use) that through analytic continuation $L(s,\chi)$ can be extended to a meromorphic function on the entire complex plane.

If χ is a nonprincipal primitive Dirichlet character of conductor f such that $\chi(-1) = (-1)^n$, then (see, e.g., [**Wan82**])

$$L(n, \chi) = (-1)^{n-1} \frac{\tau(\chi)}{2} \left(\frac{2\pi i}{f}\right)^n \frac{B_{n,\overline{\chi}}}{n!}\,.$$

Solving for the Bernoulli number yields

$$B_{n,\chi} = (-1)^{n-1} \frac{2n!}{\tau(\overline{\chi})} \left(\frac{f}{2\pi i}\right)^n L(n, \overline{\chi})\,.$$

This allows us to give decimal approximations for $B_{n,\chi}$. It remains to compute $B_{n,\chi}$ exactly (i.e., as an algebraic integer). To simplify the above expression, we define

$$K_{n,\chi} = (-1)^{n-1}\, 2n! \left(\frac{f}{2i}\right)^n$$

and write

$$B_{n,\chi} = \frac{K_{n,\chi}}{\pi^n\, \tau(\overline{\chi})}\, L(n, \overline{\chi})\,. \tag{5.2.3}$$

Note that we can compute $K_{n,\chi}$ exactly in the field $\mathbb{Q}(i)$.

The following result identifies the denominator of $B_{n,\chi}$.

Theorem 5.7. *Let n and χ be as above, and define an integer d as follows:*

$$d = \begin{cases} 1 & \textit{if } f \textit{ is divisible by two distinct primes,} \\ 2 & \textit{if } f = 4, \\ 1 & \textit{if } f = 2^\mu,\ \mu > 2, \\ np & \textit{if } f = p,\ p > 2, \\ (1 - \chi(1+p)) & \textit{if } f = p^\mu,\ p > 2,\ \mu > 1. \end{cases}$$

Then $dn^{-1} B_{n,\chi}$ is integral.

Proof. See [**Car59a**] for the proof and [**Car59b**] for further details. □

To compute the algebraic integer $dn^{-1}B_{n,\chi}$, and we compute $L(n, \overline{\chi})$ to very high precision using the Euler product (5.2.2) and the formula (5.2.3). We carry out the same computation for each of the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ conjugates of χ, which by (5.2.1) yields the conjugates of $dn^{-1}B_{n,\chi}$. We can then write down the characteristic polynomial of $dn^{-1}B_{n,\chi}$ to very high precision and recognize the coefficients as rational integers. Finally, we determine which of the roots of the characteristic polynomial is $dn^{-1}B_{n,\chi}$ by approximating them all numerically to high precision and seeing which is closest to our numerical approximation to $dn^{-1}B_{n,\chi}$. The details are similar to what is explained in Section 2.7.

5.3. Explicit Basis for the Eisenstein Subspace

Suppose χ and ψ are primitive Dirichlet characters with conductors L and R, respectively. Let

$$E_{k,\chi,\psi}(q) = c_0 + \sum_{m\geq 1}\left(\sum_{n\mid m}\psi(n)\cdot\chi(m/n)\cdot n^{k-1}\right)q^m \in \mathbb{Q}(\chi,\psi)[[q]], \tag{5.3.1}$$

where

$$c_0 = \begin{cases} 0 & \text{if } L > 1,\\ -\dfrac{B_{k,\psi}}{2k} & \text{if } L = 1.\end{cases}$$

Note that when $\chi = \psi = 1$ and $k \geq 4$, then $E_{k,\chi,\psi} = E_k$, where E_k is from Chapter 1.

Miyake proves statements that imply the following in [**Miy89**, Ch. 7].

Theorem 5.8. *Suppose t is a positive integer and χ, ψ are as above and that k is a positive integer such that $\chi(-1)\psi(-1) = (-1)^k$. Except when $k = 2$ and $\chi = \psi = 1$, the power series $E_{k,\chi,\psi}(q^t)$ defines an element of $M_k(RLt, \chi\psi)$. If $\chi = \psi = 1$, $k = 2$, $t > 1$, and $E_2(q) = E_{k,\chi,\psi}(q)$, then $E_2(q) - tE_2(q^t)$ is a modular form in $M_2(\Gamma_0(t))$.*

Theorem 5.9. *The Eisenstein series in $M_k(N,\varepsilon)$ coming from Theorem 5.8 with $RLt \mid N$ and $\chi\psi = \varepsilon$ form a basis for the Eisenstein subspace $E_k(N,\varepsilon)$.*

Theorem 5.10. *The Eisenstein series $E_{k,\chi,\psi}(q) \in M_k(RL)$ defined above are eigenforms (i.e., eigenvectors for all Hecke operators T_n). Also $E_2(q) - tE_2(q^t)$, for $t > 1$, is an eigenform.*

Since $E_{k,\chi,\psi}(q)$ is normalized so the coefficient of q is 1, the eigenvalue of T_m is the coefficient

$$\sum_{n\mid m}\psi(n)\cdot\chi(m/n)\cdot n^{k-1}$$

of q^m (see Proposition 9.10). Also for $f = E_2(q) - tE_2(q^t)$ with $t > 1$ prime, the coefficient of q is 1, $T_m(f) = \sigma_1(m)\cdot f$ for $(m,t) = 1$, and $T_t(f) = ((t+1) - t)f = f$.

Algorithm 5.11 (Enumerating Eisenstein Series)**.** *Given a weight k and a Dirichlet character ε of modulus N, this algorithm computes a basis for the Eisenstein subspace $E_k(N,\varepsilon)$ of $M_k(N,\varepsilon)$ to precision $O(q^r)$.*

(1) [Weight 2 Trivial Character?] If $k = 2$ and $\varepsilon = 1$, output the Eisenstein series $E_2(q) - tE_2(q^t)$, for each divisor $t \mid N$ with $t \neq 1$, and then terminate.

(2) [Empty Space?] If $\varepsilon(-1) \neq (-1)^k$, output the empty list.
(3) [Compute Dirichlet Group] Let $G = D(N, \mathbb{Q}(\zeta_n))$ be the group of Dirichlet characters with values in $\mathbb{Q}(\zeta_n)$, where n is the exponent of $(\mathbb{Z}/N\mathbb{Z})^*$.
(4) [Compute Conductors] Compute the conductor of every element of G using Algorithm 4.19.
(5) [List Characters χ] Form a list V of all Dirichlet characters $\chi \in G$ such that $\mathrm{cond}(\chi) \cdot \mathrm{cond}(\chi/\varepsilon)$ divides N.
(6) [Compute Eisenstein Series] For each character χ in V, let $\psi = \chi/\varepsilon$ and compute $E_{k,\chi,\psi}(q^t) \pmod{q^r}$ for each divisor t of $N/(\mathrm{cond}(\chi) \cdot \mathrm{cond}(\psi))$. Here we compute $E_{k,\chi,\psi}(q^t) \pmod{q^r}$ using (5.3.1) and Algorithm 5.2.

Remark 5.12. Algorithm 5.11 is what is currently used in SAGE. It might be better to first reduce to the prime power case by writing all characters as a product of local characters and combine steps (4) and (5) into a single step that involves orders. However, this might make things more obscure.

Example 5.13. The following is a basis of Eisenstein series for $E_2(\Gamma_1(13))$.

$$\begin{aligned}
f_1 &= \frac{1}{2} + q + 3q^2 + 4q^3 + \cdots\,,\\
f_2 &= -\frac{7}{13}\zeta_{12}^2 - \frac{11}{13} + q + \left(2\zeta_{12}^2 + 1\right) q^2 + \left(-3\zeta_{12}^2 + 1\right) q^3 + \cdots\,,\\
f_3 &= q + \left(\zeta_{12}^2 + 2\right) q^2 + \left(-\zeta_{12}^2 + 3\right) q^3 + \cdots\,,\\
f_4 &= -\zeta_{12}^2 + q + \left(2\zeta_{12}^2 - 1\right) q^2 + \left(3\zeta_{12}^2 - 2\right) q^3 + \cdots\,,\\
f_5 &= q + \left(\zeta_{12}^2 + 1\right) q^2 + \left(\zeta_{12}^2 + 2\right) q^3 + \cdots\,,\\
f_6 &= -1 + q + -q^2 + 4q^3 + \cdots\,,\\
f_7 &= q + q^2 + 4q^3 + \cdots\,,\\
f_8 &= \zeta_{12}^2 - 1 + q + \left(-2\zeta_{12}^2 + 1\right) q^2 + \left(-3\zeta_{12}^2 + 1\right) q^3 + \cdots\,,\\
f_9 &= q + \left(-\zeta_{12}^2 + 2\right) q^2 + \left(-\zeta_{12}^2 + 3\right) q^3 + \cdots\,,\\
f_{10} &= \frac{7}{13}\zeta_{12}^2 - \frac{18}{13} + q + \left(-2\zeta_{12}^2 + 3\right) q^2 + \left(3\zeta_{12}^2 - 2\right) q^3 + \cdots\,,\\
f_{11} &= q + \left(-\zeta_{12}^2 + 3\right) q^2 + \left(\zeta_{12}^2 + 2\right) q^3 + \cdots\,.
\end{aligned}$$

We computed it as follows:

```
sage: E = EisensteinForms(Gamma1(13),2)
sage: E.eisenstein_series()
```

We can also compute the parameters χ, ψ, t that define each series:

```
sage: e = E.eisenstein_series()
sage: for e in E.eisenstein_series():
...       print e.parameters()
...
([1], [1], 13)
([1], [zeta6], 1)
([zeta6], [1], 1)
([1], [zeta6 - 1], 1)
([zeta6 - 1], [1], 1)
([1], [-1], 1)
([-1], [1], 1)
([1], [-zeta6], 1)
([-zeta6], [1], 1)
([1], [-zeta6 + 1], 1)
([-zeta6 + 1], [1], 1)
```

5.4. Exercises

5.1 Suppose A and B are diagonalizable linear transformations of a finite-dimensional vector space V over an algebraically closed field K and that $AB = BA$. Prove there is a basis for V so that the matrices of A and B with respect to that basis are both simultaneously diagonal.

5.2 If ε is the trivial character of modulus 1 and B_k are as in Section 2.1, then $B_{k,\varepsilon} = B_k$, except when $k = 1$, in which case $B_{1,\varepsilon} = -B_1 = 1/2$.

5.3 Prove that for $k \geq 2$ if $\varepsilon(-1) \neq (-1)^k$, then $B_{k,\varepsilon} = 0$.

5.4 Show that the dimension of the Eisenstein subspace $E_3(\Gamma_1(13))$ is 12 by finding a basis of series $E_{k,\chi,\psi}$. You do not have to write down the q-expansions of the series, but you do have to figure out which χ, ψ to use.

Chapter 6

Dimension Formulas

When computing with spaces of modular forms, it is helpful to have easy-to-compute formulas for dimensions of these spaces. Such formulas provide a check on the output of the algorithms from Chapter 8 that compute explicit bases for spaces of modular forms. We can also use dimension formulas to improve the efficiency of some of the algorithms in Chapter 8, since we can use them to determine the ranks of certain matrices without having to explicitly compute those matrices. Dimension formulas can also be used in generating bases of q-expansions; if we know the dimension of $M_k(N, \varepsilon)$ and if we have a process for computing q-expansions of elements of $M_k(N, \varepsilon)$, e.g., multiplying together q-expansions of certain forms of smaller weight, then we can tell when we are done generating $M_k(N, \varepsilon)$.

This chapter contains formulas for dimensions of spaces of modular forms, along with some remarks about how to evaluate these formulas. In some cases we give dimension formulas for spaces that we will define in later chapters. We also give many examples, some of which were computed using the modular symbols algorithms from Chapter 8.

Many of the dimension formulas and algorithms we give below grew out of Shimura's book [**Shi94**] and a program that Bruce Kaskel wrote (around 1996) in PARI, which Kevin Buzzard extended. That program codified dimension formulas that Buzzard and Kaskel found or extracted from the literature (mainly [**Shi94**, §2.6]). The algorithms for dimensions of spaces with nontrivial character are from [**CO77**], with some refinements suggested by Kevin Buzzard.

For the rest of this chapter, N denotes a positive integer and $k \geq 2$ is an integer. We will give *no simple formulas* for dimensions of spaces of weight 1 modular forms; in fact, it might not be possible to give such formulas since the methods used to derive the formulas below do not apply in the case $k = 1$. If $k = 0$, the only modular forms are the constants, and for $k < 0$ the dimension of $M_k(N, \varepsilon)$ is 0.

For a nonzero integer N and a prime p, let $v_p(N)$ be the largest integer e such that $p^e \mid N$. In the formulas in this chapter, p always denotes a prime number. Let $M_k(N, \varepsilon)$ be the space of modular forms of level N weight k and character ε, and let $S_k(N, \varepsilon)$ and $E_k(N, \varepsilon)$ be the cuspidal and Eisenstein subspaces, respectively.

The dimension formulas below for $S_k(\Gamma_0(N))$, $S_k(\Gamma_1(N))$, $E_k(\Gamma_0(N))$ and $E_k(\Gamma_1(N))$ can be found in [**DS05**, Ch. 3], [**Shi94**, §2.6][1] and [**Miy89**, §2.5]. They are derived using the Riemann-Roch Theorem applied to the covering $X_0(N) \to X_0(1)$ or $X_1(N) \to X_1(1)$ and appropriately chosen divisors. It would be natural to give a sample argument along these lines at this point, but we will not since it easy to find such arguments in other books and survey papers (see, e.g., [**DI95**]). So you will not learn much about how to derive dimension formulas from this chapter. What you will learn is precisely what the dimension formulas are, which is something that is often hard to extract from obscure references.

In addition to reading this chapter, the reader may wish to consult [**Mar05**] for proofs of similar dimension formulas, asymptotic results, and a nonrecursive formula for dimensions of certain new subspaces.

6.1. Modular Forms for $\Gamma_0(N)$

For any prime p and any positive integer N, let $v_p(N)$ be the power of p that divides N. Also, let

$$\mu_0(N) = \prod_{p \mid N} \left(p^{v_p(N)} + p^{v_p(N)-1}\right),$$

$$\mu_{0,2}(N) = \begin{cases} 0 & \text{if } 4 \mid N, \\ \prod_{p \mid N} \left(1 + \left(\frac{-4}{p}\right)\right) & \text{otherwise,} \end{cases}$$

$$\mu_{0,3}(N) = \begin{cases} 0 & \text{if } 2 \mid N \text{ or } 9 \mid N, \\ \prod_{p \mid N} \left(1 + \left(\frac{-3}{p}\right)\right) & \text{otherwise,} \end{cases}$$

$$c_0(N) = \sum_{d \mid N} \varphi(\gcd(d, N/d)),$$

$$g_0(N) = 1 + \frac{\mu_0(N)}{12} - \frac{\mu_{0,2}(N)}{4} - \frac{\mu_{0,3}(N)}{3} - \frac{c_0(N)}{2}.$$

[1] The formulas in [**Shi94**, §2.6] contain some minor mistakes.

Note that $\mu_0(N)$ is the index of $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbb{Z})$ (see Exercise 6.1).

Proposition 6.1. *We have* $\dim S_2(\Gamma_0(N)) = g_0(N)$, *and for* $k \geq 4$ *even,*

$$\dim S_k(\Gamma_0(N)) = (k-1)\cdot(g_0(N)-1) \;+\; \left(\frac{k}{2}-1\right)\cdot c_0(N)$$
$$+\,\mu_{0,2}(N)\cdot\left\lfloor\frac{k}{4}\right\rfloor \;+\; \mu_{0,3}(N)\cdot\left\lfloor\frac{k}{3}\right\rfloor.$$

The dimension of the Eisenstein subspace is

$$\dim E_k(\Gamma_0(N)) = \begin{cases} c_0(N) & \textit{if } k \neq 2,\\ c_0(N)-1 & \textit{if } k = 2.\end{cases}$$

The following is a table of $\dim S_k(\Gamma_0(N))$ for some values of N and k:

N	$S_2(\Gamma_0(N))$	$S_4(\Gamma_0(N))$	$S_6(\Gamma_0(N))$	$S_{24}(\Gamma_0(N))$
1	0	0	0	2
10	0	3	5	33
11	1	2	4	22
100	7	36	66	336
389	32	97	161	747
1000	131	430	730	3430
2007	221	806	1346	6206
100000	14801	44800	74800	344800

Example 6.2. Use the commands `dimension_cusp_forms`, `dimension_eis`, and `dimension_modular_forms` to compute the dimensions of the three spaces $S_k(\Gamma_0(N))$, $E_k(\Gamma_0(N))$ and $M_k(\Gamma_0(N))$, respectively. For example,

```
sage: dimension_cusp_forms(Gamma0(2007),2)
221
sage: dimension_eis(Gamma0(2007),2)
7
sage: dimension_modular_forms(Gamma0(2007),2)
228
```

Remark 6.3. Csirik, Wetherell, and Zieve prove in [**CWZ01**] that a random positive integer has probability 0 of being a value of

$$g_0(N) = \dim S_2(\Gamma_0(N)),$$

and they give bounds on the size of the set of values of $g_0(N)$ below some given x. For example, they show that $150, 180, 210, 286, 304, 312, \ldots$ are the first few integers that are not of the form $g_0(N)$ for any N. See Figure 6.1.1 for a plot of the very erratic function $g_0(N)$. In contrast, the function $k \mapsto \dim S_{2k}(\Gamma_0(12))$ is very well behaved (see Figure 6.1.2).

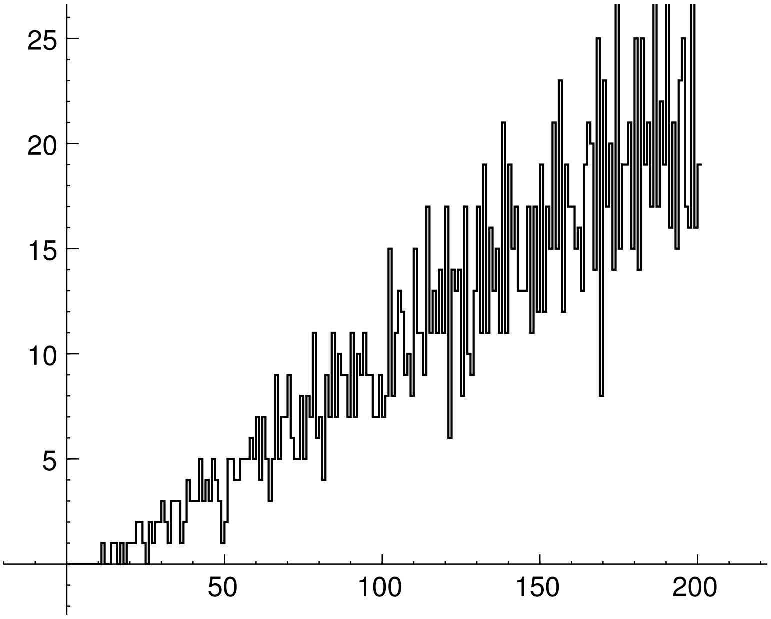

Figure 6.1.1. Dimension of $S_2(\Gamma_0(N))$ as a function of N.

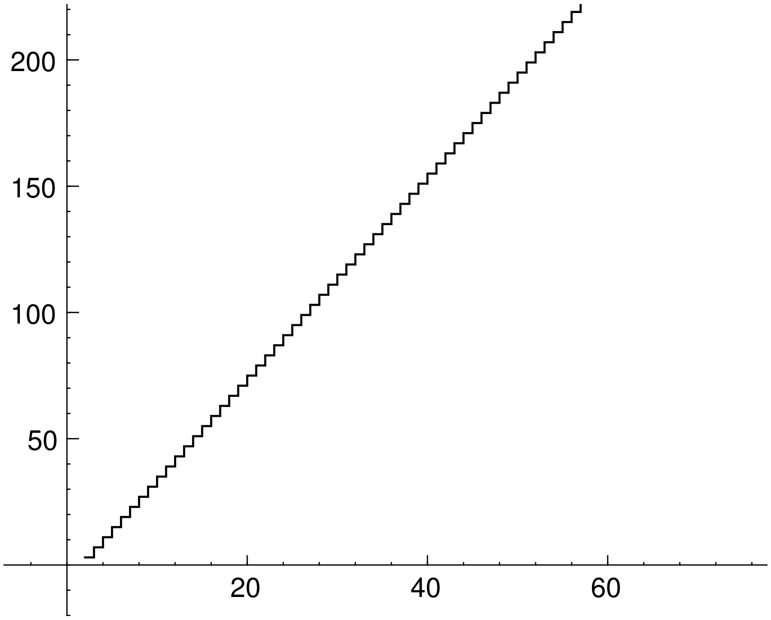

Figure 6.1.2. Dimension of $S_{2k}(\Gamma_0(12))$ as a function of k.

6.1.1. New and Old Subspaces. In this section we assume the reader is either familiar with newforms or has read Section 9.2.

For any integer R, let

$$\overline{\mu}(R) = \begin{cases} 0 & \text{if } p^3 \mid R \text{ for some } p, \\ \prod_{p\|R} -2 & \text{otherwise,} \end{cases}$$

where the product is over primes that exactly divide R. Note that $\overline{\mu}$ is *not* the Moebius function, but it has a similar flavor.

Proposition 6.4. *The dimension of the new subspace is*

$$\dim S_k(\Gamma_0(N))_{\text{new}} = \sum_{M|N} \overline{\mu}(N/M) \cdot \dim S_k(\Gamma_0(M)),$$

where the sum is over the positive divisors M of N. As a consequence of Theorem 9.4, we also have

$$\dim S_k(\Gamma_0(N)) = \sum_{M|N} \sigma_0(N/M) \dim S_k(\Gamma_0(M))_{\text{new}},$$

where $\sigma_0(N/M)$ is the number of divisors of N/M.

Example 6.5. We compute the dimension of the new subspace of $S_k(\Gamma_0(N))$ using the SAGE command `dimension_new_cusp_forms` as follows:

```
sage: dimension_new_cusp_forms(Gamma0(11),12)
8
sage: dimension_cusp_forms(Gamma0(11),12)
10
sage: dimension_new_cusp_forms(Gamma0(2007),12)
1017
sage: dimension_cusp_forms(Gamma0(2007),12)
2460
```

6.2. Modular Forms for $\Gamma_1(N)$

This section follows Section 6.1 closely, but with suitable modifications with $\Gamma_0(N)$ replaced by $\Gamma_1(N)$.

Define functions of a positive integer N by the following formulas:

$$\mu_1(N) = \begin{cases} \mu_0(N) & \text{if } N = 1, 2, \\ \dfrac{\phi(N) \cdot \mu_0(N)}{2} & \text{otherwise,} \end{cases}$$

$$\mu_{1,2}(N) = \begin{cases} 0 & \text{if } N \geq 4, \\ \mu_{0,2}(N) & \text{otherwise,} \end{cases}$$

$$\mu_{1,3}(N) = \begin{cases} 0 & \text{if } N \geq 4, \\ \mu_{0,3}(N) & \text{otherwise,} \end{cases}$$

$$c_1(N) = \begin{cases} c_0(N) & \text{if } N = 1, 2, \\ 3 & \text{if } N = 4, \\ \displaystyle\sum_{d \mid N} \frac{\phi(d)\phi(N/d)}{2} & \text{otherwise,} \end{cases}$$

$$g_1(N) = 1 + \frac{\mu_1(N)}{12} - \frac{\mu_{1,2}(N)}{4} - \frac{\mu_{1,3}(N)}{3} - \frac{c_1(N)}{2}.$$

Note that $g_1(N)$ is the genus of the modular curve $X_1(N)$ (associated to $\Gamma_1(N)$) and $c_1(N)$ is the number of cusps of $X_1(N)$.

Proposition 6.6. *We have* $\dim S_2(\Gamma_1(N)) = g_1(N)$. *If* $N \leq 2$, *then* $\Gamma_0(N) = \Gamma_1(N)$ *so*

$$\dim S_k(\Gamma_1(N)) = \dim S_k(\Gamma_0(N)),$$

where $\dim S_k(\Gamma_0(N))$ *is given by the formula of Proposition 6.1. If* $k \geq 3$, *let*

$$a(N,k) = (k-1)(g_1(N) - 1) + \left(\frac{k}{2} - 1\right) \cdot c_1(N).$$

Then for $N \geq 3$,

$$\dim S_k(\Gamma_1(N)) = \begin{cases} a + 1/2 & \textit{if } N = 4 \textit{ and } 2 \nmid k, \\ a + \lfloor k/3 \rfloor & \textit{if } N = 3, \\ a & \textit{otherwise.} \end{cases}$$

The dimension of the Eisenstein subspace is as follows:

$$\dim E_k(\Gamma_1(N)) = \begin{cases} c_1(N) & \textit{if } k \neq 2, \\ c_1(N) - 1 & \textit{if } k = 2. \end{cases}$$

The dimension of the new subspace of $M_k(\Gamma_1(N))$ *is*

$$\dim S_k(\Gamma_1(N))_{\text{new}} = \sum_{M \mid N} \overline{\mu}(N/M) \cdot \dim S_k(\Gamma_1(M)),$$

where $\overline{\mu}$ *is as in the statement of Proposition 6.4.*

Remark 6.7. Since $M_k = S_k \oplus E_k$, the formulas above for $\dim S_k$ and $\dim E_k$ also yield a formula for the dimension of M_k.

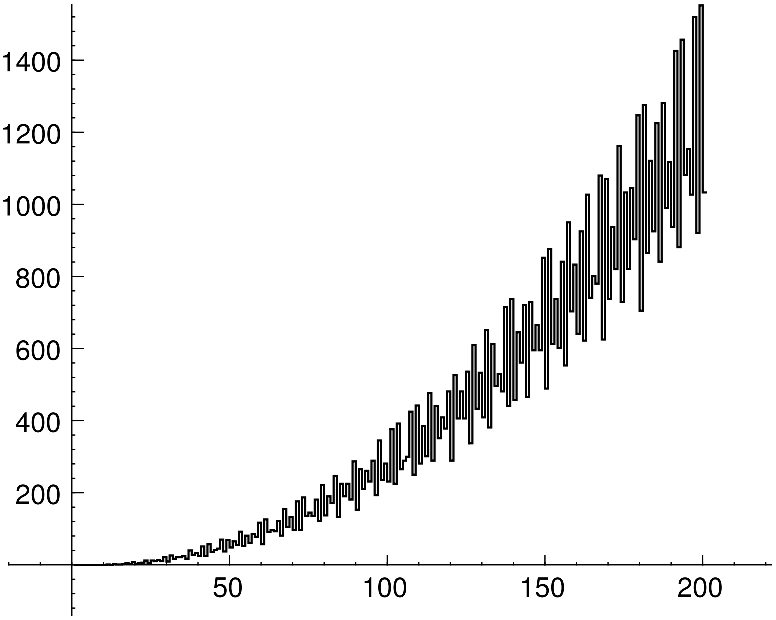

Figure 6.2.1. Dimension of $S_2(\Gamma_1(N))$ as a function of N.

The following table contains the dimension of $S_k(\Gamma_1(N))$ for some sample values of N and k:

N	$S_2(\Gamma_1(N))$	$S_3(\Gamma_1(N))$	$S_4(\Gamma_1(N))$	$S_{24}(\Gamma_1(N))$
1	0	0	0	2
10	0	2	5	65
11	1	5	10	110
100	231	530	830	6830
389	6112	12416	18721	144821
1000	28921	58920	88920	688920
2007	147409	296592	445776	3429456
100000	299792001	599792000	899792000	6899792000

Example 6.8. We compute dimensions of spaces of modular forms for $\Gamma_1(N)$:

```
sage: dimension_cusp_forms(Gamma1(2007),2)
147409
sage: dimension_eis(Gamma1(2007),2)
3551
sage: dimension_modular_forms(Gamma1(2007),2)
150960
```

6.3. Modular Forms with Character

Fix a Dirichlet character ε of modulus N, and let c be the conductor of ε (we do *not* assume that ε is primitive). Assume that $\varepsilon \neq 1$, since otherwise $M_k(N,\varepsilon) = M_k(\Gamma_0(N))$ and the formulas of Section 6.1 apply. Also, assume that $\varepsilon(-1) = (-1)^k$, since otherwise $\dim M_k(\Gamma_0(N)) = 0$. In this section we discuss formulas for computing each of $M_k(N,\varepsilon)$, $S_k(N,\varepsilon)$ and $E_k(N,\varepsilon)$.

In [**CO77**], Cohen and Oesterlé assert (without *published* proof; see Remark 6.11 below) that for any $k \in \mathbb{Z}$ and N, ε as above,

$$\begin{aligned}\dim S_k(N,\varepsilon) &- \dim M_{2-k}(N,\varepsilon)\\ &= \frac{k-1}{12}\cdot \mu_0(N) \;-\; \frac{1}{2}\cdot \prod_{p\mid N}\lambda(p,N,v_p(c))\\ &\quad + \gamma_4(k)\cdot \sum_{x\in A_4(N)}\varepsilon(x) \;+\; \gamma_3(k)\cdot\sum_{x\in A_3(N)}\varepsilon(x)\end{aligned}$$

where $\mu_0(N)$ is as in Section 6.1, $A_4(N) = \{x \in \mathbb{Z}/N\mathbb{Z} : x^2+1 = 0\}$ and $A_3(N) = \{x \in \mathbb{Z}/N\mathbb{Z} : x^2+x+1 = 0\}$, and γ_3, γ_4 are

$$\gamma_4(k) = \begin{cases} -1/4 & \text{if } k \equiv 2 \pmod 4,\\ 1/4 & \text{if } k \equiv 0 \pmod 4,\\ 0 & \text{if } k \text{ is odd.}\end{cases}$$

$$\gamma_3(k) = \begin{cases} -1/3 & \text{if } k \equiv 2 \pmod 3,\\ 1/3 & \text{if } k \equiv 0 \pmod 3,\\ 0 & \text{if } k \equiv 1 \pmod 3.\end{cases}$$

It remains to define λ. Fix a prime divisor $p \mid N$ and let $r = v_p(N)$. Then

$$\lambda(p,N,v_p(c)) = \begin{cases} p^{\frac{r}{2}} + p^{\frac{r}{2}-1} & \text{if } 2\cdot v_p(c) \le r \text{ and } 2 \mid r,\\ 2\cdot p^{\frac{r-1}{2}} & \text{if } 2\cdot v_p(c) \le r \text{ and } 2 \nmid r,\\ 2\cdot p^{r-v_p(c)} & \text{if } 2\cdot v_p(c) > r.\end{cases}$$

This flexible formula can be used to compute the dimension of $M_k(N,\varepsilon)$, $S_k(N,\varepsilon)$, and $E_k(N,\varepsilon)$ for any N, ε, $k \neq 1$, by using that

$$\begin{aligned}
\dim S_k(N,\varepsilon) &= 0 \qquad \text{if } k \leq 0,\\
\dim M_k(N,\varepsilon) &= 0 \qquad \text{if } k < 0,\\
\dim M_0(N,\varepsilon) &= 1 \qquad \text{if } k = 0.
\end{aligned}$$

One thing that is not straightforward when implementing an algorithm to compute the above dimension formulas is how to efficiently compute the sets $A_4(N)$ and $A_6(N)$. Kevin Buzzard suggested the following two algorithms. Note that if k is odd, then $\gamma_4(k) = 0$, so the sum over $A_4(N)$ is only needed when k is even.

Algorithm 6.9 (Sum over $A_4(N)$)**.** *Given a positive integer N and an even Dirichlet character ε of modulus N, this algorithm computes $\sum_{x\in A_4(N)} \varepsilon(x)$.*

```
(1) [Factor $N$] Compute the prime factorization $p_1^{e_1} \cdots p_n^{e_n}$ of $N$.
(2) [Initialize] Set $t = 1$ and $i = 0$.
(3) [Loop Over Prime Divisors] Set $i = i + 1$. If $i > n$, return $t$.
    Otherwise set $p = p_i$ and $e = e_i$.
    (a) If $p \equiv 3 \pmod 4$, return 0.
    (b) If $p = 2$ and $e > 1$, return 0.
    (c) If $p = 2$ and $e = 1$, go to step (3).
    (d) Compute a generator $a \in (\mathbb{Z}/p\mathbb{Z})^*$ using Algorithm 4.4.
    (e) Compute $\omega = a^{(p-1)/4}$.
    (f) Use the Chinese Remainder Theorem to find $x \in \mathbb{Z}/N\mathbb{Z}$ such
        that $x \equiv a \pmod p$ and $x \equiv 1 \pmod{N/p^e}$.
    (g) Set $x = x^{p^{r-1}}$.
    (h) Set $s = \varepsilon(x)$.
    (i) If $s = 1$, set $t = 2t$ and go to step (3).
    (j) If $s = -1$, set $t = -2t$ and go to step (3).
```

Proof. Note that $\varepsilon(-x) = \varepsilon(x)$, since ε is even. By the Chinese Remainder Theorem, the set $A_4(N)$ is empty if and only if there is no square root of -1 modulo some prime power divisor of p. If $A_4(N)$ is empty, the algorithm correctly detects this fact in steps (3a)–(3b). Thus assume $A_4(N)$ is nonempty. For each prime power $p_i^{e_i}$ that exactly divides N, let $x_i \in Z/N\mathbb{Z}$ be such that $x_i^2 = -1$ and $x_i \equiv 1 \pmod{p_j^{e_j}}$ for $i \neq j$. This is the value of x computed in steps (3d)–(3g) (as one sees using elementary number theory).

The next key observation is that

$$\prod_i (\varepsilon(x_i) + \varepsilon(-x_i)) = \sum_{x\in A_4(N)} \varepsilon(x), \tag{6.3.1}$$

since by the Chinese Remainder Theorem the elements of $A_4(N)$ are in bijection with the choices for a square root of -1 modulo each prime power divisors of N. The observation (6.3.1) is a huge gain from an efficiency point of view—if N had r prime factors, then $A_4(N)$ would have size 2^r, which could be prohibitive, where the product involves only r factors. To finish the proof, just note that steps (3h)–(3j) compute the local factors $\varepsilon(x_i) + \varepsilon(-x_i) = 2\varepsilon(x_i)$, where again we use that ε is even. Note that a solution of $x^2+1 \equiv 0 \pmod{p}$ lifts uniquely to a solution mod p^n for any n, because the kernel of the natural homomorphism $(\mathbb{Z}/p^n\mathbb{Z})^* \to (\mathbb{Z}/p\mathbb{Z})^*$ is a group of p-power order. □

The algorithm for computing the sum over $A_3(N)$ is similar.

For $k \geq 2$, to compute $\dim S_k(N,\varepsilon)$, use the formula directly and the fact that $\dim M_{2-k}(N,\varepsilon) = 0$, unless $\varepsilon = 1$ and $k = 2$. To compute $\dim M_k(N,\varepsilon)$ for $k \geq 2$, use the fact that the big formula at the beginning of this section is valid for any integer k to replace k by $2-k$ and that $\dim S_k(N,\varepsilon) = 0$ for $k \leq 0$ to rewrite the formula as

$$\begin{aligned}\dim M_k(N,\varepsilon) &= -(\dim S_{2-k}(N,\varepsilon) - \dim M_k(N,\varepsilon))\\ &= -\Big(\frac{1-k}{12}\cdot\mu_0(N) \;-\; \frac{1}{2}\cdot\prod_{p\mid N}\lambda(p,N,v_p(c))\\ &\qquad + \gamma_4(2-k)\cdot\sum_{x\in A_4(N)}\varepsilon(x) \;+\; \gamma_3(2-k)\cdot\sum_{x\in A_3(N)}\varepsilon(x)\Big).\end{aligned}$$

Note also that for $k = 0$, $\dim E_k(N,\varepsilon) = 1$ if and only if ε is trivial and it equals 0 otherwise. We then also obtain

$$\dim E_k(N,\varepsilon) = \dim M_k(N,\varepsilon) - \dim S_k(N,\varepsilon).$$

We can also compute $\dim E_k(N,\varepsilon)$ when $k = 1$ directly, since

$$\dim S_{2-1}(N,\varepsilon) = \dim S_1(N,\varepsilon).$$

The following table contains the dimension of $S_k(N,\varepsilon)$ for some sample values of N and k. In each case, ε is the product of characters ε_p of maximal order corresponding to the prime power factors of N (i.e., the product of the generators of the group $D(N,\mathbb{C}^*)$ of Dirichlet characters of modulus N).

N	$\dim S_2(N,\varepsilon)$	$\dim S_3(N,\varepsilon)$	$\dim S_4(N,\varepsilon)$	$\dim S_{24}(N,\varepsilon)$
1	0	0	0	2
10	0	1	0	0
11	0	1	0	0
100	13	0	43	343
389	0	64	0	0
1000	148	0	448	3448
2007	222	0	670	5150

Example 6.10. We compute the last line of the above table. First we create the character ε.

```
sage: G = DirichletGroup(2007)
sage: e = prod(G.gens(), G(1))
```

Next we compute the dimension of the four spaces.

```
sage: dimension_cusp_forms(e,2)
222
sage: dimension_cusp_forms(e,3)
0
sage: dimension_cusp_forms(e,4)
670
sage: dimension_cusp_forms(e,24)
5150
```

We can also compute dimensions of the corresponding spaces of Eisenstein series.

```
sage: dimension_eis(e,2)
4
sage: dimension_eis(e,3)
0
sage: dimension_eis(e,4)
4
sage: dimension_eis(e,24)
4
```

Remark 6.11. Cohen and Oesterlé also give dimension formulas for spaces of half-integral weight modular forms, which we do not give in this chapter. Note that [**CO77**] does not contain any *proofs* that their claimed formulas are correct, but instead they say only that "Les formules qui les donnent sont connues de beaucoup de gens et il existe plusieurs méthodes permettant de les obtenir (théorème de Riemann-Roch, application des formules de trace données par Shimura)."[2] Fortunately, in [**Que06**], Jordi Quer derives the (integral weight) formulas of [**CO77**] along with formulas for dimensions of spaces $S_k(G)$ and $M_k(G)$ for more general congruence subgroups.

Let f be the conductor of a Dirichlet character ε of modulus N. Then the dimension of the new subspace of $M_k(N,\varepsilon)$ is

$$\dim S_k(N,\varepsilon)_{\text{new}} = \sum_{M \text{ such that } f|M|N} \overline{\mu}(N/M) \cdot \dim S_k(M,\varepsilon'),$$

where $\overline{\mu}$ is as in the statement of Proposition 6.4, and ε' is the restriction of ε mod M.

Example 6.12. We compute the dimension of $S_2(2007,\varepsilon)_{\text{new}}$ for ε a quadratic character of modulus 2007.

```
sage: G = DirichletGroup(2007, QQ)
sage: e = prod(G.gens(), G(1))
sage: dimension_new_cusp_forms(e,2)
76
```

6.4. Exercises

6.1 Let μ_0 and μ_1 be as in this chapter.

(a) Prove that $\mu_0(N) = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)]$.

(b) Prove that for $N \geq 3$, $\mu_1(N) = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_1(N)]/2$, so $\mu_1(N)$ is the index of $\Gamma_1(N) \cdot \{\pm 1\}$ in $\mathrm{PSL}_2(\mathbb{Z}) = \mathrm{SL}_2(\mathbb{Z})/\{\pm 1\}$.

6.2 Use Proposition 6.4 to find a formula for $\dim S_k(\mathrm{SL}_2(\mathbb{Z}))$. Verify that this formula is the same as the one in Corollary 2.16.

6.3 Suppose either that $N = 1$ or that N is prime and $k = 2$. Prove that $M_k(\Gamma_0(N))_{\text{new}} = M_k(\Gamma_0(N))$.

6.4 Fill in the details of the proof of Algorithm 6.9.

6.5 Implement a computer program to compute $\dim S_k(\Gamma_0(N))$ as a function of k and N.

[2] The formulas that we give here are well known and there exist many methods to prove them, e.g., the Riemann-Roch theorem and applications of the trace formula of Shimura.

Chapter 7

Linear Algebra

This chapter is about several algorithms for matrix algebra over the rational numbers and cyclotomic fields. Algorithms for linear algebra over exact fields are necessary in order to implement the modular symbols algorithms that we will describe in Chapter 7. This chapter partly overlaps with [**Coh93**, Sections 2.1–2.4].

Note: We view all matrices as defining linear transformations by acting on row vectors from the right.

7.1. Echelon Forms of Matrices

Definition 7.1 (Reduced Row Echelon Form)**.** A matrix is in (reduced row) *echelon form* if each row in the matrix has more zeros at the beginning than the row above it, the first nonzero entry of every row is 1, and the first nonzero entry of any row is the only nonzero entry in its column.

Given a matrix A, there is another matrix B such that B is obtained from A by left multiplication by an invertible matrix and B is in reduced row echelon form. This matrix B is called the echelon form of A. It is unique.

A *pivot column* of A is a column of A such that the reduced row echelon form of A contains a leading 1.

Example 7.2. The following matrix is not in reduced row echelon form:

$$\begin{pmatrix} 14 & 2 & 7 & 228 & -224 \\ 0 & 0 & 3 & 78 & -70 \\ 0 & 0 & 0 & -405 & 381 \end{pmatrix}.$$

The reduced row echelon form of the above matrix is

$$\begin{pmatrix} 1 & \frac{1}{7} & 0 & 0 & -\frac{1174}{945} \\ 0 & 0 & 1 & 0 & \frac{152}{135} \\ 0 & 0 & 0 & 1 & -\frac{127}{135} \end{pmatrix}.$$

Notice that the entries of the reduced row echelon form can be rationals with large denominators even though the entries of the original matrix A are integers. Another example is the simple looking matrix

$$\begin{pmatrix} -9 & 6 & 7 & 3 & 1 & 0 & 0 & 0 \\ -10 & 3 & 8 & 2 & 0 & 1 & 0 & 0 \\ 3 & -6 & 2 & 8 & 0 & 0 & 1 & 0 \\ -8 & -6 & -8 & 6 & 0 & 0 & 0 & 1 \end{pmatrix}$$

whose echelon form is

$$\begin{pmatrix} 1 & 0 & 0 & 0 & \frac{42}{1025} & -\frac{92}{1025} & \frac{1}{25} & -\frac{9}{205} \\ 0 & 1 & 0 & 0 & \frac{716}{3075} & -\frac{641}{3075} & -\frac{2}{75} & -\frac{7}{615} \\ 0 & 0 & 1 & 0 & -\frac{83}{1025} & \frac{133}{1025} & \frac{1}{25} & -\frac{23}{410} \\ 0 & 0 & 0 & 1 & \frac{184}{1025} & -\frac{159}{1025} & \frac{2}{25} & \frac{9}{410} \end{pmatrix}.$$

A basic fact is that two matrices A and B have the same reduced row echelon form if and only if there is an invertible matrix E such that $EA = B$. Also, many standard operations in linear algebra, e.g., computation of the kernel of a linear map, intersection of subspaces, membership checking, etc., can be encoded as a question about computing the echelon form of a matrix.

The following standard algorithm computes the echelon form of a matrix.

Algorithm 7.3 (Gauss Elimination)**.** *Given an $m \times n$ matrix A over a field, the algorithm outputs the reduced row echelon form of A. Write $a_{i,j}$ for the i, j entry of A, where $0 \leq i \leq m-1$ and $0 \leq j \leq n-1$.*

(1) [Initialize] Set $k = 0$.

(2) [Clear Each Column] For each column $c = 0, 1, \ldots, n-1$, clear the cth column as follows:

   (a) [First Nonzero] Find the smallest r such that $a_{r,c} \neq 0$, or if there is no such r, go to the next column.

   (b) [Rescale] Replace row r of A by $\frac{1}{a_{r,c}}$ times row r.

   (c) [Swap] Swap row r with row k.

   (d) [Clear] For each $i = 0, \ldots, m-1$ with $i \neq k$, if $a_{i,c} \neq 0$, add $-a_{i,c}$ times row k of A to row i to clear the leading entry of the ith row.

   (e) [Increment] Set $k = k + 1$.

This algorithm takes $O(mn^2)$ arithmetic operations in the base field, where A is an $m \times n$ matrix. If the base field is $\mathbb{Q}$, the entries can become huge and arithmetic operations are then very expensive. See Section 7.3 for ways to mitigate this problem.

To conclude this section, we mention how to convert a few standard problems into questions about reduced row echelon forms of matrices. Note that one can also phrase some of these answers in terms of the echelon form, which might be easier to compute, or an LUP decomposition (lower triangular times upper triangular times permutation matrix), which the numerical analysts use.

(1) **Kernel of A:** We explain how to compute the kernel of A acting on column vectors from the right (first transpose to obtain the kernel of A acting on row vectors). Since passing to the reduced row echelon form of A is the same as multiplying on the left by an invertible matrix, the kernel of the reduce row echelon form E of A is the same as the kernel of A. There is a basis vector of $\ker(E)$ that corresponds to each nonpivot column of E. That vector has a 1 at the nonpivot column, 0's at all other nonpivot columns, and for each pivot column, the negative of the entry of A at the nonpivot column in the row with that pivot element.

(2) **Intersection of Subspaces:** Suppose W_1 and W_2 are subspace of a finite-dimensional vector space V. Let A_1 and A_2 be matrices whose columns form a basis for W_1 and W_2, respectively. Let $A = [A_1|A_2]$ be the augmented matrix formed from A_1 and A_2. Let K be the kernel of the linear transformation defined by A. Then K is isomorphic to the desired intersection. To write down the intersection explicitly, suppose that $\dim(W_1) \leq \dim(W_2)$ and do the following: For each b in a basis for K, write down the linear combination of a basis for W_1 obtained by taking the first $\dim(W_1)$ entries of the vector b. The fact that b is in $\mathrm{Ker}(A)$ implies that the vector we just wrote down is also in W_2. This is because a linear relation

$$\sum a_i w_{1,i} + \sum b_j w_{2,j} = 0,$$

i.e., an element of that kernel, is the same as

$$\sum a_i w_{1,i} = \sum -b_j w_{2,j}.$$

For more details, see [**Coh93**, Alg. 2.3.9].

7.2. Rational Reconstruction

Rational reconstruction is a process that allows one to sometimes lift an integer modulo m uniquely to a bounded rational number.

Algorithm 7.4 (Rational Reconstruction)**.** *Given an integer $a \geq 0$ and an integer $m > 1$, this algorithm computes the numerator n and denominator d of the unique rational number n/d, if it exists, with*

$$|n|, d \leq \sqrt{\frac{m}{2}} \qquad \textit{and} \qquad n \equiv ad \pmod{m}, \tag{7.2.1}$$

or it reports that there is no such number.

(1) [Reduce mod m] Replace a with the least integer between 0 and $m-1$ that is congruent to a modulo m.

(2) [Trivial Cases] If $a = 0$ or $a = 1$, return a.

(3) [Initialize] Let $b = \sqrt{m/2}$, $u = m$, $v = a$, and set $U = (1, 0, u)$ and $V = (0, 1, v)$. Use the notation U_i and V_i to refer to the ith entries of U, V, for $i = 0, 1, 2$.

(4) [Iterate] Do the following as long as $|V_2| > b$: Set $q = \lfloor U_2/V_2 \rfloor$, set $T = U - qV$, and set $U = V$ and $V = T$.

(5) [Numerator and Denominator] Set $d = |V_1|$ and $n = V_2$.

(6) [Good?] If $d \leq b$ and $\gcd(n, d) = 1$, return n/d; otherwise report that there is no rational number as in (7.2.1).

Algorithm 7.4 for rational reconstruction is described (with proof) in [**Knu**, pgs. 656–657] as the solution to Exercise 51 on page 379 in that book. See, in particular, the paragraph right in the middle of page 657, which describes the algorithm. Knuth attributes this rational reconstruction algorithm to Wang, Kornerup, and Gregory from around 1983.

We now give an indication of why Algorithm 7.4 computes the rational reconstruction of $a \pmod{m}$, leaving the precise details and uniqueness to [**Knu**, pgs. 656–657]. At each step in Algorithm 7.4, the 3-tuple $V = (v_0, v_1, v_2)$ satisfies

$$m \cdot v_0 + a \cdot v_1 = v_2, \tag{7.2.2}$$

and similarly for U. When computing the usual extended gcd, at the end $v_2 = \gcd(a, m)$ and v_0, v_1 give a representation of the v_2 as a $\mathbb{Z}$-linear combination of m and a. In Algorithm 7.4, we are instead interested in finding a rational number n/d such that $n \equiv a \cdot d \pmod{m}$. If we set $n = v_2$ and $d = v_1$ in (7.2.2) and rearrange, we obtain

$$n = a \cdot d + m \cdot v_0.$$

Thus at *every* step of the algorithm we find a rational number n/d such that $n \equiv ad \pmod{m}$. The problem at intermediate steps is that, e.g., v_0 could be 0, or n or d could be too large.

Example 7.5. We compute an example using SAGE.

```
sage: p = 389
sage: k = GF(p)
sage: a = k(7/13); a
210
sage: a.rational_reconstruction()
7/13
```

7.3. Echelon Forms over $\mathbb{Q}$

A difficulty with computation of the echelon form of a matrix over the rational numbers is that arithmetic with large rational numbers is time-consuming; each addition potentially requires a gcd and numerous additions and multiplications of integers. Moreover, the entries of A during intermediate steps of Algorithm 7.3 can be huge even though the entries of A and the answer are small. For example, suppose A is an invertible square matrix. Then the echelon form of A is the identity matrix, but during intermediate steps the numbers involved could be quite large. One technique for mitigating this is to compute the echelon form using a multimodular method.

If A is a matrix with rational entries, let $H(A)$ be the *height* of A, which is the maximum of the absolute values of the numerators and denominators of all entries of A. If x, y are rational numbers and p is a prime, we write $x \equiv y \pmod{p}$ to mean that the denominators of x and y are not divisible by p but the numerator of the rational number $x - y$ (in reduced form) is divisible by p. For example, if $x = 5/7$ and $y = 2/11$, then $x - y = 41/77$, so $x \equiv y \pmod{41}$.

Algorithm 7.6 (Multimodular Echelon Form)**.** *Given an $m \times n$ matrix A with entries in $\mathbb{Q}$, this algorithm computes the reduced row echelon form of A.*

(1) Rescale the input matrix A to have integer entries. This does not change the echelon form and makes reduction modulo many primes easier. We may thus assume A has integer entries.
(2) Let c be a guess for the height of the echelon form.
(3) List successive primes $p_1, p_2, \ldots$ such that the product of the p_i is greater than $n \cdot c \cdot H(A) + 1$, where n is the number of columns of A.
(4) Compute the echelon forms B_i of the reduction $A \pmod{p_i}$ using, e.g., Algorithm 7.3 or any other echelon algorithm.
(5) Discard any B_i whose pivot column list is not maximal among pivot lists of all B_j found so far. (The pivot list associated to B_i is the ordered list of integers k such that the kth column of B_j is a pivot

column. We mean maximal with respect to the following ordering on integer sequences: shorter integer sequences are smaller, and if two sequences have the same length, then order in reverse lexicographic order. Thus $[1, 2]$ is smaller than $[1, 2, 3]$, and $[1, 2, 7]$ is smaller than $[1, 2, 5]$. Think of maximal as "optimal", i.e., best possible pivot columns.)

(6) Use the Chinese Remainder Theorem to find a matrix B with integer entries such that $B \equiv B_i \pmod{p_i}$ for all p_i.

(7) Use Algorithm 7.4 to try to find a matrix C whose coefficients are rational numbers n/r such that $|n|, r \leq \sqrt{M/2}$, where $M = \prod p_i$, and $C \equiv B_i \pmod{p_i}$ for each prime p. If rational reconstruction fails, compute a few more echelon forms mod the next few primes (using the above steps) and attempt rational reconstruction again. Let E be the matrix over $\mathbb{Q}$ so obtained. (A trick here is to keep track of denominators found so far to avoid doing very many rational reconstructions.)

(8) Compute the denominator d of E, i.e., the smallest positive integer such that dE has integer entries. If

$$H(dE) \cdot H(A) \cdot n < \prod p_i, \tag{7.3.1}$$

then E is the reduced row echelon form of A. If not, repeat the above steps with a few more primes.

Proof. We prove that if (7.3.1) is satisfied, then the matrix E computed by the algorithm really is the reduced row echelon form R of A. First note that E is in reduced row echelon form since the set of pivot columns of all matrices B_i used to construct E are the same, so the pivot columns of E are the same as those of any B_i and all other entries in the B_i pivot columns are 0, so the other entries of E in the pivot columns are also 0.

Recall from the end of Section 7.1 that a matrix whose columns are a basis for the kernel of A can be obtained from the reduced row echelon form R. Let K be the matrix whose columns are the vectors in the kernel algorithm applied to E, so $EK = 0$. Since the reduced row echelon form is obtained by left multiplying by an invertible matrix, for each i, there is an invertible matrix V_i mod p_i such that $A \equiv V_i B_i \pmod{p_i}$ so

$$A \cdot dK \equiv V_i B_i \cdot dK \equiv V_i \cdot dE \cdot K \equiv 0 \pmod{p_i}.$$

Since dK and A are integer matrices, the Chinese remainder theorem implies that

$$A \cdot dK \equiv 0 \left(\bmod \prod p_i\right).$$

The integer entries a of $A \cdot dK$ all satisfy $|a| \leq H(A) \cdot H(dK) \cdot n$, where n is the number of columns of A. Since $H(K) \leq H(E)$, the bound (7.3.1) implies that $A \cdot dK = 0$. Thus $AK = 0$, so $\mathrm{Ker}(E) \subset \mathrm{Ker}(A)$. On the other hand, the rank of E equals the rank of each B_i (since the pivot columns are the same), so

$$\mathrm{rank}(E) = \mathrm{rank}(B_i) = \mathrm{rank}(A \pmod{p_i}) \leq \mathrm{rank}(A).$$

Thus $\dim(\mathrm{Ker}(A)) \leq \dim(\mathrm{Ker}(E))$, and combining this with the bound obtained above, we see that $\mathrm{Ker}(E) = \mathrm{Ker}(A)$. This implies that E is the reduced row echelon form of A, since two matrices have the same kernel if and only if they have the same reduced row echelon form (the echelon form is an invariant of the row space, and the kernel is the orthogonal complement of the row space).

The reason for step (5) is that the matrices B_i need *not* be the reduction of R modulo p_i, and indeed this reduction might not even be defined, e.g., if p_i divides the denominator of some element of R, then this reduction makes no sense. For example, set $p = p_i$ and suppose $A = \left(\begin{smallmatrix} p & 1 \\ 0 & 0 \end{smallmatrix}\right)$. Then $R = \begin{pmatrix} 1 & 1/p \\ 0 & 0 \end{pmatrix}$, which has no reduction modulo p; also, the reduction of A modulo B_i is $B_i = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right) \pmod{p}$, which is already in reduced row echelon form. However if we were to combine B_i with the echelon form of A modulo another prime, the result could never be lifted using rational reconstruction. Thus the reason we exclude all B_i with nonmaximal pivot column sequence is so that a rational reconstruction will exist. There are only finitely many primes that divide denominators of entries of R, so eventually all B_i will have maximal pivot column sequences, i.e., they are the reduction of the true reduced row echelon form R, so the algorithm terminates. □

Remark 7.7. Algorithm 7.6, with *sparse* matrices seems to work very well in practice. A simple but helpful modification to Algorithm 7.3 in the sparse case is to clear each column using a row with a minimal number of nonzero entries, so as to reduce the amount of "fill in" (denseness) of the matrix. There are much more sophisticated methods along these lines called "intelligent Gauss elimination". (Cryptographers are interested in linear algebra mod p with huge sparse matrices, since they come up in attacks on the discrete log problem and integer factorization.)

One can adapt Algorithm 7.6 to computation of echelon forms of matrices A over cyclotomic fields $\mathbb{Q}(\zeta_n)$. Assume A has denominator 1. Let p be a prime that splits completely in $\mathbb{Q}(\zeta_n)$. Compute the homomorphisms $f_i : \mathbb{Z}_p[\zeta_n] \to \mathbb{F}_p$ by finding the elements of order n in $\mathbb{F}_p^*$. Then compute the mod p matrix $f_i(A)$ for each i, and find its reduced row echelon form. Taken together, the maps f_i together induce an isomorphism $\Psi : \mathbb{F}_p[X]/\Phi_n(X) \cong \mathbb{F}_p^d$, where $\Phi_n(X)$ is the nth cyclotomic polynomial and d is its degree. It is easy to compute $\Psi(f(x))$ by evaluating $f(x)$ at each element of order n in $\mathbb{F}_p$. To compute Ψ^{-1}, simply use linear algebra over $\mathbb{F}_p$

to invert a matrix that represents Ψ. Use Ψ^{-1} to compute the reduced row echelon form of $A \pmod{p}$, where (p) is the nonprime ideal in $\mathbb{Z}[\zeta_n]$ generated by p. Do this for several primes p, and use rational reconstruction on each coefficient of each power of ζ_n, to recover the echelon form of A.

7.4. Echelon Forms via Matrix Multiplication

In this section we explain how to compute echelon forms using matrix multiplication. This is valuable because there are asymptotically fast, i.e., better than $O(n^3)$ field operations, algorithms for matrix multiplication, and implementations of linear algebra libraries often include highly optimized matrix multiplication algorithms. We only sketch the basic ideas behind these asymptotically fast algorithms (following [**Ste**]), since more detail would take us too far from modular forms.

The naive algorithm for multiplying two $m \times m$ matrices requires $O(m^3)$ arithmetic operations in the base ring. In [**Str69**], Strassen described a clever algorithm that computes the product of two $m \times m$ matrices in $O(m^{\log_2(7)}) = O(m^{2.807\cdots})$ arithmetic operations in the base ring. Because of numerical stability issues, Strassen's algorithm is rarely used in numerical analysis. But for matrix arithmetic over exact base rings (e.g., the rational numbers, finite fields, etc.) it is of extreme importance.

In [**Str69**], Strassen also sketched a new algorithm for computing the inverse of a square matrix using matrix multiplication. Using this algorithm, the number of operations to invert an $m \times m$ matrix is (roughly) the same as the number needed to multiply two $m \times m$ matrices. Suppose the input matrix is $2^n \times 2^n$ and we write it in block form as $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ where A, B, C, D are all $2^{n-1} \times 2^{n-1}$ matrices. Assume that any intermediate matrices below that we invert are invertible. Consider the augmented matrix

$$\left(\begin{array}{cc|cc} A & B & I & 0 \\ C & D & 0 & I \end{array}\right).$$

Multiply the top row by A^{-1} to obtain

$$\left(\begin{array}{cc|cc} I & A^{-1}B & A^{-1} & 0 \\ C & D & 0 & I \end{array}\right),$$

and write $E = A^{-1}B$. Subtract C times the first row from the second row to get

$$\left(\begin{array}{cc|cc} I & E & A^{-1} & 0 \\ 0 & D - CE & -CA^{-1} & I \end{array}\right).$$

Set $F = D - CE$ and multiply the bottom row by F^{-1} on the left to obtain

$$\left(\begin{array}{cc|cc} I & E & A^{-1} & 0 \\ 0 & I & -F^{-1}CA^{-1} & F^{-1} \end{array}\right).$$

Set $G = -F^{-1}CA^{-1}$, and subtract E times the second from the first row to arrive at

$$\left(\begin{array}{cc|cc} I & 0 & A^{-1} - EG & -EF^{-1} \\ 0 & I & G & F^{-1} \end{array}\right).$$

The idea listed above can, with significant work, be extended to a general algorithm (as is done in [**Ste06**]).

Next we very briefly sketch how to compute echelon forms of matrices using matrix multiplication and inversion. Its complexity is comparable to the complexity of matrix multiplication.

As motivation, recall the standard algorithm from undergraduate linear algebra for inverting an invertible square matrix A: form the augmented matrix $[A|I]$, and then compute the echelon form of this matrix, which is $[I|A^{-1}]$. If T is the transformation matrix to echelon form, then $T[A|I] = [I|T]$, so $T = A^{-1}$. In particular, we could find the echelon form of $[A|I]$ by multiplying on the left by A^{-1}. Likewise, for any matrix B with the same number of rows as A, we could find the echelon form of $[A|B]$ by multiplying on the left by A^{-1}. Next we extend this idea to give an algorithm to compute echelon forms using only matrix multiplication (and echelon form modulo one prime).

Algorithm 7.8 (Asymptotically Fast Echelon Form)**.** *Given a matrix A over the rational numbers (or a number field), this algorithm computes the echelon form of A.*

(1) [Find Pivots] Choose a random prime p (coprime to the denominator of any entry of A) and compute the echelon form of $A \pmod p$, e.g., using Algorithm 7.3. Let $c_0, \ldots, c_{n-1}$ be the pivot columns of $A \pmod p$. When computing the echelon form, save the positions $r_0, \ldots, r_{n-1}$ of the rows used to clear each column.

(2) [Extract Submatrix] Extract the $n \times n$ submatrix B of A whose entries are A_{r_i,c_j} for $0 \leq i, j \leq n-1$.

(3) [Compute Inverse] Compute the inverse B^{-1} of B. Note that B must be invertible since its reduction modulo p is invertible.

(4) [Multiply] Let C be the matrix whose rows are the rows $r_0, \ldots, r_{n-1}$ of A. Compute $E = B^{-1}C$. If E is not in echelon form, go to step (1).

(5) [Done?] Write down a matrix D whose columns are a basis for $\ker(E)$ as explained on page 105. Let F be the matrix whose rows are the rows of A other than rows $r_0, \ldots, r_{n-1}$. Compute the product FD. If $FD = 0$, output E, which is the echelon form of A. If $FD \neq 0$, go to step (1) and run the whole algorithm again.

Proof. We prove both that the algorithm terminates and that when it terminates, the matrix E is the echelon form of A.

First we prove that the algorithm terminates. Let E be the echelon form of A. By Exercise 7.3, for all but finitely many primes p (i.e., any prime where $A \pmod{p}$ has the same rank as A) the echelon form of $A \pmod{p}$ equals $E \pmod{p}$. For any such prime p the pivot columns of $E \pmod{p}$ are the pivot columns of E, so the algorithm will terminate for that choice of p.

We next prove that when the algorithm terminates, E is the echelon form of A. By assumption, E is in echelon form and is obtained by multiplying C on the left by an invertible matrix, so E must be *the* echelon form of C. The rows of C are a subset of those of A, so the rows of E are a subset of the rows of the echelon form of A. Thus $\ker(A) \subset \ker(E)$. To show that E equals the echelon form of A, we just need to verify that $\ker(E) \subset \ker(A)$, i.e., that $AD = 0$, where D is as in step (5). Since E is the echelon form of C, we know that $CD = 0$. By step (5) we also know that $FD = 0$. Thus $AD = 0$, since the rows of A are the union of the rows of F and C.

□

Example 7.9. Let A be the 4×8 matrix

$$A = \begin{pmatrix} -9 & 6 & 7 & 3 & 1 & 0 & 0 & 0 \\ -10 & 3 & 8 & 2 & 0 & 1 & 0 & 0 \\ 3 & -6 & 2 & 8 & 0 & 0 & 1 & 0 \\ -8 & -6 & -8 & 6 & 0 & 0 & 0 & 1 \end{pmatrix}$$

from Example 7.2.

```
sage: M = MatrixSpace(QQ,4,8)
sage: A = M([[-9,6,7,3,1,0,0,0],[-10,3,8,2,0,1,0,0],
              [3,-6,2,8,0,0,1,0],[-8,-6,-8,6,0,0,0,1]])
```

First choose the "random" prime $p = 41$, which does not divide any of the entries of A, and compute the echelon form of the reduction of A modulo 41.

```
sage: A41 = MatrixSpace(GF(41),4,8)(A)
sage: E41 = A41.echelon_form()
```

The echelon form of $A \pmod{41}$ is

$$\begin{pmatrix} 1 & 0 & 0 & 2 & 0 & 20 & 33 & 18 \\ 0 & 1 & 0 & 40 & 0 & 30 & 7 & 1 \\ 0 & 0 & 1 & 39 & 0 & 19 & 13 & 17 \\ 0 & 0 & 0 & 0 & 1 & 31 & 0 & 37 \end{pmatrix}.$$

Thus we take $c_0 = 0$, $c_1 = 1$, $c_2 = 2$, and $c_3 = 4$. Also $r_i = i$ for $i = 0, 1, 2, 3$. Next extract the submatrix B.

```
sage: B = A.matrix_from_columns([0,1,2,4])
```

The submatrix B is

$$B = \begin{pmatrix} -9 & 6 & 7 & 1 \\ -10 & 3 & 8 & 0 \\ 3 & -6 & 2 & 0 \\ -8 & -6 & -8 & 0 \end{pmatrix}.$$

The inverse of B is

$$B^{-1} = \begin{pmatrix} 0 & -\frac{5}{92} & \frac{1}{46} & -\frac{9}{184} \\ 0 & -\frac{1}{138} & -\frac{3}{23} & -\frac{11}{276} \\ 0 & \frac{11}{184} & \frac{7}{92} & -\frac{17}{368} \\ 1 & -\frac{159}{184} & \frac{41}{92} & \frac{45}{368} \end{pmatrix}.$$

Multiplying by A yields

$$E = B^{-1}A = \begin{pmatrix} 1 & 0 & 0 & -\frac{21}{92} & 0 & -\frac{5}{92} & \frac{1}{46} & -\frac{9}{184} \\ 0 & 1 & 0 & -\frac{179}{138} & 0 & -\frac{1}{138} & -\frac{3}{23} & -\frac{11}{276} \\ 0 & 0 & 1 & \frac{83}{184} & 0 & \frac{11}{184} & \frac{7}{92} & -\frac{17}{368} \\ 0 & 0 & 0 & \frac{1025}{184} & 1 & -\frac{159}{184} & \frac{41}{92} & \frac{45}{368} \end{pmatrix}.$$

```
sage: E = B^(-1)*A
```

This is *not* the echelon form of A. Indeed, it is not even in echelon form, since the last row is not normalized so the leftmost nonzero entry is 1. We thus choose another random prime, say $p = 43$. The echelon form mod 43 has columns $0, 1, 2, 3$ as pivot columns. We thus extract the matrix

$$B = \begin{pmatrix} -9 & 6 & 7 & 3 \\ -10 & 3 & 8 & 2 \\ 3 & -6 & 2 & 8 \\ -8 & -6 & -8 & 6 \end{pmatrix}.$$

```
sage: B = A.matrix_from_columns([0,1,2,3])
```

This matrix has inverse

$$B^{-1} = \begin{pmatrix} \frac{42}{1025} & -\frac{92}{1025} & \frac{1}{25} & -\frac{9}{205} \\ \frac{716}{3075} & -\frac{641}{3075} & -\frac{2}{75} & -\frac{7}{615} \\ -\frac{83}{1025} & \frac{133}{1025} & \frac{1}{25} & -\frac{23}{410} \\ \frac{184}{1025} & -\frac{159}{1025} & \frac{2}{25} & \frac{9}{410} \end{pmatrix}.$$

Finally, the echelon form of A is $E = B^{-1}A$. No further checking is needed since the product so obtained is in echelon form, and the matrix F of the last step of the algorithm has 0 rows.

Remark 7.10. Above we have given only the barest sketch of asymptotically fast "block" algorithms for linear algebra. For optimized algorithms that work in the general case, please see the source code of [**Ste06**].

7.5. Decomposing Spaces under the Action of Matrix

Efficiently solving the following problem is a crucial step in computing a basis of eigenforms for a space of modular forms (see Sections 3.7 and 9.3.2).

Problem 7.11. Suppose T is an $n \times n$ matrix with entries in a field K (typically a number field or finite field) and that the minimal polynomial of T is square-free and has degree n. View T as acting on $V = K^n$. Find a simple module decomposition $W_0 \oplus \cdots \oplus W_m$ of V as a direct sum of simple $K[T]$-modules. Equivalently, find an invertible matrix A such that $A^{-1}TA$ is a block direct sum of matrices $T_0, \ldots, T_m$ such that the minimal polynomial of each T_i is irreducible.

Remark 7.12. A generalization of Problem 7.11 to arbitrary matrices with entries in $\mathbb{Q}$ is finding the *rational Jordan form* (or rational canonical form, or Frobenius form) of T. This is like the usual Jordan form, but the resulting matrix is over $\mathbb{Q}$ and the summands of the matrix corresponding to eigenvalues are replaced by matrices whose minimal polynomials are the minimal polynomials (over $\mathbb{Q}$) of the eigenvalues. The rational Jordan form was extensively studied by Giesbrecht in his Ph.D. thesis and many successive papers, where he analyzes the complexity of his algorithms and observes that the limiting step is factoring polynomials over K. The reason is that given a polynomial $f \in K[x]$, one can easily write down a matrix T such that one can read off the factorization of f from the rational Jordan form of T (see also [**Ste97**]).

7.5.1. Characteristic Polynomials.

The computation of characteristic polynomials of matrices is crucial to modular forms computations. There are many approaches to this problems: compute $\det(xI - A)$ symbolically (bad), compute the traces of the powers of A (bad), or compute the Hessenberg form modulo many primes and use CRT (bad; see for [**Coh93**, §2.2.4] the definition of Hessenberg form and the algorithm). A more sophisticated method is to compute the rational canonical form of A using Giesbrecht's algorithm[1] (see [**GS02**]), which involves computing Krylov subspaces (see Remark 7.13 below), and building up the whole space on which A acts. This

[1] Allan Steel also invented a similar algorithm.

latter method is a generalization of Wiedemann's algorithm for computing minimal polynomials (see Section 7.5.3), but with more structure to handle the case when the characteristic polynomial is not equal to the minimal polynomial.

7.5.2. Polynomial Factorization. Factorization of polynomials in $\mathbb{Q}[X]$ (or over number fields) is an important step in computing an explicit basis of Hecke eigenforms for spaces of modular forms. The best algorithm is the van Hoeij method [**BHKS06**], which uses the LLL lattice basis reduction algorithm [**LLL82**] in a novel way to solve the optimization problems that come up in trying to lift factorizations mod p to $\mathbb{Z}$. It has been generalized by Belebas, van Hoeij, Klüners, and Steel to number fields.

7.5.3. Wiedemann's Minimal Polynomial Algorithm. In this section we describe an algorithm due to Wiedemann for computing the minimal polynomial of an $n \times n$ matrix A over a field.

Choose a random vector v and compute the iterates

$$v_0 = v, \quad v_1 = A(v), \quad v_2 = A^2(v), \quad \ldots, \quad v_{2n-1} = A^{2n-1}(v). \tag{7.5.1}$$

If $f = x^m + c_{m-1}x^{m-1} + \cdots + c_1 x + c_0$ is the minimal polynomial of A, then

$$A^m + c_{m-1}A^{m-1} + \cdots + c_0 I_n = 0,$$

where I_n is the $n \times n$ identity matrix. For any $k \geq 0$, by multiplying both sides on the right by the vector $A^k v$, we see that

$$A^{m+k}v + c_{m-1}A^{m-1+k}v + \cdots + c_0 A^k v = 0;$$

hence

$$v_{m+k} + c_{m-1}v_{m-1+k} + \cdots + c_0 v_k = 0, \qquad \text{all } k \geq 0.$$

Wiedemann's idea is to observe that any single component of the vectors $v_0, \ldots, v_{2n-1}$ satisfies the linear recurrence with coefficients $1, c_{m-1}, \ldots, c_0$. The Berlekamp-Massey algorithm (see Algorithm 7.14 below) was introduced in the 1960s in the context of coding theory to find the minimal polynomial of a linear recurrence sequence $\{a_r\}$. The minimal polynomial of this linear recurrence is by definition the unique monic polynomial g, such that if $\{a_r\}$ satisfies a linear recurrence $a_{j+k} + b_{j-1}a_{j-1+k} + \cdots + b_0 a_k = 0$ (for all $k \geq 0$), then g divides the polynomial $x^j + \sum_{i=0}^{j-1} b_i x^i$. If we apply Berlekamp-Massey to the top coordinates of the v_i, we obtain a polynomial g_0, which divides f. We then apply it to the second to the top coordinates and find a polynomial g_1 that divides f, etc. Taking the least common multiple of the first few g_i, we find a divisor of the minimal polynomial of f. One can show that with "high probability" one quickly finds f, instead of just a proper divisor of f.

Remark 7.13. In the literature, techniques that involve iterating a vector as in (7.5.1) are often called *Krylov methods*. The subspace generated by the iterates of a vector under a matrix is called a *Krylov subspace*.

Algorithm 7.14 (Berlekamp-Massey)**.** *Suppose $a_0, \ldots, a_{2n-1}$ are the first $2n$ terms of a sequence that satisfies a linear recurrence of degree at most n. This algorithm computes the minimal polynomial f of the sequence.*

```
(1) Let $R_0 = x^{2n}$, $R_1 = \sum_{i=0}^{2n-1} a_i x^i$, $V_0 = 0$, $V_1 = 1$.
(2) While $\deg(R_1) \geq n$, do the following:
    (a) Compute $Q$ and $R$ such that $R_0 = QR_1 + R$.
    (b) Let $(V_0, V_1, R_0, R_1) = (V_1, V_0 - QV_1, R_1, R)$.
(3) Let $d = \max(\deg(V_1), 1 + \deg(R_1))$ and set $P = x^d V_1(1/x)$.
(4) Let $c$ be the leading coefficient of $P$ and output $f = P/c$.
```

The above description of Berlekamp-Massey is taken from [**ADT04**], which contains some additional ideas for improvements.

Now suppose T is an $n \times n$ matrix as in Problem 7.11. We find the minimal polynomial of T by computing the minimal polynomial of $T \pmod p$ using Wiedemann's algorithm, for many primes p, and using the Chinese Remainder Theorem. (One has to bound the number of primes that must be considered; see, e.g., [**Coh93**].)

One can also compute the characteristic polynomial of T directly from the Hessenberg form of T, which can be computed in $O(n^4)$ field operations, as described in [**Coh93**]. This is simple but slow. Also, the T we consider will often be sparse, and Wiedemann is particularly good when T is sparse.

Example 7.15. We compute the minimal polynomial of

$$A = \begin{pmatrix} 3 & 0 & 0 \\ 0 & 0 & 2 \\ -1 & 1/2 & -1 \end{pmatrix}$$

using Wiedemann's algorithm. Let $v = (1,0,0)^t$. Then

$$v = (1,0,0)^t, \quad Av = (3,0,-1)^t, \quad A^2v = (9,-2,-2)^t,$$
$$A^3v = (27,-4,-8)^t, \quad A^4v = (81,-16,-21)^t, \quad A^5v = (243,-42,-68)^t.$$

The linear recurrence sequence coming from the first entries is

$$1, 3, 9, 27, 81, 243.$$

This sequence satisfies the linear recurrence

$$a_{k+1} - 3a_k = 0, \qquad \text{all } k > 0,$$

so its minimal polynomial is $x - 3$. This implies that $x - 3$ divides the minimal polynomial of the matrix A. Next we use the sequence of second coordinates of the iterates of v, which is

$$0, 0, -2, -4, -16, -42.$$

The recurrence that this sequence satisfies is slightly less obvious, so we apply the Berlekamp-Massey algorithm to find it, with $n = 3$.

(1) We have $R_0 = x^6$, $R_1 = -42x^5 - 16x^4 - 4x^3 - 2x^2$, $V_0 = 0, V_1 = 1$.

(2) (a) Dividing R_0 by R_1, we find

$$R_0 = R_1\left(-\frac{1}{42}x + \frac{4}{441}\right) + \left(\frac{22}{441}x^4 - \frac{5}{441}x^3 + \frac{8}{441}x^2\right).$$

(b) The new V_0, V_1, R_0, R_1 are

$$\begin{aligned} V_0 &= 1, \\ V_1 &= \frac{1}{42}x - \frac{4}{441}, \\ R_0 &= -42x^5 - 16x^4 - 4x^3 - 2x^2, \\ R_1 &= \frac{22}{441}x^4 - \frac{5}{441}x^3 + \frac{8}{441}x^2. \end{aligned}$$

Since $\deg(R_1) \geq n = 3$, we do the above three steps again.

(3) We repeat the above three steps.

(a) Dividing R_0 by R_1, we find

$$R_0 = R_1\left(-\frac{9261}{11}x - \frac{123921}{242}\right) + \left(\frac{1323}{242}x^3 + \frac{882}{121}x^2\right).$$

(b) The new V_0, V_1, R_0, R_1 are:

$$\begin{aligned} V_0 &= \frac{1}{42}x - \frac{4}{441}, \\ V_1 &= \frac{441}{22}x^2 + \frac{2205}{484}x + \frac{441}{121}, \\ R_0 &= \frac{22}{441}x^4 - \frac{5}{441}x^3 + \frac{8}{441}x^2, \\ R_1 &= \frac{1323}{242}x^3 + \frac{882}{121}x^2. \end{aligned}$$

(4) We have to repeat the steps yet again:

$$\begin{aligned} V_0 &= \frac{441}{22}x^2 + \frac{2205}{484}x + \frac{441}{121}, \\ V_1 &= -\frac{242}{1323}x^3 + \frac{968}{3969}x^2 + \frac{484}{3969}x - \frac{242}{3969}, \\ R_0 &= \frac{1323}{242}x^3 + \frac{882}{121}x^2, \\ R_1 &= \frac{484}{3969}x^2. \end{aligned}$$

(5) We have $d = 3$, so $P = -\frac{242}{3969}x^3 + \frac{484}{3969}x^2 + \frac{968}{3969}x - \frac{242}{1323}$.

(6) Multiply through by $-3969/242$ and output

$$x^3 - 2x^2 - 4x + 3 = (x-3)(x^2 + x - 1).$$

The minimal polynomial of T_2 is $(x-3)(x^2+x-1)$, since the minimal polynomial has degree at most 3 and is divisible by $(x-3)(x^2+x-1)$.

7.5.4. p-adic Nullspace. We will use the following algorithm of Dixon [**Dix82**] to compute p-adic approximations to solutions of linear equations over $\mathbb{Q}$. Rational reconstruction modulo p^n then allows us to recover the corresponding solutions over $\mathbb{Q}$.

Algorithm 7.16 (p-adic Nullspace)**.** *Given a matrix A with integer entries and nonzero kernel, this algorithm computes a nonzero element of* $\ker(A)$ *using successive p-adic approximations.*

(1) [Prime] Choose a random prime p.

(2) [Echelon] Compute the echelon form of A modulo p.

(3) [Done?] If A has full rank modulo p, it has full rank, so we terminate the algorithm.

(4) [Setup] Let $b_0 = 0$.

(5) [Iterate] For each $m = 0, 1, 2, \ldots, k$, use the echelon form of A modulo p to find a vector y_m with integer entries such that $Ay_m \equiv b_m \pmod{p}$, and then set

$$b_{m+1} = \frac{b_m - Ay_m}{p}.$$

(If $m = 0$, choose $y_m \neq 0$.)

(6) [p-adic Solution] Let $x = y_0 + y_1 p + y_2 p^2 + y_3 p^3 + \cdots + y_k p^k$.

(7) [Lift] Use rational reconstruction (Algorithm 7.4) to find a vector z with rational entries such that $z \equiv x \pmod{p^{k+1}}$, if such a vector exists. If the vector does not exist, increase k or use a different p. Otherwise, output z.

Proof. We verify the case $k = 2$ only. We have $Ay_0 = 0 \pmod{p}$ and $Ay_1 = -\frac{Ay_0}{p} \pmod{p}$. Thus

$$Ay_0 + pAy_1 \equiv Ay_0 + (-Ay_0) \pmod{p^2}.$$

□

7.5.5. Decomposition Using Kernels. We now know enough to give an algorithm to solve Problem 7.11.

Algorithm 7.17 (Decomposition Using Kernels)**.** *Given an $n \times n$ matrix T over a field K as in Problem 7.11, this algorithm computes the decomposition of V as a direct sum of simple $K[T]$ modules.*

```
(1) [Minimal Polynomial] Compute the minimal polynomial $f$ of $T$,
    e.g., using the multimodular Wiedemann algorithm.
(2) [Factorization] Factor $f$ using the algorithm in Section 7.5.2.
(3) [Compute Kernels] For each irreducible factor $g_i$ of $f$, compute the
    following.
    (a) Compute the matrix $A_i = g_i(T)$.
    (b) Compute $W_i = \ker(A_i)$, e.g., using Algorithm 7.16.
(4) [Output Answer] Then $V = \bigoplus W_i$.
```

Remark 7.18. As mentioned in Remark 7.12, if one can compute such decompositions $V = \bigoplus W_i$, then one can easily factor polynomials f; hence the difficulty of polynomial factorization is a lower bound on the complexity of writing V as a direct sum of simples.

7.6. Exercises

7.1 Given a subspace W of k^n, where k is a field and $n \geq 0$ is an integer, give an algorithm to find a matrix A such that $W = \mathrm{Ker}(A)$.

7.2 If $\mathrm{rref}(A)$ denotes the row reduced echelon form of A and p is a prime not dividing any denominator of any entry of A or of $\mathrm{rref}(A)$, is $\mathrm{rref}(A \pmod{p}) = \mathrm{rref}(A) \pmod{p}$?

7.3 Let A be a matrix with entries in $\mathbb{Q}$. Prove that for all but finitely many primes p we have $\mathrm{rref}(A \pmod{p}) = \mathrm{rref}(A) \pmod{p}$.

7.4 Let

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}.$$

(a) Compute the echelon form of A using each of Algorithm 7.3, Algorithm 7.6, and Algorithm 7.8.

(b) Compute the kernel of A.

(c) Find the characteristic polynomial of A using the algorithm of Section 7.5.3.

7.5 The notion of echelon form extends to matrices whose entries come from certain rings other than fields, e.g., Euclidean domains. In the case of matrices over $\mathbb{Z}$ we define a matrix to be in echelon form (or *Hermite normal form*) if it satisfies

- $a_{ij} = 0$, for $i > j$,
- $a_{ii} \geq 0$,
- $a_{ij} < a_{ii}$ for all $j < i$ (unless $a_{ii} = 0$, in which case all $a_{ij} = 0$).

There are algorithms for computing with finitely generated modules over $\mathbb{Z}$ that are analogous to the ones in this chapter for vector spaces, which depend on computation of Hermite forms.

(a) Show that the Hermite form of $\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$ is $\begin{pmatrix} 1 & 2 & 3 \\ 0 & 3 & 6 \\ 0 & 0 & 0 \end{pmatrix}$.

(b) Describe an algorithm for transforming an $n \times n$ matrix A with integer entries into Hermite form using row operations and the Euclidean algorithm.

Chapter 8

General Modular Symbols

In this chapter we explain how to generalize the notion of modular symbols given in Chapter 3 to higher weight and more general level. We define Hecke operators on them and their relation to modular forms via the integration pairing. We omit many difficult proofs that modular symbols have certain properties and instead focus on how to compute with modular symbols. For more details see the references given in this section (especially [**Mer94**]) and [**Wie05**].

Modular symbols are a formalism that make it elementary to compute with homology or cohomology related to certain Kuga-Sato varieties (these are $\mathcal{E} \times_X \cdots \times_X \mathcal{E}$, where X is a modular curve and $\mathcal{E}$ is the universal elliptic curve over it). It is not necessary to know anything about these Kuga-Sato varieties in order to compute with modular symbols.

This chapter is about spaces of modular symbols and how to compute with them. It is by far the most important chapter in this book. The algorithms that build on the theory in this chapter are central to all the computations we will do later in the book.

This chapter closely follows Loïc Merel's paper [**Mer94**]. First we define modular symbols of weight $k \geq 2$. Then we define the corresponding Manin symbols and state a theorem of Merel-Shokurov, which gives all relations between Manin symbols. (The proof of the Merel-Shokurov theorem is beyond the scope of this book but is presented nicely in [**Wie05**].) Next we describe how the Hecke operators act on both modular and Manin symbols and how to compute trace and inclusion maps between spaces of modular symbols of different levels.

Not only are modular symbols useful for computation, but they have been used to prove theoretical results about modular forms. For example, certain technical calculations with modular symbols are used in Loïc Merel's proof of the uniform boundedness conjecture for torsion points on elliptic curves over number fields (modular symbols are used to understand linear independence of Hecke operators). Another example is [**Gri05**], which distills hypotheses about Kato's Euler system in K_2 of modular curves to a simple formula involving modular symbols (when the hypotheses are satisfied, one obtains a lower bound on the Shafarevich-Tate group of an elliptic curve).

8.1. Modular Symbols

We recall from Chapter 3 the free abelian group $\mathbb{M}_2$ of modular symbols. We view these as elements of the relative homology of the extended upper half plane $\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q})$ relative to the cusps. The group $\mathbb{M}_2$ is the free abelian group on symbols $\{\alpha, \beta\}$ with

$$\alpha, \beta \in \mathbb{P}^1(\mathbb{Q}) = \mathbb{Q} \cup \{\infty\}$$

modulo the relations

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0,$$

for all $\alpha, \beta, \gamma \in \mathbb{P}^1(\mathbb{Q})$, and all torsion. More precisely,

$$\mathbb{M}_2 = (F/R)/(F/R)_{\mathrm{tor}},$$

where F is the free abelian group on all pairs (α, β) and R is the subgroup generated by all elements of the form $(\alpha, \beta) + (\beta, \gamma) + (\gamma, \alpha)$. Note that $\mathbb{M}_2$ is a huge free abelian group of countable rank.

For any integer $n \geq 0$, let $\mathbb{Z}[X, Y]_n$ be the abelian group of homogeneous polynomials of degree n in two variables X, Y.

Remark 8.1. Note that $\mathbb{Z}[X, Y]_n$ is isomorphic to $\mathrm{Sym}^n(\mathbb{Z} \times \mathbb{Z})$ as a group, but certain natural actions are different. In [**Mer94**], Merel uses the notation $\mathbb{Z}_n[X, Y]$ for what we denote by $\mathbb{Z}[X, Y]_n$.

Now fix an integer $k \geq 2$. Set

$$\mathbb{M}_k = \mathbb{Z}[X, Y]_{k-2} \otimes_{\mathbb{Z}} \mathbb{M}_2,$$

which is a torsion-free abelian group whose elements are sums of expressions of the form $X^i Y^{k-2-i} \otimes \{\alpha, \beta\}$. For example,

$$X^3 \otimes \{0, 1/2\} - 17XY^2 \otimes \{\infty, 1/7\} \in \mathbb{M}_5.$$

Fix a finite index subgroup G of $\mathrm{SL}_2(\mathbb{Z})$. Define a *left action of* G on $\mathbb{Z}[X,Y]_{k-2}$ as follows. If $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in G$ and $P(X,Y) \in \mathbb{Z}[X,Y]_{k-2}$, let

$$(gP)(X,Y) = P(dX - bY, -cX + aY).$$

Note that if we think of $z = (X,Y)$ as a column vector, then

$$(gP)(z) = P(g^{-1}z),$$

since $g^{-1} = \left(\begin{smallmatrix} d & -b \\ -c & a \end{smallmatrix}\right)$. The reason for the inverse is so that this is a left action instead of a right action, e.g., if $g, h \in G$, then

$$((gh)P)(z) = P((gh)^{-1}z) = P(h^{-1}g^{-1}z) = (hP)(g^{-1}z) = (g(hP))(z).$$

Recall that we let G act on the left on $\mathbb{M}_2$ by

$$g\{\alpha,\beta\} = \{g(\alpha), g(\beta)\},$$

where G acts via linear fractional transformations, so if $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then

$$g(\alpha) = \frac{a\alpha + b}{c\alpha + d}.$$

For example, useful special cases to remember are that if $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then

$$g(0) = \frac{b}{d} \qquad \text{and} \qquad g(\infty) = \frac{a}{c}.$$

(Here we view ∞ as $1/0$ in order to describe the action.)

We now combine these two actions to obtain a left action of G on $\mathbb{M}_k$, which is given by

$$g(P \otimes \{\alpha,\beta\}) = (gP) \otimes \{g(\alpha), g(\beta)\}.$$

For example,

$$\begin{aligned}\begin{pmatrix} 1 & 2 \\ -2 & -3 \end{pmatrix} (X^3 \otimes \{0, 1/2\}) &= (-3X - 2Y)^3 \otimes \left\{-\frac{2}{3}, -\frac{5}{8}\right\} \\ &= (-27X^3 - 54X^2Y - 36XY^2 - 8Y^3) \otimes \left\{-\frac{2}{3}, -\frac{5}{8}\right\}.\end{aligned}$$

We will often write $P(X,Y)\{\alpha,\beta\}$ for $P(X,Y) \otimes \{\alpha,\beta\}$.

Definition 8.2 (Modular Symbols)**.** Let $k \geq 2$ be an integer and let G be a finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$. The space $\mathbb{M}_k(G)$ of *weight* k *modular symbols for* G is the quotient of $\mathbb{M}_k$ by all relations $gx - x$ for $x \in \mathbb{M}_k$, $g \in G$, and by any torsion.

Note that $\mathbb{M}_k$ is a torsion-free abelian group, and it is a nontrivial fact that $\mathbb{M}_k$ has finite rank. We denote modular symbols for G in exactly the same way we denote elements of $\mathbb{M}_k$; the group G will be clear from context.

The space of *modular symbols over a ring R* is

$$\mathbb{M}_k(G; R) = \mathbb{M}_k(G) \otimes_{\mathbb{Z}} R.$$

8.2. Manin Symbols

Let G be a finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$ and $k \geq 2$ an integer. Just as in Chapter 3 it is possible to compute $\mathbb{M}_k(G)$ using a computer, despite that, as defined above, $\mathbb{M}_k(G)$ is the quotient of one infinitely generated abelian group by another one. This section is about Manin symbols, which are a distinguished subset of $\mathbb{M}_k(G)$ that lead to a finite presentation for $\mathbb{M}_k(G)$. Formulas written in terms of Manin symbols are frequently much easier to compute using a computer than formulas in terms of modular symbols.

Suppose $P \in \mathbb{Z}[X, Y]_{k-2}$ and $g \in \mathrm{SL}_2(\mathbb{Z})$. Then the *Manin symbol* associated to this pair of elements is

$$[P, g] = g(P\{0, \infty\}) \in \mathbb{M}_k(G).$$

Notice that if $Gg = Gh$, then $[P, g] = [P, h]$, since the symbol $g(P\{0, \infty\})$ is invariant by the action of G on the left (by definition, since it is a modular symbol for G). Thus for a right coset Gg it makes sense to write $[P, Gg]$ for the symbol $[P, h]$ for any $h \in Gg$. Since G has finite index in $\mathrm{SL}_2(\mathbb{Z})$, the abelian group generated by Manin symbols is of finite rank, generated by

$$\left\{[X^{k-2-i}Y^i,\, Gg_j] \,:\, i = 0, \ldots, k-2 \quad \text{and} \quad j = 0, \ldots, r\right\},$$

where $g_0, \ldots, g_r$ run through representatives for the right cosets $G\backslash \mathrm{SL}_2(\mathbb{Z})$.

We next show that every modular symbol can be written as a $\mathbb{Z}$-linear combination of Manin symbols, so they generate $\mathbb{M}_k(G)$.

Proposition 8.3. *The Manin symbols generate* $\mathbb{M}_k(G)$.

Proof. The proof if very similar to that of Proposition 3.11 except we introduce an extra twist to deal with the polynomial part. Suppose that we are given a modular symbol $P\{\alpha, \beta\}$ and wish to represent it as a sum of Manin symbols. Because

$$P\{a/b, c/d\} = P\{a/b, 0\} + P\{0, c/d\},$$

it suffices to write $P\{0, a/b\}$ in terms of Manin symbols. Let

$$0 = \frac{p_{-2}}{q_{-2}} = \frac{0}{1},\ \frac{p_{-1}}{q_{-1}} = \frac{1}{0},\ \frac{p_0}{1} = \frac{p_0}{q_0},\ \frac{p_1}{q_1},\ \frac{p_2}{q_2},\ \ldots,\ \frac{p_r}{q_r} = \frac{a}{b}$$

denote the continued fraction convergents of the rational number a/b. Then

$$p_j q_{j-1} - p_{j-1} q_j = (-1)^{j-1} \qquad \text{for } -1 \leq j \leq r.$$

If we let $g_j = \begin{pmatrix} (-1)^{j-1}p_j & p_{j-1} \\ (-1)^{j-1}q_j & q_{j-1} \end{pmatrix}$, then $g_j \in \mathrm{SL}_2(\mathbb{Z})$ and

$$\begin{aligned} P\{0, a/b\} &= P \sum_{j=-1}^{r} \left\{ \frac{p_{j-1}}{q_{j-1}}, \frac{p_j}{q_j} \right\} \\ &= \sum_{j=-1}^{r} g_j((g_j^{-1}P)\{0, \infty\}) \\ &= \sum_{j=-1}^{r} [g_j^{-1}P,\ g_j]. \end{aligned}$$

Since $g_j \in \mathrm{SL}_2(\mathbb{Z})$ and P has integer coefficients, the polynomial $g_j^{-1}P$ also has integer coefficients, so we introduce no denominators. □

Now that we know the Manin symbols generate $\mathbb{M}_k(G)$, we next consider the relations between Manin symbols. Fortunately, the answer is fairly simple (though the proof is not). Let

$$\sigma = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad \tau = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad J = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Define a *right action of* $\mathrm{SL}_2(\mathbb{Z})$ on Manin symbols as follows. If $h \in \mathrm{SL}_2(\mathbb{Z})$, let

$$[P, g]h = [h^{-1}P, gh].$$

This is a right action because both $P \mapsto h^{-1}P$ and $g \mapsto gh$ are right actions.

Theorem 8.4. *If x is a Manin symbol, then*

$$x + x\sigma = 0, \tag{8.2.1}$$

$$x + x\tau + x\tau^2 = 0, \tag{8.2.2}$$

$$x - xJ = 0. \tag{8.2.3}$$

Moreover, these are all the relations between Manin symbols, in the sense that the space $\mathbb{M}_k(G)$ of modular symbols is isomorphic to the quotient of the free abelian group on the finitely many symbols $[X^iY^{k-2-i}, Gg]$ (for $i = 0, \ldots, k-2$ and $Gg \in G\backslash \mathrm{SL}_2(\mathbb{Z})$) by the above relations and any torsion.

Proof. First we prove that the Manin symbols satisfy the above relations. We follow Merel's proof (see [**Mer94**, §1.2]). Note that

$$\sigma(0) = \sigma^2(\infty) = \infty \qquad \text{and} \qquad \tau(1) = \tau^2(0) = \infty.$$

Writing $x = [P, g]$, we have

$$\begin{aligned}
[P, g] + [P, g]\sigma &= [P, g] + [\sigma^{-1}P, g\sigma] \\
&= g(P\{0, \infty\}) + g\sigma(\sigma^{-1}P\{0, \infty\}) \\
&= (gP)\{g(0), g(\infty)\} + (g\sigma)(\sigma^{-1}P)\{g\sigma(0), g\sigma(\infty)\} \\
&= (gP)\{g(0), g(\infty)\} + (gP)\{g(\infty), g(0)\} \\
&= (gP)\{g(0), g(\infty)\} + \{g(\infty), g(0)\}) \\
&= 0.
\end{aligned}$$

Also,

$$\begin{aligned}
&[P, g] + [P, g]\tau + [P, g]\tau^2 = [P, g] + [\tau^{-1}P, g\tau] + [\tau^{-2}P, g\tau^2] \\
&\quad = g(P\{0, \infty\}) + g\tau(\tau^{-1}P\{0, \infty\}) + g\tau^2(\tau^{-2}P\{0, \infty\}) \\
&\quad = (gP)\{g(0), g(\infty)\} + (gP)\{g\tau(0), g\tau(\infty)\} + (gP)\{g\tau^2(0), \tau^2(\infty)\} \\
&\quad = (gP)\{g(0), g(\infty)\} + (gP)\{g(1), g(0)\}) + (gP)\{g(\infty), g(1)\} \\
&\quad = (gP)\big(\{g(0), g(\infty)\} + \{g(\infty), g(1)\} + \{g(1), g(0)\}\big) \\
&\quad = 0.
\end{aligned}$$

Finally,

$$\begin{aligned}
[P, g] + [P, g]J &= g(P\{0, \infty\}) - gJ(J^{-1}P\{gJ(0), gJ(\infty)\} \\
&= (gP)\{g(0), g(\infty)\} - (gP)\{g(0), g(\infty)\} \\
&= 0,
\end{aligned}$$

where we use that J acts trivially via linear fractional transformations. This proves that the listed relations are all satisfied.

That the listed relations are all relations is more difficult to prove. One approach is to show (as in [**Mer94**, §1.3]) that the quotient of Manin symbols by the above relations and torsion is isomorphic to a space of Shokurov symbols, which is in turn isomorphic to $\mathbb{M}_k(G)$. A much better approach is to apply some results from group cohomology, as in [**Wie05**]. □

If G is a finite index subgroup and we have an algorithm to enumerate the right cosets $G\backslash \mathrm{SL}_2(\mathbb{Z})$ and to decide which coset an arbitrary element of $\mathrm{SL}_2(\mathbb{Z})$ belongs to, then Theorem 8.4 and the algorithms of Chapter 7 yield an algorithm to compute $\mathbb{M}_k(G; \mathbb{Q})$. Note that if $J \in G$, then the relation $x - xJ = 0$ is automatic.

Remark 8.5. The matrices σ and τ *do not commute*, so in computing $\mathbb{M}_k(G; \mathbb{Q})$, one cannot first quotient out by the two-term σ relations, then quotient out only the remaining free generators by the τ relations, and get the right answer in general.

8.2.1. Coset Representatives and Manin Symbols.

The following is analogous to Proposition 3.10:

Proposition 8.6. *The right cosets $\Gamma_1(N)\backslash \mathrm{SL}_2(\mathbf{Z})$ are in bijection with pairs (c, d) where $c, d \in \mathbf{Z}/N\mathbf{Z}$ and $\gcd(c, d, N) = 1$. The coset containing a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ corresponds to (c, d).*

Proof. This proof is copied from [**Cre92**, pg. 203], except in that paper Cremona works with the analogue of $\Gamma_1(N)$ in $\mathrm{PSL}_2(\mathbf{Z})$, so his result is slightly different. Suppose $\gamma_i = \left(\begin{smallmatrix} a_i & b_i \\ c_i & d_i \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z})$, for $i = 1, 2$. We have

$$\gamma_1\gamma_2^{-1} = \begin{pmatrix} a_1 & b_1 \\ c_1 & d_1 \end{pmatrix}\begin{pmatrix} d_2 & -b_2 \\ -c_2 & a_2 \end{pmatrix} = \begin{pmatrix} a_1d_2 - b_1c_2 & * \\ c_1d_2 - d_1c_2 & a_2d_1 - b_2c_1 \end{pmatrix},$$

which is in $\Gamma_1(N)$ if and only if

$$c_1d_2 - d_1c_2 \equiv 0 \pmod{N} \tag{8.2.4}$$

and

$$a_2d_1 - b_2c_1 \equiv a_1d_2 - b_1c_2 \equiv 1 \pmod{N}. \tag{8.2.5}$$

Since the γ_i have determinant 1, if $(c_1, d_1) = (c_2, d_2) \pmod{N}$, then the congruences (8.2.4)–(8.2.5) hold. Conversely, if (8.2.4)–(8.2.5) hold, then

$$\begin{aligned} c_2 &\equiv a_2d_1c_2 - b_2c_1c_2 \\ &\equiv a_2d_2c_1 - b_2c_2c_1 \quad \text{since } d_1c_2 \equiv d_2c_1 \pmod{N} \\ &\equiv c_1 \quad \text{since } a_2d_2 - b_2c_2 = 1, \end{aligned}$$

and likewise

$$d_2 \equiv a_2d_1d_2 - b_2c_1d_2 \equiv a_2d_1d_2 - b_2d_1c_2 \equiv d_1 \pmod{N}.$$

□

Thus we may view weight k Manin symbols for $\Gamma_1(N)$ as triples of integers (i, c, d), where $0 \leq i \leq k-2$ and $c, d \in \mathbf{Z}/N\mathbf{Z}$ with $\gcd(c, d, N) = 1$. Here (i, c, d) corresponds to the Manin symbol $[X^iY^{k-2-i}, \left(\begin{smallmatrix} a & b \\ c' & d' \end{smallmatrix}\right)]$, where c' and d' are congruent to $c, d \pmod{N}$. The relations of Theorem 8.4 become

$$(i,\, c, d) + (-1)^i(k-2-i,\, d, -c) = 0,$$

$$\begin{aligned}(i,\, c, d) \quad + \quad &(-1)^{k-2}\sum_{j=0}^{k-2-i}(-1)^j\binom{k-2-i}{j}(j,\, d, -c-d) \\ + \quad &(-1)^{k-2-i}\sum_{j=0}^{i}(-1)^j\binom{i}{j}(k-2-i+j,\, -c-d, c) = 0,\end{aligned}$$

$$(i,\, c, d) - (-1)^{k-2}(i,\, -c, -d) = 0.$$

Recall that Proposition 3.10 gives a similar description for $\Gamma_0(N)$.

8.2.2. Modular Symbols with Character. Suppose $G = \Gamma_1(N)$. Define an action of *diamond-bracket operators* $\langle d \rangle$o, with $\gcd(d, N) = 1$ on Manin symbols as follows:

$$\langle d \rangle([P,(u,v)]) = [P,(du,dv)] .$$

Let

$$\varepsilon : (\mathbb{Z}/N\mathbb{Z})^* \to \mathbb{Q}(\zeta)^*$$

be a Dirichlet character, where ζ is an nth root of unity and n is the order of ε. Let $\mathbb{M}_k(N,\varepsilon)$ be the quotient of $\mathbb{M}_k(\Gamma_1(N);\mathbb{Z}[\zeta])$ by the relations (given in terms of Manin symbols)

$$\langle d \rangle x - \varepsilon(d)x = 0,$$

for all $x \in \mathbb{M}_k(\Gamma_1(N);\mathbb{Z}[\zeta])$, $d \in (\mathbb{Z}/N\mathbb{Z})^*$, and by any $\mathbb{Z}$-torsion. Thus $\mathbb{M}_k(N,\varepsilon)$ is a $\mathbb{Z}[\varepsilon]$-module that has no torsion when viewed as a $\mathbb{Z}$-module.

8.3. Hecke Operators

Suppose Γ is a subgroup of $\mathrm{SL}_2(\mathbb{Z})$ of level N that contains $\Gamma_1(N)$. Just as for modular forms, there is a commutative *Hecke algebra* $\mathbb{T} = \mathbb{Z}[T_1, T_2, \ldots]$, which is the subring of $\mathrm{End}(\mathbb{M}_k(\Gamma))$ generated by all Hecke operators. Let

$$R_p = \left\{ \begin{pmatrix} 1 & r \\ 0 & p \end{pmatrix} : r = 0, 1, \ldots, p-1 \right\} \cup \left\{ \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \right\},$$

where we omit $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ if $p \mid N$. Then the *Hecke operator* T_p on $\mathbb{M}_k(\Gamma)$ is given by

$$T_p(x) = \sum_{g \in R_p} gx.$$

Notice when $p \nmid N$ that T_p is defined by summing over $p+1$ matrices that correspond to the $p+1$ subgroups of $\mathbb{Z} \times \mathbb{Z}$ of index p. This is exactly how we defined T_p on modular forms in Definition 2.26.

8.3.1. General Definition of Hecke Operators. Let Γ be a finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$ and suppose

$$\Delta \subset \mathrm{GL}_2(\mathbb{Q})$$

is a set such that $\Gamma\Delta = \Delta\Gamma = \Delta$ and $\Gamma\backslash\Delta$ is finite. For example, $\Delta = \Gamma$ satisfies this condition. Also, if $\Gamma = \Gamma_1(N)$, then for any positive integer n, the set

$$\Delta_n = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{Mat}_2(\mathbb{Z}) \,:\, ad - bc = n, \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \pmod{N} \right\}$$

also satisfies this condition, as we will now prove.

Lemma 8.7. *We have*

$$\Gamma_1(N) \cdot \Delta_n = \Delta_n \cdot \Gamma_1(N) = \Delta_n$$

and

$$\Delta_n = \bigcup_{a,b} \Gamma_1(N) \cdot \sigma_a \begin{pmatrix} a & b \\ 0 & n/a \end{pmatrix},$$

where $\sigma_a \equiv \left(\begin{smallmatrix} 1/a & 0 \\ 0 & a \end{smallmatrix}\right) \pmod{N}$*, the union is disjoint and* $1 \leq a \leq n$ *with* $a \mid n$*,* $\gcd(a, N) = 1$*, and* $0 \leq b < n/a$*. In particular, the set of cosets* $\Gamma_1(N)\backslash\Delta_n$ *is finite.*

Proof. (This is Lemma 1 of [**Mer94**, §2.3].) If $\gamma \in \Gamma_1(N)$ and $\delta \in \Delta_n$, then

$$\begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \cdot \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \pmod{N}.$$

Thus $\Gamma_1(N)\Delta_n \subset \Delta_n$, and since $\Gamma_1(N)$ is a group, $\Gamma_1(N)\Delta_n = \Delta_n$; likewise $\Delta_n\Gamma_1(N) = \Delta_n$.

For the coset decomposition, we first prove the statement for $N = 1$, i.e., for $\Gamma_1(N) = \mathrm{SL}_2(\mathbb{Z})$. If A is an arbitrary element of $\mathrm{Mat}_2(\mathbb{Z})$ with determinant n, then using row operators on the left with determinant 1, i.e., left multiplication by elements of $\mathrm{SL}_2(\mathbb{Z})$, we can transform A into the form $\left(\begin{smallmatrix} a & b \\ 0 & n/a \end{smallmatrix}\right)$, with $1 \leq a \leq n$ and $0 \leq b < n$. (Just imagine applying the Euclidean algorithm to the two entries in the first column of A. Then a is the gcd of the two entries in the first column, and the lower left entry is 0. Next subtract n/a from b until $0 \leq b < n/a$.)

Next suppose N is arbitrary. Let $g_1, \ldots, g_r$ be such that

$$g_1\Gamma_1(N) \cup \cdots \cup g_r\Gamma_1(N) = \mathrm{SL}_2(\mathbb{Z})$$

is a disjoint union. If $A \in \Delta_n$ is arbitrary, then as we showed above, there is some $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, so that $\gamma \cdot A = \left(\begin{smallmatrix} a & b \\ 0 & n/a \end{smallmatrix}\right)$, with $1 \leq a \leq n$ and $0 \leq b < n/a$, and $a \mid n$. Write $\gamma = g_i \cdot \alpha$, with $\alpha \in \Gamma_1(N)$. Then

$$\alpha \cdot A = g_i^{-1} \cdot \begin{pmatrix} a & b \\ 0 & n/a \end{pmatrix} \equiv \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \pmod{N}.$$

It follows that

$$g_i^{-1} \equiv \begin{pmatrix} 1 & * \\ 0 & n \end{pmatrix} \cdot \begin{pmatrix} a & b \\ 0 & n/a \end{pmatrix}^{-1} \equiv \begin{pmatrix} 1/a & * \\ 0 & a \end{pmatrix} \pmod{N}.$$

Since $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) \in \Gamma_1(N)$ and $\gcd(a, N) = 1$, there is $\gamma' \in \Gamma_1(N)$ such that

$$\gamma' g_i^{-1} \equiv \begin{pmatrix} 1/a & 0 \\ 0 & a \end{pmatrix} \pmod{N}.$$

We may then choose $\sigma_a = \gamma' g_i^{-1}$. Thus every $A \in \Delta_n$ is of the form $\gamma\sigma_a \left(\begin{smallmatrix} a & b \\ 0 & n/a \end{smallmatrix}\right)$, with $\gamma \in \Gamma_1(N)$ and a, b suitably bounded. This proves the second claim. $\square$

Let any element $\delta = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$ act on the left on modular symbols $\mathbb{M}_k \otimes \mathbb{Q}$ by

$$\delta(P\{\alpha, \beta\}) = P(dX - bY, -cX + aY)\{\delta(\alpha), \delta(\beta)\}.$$

(Until now we had only defined an action of $\mathrm{SL}_2(\mathbb{Z})$ on modular symbols.) For $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$, let

$$\tilde{g} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} = \det(g) \cdot g^{-1}. \tag{8.3.1}$$

Note that $\tilde{\tilde{g}} = g$. Also, $\delta P(X, Y) = (P \circ \tilde{g})(X, Y)$, where we set

$$\tilde{g}(X, Y) = (dX - bY, -cX + aY).$$

Suppose Γ and Δ are as above. Fix a finite set R of representatives for $\Gamma\backslash\Delta$. Let

$$T_\Delta : \mathbb{M}_k(\Gamma) \to \mathbb{M}_k(\Gamma)$$

be the linear map

$$T_\Delta(x) = \sum_{\delta \in R} \delta x.$$

This map is well defined because if $\gamma \in \Gamma$ and $x \in \mathbb{M}_k(\Gamma)$, then

$$\sum_{\delta \in R} \delta\gamma x = \sum_{\text{certain } \delta'} \gamma\delta' x = \sum_{\text{certain } \delta'} \delta' x = \sum_{\delta \in R} \delta x,$$

where we have used that $\Delta\Gamma = \Gamma\Delta$, and Γ acts trivially on $\mathbb{M}_k(\Gamma)$.

Let $\Gamma = \Gamma_1(N)$ and $\Delta = \Delta_n$. Then the nth Hecke operator T_n is T_{Δ_n}, and by Lemma 8.7,

$$T_n(x) = \sum_{a,b} \sigma_a \begin{pmatrix} a & b \\ 0 & n/a \end{pmatrix} \cdot x,$$

where a, b are as in Lemma 8.7.

Given this definition, we can compute the Hecke operators on $M_k(\Gamma_1(N))$ as follows. Write x as a modular symbol $P\{\alpha, \beta\}$, compute $T_n(x)$ as a modular symbol, and then convert to Manin symbols using continued fractions expansions. This is extremely inefficient; fortunately Loïc Merel (following [**Maz73**]) found a much better way, which we now describe (see [**Mer94**]).

8.3.2. Hecke Operators on Manin Symbols. If S is a subset of $\mathrm{GL}_2(\mathbb{Q})$, let

$$\tilde{S} = \{\tilde{g} : g \in S\},$$

where $\tilde{g}$ is as in (8.3.1). Also, for any ring R and any subset $S \subset \mathrm{Mat}_2(\mathbb{Z})$, let $R[S]$ denote the free R-module with basis the elements of S, so the elements of $R[S]$ are the finite R-linear combinations of the elements of S.

One of the main theorems of [**Mer94**] is that for any Γ, Δ satisfying the condition at the beginning of Section 8.3.1, if we can find $\sum u_M M \in \mathbb{C}[\mathrm{Mat}_2(\mathbb{Z})]$ and a map

$$\phi : \tilde{\Delta}\,\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z})$$

that satisfies certain conditions, then for any Manin symbol $[P, g] \in \mathbb{M}_k(\Gamma)$, we have

$$T_\Delta([P, g]) = \sum_{gM \in \tilde{\Delta}\,\mathrm{SL}_2(\mathbb{Z}) \text{ with } M \in \mathrm{SL}_2(\mathbb{Z})} u_M[\tilde{M} \cdot P,\ \phi(gM)].$$

The paper [**Mer94**] contains many examples of ϕ and $\sum u_M M \in \mathbb{C}[\mathrm{Mat}_2(\mathbb{Z})]$ that satisfy all of the conditions.

When $\Gamma = \Gamma_1(N)$, the complicated list of conditions becomes simpler. Let $\mathrm{Mat}_2(\mathbb{Z})_n$ be the set of 2×2 matrices with determinant n. An element

$$h = \sum u_M[M] \in \mathbb{C}[\mathrm{Mat}_2(\mathbb{Z})_n]$$

satisfies condition C_n if for every $K \in \mathrm{Mat}_2(\mathbb{Z})_n/\,\mathrm{SL}_2(\mathbb{Z})$, we have that

$$\sum_{M \in K} u_M([M\infty] - [M0]) = [\infty] - [0] \in \mathbb{C}[P^1(\mathbb{Q})]. \tag{8.3.2}$$

If h satisfies condition C_n, then for any Manin symbol $[P, g] \in M_k(\Gamma_1(N))$, Merel proves that

$$T_n([P, (u, v)]) = \sum_M u_M[P(aX + bY,\, cX + dY), (u, v)M]. \tag{8.3.3}$$

Here $(u, v) \in (\mathbb{Z}/N\mathbb{Z})^2$ corresponds via Proposition 8.6 to a coset of $\Gamma_1(N)$ in $\mathrm{SL}_2(\mathbb{Z})$, and if $(u', v') = (u, v)M \in (\mathbb{Z}/N\mathbb{Z})^2$ and $\gcd(u', v', N) \neq 1$, then we omit the corresponding summand.

For example, we will now check directly that the element

$$h_2 = \left[\begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}\right] + \left[\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}\right] + \left[\begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix}\right] + \left[\begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix}\right]$$

satisfies condition C_2. We have, as in the proof of Lemma 8.7 (but using elementary column operations), that

$$\begin{aligned}\mathrm{Mat}_2(\mathbb{Z})_2/\operatorname{SL}_2(\mathbb{Z}) &= \left\{\begin{pmatrix} a & 0 \\ b & 2/a\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}) : a = 1, 2 \text{ and } 0 \le b < 2/a\right\} \\ &= \left\{\begin{pmatrix} 1 & 0 \\ 0 & 2\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}),\ \begin{pmatrix} 1 & 0 \\ 1 & 2\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}),\ \begin{pmatrix} 2 & 0 \\ 0 & 1\end{pmatrix}\operatorname{SL}_2(\mathbb{Z})\right\}.\end{aligned}$$

To verify condition C_2, we consider in turn each of the three elements of $\mathrm{Mat}_2(\mathbb{Z})_2/\operatorname{SL}_2(\mathbb{Z})$ and check that (8.3.2) holds. We have that

$$\begin{pmatrix} 1 & 0 \\ 0 & 2\end{pmatrix} \in \begin{pmatrix} 1 & 0 \\ 0 & 2\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}),$$

$$\begin{pmatrix} 2 & 1 \\ 0 & 1\end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & 2\end{pmatrix} \in \begin{pmatrix} 1 & 0 \\ 1 & 2\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}),$$

and

$$\begin{pmatrix} 2 & 0 \\ 0 & 1\end{pmatrix} \in \begin{pmatrix} 2 & 0 \\ 0 & 1\end{pmatrix}\operatorname{SL}_2(\mathbb{Z}).$$

Thus if $K = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2\end{smallmatrix}\right)\operatorname{SL}_2(\mathbb{Z})$, the left sum of (8.3.2) is $[\left(\begin{smallmatrix} 1 & 0 \\ 0 & 2\end{smallmatrix}\right)(\infty)] - [\left(\begin{smallmatrix} 1 & 0 \\ 0 & 2\end{smallmatrix}\right)(0)] = [\infty] - [0]$, as required. If $K = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 2\end{smallmatrix}\right)\operatorname{SL}_2(\mathbb{Z})$, then the left side of (8.3.2) is

$$\begin{aligned}&[\left(\begin{smallmatrix} 2 & 1 \\ 0 & 1\end{smallmatrix}\right)(\infty)] - [\left(\begin{smallmatrix} 2 & 1 \\ 0 & 1\end{smallmatrix}\right)(0)] + [\left(\begin{smallmatrix} 1 & 0 \\ 1 & 2\end{smallmatrix}\right)(\infty)] - [\left(\begin{smallmatrix} 1 & 0 \\ 1 & 2\end{smallmatrix}\right)(0)] \\ &\qquad = [\infty] - [1] + [1] - [0] = [\infty] - [0].\end{aligned}$$

Finally, for $K = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1\end{smallmatrix}\right)\operatorname{SL}_2(\mathbb{Z})$ we also have $[\left(\begin{smallmatrix} 2 & 0 \\ 0 & 1\end{smallmatrix}\right)(\infty)] - [\left(\begin{smallmatrix} 2 & 0 \\ 0 & 1\end{smallmatrix}\right)(0)] = [\infty] - [0]$, as required. Thus by (8.3.3) we can compute T_2 on *any* Manin symbol, by summing over the action of the four matrices $\left(\begin{smallmatrix} 2 & 0 \\ 0 & 1\end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2\end{smallmatrix}\right), \left(\begin{smallmatrix} 2 & 1 \\ 0 & 1\end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 0 \\ 1 & 2\end{smallmatrix}\right)$.

Proposition 8.8 (Merel)**.** *The element*

$$\sum_{\substack{a>b\geq 0\\ d>c\geq 0\\ ad-bc=n}} \left[\begin{pmatrix} a & b \\ c & d\end{pmatrix}\right] \in \mathbb{Z}[\mathrm{Mat}_2(\mathbb{Z})_n]$$

satisfies condition C_n.

Merel's two-page proof of Proposition 8.8 is fairly elementary.

Remark 8.9. In [**Cre97a**, §2.4], Cremona discusses the work of Merel and Mazur on Heilbronn matrices in the special cases $\Gamma = \Gamma_0(N)$ and weight 2. He gives a simple proof that the action of T_p on Manin symbols can be computed by summing the action of some set R_p of matrices of determinant p. He then describes the set R_p and gives an efficient continued fractions algorithm for computing it (but he does not prove that his R_p satisfy Merel's hypothesis).

8.3.3. Remarks on Complexity. Merel gives another family $\mathcal{S}_n$ of matrices that satisfy condition C_n, and he proves that as $n \to \infty$,

$$\#\mathcal{S}_n \sim \frac{12\log(2)}{\pi^2} \cdot \sigma_1(n)\log(n),$$

where $\sigma_1(n)$ is the sum of the divisors of n. Thus for a fixed space $\mathbb{M}_k(\Gamma)$ of modular symbols, one can compute T_n using $O(\sigma_1(n)\log(n))$ arithmetic operations. Note that we have fixed $\mathbb{M}_k(\Gamma)$, so we ignore the linear algebra involved in computation of a presentation; also, adding elements takes a bounded number of field operations when the space is fixed. Thus, using Manin symbols the complexity of computing T_p, for p prime, is $O((p+1)\log(p))$ field operations, which is *exponential* in the number of digits of p.

8.3.4. Basmaji's Trick. There is a trick of Basmaji (see [**Bas96**]) for computing a matrix of T_n on $\mathbb{M}_k(\Gamma)$, when n is very large, and it is more efficient than one might naively expect. Basmaji's trick does not improve the big-oh complexity for a fixed space, but it does improve the complexity by a constant factor of the dimension of $\mathbb{M}_k(\Gamma;\mathbb{Q})$. Suppose we are interested in computing the matrix for T_n for some massive integer n and that $\mathbb{M}_k(\Gamma;\mathbb{Q})$ has large dimension. The trick is as follows. Choose a list

$$x_1 = [P_1, g_1], \ldots, x_r = [P_r, g_r] \in V = \mathbb{M}_k(\Gamma;\mathbb{Q})$$

of Manin symbols such that the map $\Psi : \mathbb{T} \to V^r$ given by

$$t \mapsto (tx_1, \ldots, tx_r)$$

is injective. In practice, it is often possible to do this with r "very small". Also, we emphasize that V^r is a $\mathbb{Q}$-vector space of dimension $r \cdot \dim(V)$.

Next find Hecke operators T_i, with i small, whose images form a basis for the image of Ψ. Now with the above data precomputed, which only required working with Hecke operators T_i for small i, we are ready to compute T_n with n huge. Compute $y_i = T_n(x_i)$, for each $i = 1, \ldots, r$, which we can compute using Heilbronn matrices since each $x_i = [P_i, g_i]$ is a Manin symbol. We thus obtain $\Psi(T_n) \in V^r$. Since we have precomputed Hecke operators T_j such that $\Psi(T_j)$ generate V^r, we can find a_j such that $\sum a_j \Psi(T_j) = \Psi(T_n)$. Then since Ψ is injective, we have $T_n = \sum a_j T_j$, which gives the full matrix of T_n on $M_k(\Gamma;\mathbb{Q})$.

8.4. Cuspidal Modular Symbols

Let $\mathbb{B}$ be the free abelian group on symbols $\{\alpha\}$, for $\alpha \in \mathbb{P}^1(\mathbb{Q})$, and set

$$\mathbb{B}_k = \mathbb{Z}[X,Y]_{k-2} \otimes \mathbb{B}.$$

Define a *left action of* $\mathrm{SL}_2(\mathbb{Z})$ on $\mathbb{B}_k$ by

$$g(P\{\alpha\}) = (gP)\{g(\alpha)\},$$

for $g \in \mathrm{SL}_2(\mathbb{Z})$. For any finite index subgroup $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$, let $\mathbb{B}_k(\Gamma)$ be the quotient of $\mathbb{B}_k$ by the relations $x - gx$ for all $g \in \Gamma$ and by any torsion. Thus $\mathbb{B}_k(\Gamma)$ is a torsion-free abelian group.

The *boundary map* is the map

$$b : \mathbb{M}_k(\Gamma) \to \mathbb{B}_k(\Gamma)$$

given by extending the map

$$b(P\{\alpha, \beta\}) = P\{\beta\} - P\{\alpha\}$$

linearly. The space $\mathbb{S}_k(\Gamma)$ of *cuspidal modular symbols* is the kernel

$$\mathbb{S}_k(\Gamma) = \ker(\mathbb{M}_k(\Gamma) \to \mathbb{B}_k(\Gamma)),$$

so we have an exact sequence

$$0 \to \mathbb{S}_k(\Gamma) \to \mathbb{M}_k(\Gamma) \to \mathbb{B}_k(\Gamma).$$

One can prove that when $k > 2$, this sequence is exact on the right.

Next we give a presentation of $\mathbb{B}_k(\Gamma)$ in terms of “boundary Manin symbols”.

8.4.1. Boundary Manin Symbols.

We give an explicit description of the boundary map in terms of Manin symbols for $\Gamma = \Gamma_1(N)$, then describe an efficient way to compute the boundary map.

Let $\mathcal{R}$ be the equivalence relation on $\Gamma\backslash\mathbb{Q}^2$ given by

$$[\Gamma \left(\begin{smallmatrix} \lambda u \\ \lambda v \end{smallmatrix}\right)] \sim \mathrm{sign}(\lambda)^k [\Gamma \left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)],$$

for any $\lambda \in \mathbb{Q}^*$. Denote by $B_k(\Gamma)$ the finite-dimensional $\mathbb{Q}$-vector space with basis the equivalence classes $(\Gamma\backslash\mathbb{Q}^2)/\mathcal{R}$. The following two propositions are proved in [**Mer94**].

Proposition 8.10. *The map*

$$\mu : \mathbb{B}_k(\Gamma) \to B_k(\Gamma), \qquad P\left\{\frac{u}{v}\right\} \mapsto P(u,v)\left[\Gamma\begin{pmatrix} u \\ v \end{pmatrix}\right]$$

is well defined and injective. Here u and v are assumed coprime.

Thus the kernel of $\delta : \mathbb{S}_k(\Gamma) \to \mathbb{B}_k(\Gamma)$ is the same as the kernel of $\mu \circ \delta$.

Proposition 8.11. *Let $P \in V_{k-2}$ and $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$. We have*

$$\mu \circ \delta([P, (c,d)]) = P(1,0)[\Gamma \left(\begin{smallmatrix} a \\ c \end{smallmatrix}\right)] - P(0,1)[\Gamma \left(\begin{smallmatrix} b \\ d \end{smallmatrix}\right)].$$

We next describe how to explicitly compute $\mu \circ \delta : \mathbb{M}_k(N, \varepsilon) \to B_k(N, \varepsilon)$ by generalizing the algorithm of [**Cre97a**, §2.2]. To compute the image of $[P, (c,d)]$, with $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, we must compute the class of $[\left(\begin{smallmatrix} a \\ c \end{smallmatrix}\right)]$ and of $[\left(\begin{smallmatrix} b \\ d \end{smallmatrix}\right)]$. Instead of finding a canonical form for cusps, we use a quick test for equivalence modulo scalars. In the following algorithm, by the ith symbol we mean the ith basis vector for a basis of $B_k(N, \varepsilon)$. This basis is constructed as the algorithm is called successively. We first give the algorithm, and then prove the facts used by the algorithm in testing equivalence.

Algorithm 8.12 (Cusp Representation)**.** *Given a boundary Manin symbol $[(\begin{smallmatrix} u \\ v \end{smallmatrix})]$, this algorithm outputs an integer i and a scalar α such that $[(\begin{smallmatrix} u \\ v \end{smallmatrix})]$ is equivalent to α times the ith symbol found so far. (We call this algorithm repeatedly and maintain a running list of cusps seen so far.)*

(1) Use Proposition 3.21 to check whether or not $[(\begin{smallmatrix} u \\ v \end{smallmatrix})]$ is equivalent, modulo scalars, to any cusp found. If so, return the representative, its index, and the scalar. If not, record $(\begin{smallmatrix} u \\ v \end{smallmatrix})$ in the representative list.

(2) Using Proposition 8.16, check whether or not $[(\begin{smallmatrix} u \\ v \end{smallmatrix})]$ is forced to equal 0 by the relations. If it does not equal 0, return its position in the list and the scalar 1. If it equals 0, return the scalar 0 and the position 1; keep $(\begin{smallmatrix} u \\ v \end{smallmatrix})$ in the list, and record that it is equivalent to 0.

The case considered in Cremona's book [**Cre97a**] only involve the trivial character, so no cusp classes are forced to vanish. Cremona gives the following two criteria for equivalence.

Proposition 8.13 (Cremona)**.** *Consider $(\begin{smallmatrix} u_i \\ v_i \end{smallmatrix})$, $i = 1, 2$, with u_i, v_i integers such that $\gcd(u_i, v_i) = 1$ for each i.*

(1) *There exists $g \in \Gamma_0(N)$ such that $g\,(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}) = (\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix})$ if and only if*

$$s_1 v_2 \equiv s_2 v_1 \pmod{\gcd(v_1 v_2, N)}, \text{ where } s_j \text{ satisfies } u_j s_j \equiv 1 \pmod{v_j}.$$

(2) *There exists $g \in \Gamma_1(N)$ such that $g\,(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}) = (\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix})$ if and only if*

$$v_2 \equiv v_1 \pmod{N} \text{ and } u_2 \equiv u_1 \pmod{\gcd(v_1, N)}.$$

Proof. The first statement is [**Cre97a**, Prop. 2.2.3], and the second is [**Cre92**, Lem. 3.2]. □

Algorithm 8.14 (Explicit Cusp Equivalence)**.** *Suppose $(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix})$ and $(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix})$ are equivalent modulo $\Gamma_0(N)$. This algorithm computes a matrix $g \in \Gamma_0(N)$ such that $g\,(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}) = (\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix})$.*

(1) Let s_1, s_2, r_1, r_2 be solutions to $s_1 u_1 - r_1 v_1 = 1$ and $s_2 u_2 - r_2 v_2 = 1$.
(2) Find integers x_0 and y_0 such that $x_0 v_1 v_2 + y_0 N = 1$.
(3) Let $x = -x_0(s_1 v_2 - s_2 v_1)/(v_1 v_2, N)$ and $s_1' = s_1 + x v_1$.
(4) Output $g = (\begin{smallmatrix} u_2 & r_2 \\ v_2 & s_2 \end{smallmatrix}) \cdot \left(\begin{smallmatrix} u_1 & r_1 \\ v_1 & s_1' \end{smallmatrix}\right)^{-1}$, which sends $(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix})$ to $(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix})$.

Proof. See the proof of [**Cre97a**, Prop. 8.13]. □

The ε relations can make the situation more complicated, since it is possible that $\varepsilon(\alpha) \neq \varepsilon(\beta)$ but

$$\varepsilon(\alpha)\left[\begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\gamma_\alpha \begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\gamma_\beta \begin{pmatrix} u \\ v \end{pmatrix}\right] = \varepsilon(\beta)\left[\begin{pmatrix} u \\ v \end{pmatrix}\right].$$

One way out of this difficulty is to construct the cusp classes for $\Gamma_1(N)$, and then quotient out by the additional ε relations using Gaussian elimination. This is far too inefficient to be useful in practice because the number of $\Gamma_1(N)$ cusp classes can be unreasonably large. Instead, we give a quick test to determine whether or not a cusp vanishes modulo the ε-relations.

Lemma 8.15. *Suppose α and α' are integers such that $\gcd(\alpha, \alpha', N) = 1$. Then there exist integers β and β', congruent to α and α' modulo N, respectively, such that $\gcd(\beta, \beta') = 1$.*

Proof. By Exercise 8.2 the map $\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ is surjective. By the Euclidean algorithm, there exist integers x, y and z such that $x\alpha + y\alpha' + zN = 1$. Consider the matrix $\left(\begin{smallmatrix} y & -x \\ \alpha & \alpha' \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ and take β, β' to be the bottom row of a lift of this matrix to $\mathrm{SL}_2(\mathbb{Z})$. □

Proposition 8.16. *Let N be a positive integer and ε a Dirichlet character of modulus N. Suppose $\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$ is a cusp with u and v coprime. Then $\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$ vanishes modulo the relations*

$$[\gamma\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)] = \varepsilon(\gamma)\,[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)], \qquad \textit{all } \gamma \in \Gamma_0(N),$$

if and only if there exists $\alpha \in (\mathbb{Z}/N\mathbb{Z})^*$, with $\varepsilon(\alpha) \neq 1$, such that

$$\begin{aligned} v &\equiv \alpha v \pmod{N}, \\ u &\equiv \alpha u \pmod{\gcd(v, N)}. \end{aligned}$$

Proof. First suppose such an α exists. By Lemma 8.15 there exists $\beta, \beta' \in \mathbb{Z}$ lifting α, α^{-1} such that $\gcd(\beta, \beta') = 1$. The cusp $\left(\begin{smallmatrix} \beta u \\ \beta' v \end{smallmatrix}\right)$ has coprime coordinates so, by Proposition 8.13 and our congruence conditions on α, the cusps $\left(\begin{smallmatrix} \beta u \\ \beta' v \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$ are equivalent by an element of $\Gamma_1(N)$. This implies that $\left[\left(\begin{smallmatrix} \beta u \\ \beta' v \end{smallmatrix}\right)\right] = [\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)]$. Since $\left[\left(\begin{smallmatrix} \beta u \\ \beta' v \end{smallmatrix}\right)\right] = \varepsilon(\alpha)\,[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)]$ and $\varepsilon(\alpha) \neq 1$, we have $[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)] = 0$.

Conversely, suppose $[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)] = 0$. Because all relations are two-term relations and the $\Gamma_1(N)$-relations identify $\Gamma_1(N)$-orbits, there must exists α and β with

$$\left[\gamma_\alpha \begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\gamma_\beta \begin{pmatrix} u \\ v \end{pmatrix}\right] \qquad \text{and } \varepsilon(\alpha) \neq \varepsilon(\beta).$$

Indeed, if this did not occur, then we could mod out by the ε relations by writing each $[\gamma_\alpha \left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)]$ in terms of $[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)]$, and there would be no further relations left to kill $[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)]$. Next observe that

$$\begin{aligned}\left[\gamma_{\beta^{-1}\alpha}\begin{pmatrix} u \\ v \end{pmatrix}\right] &= \left[\gamma_{\beta^{-1}}\gamma_\alpha\begin{pmatrix} u \\ v \end{pmatrix}\right] \\ &= \varepsilon(\beta^{-1})\left[\gamma_\alpha\begin{pmatrix} u \\ v \end{pmatrix}\right] = \varepsilon(\beta^{-1})\left[\gamma_\beta\begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\begin{pmatrix} u \\ v \end{pmatrix}\right].\end{aligned}$$

Applying Proposition 8.13 and noting that $\varepsilon(\beta^{-1}\alpha) \neq 1$ shows that $\beta^{-1}\alpha$ satisfies the properties of the "α" in the statement of the proposition. □

We enumerate the possible α appearing in Proposition 8.16 as follows. Let $g = (v, N)$ and list the $\alpha = v \cdot \frac{N}{g} \cdot a + 1$, for $a = 0, \ldots, g-1$, such that $\varepsilon(\alpha) \neq 0$.

8.5. Pairing Modular Symbols and Modular Forms

In this section we define a pairing between modular symbols and modular forms that the Hecke operators respect. We also define an involution on modular symbols and study its relationship with the pairing. This pairing is crucial in much that follows, because it gives rise to period maps from modular symbols to certain complex vector spaces.

Fix an integer weight $k \geq 2$ and a finite index subgroup Γ of $\mathrm{SL}_2(\mathbb{Z})$. Let $M_k(\Gamma)$ denote the space of holomorphic modular forms of weight k for Γ, and let $S_k(\Gamma)$ denote its cuspidal subspace. Following [**Mer94**, §1.5], let

$$\overline{S}_k(\Gamma) = \{\overline{f} : f \in S_k(\Gamma)\} \tag{8.5.1}$$

denote the space of *antiholomorphic* cusp forms. Here $\overline{f}$ is the function on $\mathfrak{h}^*$ given by $\overline{f}(z) = \overline{f(z)}$.

Define a pairing

$$(S_k(\Gamma) \oplus \overline{S}_k(\Gamma)) \times \mathbb{M}_k(\Gamma) \to \mathbb{C} \tag{8.5.2}$$

by letting

$$\langle (f_1, f_2), P\{\alpha, \beta\}\rangle = \int_\alpha^\beta f_1(z)P(z,1)dz + \int_\alpha^\beta f_2(z)P(\overline{z},1)d\overline{z}$$

and extending linearly. Here the integral is a complex path integral along a simple path from α to β in $\mathfrak{h}$ (so, e.g., write $z(t) = x(t) + iy(t)$, where $(x(t), y(t))$ traces out the path and consider two real integrals).

Proposition 8.17. *The integration pairing is well defined, i.e., if we replace $P\{\alpha, \beta\}$ by an equivalent modular symbol (equivalent modulo the left action of Γ), then the integral is the same.*

Proof. This follows from the change of variables formulas for integration and the fact that $f_1 \in S_k(\Gamma)$ and $f_2 \in \overline{S}_k(\Gamma)$. For example, if $k = 2$, $g \in \Gamma$ and $f \in S_k(\Gamma)$, then

$$\begin{aligned}\langle f, g\{\alpha, \beta\}\rangle &= \langle f, \{g(\alpha), g(\beta)\}\rangle \\ &= \int_{g(\alpha)}^{g(\beta)} f(z)dz \\ &= \int_{\alpha}^{\beta} f(g(z))dg(z) \\ &= \int_{\alpha}^{\beta} f(z)dz = \langle f, \{\alpha, \beta\}\rangle,\end{aligned}$$

where $f(g(z))dg(z) = f(z)dz$ because f is a weight 2 modular form. For the case of arbitrary weight $k > 2$, see Exercise 8.4. □

The integration pairing is very relevant to the study of special values of L-functions. The L-function of a cusp form $f = \sum a_n q^n \in S_k(\Gamma_1(N))$ is

$$L(f, s) = (2\pi)^s \Gamma(s)^{-1} \int_0^\infty f(it)t^s \frac{dt}{t} \tag{8.5.3}$$

$$= \sum_{n=1}^{\infty} \frac{a_n}{n^s} \qquad \text{for } \mathrm{Re}(s) \gg 0. \tag{8.5.4}$$

The equality of the integral and the Dirichlet series follows by switching the order of summation and integration, which is justified using standard estimates on $|a_n|$ (see, e.g., [**Kna92**, Section VIII.5]).

For each integer j with $1 \leq j \leq k-1$, we have, setting $s = j$ and making the change of variables $t \mapsto -it$ in (8.5.3), that

$$L(f, j) = \frac{(-2\pi i)^j}{(j-1)!} \cdot \left\langle f,\ X^{j-1}Y^{k-2-(j-1)}\{0, \infty\}\right\rangle. \tag{8.5.5}$$

The integers j as above are called *critical integers*. When f is an eigenform, they have deep conjectural significance (see [**BK90, Sch90**]). One can approximate $L(f, j)$ to any desired precision by computing the above pairing explicitly using the method described in Chapter 10. Alternatively, [**Dok04**] contains methods for computing special values of very general L-functions, which can be used for approximating $L(f, s)$ for arbitrary s, in addition to just the critical integers $1, \ldots, k-1$.

Theorem 8.18 (Shokoruv)**.** *The pairing*

$$\langle \cdot\,, \cdot\rangle : (S_k(\Gamma) \oplus \overline{S}_k(\Gamma)) \times \mathbb{S}_k(\Gamma, \mathbb{C}) \to \mathbb{C}$$

is a nondegenerate pairing of complex vector spaces.

Proof. This is [**Sho80b**, Thm. 0.2] and [**Mer94**, §1.5]. □

Corollary 8.19. *We have*

$$\dim_{\mathbb{C}} \mathbb{S}_k(\Gamma, \mathbb{C}) = 2 \dim_{\mathbb{C}} S_2(\Gamma).$$

The pairing is also compatible with Hecke operators. Before proving this, we define an *action of Hecke operators* on $M_k(\Gamma_1(N))$ and on $\overline{S}_k(\Gamma_1(N))$. The definition is similar to the one we gave in Section 2.4 for modular forms of level 1. For a positive integer n, let R_n be a set of coset representatives for $\Gamma_1(N)\backslash\Delta_n$ from Lemma 8.7. For any $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$ and $f \in M_k(\Gamma_1(N))$ set

$$f^{[\gamma]_k} = \det(\gamma)^{k-1}(cz+d)^{-k} f(\gamma(z)).$$

Also, for $f \in \overline{S}_k(\Gamma_1(N))$, set

$$f^{[\gamma]'_k} = \det(\gamma)^{k-1}(c\overline{z}+d)^{-k} f(\gamma(z)).$$

Then for $f \in M_k(\Gamma_1(N))$,

$$T_n(f) = \sum_{\gamma \in R_n} f^{[\gamma]_k}$$

and for $f \in \overline{S}_k(\Gamma_1(N))$,

$$T_n(f) = \sum_{\gamma \in R_n} f^{[\gamma]'_k}.$$

This agrees with the definition from Section 2.4 when $N = 1$.

Remark 8.20. If Γ is an arbitrary finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$, then we can define operators T_Δ on $M_k(\Gamma)$ for any Δ with $\Delta\Gamma = \Gamma\Delta = \Delta$ and $\Gamma\backslash\Delta$ finite. For concreteness we do not do the general case here or in the theorem below, but the proof is exactly the same (see [**Mer94**, §1.5]).

Finally we prove the promised Hecke compatibility of the pairing. This proof should convince you that the definition of modular symbols is sensible, in that they are natural objects to integrate against modular forms.

Theorem 8.21. *If*

$$f = (f_1, f_2) \in S_k(\Gamma_1(N)) \oplus \overline{S}_k(\Gamma_1(N))$$

and $x \in \mathbb{M}_k(\Gamma_1(N))$*, then for any* n*,*

$$\langle T_n(f), x\rangle = \langle f, T_n(x)\rangle.$$

Proof. We follow [**Mer94**, §2.1] (but with more details) and will only prove the theorem when $f = f_1 \in S_k(\Gamma_1(N))$, the proof in the general case being the same.

Let $\alpha, \beta \in \mathbb{P}^1(\mathbb{Q})$, $P \in \mathbb{Z}[X,Y]_{k-2}$, and for $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Q})$, set

$$j(g, z) = cz + d.$$

Let n be any positive integer, and let R_n be a set of coset representatives for $\Gamma_1(N)\backslash\Delta_n$ from Lemma 8.7.

We have

$$\begin{aligned}\langle T_n(f), P\{\alpha,\beta\}\rangle &= \int_\alpha^\beta T_n(f)P(z,1)dz\\ &= \sum_{\delta\in R}\int_\alpha^\beta \det(\delta)^{k-1} f(\delta(z))j(\delta,z)^{-k}P(z,1)dz.\end{aligned}$$

Now for each summand corresponding to the $\delta \in R$, make the change of variables $u = \delta z$. Thus we make $\#R$ change of variables. Also, we will use the notation

$$\tilde{g} = \begin{pmatrix} d & -b\\ -c & a\end{pmatrix} = \det(g)\cdot g^{-1}$$

for $g \in \mathrm{GL}_2(\mathbb{Q})$. We have

$$\langle T_n(f), P\{\alpha,\beta\}\rangle = \\ \sum_{\delta\in R}\int_{\delta(\alpha)}^{\delta(\beta)} \det(\delta)^{k-1} f(u)j(\delta,\delta^{-1}(u))^{-k}P(\delta^{-1}(u),1)d(\delta^{-1}(u)).$$

We have $\delta^{-1}(u) = \tilde{\delta}(u)$, since a linear fractional transformation is unchanged by a nonzero rescaling of a matrix that induces it. Thus by the quotient rule, using that $\tilde{\delta}$ has determinant $\det(\delta)$, we see that

$$d(\delta^{-1}(u)) = d(\tilde{\delta}(u)) = \frac{\det(\delta)du}{j(\tilde{\delta},u)^2}.$$

We next show that

$$j(\delta,\delta^{-1}(u))^{-k}P(\delta^{-1}(u),1) = j(\tilde{\delta},u)^k\det(\delta)^{-k}P(\tilde{\delta}(u),1). \tag{8.5.6}$$

From the definitions, and again using that $\delta^{-1}(u) = \tilde{\delta}(u)$, we see that

$$j(\delta,\delta^{-1}(u)) = \frac{\det(\delta)}{j(\tilde{\delta},u)},$$

which proves that (8.5.6) holds. Thus

$$\langle T_n(f), P\{\alpha,\beta\}\rangle = \\ \sum_{\delta\in R}\int_{\delta(\alpha)}^{\delta(\beta)} \det(\delta)^{k-1} f(u)j(\tilde{\delta},u)^k\det(\delta)^{-k}P(\tilde{\delta}(u),1)\frac{\det(\delta)du}{j(\tilde{\delta},u)^2}.$$

Next we use that

$$(\delta P)(u,1) = j(\tilde{\delta},u)^{k-2}P(\tilde{\delta}(u),1).$$

To see this, note that $P(X,Y) = P(X/Y,1)\cdot Y^{k-2}$. Using this we see that

$$\begin{aligned}(\delta P)(X,Y) &= (P\circ\tilde{\delta})(X,Y)\\ &= P\left(\tilde{\delta}\left(\frac{X}{Y}\right),1\right)\left(-c\cdot\frac{X}{Y}+a\right)^{k-2}\cdot Y^{k-2}.\end{aligned}$$

Now substituting $(u,1)$ for $(X,1)$, we see that

$$(\delta P)(u,1) = P(\tilde{\delta}(u),1)\cdot(-cu+a)^{k-2},$$

as required. Thus finally

$$\begin{aligned}\langle T_n(f), P\{\alpha,\beta\}\rangle &= \sum_{\delta\in R}\int_{\delta(\alpha)}^{\delta(\beta)} f(u)j(\tilde{\delta},u)^{k-2}P(\tilde{\delta}(u),1)du\\ &= \sum_{\delta\in R}\int_{\delta(\alpha)}^{\delta(\beta)} f(u)\cdot((\delta P)(u,1))du\\ &= \langle f,\, T_n(P\{\alpha,\beta\})\rangle.\end{aligned}$$

□

Suppose that Γ is a finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$ such that if $\eta = \left(\begin{smallmatrix}-1&0\\0&1\end{smallmatrix}\right)$, then

$$\eta\Gamma\eta = \Gamma.$$

For example, $\Gamma = \Gamma_1(N)$ satisfies this condition. There is an involution ι^* on $\mathbb{M}_k(\Gamma)$ given by

$$\iota^*(P(X,Y)\{\alpha,\beta\}) = -P(X,-Y)\{-\alpha,-\beta\}, \tag{8.5.7}$$

which we call the *star involution*. On Manin symbols, ι^* is

$$\iota^*[P,(u,v)] = -[P(-X,Y),(-u,v)]. \tag{8.5.8}$$

Let $\mathbb{S}_k(\Gamma)^+$ be the $+1$ eigenspace for ι^* on $\mathbb{S}_k(\Gamma)$, and let $\mathbb{S}_k(\Gamma)^-$ be the -1 eigenspace. There is also a map ι on modular forms, which is adjoint to ι^*.

Remark 8.22. Notice the minus sign in front of $-P(X,-Y)\{-\alpha,-\beta\}$ in (8.5.7). This sign is missing in [**Cre97a**], which is a potential source of confusion (this is not a mistake, but a different choice of convention).

We now state the final result about the pairing, which explains how modular symbols and modular forms are related.

Theorem 8.23. *The integration pairing $\langle\cdot\,,\,\cdot\rangle$ induces nondegenerate Hecke compatible bilinear pairings*

$$\mathbb{S}_k(\Gamma)^+\times S_k(\Gamma)\to\mathbb{C}\qquad\textit{and}\qquad\mathbb{S}_k(\Gamma)^-\times\overline{S}_k(\Gamma)\to\mathbb{C}.$$

Remark 8.24. We make some remarks about computing the boundary map of Section 8.4.1 when working in the ±1 quotient. Let s be a sign, either $+1$ or -1. To compute $\mathbb{S}_k(N,\varepsilon)_s$, it is necessary to replace $B_k(N,\varepsilon)$ by its quotient modulo the additional relations $[\left(\begin{smallmatrix}-u\\v\end{smallmatrix}\right)] = s\,[\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)]$ for all cusps $\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$. Algorithm 8.12 can be modified to deal with this situation as follows. Given a cusp $x = \left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$, proceed as in Algorithm 8.12 and check if either $\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$ or $\left(\begin{smallmatrix}-u\\v\end{smallmatrix}\right)$ is equivalent (modulo scalars) to any cusp seen so far. If not, use the following trick to determine whether the ε and s-relations kill the class of $\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$: use the unmodified Algorithm 8.12 to compute the scalars α_1, α_2 and indices i_1, i_2 associated to $\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}-u\\v\end{smallmatrix}\right)$, respectively. The s-relation kills the class of $\left(\begin{smallmatrix}u\\v\end{smallmatrix}\right)$ if and only if $i_1 = i_2$ but $\alpha_1 \neq s\alpha_2$.

8.6. Degeneracy Maps

In this section, we describe natural maps between spaces of modular symbols with character of different levels. We consider spaces with character, since they are so important in applications.

Fix a positive integer N and a Dirichlet character $\varepsilon : (\mathbb{Z}/N\mathbb{Z})^* \to \mathbb{C}^*$. Let M be a positive divisor of N that is divisible by the conductor of ε, in the sense that ε factors through $(\mathbb{Z}/M\mathbb{Z})^*$ via the natural map $(\mathbb{Z}/N\mathbb{Z})^* \to (\mathbb{Z}/M\mathbb{Z})^*$ composed with some uniquely defined character $\varepsilon' : (\mathbb{Z}/M\mathbb{Z})^* \to \mathbb{C}^*$. For any positive divisor t of N/M, let $T = \left(\begin{smallmatrix}1&0\\0&t\end{smallmatrix}\right)$ and fix a choice $D_t = \{T\gamma_i : i = 1, \ldots, n\}$ of coset representatives for $\Gamma_0(N)\backslash T\Gamma_0(M)$.

Remark 8.25. Note that [**Mer94**, §2.6] contains a typo: The quotient "$\Gamma_1(N)\backslash\Gamma_1(M)T$" should be replaced by "$\Gamma_1(N)\backslash T\Gamma_1(M)$".

Proposition 8.26. *For each divisor t of N/M there are well-defined linear maps*

$$\alpha_t : \mathbb{M}_k(N,\varepsilon) \to \mathbb{M}_k(M,\varepsilon'), \qquad \alpha_t(x) = (tT^{-1})x = \begin{pmatrix}t&0\\0&1\end{pmatrix}x,$$

$$\beta_t : \mathbb{M}_k(M,\varepsilon') \to \mathbb{M}_k(N,\varepsilon), \qquad \beta_t(x) = \sum_{T\gamma_i\in D_t} \varepsilon'(\gamma_i)^{-1}T\gamma_i x.$$

Furthermore, $\alpha_t \circ \beta_t$ is multiplication by $t^{k-2}\cdot[\Gamma_0(M) : \Gamma_0(N)]$.

Proof. To show that α_t is well defined, we must show that for each $x \in \mathbb{M}_k(N,\varepsilon)$ and $\gamma = \left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right) \in \Gamma_0(N)$, we have

$$\alpha_t(\gamma x - \varepsilon(\gamma)x) = 0 \in \mathbb{M}_k(M,\varepsilon').$$

We have

$$\alpha_t(\gamma x) = \begin{pmatrix}t&0\\0&1\end{pmatrix}\gamma x = \begin{pmatrix}a&tb\\c/t&d\end{pmatrix}\begin{pmatrix}t&0\\0&1\end{pmatrix}x = \varepsilon'(a)\begin{pmatrix}t&0\\0&1\end{pmatrix}x,$$

so

$$\alpha_t(\gamma x - \varepsilon(\gamma)x) = \varepsilon'(a)\alpha_t(x) - \varepsilon(\gamma)\alpha_t(x) = 0.$$

We next verify that β_t is well defined. Suppose that $x \in \mathbb{M}_k(M, \varepsilon')$ and $\gamma \in \Gamma_0(M)$; then $\varepsilon'(\gamma)^{-1}\gamma x = x$, so

$$\begin{aligned}\beta_t(x) &= \sum_{T\gamma_i \in D_t} \varepsilon'(\gamma_i)^{-1} T\gamma_i \varepsilon'(\gamma)^{-1}\gamma x \\ &= \sum_{T\gamma_i\gamma \in D_t} \varepsilon'(\gamma_i\gamma)^{-1} T\gamma_i\gamma x.\end{aligned}$$

This computation shows that the definition of β_t does not depend on the choice D_t of coset representatives. To finish the proof that β_t is well defined, we must show that, for $\gamma \in \Gamma_0(M)$, we have $\beta_t(\gamma x) = \varepsilon'(\gamma)\beta_t(x)$ so that β_t respects the relations that define $\mathbb{M}_k(M, \varepsilon)$. Using that β_t does not depend on the choice of coset representative, we find that for $\gamma \in \Gamma_0(M)$,

$$\begin{aligned}\beta_t(\gamma x) &= \sum_{T\gamma_i \in D_t} \varepsilon'(\gamma_i)^{-1} T\gamma_i\gamma x \\ &= \sum_{T\gamma_i\gamma^{-1} \in D_t} \varepsilon'(\gamma_i\gamma^{-1})^{-1} T\gamma_i\gamma^{-1}\gamma x \\ &= \varepsilon'(\gamma)\beta_t(x).\end{aligned}$$

To compute $\alpha_t \circ \beta_t$, we use that $\#D_t = [\Gamma_0(N) : \Gamma_0(M)]$:

$$\begin{aligned}\alpha_t(\beta_t(x)) &= \alpha_t\left(\sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1} T\gamma_i x\right) \\ &= \sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1}(tT^{-1})T\gamma_i x \\ &= t^{k-2}\sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1}\gamma_i x \\ &= t^{k-2}\sum_{T\gamma_i} x \\ &= t^{k-2} \cdot [\Gamma_0(N) : \Gamma_0(M)] \cdot x.\end{aligned}$$

The scalar factor of t^{k-2} appears instead of t, because t is acting on x as an element of $\mathrm{GL}_2(\mathbb{Q})$ and *not* as an an element of $\mathbb{Q}$. □

Definition 8.27 (New and Old Modular Symbols). The space $\mathbb{M}_k(N, \varepsilon)_{\mathrm{new}}$ of *new modular symbols* is the intersection of the kernels of the α_t as t runs through all positive divisors of N/M and M runs through positive divisors of M strictly less than N and divisible by the conductor of ε. The subspace

$\mathbb{M}_k(N,\varepsilon)_{\text{old}}$ of *old modular symbols* is the subspace generated by the images of the β_t where t runs through all positive divisors of N/M and M runs through positive divisors of M strictly less than N and divisible by the conductor of ε. The new and old subspaces of cuspidal modular symbols are the intersections of the above spaces with $\mathbb{S}_k(N,\varepsilon)$.

Example 8.28. The new and old subspaces need not be disjoint, as the following example illustrates! (This contradicts [**Mer94**, pg. 80].) Consider, for example, the case $N = 6$, $k = 2$, and trivial character. The spaces $\mathbb{M}_2(\Gamma_0(2))$ and $\mathbb{M}_2(\Gamma_0(3))$ are each of dimension 1, and each is generated by the modular symbol $\{\infty, 0\}$. The space $\mathbb{M}_2(\Gamma_0(6))$ is of dimension 3 and is generated by the three modular symbols $\{\infty, 0\}$, $\{-1/4, 0\}$, and $\{-1/2, -1/3\}$. The space generated by the two images of $\mathbb{M}_2(\Gamma_0(2))$ under the two degeneracy maps has dimension 2, and likewise for $\mathbb{M}_2(\Gamma_0(3))$. Together these images generate $\mathbb{M}_2(\Gamma_0(6))$, so $\mathbb{M}_2(\Gamma_0(6))$ is equal to its old subspace. However, the new subspace is nontrivial because the two degeneracy maps $\mathbb{M}_2(\Gamma_0(6)) \to \mathbb{M}_2(\Gamma_0(2))$ are equal, as are the two degeneracy maps

$$\mathbb{M}_2(\Gamma_0(6)) \to \mathbb{M}_2(\Gamma_0(3)).$$

In particular, the intersection of the kernels of the degeneracy maps has dimension at least 1 (in fact, it equals 1). We verify some of the above claims using SAGE.

```

8.7. Explicitly Computing $\mathbb{M}_k(\Gamma_0(N))$

In this section we explicitly compute $\mathbb{M}_k(\Gamma_0(N))$ for various k and N. We represent Manin symbols for $\Gamma_0(N)$ as triples of integers (i, u, v), where $(u, v) \in \mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$, and (i, u, v) corresponds to $[X^iY^{k-2-i}, (u, v)]$ in the usual notation. Also, recall from Proposition 3.10 that (u, v) corresponds to the right coset of $\Gamma_0(N)$ that contains a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with $(u, v) \equiv (c, d)$ as elements of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$, i.e., up to rescaling by an element of $(\mathbb{Z}/N\mathbb{Z})^*$.

8.7.1. Computing $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. In this section we give an algorithm to compute a canonical representative for each element of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. This algorithm is extremely important because modular symbols implementations use it a huge number of times. A more naive approach would be to store all pairs $(u, v) \in (\mathbb{Z}/N\mathbb{Z})^2$ and a fixed reduced representative, but this wastes a huge amount of memory. For example, if $N = 10^5$, we would store an array of

$$2 \cdot 10^5 \cdot 10^5 = 20 \text{ billion integers.}$$

Another approach to enumerating $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$ is described at the end of [**Cre97a**, §2.2]. It uses the fact that is easy to test whether two pairs $(u_0, v_0), (u_1, v_1)$ define the same element of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$; they do if and only if we have equality of cross terms $u_0v_1 = v_0u_1 \pmod N$ (see [**Cre97a**, Prop. 2.2.1]). So we consider the 0-based list of elements

$$(1, 0), (1, 1), \ldots, (1, N - 1), (0, 1) \tag{8.7.1}$$

concatenated with the list of nonequivalent elements (d, a) for $d \mid N$ and $a = 1, \ldots, N - 1$, checking each time we add a new element to our list (of (d, a)) whether we have already seen it.

Given a random pair (u, v), the problem is then to find the index of the element of our list of the equivalent representative in $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. We use the following algorithm, which finds a canonical representative for each element of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. Given an arbitrary (u, v), we first find the canonical equivalent elements (u', v'). If $u' = 1$, then the index is v'. If $u' \neq 1$, we find the corresponding element in an explicit sorted list, e.g., using binary search.

In the following algorithm, $a \pmod N$ denotes the residue of a modulo N that satisfies $0 \leq a < N$. Note that we *never* create and store the list (8.7.1) itself in memory.

Algorithm 8.29 (Reduction in $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$ to Canonical Form)**.** *Given u and v and a positive integer N, this algorithm outputs a pair u_0, v_0 such that $(u, v) \equiv (u_0, v_0)$ as elements of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$ and $s \in \mathbb{Z}$ such that $(u, v) = (su_0, sv_0) \pmod{\mathbb{Z}/n\mathbb{Z}}$. Moreover, the element (u_0, v_0) does not depend on the class of (u, v), i.e., for any s with $\gcd(N, s) = 1$ the input (su, sv) also outputs (u_0, v_0). If (u, v) is not in $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$, this algorithm outputs $(0, 0), 0$.*

(1) [Reduce] Reduce both u and v modulo N.

(2) [Easy $(0, 1)$ Case] If $u = 0$, check that $\gcd(v, N) = 1$. If so, return $s = 1$ and $(0, 1)$; otherwise return 0.

(3) [GCD] Compute $g = \gcd(u, N)$ and $s, t \in \mathbb{Z}$ such that $g = su + tN$.

(4) [Not in P^1?] We have $\gcd(u, v, N) = \gcd(g, v)$, so if $\gcd(g, v) > 1$, then $(u, v) \notin \mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$, and we return 0.

(5) [Pseudo-Inverse] Now $g = su+tN$, so we may think of s as "pseudo-inverse" of $u \pmod N$, in the sense that su is as close as possible to being 1 modulo N. Note that since $g \mid u$, changing s modulo N/g does not change $su \pmod N$. We can adjust s modulo N/g so it is coprime to N (by adding multiples of N/g to s). (This is because $1 = su/g + tN/g$, so s is a unit mod N/g, and the map $(\mathbb{Z}/N\mathbb{Z})^* \to (\mathbb{Z}/(N/g)\mathbb{Z})^*$ is surjective, e.g., as we saw in the proof of Algorithm 4.28.)

(6) [Multiply by s] Multiply (u, v) by s, and replace (u, v) by the equivalent element (g, sv) of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$.

(7) [Normalize] Compute the unique pair (g, v') equivalent to (g, v) that minimizes v, as follows:

   (a) [Easy Case] If $g = 1$, this pair is $(1, v)$.

   (b) [Enumerate and Find Best] Otherwise, note that if $1 \neq t \in (\mathbb{Z}/N\mathbb{Z})^*$ and $tg \equiv g \pmod N$, then $(t-1)g \equiv 0 \pmod N$, so $t - 1 = kN/g$ for some k with $1 \leq k \leq g-1$. Then for $t = 1+kN/g$ coprime to N, we have $(gt, vt) = (g, v+kvN/g)$. So we compute all pairs $(g, v+kvN/g)$ and pick out the one that minimizes the least nonnegative residue of vt modulo N.

   (c) [Invert s and Output] The s that we computed in the above steps multiplies the input (u, v) to give the output (u_0, v_0). Thus we invert it, since the scalar we output multiplies (u_0, v_0) to give (u, v).

Remark 8.30. In the above algorithm, there are many gcd's with N so one should create a table of the gcd's of $0, 1, 2, \ldots, N-1$ with N.

Remark 8.31. Another approach is to instead use that

$$\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z}) \cong \prod_{p \mid N} \mathbb{P}^1(\mathbb{Z}/p^{\nu_p}\mathbb{Z}),$$

where $\nu_p = \mathrm{ord}_p(N)$, and that it is relatively easy to enumerate the elements of $\mathbb{P}^1(\mathbb{Z}/p^n\mathbb{Z})$ for a prime power p^n.

Algorithm 8.32 (List $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$)**.** *Given an integer $N > 1$, this algorithm makes a sorted list of the distinct representatives (c, d) of $\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$ with $c \neq 0, 1$, as output by Algorithm 8.29.*

(1) For each $c = 1, \ldots, N-1$ with $g = \gcd(c, N) > 1$ do the following:

   (a) Use Algorithm 8.29 to compute the canonical representative (u', v') equivalent to $(c, 1)$, and include it in the list.

   (b) If $g = c$, for each $d = 2, \dots, N-1$ with $\gcd(d, N) > 1$ and $\gcd(c, d) = 1$, append the normalized representative of (c, d) to the list.

(2) Sort the list.

(3) Pass through the sorted list and delete any duplicates.

8.8. Explicit Examples

Explicit detailed examples are crucial when implementing modular symbols algorithms from scratch. This section contains a number of such examples.

8.8.1. Examples of Computation of $\mathbb{M}_k(\Gamma_0(N))$. In this section, we compute $\mathbb{M}_k(\Gamma_0(N))$ explicitly in a few cases.

Example 8.33. We compute $V = \mathbb{M}_4(\Gamma_0(1))$. Because $S_k(\Gamma_0(1)) = 0$ and $M_k(\Gamma_0(1)) = \mathbb{C}E_4$, we expect V to have dimension 1 and for each integer n the Hecke operator T_n to have eigenvalue the sum $\sigma_3(n)$ of the cubes of positive divisors of n.

The Manin symbols are

$$x_0 = (0,0,0), \quad x_1 = (1,0,0), \quad x_2 = (2,0,0).$$

The relation matrix is

$$\left(\begin{array}{ccc} 1 & 0 & 1 \\ 0 & 0 & 0 \\ \hline 2 & -2 & 2 \\ 1 & -1 & 1 \\ 2 & -2 & 2 \end{array}\right),$$

where the first two rows correspond to S-relations and the second three to T-relations. Note that we do not include all S-relations, since it is obvious that some are redundant, e.g., $x + xS = 0$ and $(xS) + (xS)S = xS + x = 0$ are the same since S has order 2.

The echelon form of the relation matrix is

$$\begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix},$$

where we have deleted the zero rows from the bottom. Thus we may replace the above complicated list of relations with the following simpler list of relations:

$$\begin{aligned} x_0 + x_2 &= 0, \\ x_1 &= 0 \end{aligned}$$

from which we immediately read off that the second generator x_1 is 0 and $x_0 = -x_2$. Thus $\mathbb{M}_4(\Gamma_0(1))$ has dimension 1, with basis the equivalence class of x_2 (or of x_0).

Next we compute the Hecke operator T_2 on $\mathbb{M}_4(\Gamma_0(1))$. The Heilbronn matrices of determinant 2 from Proposition 8.8 are

$$\begin{aligned}
h_0 &= \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix},\\
h_1 &= \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix},\\
h_2 &= \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix},\\
h_3 &= \begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix}.
\end{aligned}$$

To compute T_2, we apply each of these matrices to x_0, then reduce modulo the relations. We have

$$\begin{aligned}
x_2 \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} &= [X^2,(0,0)] \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} x_2,\\
x_2 \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix} &= [X^2,(0,0)] = x_2,\\
x_2 \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} &= [(2X)^2,(0,0)] = 4x_2,\\
x_2 \begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix} &= [(2X+1)^2,(0,0)] = x_0 + 4x_1 + 4x_2 \sim 3x_2.
\end{aligned}$$

Summing we see that $T_2(x_2) \sim 9x_2$ in $\mathbb{M}_4(\Gamma_0(1))$. Notice that

$$9 = 1^3 + 2^3 = \sigma_3(2).$$

The Heilbronn matrices of determinant 3 from Proposition 8.8 are

$$\begin{aligned}
h_0 &= \begin{pmatrix} 1 & 0 \\ 0 & 3 \end{pmatrix}, & h_1 &= \begin{pmatrix} 1 & 0 \\ 1 & 3 \end{pmatrix},\\
h_2 &= \begin{pmatrix} 1 & 0 \\ 2 & 3 \end{pmatrix}, & h_3 &= \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix},\\
h_4 &= \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}, & h_5 &= \begin{pmatrix} 3 & 1 \\ 0 & 1 \end{pmatrix},\\
h_6 &= \begin{pmatrix} 3 & 2 \\ 0 & 1 \end{pmatrix}.
\end{aligned}$$

We have

$$\begin{aligned}
x_2 \begin{pmatrix} 1 & 0 \\ 0 & 3 \end{pmatrix} &= [X^2, (0,0)] \begin{pmatrix} 1 & 0 \\ 0 & 3 \end{pmatrix} = x_2, \\
x_2 \begin{pmatrix} 1 & 0 \\ 1 & 3 \end{pmatrix} &= [X^2, (0,0)] = x_2, \\
x_2 \begin{pmatrix} 1 & 0 \\ 2 & 3 \end{pmatrix} &= [X^2, (0,0)] = x_2, \\
x_2 \begin{pmatrix} 2 & 1 \\ 2 & 2 \end{pmatrix} &= [(2X+1)^2, (0,0)] = x_0 + 4x_1 + 4x_2 \sim 3x_2, \\
x_2 \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix} &= [(3X)^2, (0,0)] = 9x_2, \\
x_2 \begin{pmatrix} 3 & 1 \\ 0 & 1 \end{pmatrix} &= [(3X+1)^2, (0,0)] = x_0 + 6x_1 + 9x_2 \sim 8x_2, \\
x_2 \begin{pmatrix} 3 & 2 \\ 0 & 1 \end{pmatrix} &= [(3X+2)^2, (0,0)] = 4x_0 + 12x_1 + 9x_2 \sim 5x_2.
\end{aligned}$$

Summing we see that

$$T_3(x_2) \sim x_2 + x_2 + x_2 + 3x_2 + 9x_2 + 8x_2 + 5x_2 = 28x_2.$$

Notice that

$$28 = 1^3 + 3^3 = \sigma_3(3).$$

Example 8.34. Next we compute $\mathbb{M}_2(\Gamma_0(11))$ explicitly. The Manin symbol generators are

$$x_0 = (0,1),\ x_1 = (1,0),\ x_2 = (1,1),\ x_3 = (1,2),\ x_4 = (1,3),\ x_5 = (1,4),$$

$$x_6 = (1,5),\ x_7 = (1,6),\ x_8 = (1,7),\ x_9 = (1,8),\ x_{10} = (1,9),\ x_{11} = (1,10).$$

The relation matrix is as follows, where the S-relations are above the line and the T-relations are below it:

$$\left(\begin{array}{cccccccccccc}
1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
\hline
1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0
\end{array}\right).$$

In weight 2, two out of three T-relations are redundant, so we do not include them. The reduced row echelon form of the relation matrix is

$$\left(\begin{array}{cccccccccccc}
1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0\\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & -1 & 0\\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}\right).$$

From the echelon form we see that every symbol is equivalent to a combination of $x_1 = (1,0)$, $x_9 = (1,8)$, and $x_{10} = (1,9)$. (Notice that columns 1, 9, and 10 are the pivot columns, where we index columns starting at 0.)

To compute T_2, we apply each of the Heilbronn matrices of determinant 2 from Proposition 8.8 to x_1, then to x_9, and finally to x_{10}. The matrices are as in Example 8.33 above. We have

$$T_2(x_1) = 3(1,0) + (1,6) \sim 3x_1 - x_{10}.$$

Applying T_2 to $x_9 = (1,8)$, we get

$$T_2(x_9) = (1,3) + (1,4) + (1,5) + (1,10) \sim -2x_9.$$

Applying T_2 to $x_{10} = (1,9)$, we get

$$T_2(x_{10}) = (1,4) + (1,5) + (1,7) + (1,10) \sim -x_1 - 2x_{10}.$$

Thus the matrix of T_2 with respect to this basis is

$$T_2 = \begin{pmatrix} 3 & 0 & 0 \\ 0 & -2 & 0 \\ -1 & 0 & -2 \end{pmatrix},$$

where we write the matrix as an operator on the left on vectors written in terms of x_1, x_9, and x_{10}. The matrix T_2 has characteristic polynomial

$$(x-3)(x+2)^2.$$

The $(x-3)$ factor corresponds to the weight 2 Eisenstein series, and the $x+2$ factor corresponds to the elliptic curve $E = X_0(11)$, which has

$$a_2 = -2 = 2 + 1 - \#E(\mathbb{F}_2).$$

Example 8.35. In this example, we compute $\mathbb{M}_6(\Gamma_0(3))$, which illustrates both weight greater than 2 and level greater than 1. We have the following generating Manin symbols:

$$\begin{aligned} x_0 &= [XY^4,(0,1)], & x_1 &= [XY^4,(1,0)],\\ x_2 &= [XY^4,(1,1)], & x_3 &= [XY^4,(1,2)],\\ x_4 &= [XY^3,(0,1)], & x_5 &= [XY^3,(1,0)],\\ x_6 &= [XY^3,(1,1)], & x_7 &= [XY^3,(1,2)],\\ x_8 &= [X^2Y^2,(0,1)], & x_9 &= [X^2Y^2,(1,0)],\\ x_{10} &= [X^2Y^2,(1,1)], & x_{11} &= [X^2Y^2,(1,2)],\\ x_{12} &= [X^3Y,(0,1)], & x_{13} &= [X^3Y,(1,0)],\\ x_{14} &= [X^3Y,(1,1)], & x_{15} &= [X^3Y,(1,2)],\\ x_{16} &= [X^4Y,(0,1)], & x_{17} &= [X^4Y,(1,0)],\\ x_{18} &= [X^4Y,(1,1)], & x_{19} &= [X^4Y,(1,2)]. \end{aligned}$$

The relation matrix is already very large for $\mathbb{M}_6(\Gamma_0(3))$. It is as follows, where the S-relations are before the line and the T-relations after it:

$$\left(\begin{array}{cccccccccccccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0\\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0\\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1\\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0\\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
\hline
1 & 0 & 0 & 1 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 1 & 0 & 1\\
1 & 1 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 1 & 0 & 0 & 1\\
0 & 0 & 2 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 2 & 0\\
0 & 1 & 0 & 1 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 1 & 1 & 0 & 0\\
0 & 0 & 0 & 1 & 1 & 0 & 0 & -3 & 0 & 0 & 0 & 3 & 0 & -1 & 0 & -1 & 0 & 1 & 0 & 0\\
1 & 0 & 0 & 0 & -3 & 1 & 0 & 0 & 3 & 0 & 0 & 0 & -1 & 0 & 0 & -1 & 0 & 0 & 0 & 1\\
0 & 0 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 3 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 1 & 0\\
0 & 1 & 0 & 0 & 0 & -3 & 0 & 1 & 0 & 3 & 0 & 0 & -1 & -1 & 0 & 0 & 1 & 0 & 0 & 0\\
0 & 0 & 0 & 1 & 0 & 0 & 0 & -2 & 1 & 1 & 0 & 1 & 0 & -2 & 0 & 0 & 0 & 1 & 0 & 0\\
1 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 1\\
0 & 0 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 3 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 1 & 0\\
0 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 1 & 1 & 0 & 1 & -2 & 0 & 0 & 0 & 1 & 0 & 0 & 0\\
0 & 0 & 0 & 1 & 0 & -1 & 0 & -1 & 0 & 3 & 0 & 0 & 1 & -3 & 0 & 0 & 0 & 1 & 0 & 0\\
1 & 0 & 0 & 0 & -1 & 0 & 0 & -1 & 0 & 0 & 0 & 3 & 0 & 1 & 0 & -3 & 0 & 0 & 0 & 1\\
0 & 0 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 3 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 1 & 0\\
0 & 1 & 0 & 0 & -1 & -1 & 0 & 0 & 3 & 0 & 0 & 0 & -3 & 0 & 0 & 1 & 1 & 0 & 0 & 0\\
0 & 1 & 0 & 1 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 1 & 1 & 0 & 0\\
1 & 0 & 0 & 1 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 1 & 0 & 1\\
0 & 0 & 2 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 2 & 0\\
1 & 1 & 0 & 0 & -4 & 0 & 0 & 0 & 6 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 1 & 0 & 0 & 1
\end{array}\right).$$

The reduced row echelon form of the relations matrix, with zero rows removed is

$$\left(\begin{array}{cccccccccccccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 3/16 & -3/16 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1/16 & 1/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1/2 & -5/16 & -3/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1/2 & 3/16 & 5/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1/6 & 1/12 & 1/12 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1/6 & -1/12 & -1/12 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1/4 & -1/4 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1/4 & 1/4 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & -1/16 & 1/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 3/16 & -3/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1/2 & 3/16 & 5/16 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1/2 & -5/16 & -3/16
\end{array}\right).$$

Since these relations are equivalent to the original relations, we see how $x_0, \ldots, x_{15}$ can be expressed in terms of x_{16}, x_{17}, x_{18}, and x_{19}. Thus $\mathbb{M}_6(\Gamma_0(3))$ has dimension 4. For example,

$$x_{15} \sim \frac{1}{2}x_{17} - \frac{5}{16}x_{18} - \frac{3}{16}x_{19}.$$

Notice that the number of relations is already quite large. It is perhaps surprising how complicated the presentation is already for $\mathbb{M}_6(\Gamma_0(3))$. Because there are denominators in the relations, the above calculation is only a computation of $\mathbb{M}_6(\Gamma_0(3);\mathbb{Q})$. Computing $\mathbb{M}_6(\Gamma_0(3);\mathbb{Z})$ involves finding a $\mathbb{Z}$-basis for the kernel of the relation matrix (see Exercise 7.5).

As before, we find that with respect to the basis x_{16}, x_{17}, x_{18}, and x_{19}

$$T_2 = \begin{pmatrix} 33 & 0 & 0 & 0 \\ 3 & 6 & 12 & 12 \\ -3/2 & 27/2 & 15/2 & 27/2 \\ -3/2 & 27/2 & 27/2 & 15/2 \end{pmatrix}.$$

Notice that there are denominators in the matrix for T_2 with respect to this basis. It is clear from the definition of T_2 acting on Manin symbols that T_2 preserves the $\mathbb{Z}$-module $\mathbb{M}_6(\Gamma_0(3))$, so there is some basis for $\mathbb{M}_6(\Gamma_0(3))$ such that T_2 is given by an integer matrix. Thus the characteristic polynomial f_2 of T_2 will have integer coefficients; indeed,

$$f_2 = (x-33)^2 \cdot (x+6)^2.$$

Note the factor $(x-33)^2$, which comes from the two images of the Eisenstein series E_4 of level 1. The factor $x+6$ comes from the cusp form

$$g = q - 6q^2 + \cdots \in S_6(\Gamma_0(3)).$$

By computing more Hecke operators T_n, we can find more coefficients of g. For example, the charpoly of T_3 is $(x-1)(x-243)(x-9)^2$, and the matrix of T_5 is

$$T_5 = \begin{pmatrix} 3126 & 0 & 0 & 0 \\ 240 & 966 & 960 & 960 \\ -120 & 1080 & 1086 & 1080 \\ -120 & 1080 & 1080 & 1086 \end{pmatrix},$$

which has characteristic polynomial

$$f_5 = (x - 3126)^2(x - 6)^2.$$

The matrix of T_7 is

$$T_7 = \begin{pmatrix} 16808 & 0 & 0 & 0 \\ 1296 & 5144 & 5184 & 5184 \\ -648 & 5832 & 5792 & 5832 \\ -648 & 5832 & 5832 & 5792 \end{pmatrix},$$

with characteristic polynomial

$$f_7 = (x - 16808)^2(x + 40)^2.$$

One can put this information together to deduce that

$$g = q - 6q^2 + 9q^3 + 4q^4 + 6q^5 - 54q^6 - 40q^7 + \cdots .$$

Example 8.36. Consider $\mathbb{M}_2(\Gamma_0(43))$, which has dimension 7. With respect to the symbols

$$x_1 = (1, 0), \quad x_{32} = (1, 31), \quad x_{33} = (1, 32),$$
$$x_{39} = (1, 38), \quad x_{40} = (1, 39), \quad x_{41} = (1, 40), \quad x_{42} = (1, 41),$$

the matrix of T_2 is

$$T_2 = \begin{pmatrix} 3 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -2 & -1 & -1 & -1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & -2 & -1 \\ 0 & 0 & 1 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 2 & 1 & 2 & 1 \\ 0 & 0 & -1 & -1 & -1 & -2 & 0 \\ -1 & 0 & 0 & 1 & 1 & 1 & -1 \end{pmatrix},$$

which has characteristic polynomial

$$(x - 3)(x + 2)^2(x^2 - 2)^2.$$

There is one Eisenstein series and there are three cusp forms with $a_2 = -2$ and $a_2 = \pm\sqrt{2}$.

Example 8.37. To compute $\mathbb{M}_2(\Gamma_0(2004); \mathbb{Q})$, we first make a list of the

$$4032 = (2^2 + 2) \cdot (3 + 1) \cdot (167 + 1)$$

elements $(a, b) \in \mathbb{P}^1(\mathbb{Z}/2004\mathbb{Z})$ using Algorithm 8.29. The list looks like this:

$$(0, 1), (1, 0), (1, 1), (1, 2), \ldots, (668, 1), (668, 3), (668, 5), (1002, 1).$$

For each of the symbols x_i, we consider the S-relations and T-relations. Ignoring the redundant relations, we find 2016 S-relations and 1344 T-relations. It is simple to quotient out by the S-relations, e.g., by identifying x_i with $-x_iS = -x_j$ for some j (or setting $x_i = 0$ if $x_iS = x_i$). Once we have taken the quotient by the S-relations, we take the *image* of all 1344 of the T-relations modulo the S-relations and quotient out by those relations. Because S and T do not commutate, we cannot only quotient out by T-relations $x_i + x_iT + x_iT^2 = 0$ where the x_i are the basis after quotienting out by the S-relations. The relation matrix has rank 3359, so $\mathbb{M}_2(\Gamma_0(2004);\mathbb{Q})$ has dimension 673.

If we instead compute the quotient $\mathbb{M}_2(\Gamma_0(2004);\mathbb{Q})^+$ of $\mathbb{M}_2(\Gamma_0(2004);\mathbb{Q})$ by the subspace of elements $x - \eta^*(x)$, we include relations $x_i + x_iI = 0$, where $I = \left(\begin{smallmatrix}-1 & 0\\ 0 & 1\end{smallmatrix}\right)$. There are now 2016 S-relations, 2024 I-relations, and 1344 T-relations. Again, it is relatively easy to quotient out by the S-relations by identifying x_i and $-x_iS$. We then take the image of all 2024 I-relations modulo the S-relations, and again directly quotient out by the I-relations by identifying $[x_i]$ with $-[x_iI] = -[x_j]$ for some j, where by $[x_i]$ we mean the class of x_i modulo the S-relations. Finally, we quotient out by the 1344 T-relations, which involves sparse Gauss elimination on a matrix with 1344 rows and at most three nonzero entries per row. The dimension of $\mathbb{M}_2(\Gamma_0(2004);\mathbb{Q})^+$ is 331.

8.9. Refined Algorithm for the Presentation

Algorithm 8.38 (Modular Symbols Presentation)**.** *This is an algorithm to compute $\mathbb{M}_k(\Gamma_0(N);\mathbb{Q})$ or $\mathbb{M}_k(\Gamma_0(N);\mathbb{Q})^\pm$, which only requires doing generic sparse linear algebra to deal with the three term T-relations.*

(1) Let $x_0, \ldots, x_n$ by a list of all Manin symbols.

(2) Quotient out the two-term S-relations and if the ± quotient is desired, by the two-term η-relations. (Note that this is more subtle than just "identifying symbols in pairs", since complicated relations can cause generators to surprisingly equal 0.) Let $[x_i]$ denote the class of x_i after this quotienting process.

(3) Create a sparse matrix A with m columns, whose rows encode the relations

$$[x_i] + [x_iT] + [x_iT^2] = 0.$$

For example, there are about $n/3$ such rows when $k = 2$. The number of nonzero entries per row is at most $3(k-1)$. Note that we must include rows for *all* i, since even if $[x_i] = [x_j]$, it need not be the case that $[x_iT] = [x_jT]$, since the matrices S and T do not commute. However, we have an a priori formula for the dimension of the quotient by all these relations, so we could omit many relations and just check that there are enough at the end—if there are not, we add in more.

(4) Compute the reduced row echelon form of A using Algorithm 7.6. For $k = 2$, this is the echelon form of a matrix with size about $n/3 \times n/4$.

(5) Use what we have done above to read off a sparse matrix R that expresses each of the n Manin symbols in terms of a basis of Manin symbols, modulo the relations.

8.10. Applications

8.10.1. Later in This Book. We sketch some of the ways in which we will apply the modular symbols algorithms of this chapter later in this book.

Cuspidal modular symbols are in Hecke-equivariant duality with cuspidal modular forms, and as such we can compute modular forms by computing systems of eigenvalues for the Hecke operators acting on modular symbols. By the Atkin-Lehner-Li theory of newforms (see, e.g., Theorem 9.4), we can construct $S_k(N, \varepsilon)$ for any N, any ε, and $k \geq 2$ using this method. See Chapter 1 for more details.

Once we can compute spaces of modular symbols, we move to computing the corresponding modular forms. We define inclusion and trace maps from modular symbols of one level N to modular symbols of level a multiple or divisor of N. Using these, we compute the quotient V of the new subspace of cuspidal modular symbols on which a "star involution" acts as $+1$. The Hecke operators act by diagonalizable commuting matrices on this space, and computing the systems of Hecke eigenvalues is equivalent to computing newforms $\sum a_n q^n$. In this way, we obtain a list of *all* newforms (normalized eigenforms) in $S_k(N, \varepsilon)$ for any N, ε, and $k \geq 2$.

In Chapter 10, we compute with the period mapping from modular symbols to $\mathbb{C}$ attached to a newform $f \in S_k(N, \varepsilon)$. When $k = 2, \varepsilon = 1$ and f has rational Fourier coefficients, this gives a method to compute the period lattice associated to a modular elliptic curve attached to a newform (see Section 10.7). In general, computation of this map is important when finding equations for modular $\mathbb{Q}$-curves, CM curves, and curves with a given modular Jacobian. It is also important for computing special values of the L-function $L(f, s)$ at integer points in the critical strip.

8.10.2. Discussion of the Literature and Research. Modular symbols were introduced by Birch [**Bir71**] for computations in support of the Birch and Swinnerton-Dyer conjecture. Manin [**Man72**] used modular symbols to prove rationality results about special values of L-functions.

Merel's paper [**Mer94**] builds on work of Shokurov (mainly [**Sho80a**]), which develops a higher-weight generalization of Manin's work partly to understand rationality properties of special values of L-functions. Cremona's book [**Cre97a**] discusses how to compute the space of weight 2 modular symbols for $\Gamma_0(N)$, in connection with the problem of enumerating all elliptic curves of given conductor, and his article [**Cre92**] discusses the $\Gamma_1(N)$ case and computation of modular symbols with character.

There have been several Ph.D. theses about modular symbols. Basmaji's thesis [**Bas96**] contains tricks to efficiently compute Hecke operators T_p, with p very large (see Section 8.3.4), and also discusses how to compute spaces of half integral weight modular forms building on what one can get from modular symbols of integral weight. The author's Ph.D. thesis [**Ste00**] discusses higher-weight modular symbols and applies modular symbols to study Shafarevich-Tate groups (see also [**Aga00**]). Martin's thesis [**Mar01**] is about an attempt to study an analogue of analytic modular symbols for weight 1. Gabor Wiese's thesis [**Wie05**] uses modular symbols methods to study weight 1 modular forms modulo p. Lemelin's thesis [**Lem01**] discusses modular symbols for quadratic imaginary fields in the context of p-adic analogues of the Birch and Swinnerton-Dyer conjecture. See also the survey paper [**FM99**], which discusses computation with weight 2 modular symbols in the context of modular abelian varieties.

The appendix of this book is about analogues of modular symbols for groups besides finite index subgroups of $\mathrm{SL}_2(\mathbb{Z})$, e.g., for subgroup of higher rank groups such as $\mathrm{SL}_3(\mathbb{Z})$. There has also been work on computing Hilbert modular forms, e.g., by Lassina Dembelé [**Dem05**] Hilbert modular forms are functions on a product of copies of $\mathfrak{h}$, and $\mathrm{SL}_2(\mathbb{Z})$ is replaced by a group of matrices with entries in a totally real field.

Glenn Stevens, Robert Pollack and Henri Darmon (see [**DP04**]) have worked for many years to develop an analogue of modular symbols in a rigid analytic context, which is helpful for questions about computing with overconvergent p-adic modular forms or proving results about p-adic L-functions.

Finally we mention that Barry Mazur and some other authors use the term "modular symbol" in a different way than we do. They use the term in a way that is dual to our usage; for example, they attach a "modular symbol" to a modular form or elliptic curve. See [**MTT86**] for an extensive discussion of modular symbols from this point of view, where they are used to construct p-adic L-functions.

8.11. Exercises

8.1 Suppose M is an integer multiple of N. Prove that the natural map $(\mathbb{Z}/M\mathbb{Z})^* \to (\mathbb{Z}/N\mathbb{Z})^*$ is surjective.

8.2 Prove that $\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ is surjective (see Lemma 8.15).

8.3 Compute $\mathbb{M}_3(\Gamma_1(3))$. List each Manin symbol the relations they satisfy, compute the quotient, etc. Find the matrix of T_2. (Check: The dimension of $\mathbb{M}_3(\Gamma_1(3))$ is 2, and the characteristic polynomial of T_2 is $(x-3)(x+3)$.)

8.4 Finish the proof of Proposition 8.17.

8.5 (a) Show that if $\eta = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, then $\eta\Gamma\eta = \Gamma$ for $\Gamma = \Gamma_0(N)$ and $\Gamma = \Gamma_1(N)$.

(b) (*) Give an example of a finite index subgroup Γ such that $\eta\Gamma\eta \neq \Gamma$.

Chapter 9

Computing with Newforms

In this chapter we pull together results and algorithms from Chapter 3, 4, 7, and 8 and explain how to use linear algebra techniques to compute cusp forms and eigenforms using modular symbols.

We first discuss in Section 9.1 how to decompose $M_k(\Gamma_1(N))$ as a direct sum of subspaces corresponding to Dirichlet characters. Next in Section 9.2 we state the main theorems of Atkin-Lehner-Li theory, which decomposes $S_k(\Gamma_1(N))$ into subspaces on which the Hecke operators act diagonalizably with "multiplicity one". In Section 9.3 we describe two algorithms for computing modular forms. One algorithm finds a basis of q-expansions, and the other computes eigenvalues of newforms.

9.1. Dirichlet Character Decomposition

The group $(\mathbb{Z}/N\mathbb{Z})^*$ acts on $M_k(\Gamma_1(N))$ through *diamond-bracket operators* $\langle d\rangle$, as follows. For $d \in (\mathbb{Z}/N\mathbb{Z})^*$, define

$$f|\langle d\rangle = f^{\left[\left(\begin{smallmatrix} a & b \\ c & d' \end{smallmatrix}\right)\right]_k},$$

where $\left(\begin{smallmatrix} a & b \\ c & d' \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ is congruent to $\left(\begin{smallmatrix} d^{-1} & 0 \\ 0 & d \end{smallmatrix}\right) \pmod{N}$. Note that the map $\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ is surjective (see Exercise 8.2), so the matrix $\left(\begin{smallmatrix} a & b \\ c & d' \end{smallmatrix}\right)$ exists. To prove that $\langle d\rangle$ preserves $M_k(\Gamma_1(N))$, we prove the more general fact that $\Gamma_1(N)$ is a normal subgroup of

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{N} \right\}.$$

This will imply that $\langle d\rangle$ preserves $M_k(\Gamma_1(N))$ since $\left(\begin{smallmatrix} a & b \\ c & d' \end{smallmatrix}\right) \in \Gamma_0(N)$.

Lemma 9.1. *The group $\Gamma_1(N)$ is a normal subgroup of $\Gamma_0(N)$, and the quotient $\Gamma_0(N)/\Gamma_1(N)$ is isomorphic to $(\mathbb{Z}/N\mathbb{Z})^*$.*

Proof. See Exercise 9.1. □

Alternatively, one can prove that $\langle d\rangle$ preserves $M_k(\Gamma_1(N))$ by showing that $\langle d\rangle \in \mathbb{T}$ and noting that $M_k(\Gamma_1(N))$ is preserved by $\mathbb{T}$ (see Remark 9.11).

The *diamond-bracket action* is the action of $\Gamma_0(N)/\Gamma_1(N) \cong (\mathbb{Z}/N\mathbb{Z})^*$ on $M_k(\Gamma_1(N))$. Since $M_k(\Gamma_1(N))$ is a finite-dimensional vector space over $\mathbb{C}$, the $\langle d\rangle$ action breaks $M_k(\Gamma_1(N))$ up as a direct sum of factors corresponding to the Dirichlet characters $D(N,\mathbb{C})$ of modulus N.

Proposition 9.2. *We have*

$$M_k(\Gamma_1(N)) = \bigoplus_{\varepsilon \in D(N,\mathbb{C})} M_k(N,\varepsilon),$$

where

$$M_k(N,\varepsilon) = \left\{ f \in \mathbb{M}_k(\Gamma_1(N)) : f|\langle d\rangle = \varepsilon(d) f, \text{ all } d \in (\mathbb{Z}/N\mathbb{Z})^* \right\}.$$

Proof. The linear transformations $\langle d\rangle$, for the $d \in (\mathbb{Z}/N\mathbb{Z})^*$, all commute, since $\langle d\rangle$ acts through the abelian group $\Gamma_0(N)/\Gamma_1(N)$. Also, if e is the exponent of $(\mathbb{Z}/N\mathbb{Z})^*$, then $\langle d\rangle^e = \langle d^e\rangle = \langle 1\rangle = 1$, so the matrix of $\langle d\rangle$ is diagonalizable. It is a standard fact from linear algebra that any commuting family of diagonalizable linear transformations is simultaneously diagonalizable (see Exercise 5.1), so there is a basis $f_1, \ldots, f_n$ for $M_k(\Gamma_1(N))$ such that all $\langle d\rangle$ act by diagonal matrices. The system of eigenvalues of the action of $(\mathbb{Z}/N\mathbb{Z})^*$ on a fixed f_i defines a Dirichlet character, i.e., each f_i has the property that $f_i|\langle d\rangle = \varepsilon_i(d)$, for all $d \in (\mathbb{Z}/N\mathbb{Z})^*$ and some Dirichlet character ε_i. The f_i for a given ε then span $M_k(N,\varepsilon)$, and taken together the $M_k(N,\varepsilon)$ must span $M_k(\Gamma_1(N))$. □

Definition 9.3 (Character of Modular Form)**.** If $f \in M_k(N,\varepsilon)$, we say that ε is the *character of the modular form f*.

The spaces $M_k(N,\varepsilon)$ are a direct sum of subspaces $S_k(N,\varepsilon)$ and $E_k(N,\varepsilon)$, where $S_k(N,\varepsilon)$ is the subspace of cusp forms, i.e., forms that vanish at *all* cusps (elements of $\mathbb{Q} \cup \{\infty\}$), and $E_k(N,\varepsilon)$ is the subspace of Eisenstein series, which is the unique subspace of $M_k(N,\varepsilon)$ that is invariant under all Hecke operators and is such that $M_k(N,\varepsilon) = S_k(N,\varepsilon) \oplus E_k(N,\varepsilon)$. The space $E_k(N,\varepsilon)$ can also be defined as the space spanned by all Eisenstein series of weight k and level N, as defined in Chapter 5. The space $E_k(N,\varepsilon)$ can be defined in a third way using the Petersson inner product (see [**Lan95**, §VII.5]).

The diamond-bracket operators preserve cusp forms, so the isomorphism of Proposition 9.2 restricts to an isomorphism of the corresponding cuspidal subspaces. We illustrate how to use SAGE to make a table of dimension of $M_k(\Gamma_1(N))$ and $M_k(N, \varepsilon)$ for $N = 13$.

9.2. Atkin-Lehner-Li Theory

In Section 8.6 we defined maps between modular symbols spaces of different level. There are similar maps between spaces of cusp forms. Suppose N and M are positive integers with $M \mid N$ and that t is a divisor of N/M. Let

$$\alpha_t : S_k(\Gamma_1(M)) \to S_k(\Gamma_1(N)) \tag{9.2.1}$$

be the *degeneracy map*, which is given by $f(q) \mapsto f(q^t)$. There are also maps β_t in the other direction; see [**Lan95**, Ch. VIII].

The *old subspace* of $S_k(\Gamma_1(N))$, denoted $S_k(\Gamma_1(N))_{\mathrm{old}}$, is the sum of the images of all maps α_t with M a proper divisor of N and t any divisor of N/M (note that α_t depends on t, N, and M, so there is a slight abuse of notation). The *new subspace* of $S_k(\Gamma_1(N))$, which we denote by $S_k(\Gamma_1(N))_{\mathrm{new}}$, is the intersection of the kernel of all maps β_t with M a proper divisor of N. One can use the Petersson inner product to show that

$$S_k(\Gamma_1(N)) = S_k(\Gamma_1(N))_{\mathrm{new}} \oplus S_k(\Gamma_1(N))_{\mathrm{old}}.$$

Moreover, the new and old subspaces are preserved by all Hecke operators.

Let $\mathbb{T} = \mathbb{Z}[T_1, T_2, \ldots]$ be the commutative polynomial ring in infinitely many indeterminates T_n. This ring acts (via T_n acting as the nth Hecke operator) on $S_k(\Gamma_1(N))$ for every integer N. Let $\mathbb{T}^{(N)}$ be the subring of $\mathbb{T}$ generated by the T_n with $\gcd(n, N) = 1$.

Theorem 9.4 (Atkin, Lehner, Li)**.** *We have a decomposition*

$$S_k(\Gamma_1(N)) = \bigoplus_{M \mid N} \bigoplus_{d \mid N/M} \alpha_d(S_k(\Gamma_1(M))_{\mathrm{new}}). \tag{9.2.2}$$

Each space $S_k(\Gamma_1(M))_{\mathrm{new}}$ is a direct sum of distinct (nonisomorphic) simple $\mathbb{T}_{\mathbb{C}}^{(N)}$-modules.

Proof. The complete proof is in [**Li75**]. See also [**DS05**, Ch. 5] for a beautiful modern treatment of this and related results. □

The analogue of Theorem 9.4 with Γ_1 replaced by Γ_0 is also true (this is what was proved in [**AL70**]). The analogue for $S_k(N, \varepsilon)$ is also valid, as long as we omit the spaces $S_k(\Gamma_1(M), \varepsilon)$ for which $\mathrm{cond}(\varepsilon) \nmid M$.

Example 9.5. If N is prime and $k \leq 11$, then $S_k(\Gamma_1(N))_{\mathrm{new}} = S_k(\Gamma_1(N))$, since $S_k(\Gamma_1(1)) = 0$.

One can prove using the Petersson inner product that the operators T_n on $S_k(\Gamma_1(N))$, with $\gcd(n, N) = 1$, are diagonalizable. Another result of Atkin-Lehner-Li theory is that the ring of endomorphisms of $S_k(\Gamma_1(N))_{\mathrm{new}}$ generated by all Hecke operators equals the ring generated by the Hecke operators T_n with $(n, N) = 1$. This statement need not be true if we do not restrict to the new subspace, as the following example shows.

Example 9.6. We have

$$S_2(\Gamma_0(22)) = S_2(\Gamma_0(11)) \oplus \alpha_2(S_2(\Gamma_0(11))),$$

where each of the spaces $S_2(\Gamma_0(11))$ has dimension 1. Thus $S_2(\Gamma_0(22))_{\mathrm{new}} = 0$. The Hecke operator T_2 on $S_2(\Gamma_0(22))$ has characteristic polynomial $x^2 + 2x + 2$, which is irreducible. Since α_2 commutes with all Hecke operators T_n, with $\gcd(n, 2) = 1$, the subring $\mathbb{T}^{(22)}$ of the Hecke algebra generated by operators T_n with n odd is isomorphic to $\mathbb{Z}$ (the 2×2 scalar matrices). Thus on the full space $S_2(\Gamma_0(22))$, we do not have $\mathbb{T}^{(22)} = \mathbb{T}$. However, on the new subspace we do have this equality, since the new subspace has dimension 0.

Example 9.7. The space $S_2(\Gamma_0(45))$ has dimension 3 and basis

$$\begin{aligned} f_0 &= q - q^4 - q^{10} - 2q^{13} - q^{16} + 4q^{19} + \cdots , \\ f_1 &= q^2 - q^5 - 3q^8 + 4q^{11} - 2q^{17} + \cdots , \\ f_2 &= q^3 - q^6 - q^9 - q^{12} + q^{15} + q^{18} + \cdots . \end{aligned}$$

The new subspace $S_2(\Gamma_0(45))_{\text{new}}$ is spanned by the single cusp form

$$q + q^2 - q^4 - q^5 - 3q^8 - q^{10} + 4q^{11} - 2q^{13} + \cdots .$$

We have $S_2(\Gamma_0(45/5)) = 0$ and $S_2(\Gamma_0(15))$ has dimension 1 with basis

$$q - q^2 - q^3 - q^4 + q^5 + q^6 + 3q^8 + q^9 - q^{10} - 4q^{11} + q^{12} - 2q^{13} + \cdots .$$

We use SAGE to verify the above assertions.

```

Example 9.8. This example is similar to Example 9.6, except that there are newforms. We have

$$S_2(\Gamma_0(55)) = S_2(\Gamma_0(11)) \oplus \alpha_5(S_2(\Gamma_0(11))) \oplus S_2(\Gamma_0(55))_{\text{new}},$$

where $S_2(\Gamma_0(11))$ has dimension 1 and $S_2(\Gamma_0(55))_{\mathrm{new}}$ has dimension 3. The Hecke operator T_5 on $S_2(\Gamma_0(55))_{\mathrm{new}}$ acts via the matrix

$$\begin{pmatrix} -2 & 2 & -1 \\ -1 & 1 & -1 \\ 1 & -2 & 0 \end{pmatrix}$$

with respect to some basis. This matrix has eigenvalues 1 and -1. Atkin-Lehner theory asserts that T_5 must be a linear combination of T_n, with $\gcd(n, 55) = 1$. Upon computing the matrix for T_2, we find by simple linear algebra that $T_5 = 2T_2 - T_4$.

Definition 9.9 (Newform)**.** A *newform* is a $\mathbb{T}$-eigenform $f \in S_k(\Gamma_1(N))_{\mathrm{new}}$ that is normalized so that the coefficient of q is 1.

We now motivate this definition by explaining why any $\mathbb{T}$-eigenform can be normalized so that the coefficient of q is 1 and how such an eigenform has the property that its Fourier coefficients are exactly the Hecke eigenvalues.

Proposition 9.10. *If $f = \sum_{n=0}^{\infty} a_n q^n \in M_k(N, \varepsilon)$ is an eigenvector for all Hecke operators T_n normalized so that $a_1 = 1$, then $T_n(f) = a_n f$.*

Proof. If $\varepsilon = 1$, then $f \in M_k(\Gamma_0(N))$ and this is Lemma 3.22. However, we have not yet considered Hecke operators on q-expansions for more general spaces of modular forms.

The Hecke operators T_p, for p prime, act on $S_k(N, \varepsilon)$ by

$$T_p\left(\sum_{n=0}^{\infty} a_n q^n\right) = \sum_{n=0}^{\infty}\left(a_{np} q^n + \varepsilon(p) p^{k-1} a_n q^{np}\right),$$

and there is a similar formula for T_m with m composite. If $f = \sum_{n=0}^{\infty} a_n q^n$ is an eigenform for all T_p, with eigenvalues λ_p, then by the above formula

$$(9.2.3) \qquad \lambda_p f = \lambda_p a_1 q + \lambda_p a_2 q^2 + \cdots = T_p(f) = a_p q + \text{higher terms.}$$

Equating coefficients of q, we see that if $a_1 = 0$, then $a_p = 0$ for all p; hence $a_n = 0$ for all n, because of the multiplicativity of Fourier coefficients and the recurrence

$$a_{p^r} = a_{p^{r-1}} a_p - \varepsilon(p) p^{k-1} a_{p^{r-2}}.$$

This would mean that $f = 0$, a contradiction. Thus $a_1 \neq 0$, and it makes sense to normalize f so that $a_1 = 1$. With this normalization, (9.2.3) implies that $\lambda_p = a_p$, as desired. □

Remark 9.11. The Hecke algebra $\mathbb{T}_{\mathbb{Q}}$ on $M_k(\Gamma_1(N))$ contains the operators $\langle d\rangle$, since they satisfy the relation $T_{p^2} = T_p^2 - \langle p\rangle p^{k-1}$. Thus any $\mathbb{T}$-eigenform in $M_k(\Gamma_1(N))$ lies in a subspace $M_k(N, \varepsilon)$ for some Dirichlet character ε. Also, one can even prove that $\langle d\rangle \in \mathbb{Z}[\ldots, T_n, \ldots]$ (see Exercise 9.2).

9.3. Computing Cusp Forms

Let $\mathbb{S}_k(N,\varepsilon;\mathbb{C})$ be the space of cuspidal modular symbols as in Chapter 8. Let ι^* be the map of (8.5.8), and let $\mathbb{S}_k(N,\varepsilon;\mathbb{C})^+$ be the *plus one quotient* of cuspidal modular symbols, i.e., the quotient of $\mathbb{S}_k(N,\varepsilon;\mathbb{C})$ by the image of ι^*-1. It follows from Theorem 8.23 and compatibility of the degeneracy maps (for modular symbols they are defined in Section 8.6) that the $\mathbb{T}$-modules $S_k(N,\varepsilon)_{\text{new}}$ and $\mathbb{S}_k(N,\varepsilon;\mathbb{C})^+_{\text{new}}$ are dual as $\mathbb{T}$-modules. Thus finding the systems of $\mathbb{T}$-eigenvalues on cusp forms is the same as finding the systems of $\mathbb{T}$-eigenvalues on cuspidal modular symbols.

Our strategy to compute $S_k(N,\varepsilon)$ is to first compute spaces $S_k(N,\varepsilon)_{\text{new}}$ using the Atkin-Lehner-Li decomposition (9.2.2). To compute $S_k(N,\varepsilon)_{\text{new}}$ to a given precision, we compute the systems of eigenvalues of the Hecke operators T_p on the space $V=\mathbb{S}_k(N,\varepsilon;\mathbb{C})^+_{\text{new}}$, which we will define below. Using Proposition 9.10, we then recover a basis of q-expansions for newforms. Note that we only need to compute Hecke eigenvalues T_p, for p prime, not the T_n for n composite, since the a_n can be quickly recovered in terms of the a_p using multiplicativity and the recurrence.

For some problems, e.g., construction of models for modular curves, having a basis of q-expansions is enough. For many other problems, e.g., enumeration of modular abelian varieties, one is really interested in the newforms. We next discuss algorithms aimed at each of these problems.

9.3.1. A Basis of q-Expansions.

The following algorithm generalizes Algorithm 3.26. It computes $S_k(N,\varepsilon)$ without finding any eigenspaces.

Algorithm 9.12 (Merel's Algorithm for Computing a Basis)**.** *Given integers m, N and k and a Dirichlet character ε with modulus N, this algorithm computes a basis of q-expansions for $S_k(N,\varepsilon)$ to precision $O(q^{m+1})$.*

(1) [Compute Modular Symbols] Use Algorithm 8.38 to compute

$$V=\mathbb{S}_k(N,\varepsilon)^+\otimes\mathbb{Q}(\varepsilon),$$

viewed as a $K=\mathbb{Q}(\varepsilon)$ vector space, with an action of the T_n.

(2) [Basis for Linear Dual] Write down a basis for $V^*=\text{Hom}(V,\mathbb{Q}(\varepsilon))$. E.g., if we identify V with K^n viewed as column vectors, then V^* is the space of row vectors of length n, and the pairing is the row × column product.

(3) [Find Generator] Find $x\in V$ such that $\mathbb{T}x=V$ by choosing random x until we find one that generates. The set of x that fail to generate lie in a union of a finite number of proper subspaces.

(4) [Compute Basis] The set of power series

$$f_i = \sum_{n=1}^{m} \psi_i(T_n(x))q^n + O(q^{m+1})$$

forms a basis for $S_k(N, \varepsilon)$ to precision m.

In practice Algorithm 9.12 seems slower than the eigenspace algorithm that we will describe in the rest of this chapter. The theoretical complexity of Algorithm 9.12 *may* be better, because it is not necessary to factor any polynomials. Polynomial factorization is difficult from the worst-case complexity point of view, though it is usually fast in practice. The eigenvalue algorithm only requires computing a few images $T_p(x)$ for p prime and x a Manin symbol on which T_p can easily be computed. The Merel algorithm involves computing $T_n(x)$ for all n and for a fairly easy x, which is potentially more work.

Remark 9.13. By "easy x", I mean that computing $T_n(x)$ is easier on x than on a completely random element of $\mathbb{S}_k(N, \varepsilon)^+$, e.g., x could be a Manin symbol.

9.3.2. Newforms: Systems of Eigenvalues. In this section we describe an algorithm for computing the system of Hecke eigenvalues associated to a simple subspace of a space of modular symbols. This algorithm is better than doing linear algebra directly over the number field generated by the eigenvalues. It only involves linear algebra over the base field and also yields a compact representation for the answer, which is better than writing the eigenvalues in terms of a power basis for a number field. In order to use this algorithm, it is necessary to decompose the space of cuspidal modular symbols as a direct sum of simples, e.g., using Algorithm 7.17.

Fix N and a Dirichlet character ε of modulus N, and let

$$V = \mathbb{M}_k(N, \varepsilon)^+$$

be the $+1$ quotient of modular symbols (see equation (8.5.8)).

Algorithm 9.14 (System of Eigenvalues)**.** *Given a $\mathbb{T}$-simple subspace $W \subset V$ of modular symbols, this algorithm outputs maps ψ and e, where $\psi : \mathbb{T}_K \to W$ is a K-linear map and $e : W \cong L$ is an isomorphism of W with a number field L, such that $a_n = e(\psi(T_n))$ is the eigenvalue of the nth Hecke operator acting on a fixed $\mathbb{T}$-eigenvector in $W \otimes \overline{\mathbb{Q}}$. (Thus $f = \sum_{n=1}^{\infty} e(\psi(T_n))q^n$ is a newform.)*

(1) [Compute Projection] Let $\varphi : V \to W'$ be any surjective linear map such that $\ker(\varphi)$ equals the kernel of the $\mathbb{T}$-invariant projection onto W. For example, compute φ by finding a simple submodule

of $V^* = \mathrm{Hom}(V, K)$ that is isomorphic to W, e.g., by applying Algorithm 7.17 to V^* with T replaced by the transpose of T.

(2) [Choose v] Choose a nonzero element $v \in V$ such that $\pi(v) \neq 0$ and computation of $T_n(v)$ is "easy", e.g., choose v to be a Manin symbol.

(3) [Map from Hecke Ring] Let ψ be the map $\mathbb{T} \to W'$, given by $\psi(t) = \pi(tv)$. Note that computation of ψ is relatively easy, because v was chosen so that tv is relatively easy to compute. In particular, if $t = T_p$, we do not need to compute the full matrix of T_p on V; instead we just compute $T_p(v)$.

(4) [Find Generator] Find a random $T \in \mathbb{T}$ such that the iterates

$$\psi(T^0), \quad \psi(T), \quad \psi(T^2), \quad \ldots, \quad \psi(T^{d-1})$$

are a basis for W', where W has dimension d.

(5) [Characteristic Polynomial] Compute the characteristic polynomial f of $T|_W$, and let $L = K[x]/(f)$. Because of how we chose T in step (4), the minimal and characteristic polynomials of $T|_W$ are equal, and both are irreducible, so L is an extension of K of degree $d = \dim(W)$.

(6) [Field Structure] In this step we endow W' with a field structure. Let $e : W' \to L$ be the unique K-linear isomorphism such that

$$e(\psi(T^i)) \equiv x^i \pmod{f}$$

for $i = 0, 1, 2, ..., \deg(f) - 1$. The map e is uniquely determined since the $\psi(T^i)$ are a basis for W'. To compute e, we compute the change of basis matrix from the standard basis for W' to the basis $\{\psi(T^i)\}$. This change of basis matrix is the inverse of the matrix whose rows are the $\psi(T^i)$ for $i = 0, ..., \deg(f) - 1$.

(7) [Hecke Eigenvalues] Finally for each integer $n \geq 1$, we have

$$a_n = e(\psi(T_n)) = e(\pi(T_n(v))),$$

where a_n is the eigenvalue of T_n. Output the maps ψ and e and terminate.

One reason we separate ψ and e is that when $\dim(W)$ is large, the values $\psi(T_n)$ take less space to store and are easier to compute, whereas each one of the values $e(\psi(n))$ is huge.[1] The function e typically involves large numbers if $\dim(W)$ is large, since e is obtained from the iterates of a single vector. For many applications, e.g., databases, it is better to store a matrix that defines e and the images under ψ of many T_n.

[1] John Cremona initially suggested to me the idea of separating these two maps.

Example 9.15. The space $S_2(\Gamma_0(23))$ of cusp forms has dimension 2 and is spanned by two $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugate newforms, one of which is

$$f = q + aq^2 + (-2a-1)q^3 + (-a-1)q^4 + 2aq^5 + \cdots,$$

where $a = (-1+\sqrt{5})/2$. We will use Algorithm 9.14 to compute a few of these coefficients.

The space $\mathbb{M}_2(\Gamma_0(23))^+$ of modular symbols has dimension 3. It has the following basis of Manin symbols:

$$[(0,0)], \quad [(1,0)], \quad [(0,1)],$$

where we use square brackets to differentiate Manin symbols from vectors. The Hecke operator

$$T_2 = \begin{pmatrix} 3 & 0 & 0 \\ 0 & 0 & 2 \\ -1 & 1/2 & -1 \end{pmatrix}$$

has characteristic polynomial $(x-3)(x^2+x-1)$. The kernel of $T_2 - 3$ corresponds to the span of the Eisenstein series of level 23 and weight 2, and the kernel V of $T_2^2 + T_2 - 1$ corresponds to $S_2(\Gamma_0(23))$. (We could also have computed V as the kernel of the boundary map $\mathbb{M}_2(\Gamma_0(23))^+ \to \mathbb{B}_2(\Gamma_0(23))^+$.) Each of the following steps corresponds to the step of Algorithm 9.14 with the same number.

(1) [Compute Projection] We compute projection onto V (this will suffice to give us a map ϕ as in the algorithm). The matrix whose first two columns are the echelon basis for V and whose last column is the echelon basis for the Eisenstein subspace is

$$\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & -2/11 \\ 0 & 1 & -3/11 \end{pmatrix}$$

and

$$B^{-1} = \begin{pmatrix} 2/11 & 1 & 0 \\ 3/11 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

so projection onto V is given by the first two rows:

$$\pi = \begin{pmatrix} 2/11 & 1 & 0 \\ 3/11 & 0 & 1 \end{pmatrix}.$$

(2) [Choose v] Let $v = (0,1,0)^t$. Notice that $\pi(v) = (1,0)^t \neq 0$, and $v = [(1,0)]$ is a sum of only one Manin symbol.

(3) [Map from Hecke Ring] This step is purely conceptual, since no actual work needs to be done. We illustrate it by computing $\psi(T_1)$ and $\psi(T_2)$. We have

$$\psi(T_1) = \pi(v) = (1,0)^t$$

and

$$\psi(T_2) = \pi(T_2(v)) = \pi((0,0,1/2)^t) = (0,1/2)^t.$$

(4) [Find Generator] We have

$$\psi(T_2^0) = \psi(T_1) = (1,0)^t,$$

which is clearly independent from $\psi(T_2) = (0,1/2)^t$. Thus we find that the image of the powers of $T = T_2$ generate V.

(5) [Characteristic Polynomial] The matrix of $T_2|_V$ is $\begin{pmatrix} 0 & 2 \\ 1/2 & -1 \end{pmatrix}$, which has characteristic polynomial $f = x^2 + x - 1$. Of course, we already knew this because we computed V as the kernel of $T_2^2 + T_2 - 1$.

(6) [Field Structure] We have

$$\psi(T_2^0) = \pi(v) = (1,0)^t \text{ and } \psi(T_2) = (0,1/2).$$

The matrix with rows the $\psi(T_2^i)$ is $\begin{pmatrix} 1 & 0 \\ 0 & 1/2 \end{pmatrix}$, which has inverse $e = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2 \end{smallmatrix}\right)$. The matrix e defines an isomorphism between V and the field

$$L = \mathbb{Q}[x]/(f) = \mathbb{Q}((-1+\sqrt{5})/2).$$

I.e., $e((1,0)) = 1$ and $e((0,1)) = 2x$, where $x = (-1+\sqrt{5})/2$.

(7) [Hecke Eigenvalues] We have $a_n = e(\Psi(T_n))$. For example,

$$\begin{aligned}
a_1 &= e(\Psi(T_1)) = e((1,0)) = 1,\\
a_2 &= e(\Psi(T_2)) = e((0,1/2)) = x,\\
a_3 &= e(\Psi(T_3)) = e(\pi(T_3(v))) = e(\pi((0,-1,-1)^t))\\
&= e((-1,-1)^t) = -1-2x,\\
a_4 &= e(\Psi(T_4)) = e(\pi((0,-1,-1/2)^t)) = e((-1,-1/2)^t) = -1-x,\\
a_5 &= e(\Psi(T_5)) = e(\pi((0,0,1)^t)) = e((0,1)^t) = 2x,\\
a_{23} &= e(\Psi(T_{23})) = e(\pi((0,1,0)^t)) = e((1,0)^t) = 1,\\
a_{97} &= e(\Psi(T_{23})) = e(\pi((0,14,3)^t)) = e((14,3)^t) = 14+6x.
\end{aligned}$$

Example 9.16. It is easier to appreciate Algorithm 9.14 after seeing how big the coefficients of the power series expansion of a newform typically are, when the newform is defined over a large field. For example, there is a newform

$$f = \sum_{n=1}^{\infty} a_n q^n \in S_2(\Gamma_0(389))$$

such that if $\alpha = a_2$, then

$$\begin{aligned}1097385680{\cdot}a_3(f) = &-20146763x^{19} + 102331615x^{18} + 479539092x^{17}\\ &- 3014444212x^{16} - 3813583550x^{15} + 36114755350x^{14}\\ &+ 6349339639x^{13} - 227515736964x^{12} + 71555185319x^{11}\\ &+ 816654992625x^{10} - 446376673498x^{9} - 1698789732650x^{8}\\ &+ 1063778499268x^{7} + 1996558922610x^{6} - 1167579836501x^{5}\\ &- 1238356001958x^{4} + 523532113822x^{3} + 352838824320x^{2}\\ &- 58584308844x - 25674258672.\end{aligned}$$

In contrast, if we take $v = \{0, \infty\} = (0, 1) \in \mathbb{M}_2(\Gamma_0(389))^+$, then

$$T_3(v) = -4(1,0) + 2(1,291) - 2(1,294) - 2(1,310) + 2(1,313) + 2(1,383).$$

Storing $T_3(v), T_5(v), \ldots$ as vectors is more compact than storing $a_3(f)$, $a_5(f)$, $\ldots$ directly as polynomials in a_2!

9.4. Congruences between Newforms

This section is about congruences between modular forms. Understanding congruences is crucial for studying Serre's conjectures, Galois representations, and explicit construction of Hecke algebras. We assume more background in algebraic number theory here than elsewhere in this book.

9.4.1. Congruences between Modular Forms. Let Γ be an arbitrary congruence subgroup of $\mathrm{SL}_2(\mathbb{Z})$, and suppose $f \in M_k(\Gamma)$ is a modular form of integer weight k for Γ. Since $\left(\begin{smallmatrix}1 & N\\ 0 & 1\end{smallmatrix}\right) \in \Gamma$ for some integer N, the form f has a Fourier expansion in nonnegative powers of $q^{1/N}$. For a rational number n, let $a_n(f)$ be the coefficient of q^n in the Fourier expansion of f. Put

$$\mathrm{ord}_q(f) = \min\{n \in \mathbb{Q} : a_n \neq 0\},$$

where by convention we take $\min \emptyset = +\infty$, so $\mathrm{ord}_q(0) = +\infty$.

9.4.1.1. *The j-invariant.* Let

$$j = \frac{1}{q} + 744 + 196884q + \cdots$$

be the j-function, which is a weight 0 modular function that is holomorphic except for a simple pole at ∞ and has integer Fourier coefficients (see, e.g., [**Ser73**, Section VIII.3.3]).

Lemma 9.17. *Suppose g is a weight 0 level 1 modular function that is holomorphic except possibly with a pole of order n at ∞. Then g is a polynomial in j of degree at most n. Moreover, the coefficients of this polynomial lie in the ideal I generated by the coefficients $a_m(g)$ with $m \leq 0$.*

Proof. If $n = 0$, then $g \in M_0(\mathrm{SL}_2(\mathbb{Z})) = \mathbb{C}$, so g is constant with constant term in I, so the statement is true. Next suppose $n > 0$ and the lemma has been proved for all functions with smaller order poles. Let $\alpha = a_n(g)$, and note that

$$\mathrm{ord}_q(g - \alpha j^n) = \mathrm{ord}_q\left(g - \alpha \cdot \left(\frac{1}{q} + 744 + 196884q + \cdots\right)^n\right) > -n.$$

Thus by induction $h = g - \alpha j^n$ is a polynomial in j of degree $< n$ with coefficients in the ideal generated by the coefficients $a_m(g)$ with $m < 0$. It follows that $g = \alpha \cdot j^n - h$ satisfies the conclusion of the lemma. □

9.4.1.2. *Sturm's Theorem.* If $\mathcal{O}$ is the ring of integers of a number field, $\mathfrak{m}$ is a maximal ideal of $\mathcal{O}$, and $f = \sum a_n q^n \in \mathcal{O}[[q^{1/N}]]$ for some integer N, let

$$\mathrm{ord}_{\mathfrak{m}}(f) = \mathrm{ord}_q(f \mod \mathfrak{m}) = \min\{n \in \mathbb{Q} : a_n \notin \mathfrak{m}\}.$$

Note that $\mathrm{ord}_{\mathfrak{m}}(fg) = \mathrm{ord}_{\mathfrak{m}}(f) + \mathrm{ord}_{\mathfrak{m}}(g)$. The following theorem was first proved in [**Stu87**].

Theorem 9.18 (Sturm)**.** *Let $\mathfrak{m}$ be a prime ideal in the ring of integers $\mathcal{O}$ of a number field K, and let Γ be a congruence subgroup of $\mathrm{SL}_2(\mathbb{Z})$ of index m and level N. Suppose $f \in M_k(\Gamma, \mathcal{O})$ is a modular form and*

$$\mathrm{ord}_{\mathfrak{m}}(f) > \frac{km}{12}$$

or $f \in S_k(\Gamma, \mathcal{O})$ is a cusp form and

$$\mathrm{ord}_{\mathfrak{m}}(f) > \frac{km}{12} - \frac{m-1}{N}.$$

Then $f \equiv 0 \pmod{\mathfrak{m}}$.

Proof. Case 1: First we assume $\Gamma = \mathrm{SL}_2(\mathbb{Z})$.
Let

$$\Delta = q + 24q^2 + \cdots \in S_{12}(\mathrm{SL}_2(\mathbb{Z}), \mathbb{Z})$$

be the Δ function. Since $\mathrm{ord}_{\mathfrak{m}}(f) > k/12$, we have $\mathrm{ord}_{\mathfrak{m}}(f^{12}) > k$. We have

$$\mathrm{ord}_q(f^{12} \cdot \Delta^{-k}) = 12 \cdot \mathrm{ord}_q(f) - k \cdot \mathrm{ord}_q(\Delta) \geq -k, \tag{9.4.1}$$

since f is holomorphic at infinity and Δ has a zero of order 1. Also

$$\mathrm{ord}_{\mathfrak{m}}(f^{12} \cdot \Delta^{-k}) = \mathrm{ord}_{\mathfrak{m}}(f^{12}) - k \cdot \mathrm{ord}_{\mathfrak{m}}(\Delta) > k - k = 0. \tag{9.4.2}$$

Combining (9.4.1) and (9.4.2), we see that

$$f^{12}\cdot\Delta^{-k}=\sum_{n\geq -k} b_n q^n,$$

with $b_n\in\mathcal{O}$ and $b_n\in\mathfrak{m}$ if $n\leq 0$.

By Lemma 9.17,

$$f^{12}\cdot\Delta^{-k}\in\mathfrak{m}[j]$$

is a polynomial in j of degree at most k with coefficients in $\mathfrak{m}$. Thus

$$f^{12}\in\mathfrak{m}[j]\cdot\Delta^{k},$$

so since the coefficients of Δ are integers, every coefficient of f^{12} is in $\mathfrak{m}$. Thus $\mathrm{ord}_{\mathfrak{m}}(f^{12})=+\infty$, hence $\mathrm{ord}_{\mathfrak{m}}(f)=+\infty$, so $f=0$, as claimed.

Case 2: Γ Arbitrary

Let N be such that $\Gamma(N)\subset\Gamma$, so also $f\in M_k(\Gamma(N))$. If $g\in M_k(\Gamma(N))$ is arbitrary, then because $\Gamma(N)$ is a normal subgroup of $\mathrm{SL}_2(\mathbb{Z})$, we have that for any $\gamma\in\Gamma(N)$ and $\delta\in\mathrm{SL}_2(\mathbb{Z})$,

$$(g^{[\delta]_k})^{[\gamma]_k}=g^{[\delta\gamma]_k}=g^{[\gamma'\delta]_k}=(g^{[\gamma']_k})^{[\delta]_k}=g^{[\delta]_k},$$

where $\gamma'\in\mathrm{SL}_2(\mathbb{Z})$. Thus for any $\delta\in\mathrm{SL}_2(\mathbb{Z})$, we have that $g^{[\delta]_k}\in M_k(\Gamma(N))$, so $\mathrm{SL}_2(\mathbb{Z})$ acts on $M_k(\Gamma(N))$.

It is a standard (but nontrivial) fact about modular forms, which comes from the geometry of the modular curve $X(N)$ over $\mathbb{Q}(\zeta_N)$ and $\mathbb{Z}[\zeta_N]$, that $M_k(\Gamma(N))$ has a basis with Fourier expansions in $\mathbb{Z}[\zeta_N][[q^{1/N}]]$ and that the action of $\mathrm{SL}_2(\mathbb{Z})$ on $M_k(\Gamma(N))$ preserves

$$M_k(\Gamma(N),\mathbb{Q}(\zeta_N))=M_k(\Gamma(N))\cap(\mathbb{Q}(\zeta_N)[[q^{1/N}]])$$

and the cuspidal subspace $S_k(\Gamma(N),\mathbb{Q}(\zeta_N))$. In particular, for any $\gamma\in\mathrm{SL}_2(\mathbb{Z})$,

$$f^{[\gamma]_k}\in M_k(\Gamma(N),K(\zeta_N))$$

Moreover, the denominators of $f^{[\gamma]_k}$ are bounded, since f is an $\mathcal{O}[\zeta_N]$-linear combination of a basis for $M_k(\Gamma(N),\mathbb{Z}[\zeta_N])$, and the denominators of $f^{[\gamma]_k}$ divide the product of the denominators of the images of each of these basis vectors under $[\gamma]_k$.

Let $L=K(\zeta_N)$. Let $\mathfrak{M}$ be a prime of $\mathcal{O}_L$ that divides $\mathfrak{m}\mathcal{O}_L$. We will now show that for each $\gamma\in\mathrm{SL}_2(\mathbb{Z})$, the Chinese Remainder Theorem implies that there is an element $A_\gamma\in L^*$ such that

$$A_\gamma\cdot f^{[\gamma]_k}\in M_k(\Gamma(N),\mathcal{O}_L)\qquad\text{and}\qquad \mathrm{ord}_{\mathfrak{M}}(A_\gamma\cdot f^{[\gamma]_k})<\infty.\tag{9.4.3}$$

First find $A\in L^*$ such that $A\cdot f^{[\gamma]_k}$ has coefficients in $\mathcal{O}_L$. Choose $\alpha\in\mathfrak{M}$ with $\alpha\notin\mathfrak{M}^2$, and find a negative power α^t such that $\alpha^t\cdot A\cdot f^{[\gamma]_k}$ has $\mathfrak{M}$-integral coefficients and finite valuation. This is possible because we assumed that f is nonzero. Use the Chinese Remainder Theorem to find $\beta \in \mathcal{O}_L$ such that $\beta \equiv 1 \pmod{\mathfrak{M}}$ and $\beta \equiv 0 \pmod{\wp}$ for each prime $\wp \neq \mathfrak{M}$ that divides (α). Then for some s we have

$$\beta^s \cdot \alpha^t \cdot A \cdot f^{[\gamma]_k} = A_\gamma \cdot f^{[\gamma]_k} \in M_k(\Gamma(N), \mathcal{O}_L)$$

and $\mathrm{ord}_{\mathfrak{M}}(A_\gamma \cdot f^{[\gamma]_k}) < \infty$.

Write

$$\mathrm{SL}_2(\mathbb{Z}) = \bigcup_{i=1}^{m} \Gamma\gamma_i$$

with $\gamma_1 = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and let

$$F = f \cdot \prod_{i=2}^{m} A_{\gamma_i} \cdot f^{[\gamma_i]_k}.$$

Then $F \in M_{km}(\mathrm{SL}_2(\mathbb{Z}))$ and since $\mathfrak{M} \cap \mathcal{O}_K = \mathfrak{m}$, we have $\mathrm{ord}_{\mathfrak{M}}(f) = \mathrm{ord}_{\mathfrak{m}}(f)$, so

$$\mathrm{ord}_{\mathfrak{M}}(F) \geq \mathrm{ord}_{\mathfrak{M}}(f) = \mathrm{ord}_{\mathfrak{m}}(f) > \frac{km}{12}.$$

Thus we can apply Case 1 to conclude that

$$\mathrm{ord}_{\mathfrak{M}}(F) = +\infty.$$

Thus

$$\infty = \mathrm{ord}_{\mathfrak{M}}(F) = \mathrm{ord}_{\mathfrak{m}}(f) + \sum_{i=2}^{m} \mathrm{ord}_{\mathfrak{M}}(A_{\gamma_i} f^{[\gamma]_k}), \tag{9.4.4}$$

so $\mathrm{ord}_{\mathfrak{m}}(f) = +\infty$, because of (9.4.3).

We next obtain a better bound when f is a cusp form. Since $[\gamma]_k$ preserves cusp forms, $\mathrm{ord}_{\mathfrak{M}}(A_{\gamma_i} f^{[\gamma]_k}) \geq \frac{1}{N}$ for each i. Thus

$$\mathrm{ord}_{\mathfrak{M}}(F) \geq \mathrm{ord}_{\mathfrak{M}}(f) + \frac{m-1}{N} = \mathrm{ord}_{\mathfrak{m}}(f) + \frac{m-1}{N} > \frac{km}{12},$$

since now we are merely assuming that

$$\mathrm{ord}_{\mathfrak{m}}(f) > \frac{km}{12} - \frac{m-1}{N}.$$

Thus we again apply Case 1 to conclude that $\mathrm{ord}_{\mathfrak{M}}(F) = +\infty$, and using (9.4.4), conclude that $\mathrm{ord}_{\mathfrak{m}}(f) = +\infty$. □

Corollary 9.19. *Let $\mathfrak{m}$ be a prime ideal in the ring of integers $\mathcal{O}$ of a number field. Suppose $f, g \in M_k(\Gamma, \mathcal{O})$ are modular forms and*

$$a_n(f) \equiv a_n(g) \pmod{\mathfrak{m}}$$

for all

$$n \leq \begin{cases} \dfrac{km}{12} - \dfrac{m-1}{N} & \text{if } f - g \in S_k(\Gamma, \mathcal{O}), \\ \dfrac{km}{12} & \text{otherwise,} \end{cases}$$

where $m = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma]$. *Then* $f \equiv g \pmod{\mathfrak{m}}$.

Buzzard proved the following corollary, which is extremely useful in practical computations. It asserts that the Sturm bound for modular forms with character is the same as the Sturm bound for $\Gamma_0(N)$.

Corollary 9.20 (Buzzard). *Let* $\mathfrak{m}$ *be a prime ideal in the ring of integers* $\mathcal{O}$ *of a number field. Suppose* $f, g \in M_k(N, \varepsilon, \mathcal{O})$ *are modular forms with Dirichlet character* $\varepsilon : (\mathbb{Z}/N\mathbb{Z})^* \to \mathbb{C}^*$ *and assume that*

$$a_n(f) \equiv a_n(g) \pmod{\mathfrak{m}} \qquad \text{for all} \qquad n \leq \frac{km}{12},$$

where

$$m = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)] = \#\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z}) = N \cdot \prod_{p \mid N} \left(1 + \frac{1}{p}\right).$$

Then $f \equiv g \pmod{\mathfrak{m}}$.

Proof. Let $h = f - g$ and let $r = km/12$, so $\mathrm{ord}_{\mathfrak{m}}(h) > r$. Let s be the order of the Dirichlet character ε. Then $h^s \in M_{ks}(\Gamma_0(N))$ and

$$\mathrm{ord}_{\mathfrak{m}}(h^s) > sr = \frac{ksm}{12}.$$

By Theorem 9.18, we have $\mathrm{ord}_{\mathfrak{m}}(h^s) = \infty$, so $\mathrm{ord}_{\mathfrak{m}}(h) = \infty$. It follows that $f \equiv g \pmod{\mathfrak{m}}$. □

9.4.1.3. *Congruence for Newforms.* Sturm's paper [**Stu87**] also applies some results of Asai on q-expansions at various cusps to obtain a more refined result for newforms.

Theorem 9.21 (Sturm). *Let* N *be a positive integer that is square-free, and suppose* f *and* g *are two newforms in* $S_k(N, \varepsilon, \mathcal{O})$, *where* $\mathcal{O}$ *is the ring of integers of a number field, and suppose that* $\mathfrak{m}$ *is a maximal ideal of* $\mathcal{O}$. *Let* I *be an arbitrary subset of the prime divisors of* N. *If* $a_p(f) = a_p(g)$ *for all* $p \in I$ *and if*

$$a_p(f) \equiv a_p(g) \pmod{\mathfrak{m}}$$

for all primes

$$p \leq \frac{k \cdot [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)]}{12 \cdot 2^{\#I}},$$

then $f \equiv g \pmod{\mathfrak{m}}$.

The paper [**BS02**] contains a similar result about congruences between newforms, which does not require that the level be square-free. Recall from Definition 4.18 that the conductor of a Dirichlet character ε is the largest divisor c of N such that ε factors through $(\mathbb{Z}/c\mathbb{Z})^\times$.

Theorem 9.22. *Let $N > 4$ be any integer, and suppose f and g are two normalized eigenforms in $S_k(N, \varepsilon; \mathcal{O})$, where $\mathcal{O}$ is the ring of integers of a number field, and suppose that $\mathfrak{m}$ is a maximal ideal of $\mathcal{O}$. Let I be the set of prime divisors of N that do not divide $\frac{N}{\mathrm{cond}(\varepsilon)}$. If*

$$a_p(f) \equiv a_p(g) \pmod{\mathfrak{m}}$$

for all primes $p \in I$ and for all primes

$$p \leq \frac{k \cdot [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)]}{12 \cdot 2^{\#I}},$$

then $f \equiv g \pmod{\mathfrak{m}}$.

For the proof, see Lemma 1.4 and Corollary 1.7 in [**BS02**, §1.3].

9.4.2. Generating the Hecke Algebra.

The following theorem appeared in [**LS02**, Appendix], except that we give a better bound here. It is a nice application of the congruence result above, which makes possible explicit computations with Hecke rings $\mathbb{T}$.

Theorem 9.23. *Suppose Γ is a congruence subgroup that contains $\Gamma_1(N)$ and let*

$$r = \frac{km}{12} - \frac{m-1}{N}, \tag{9.4.5}$$

where $m = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma]$. Then the Hecke algebra

$$\mathbb{T} = \mathbb{Z}[\ldots, T_n, \ldots] \subset \mathrm{End}(S_k(\Gamma))$$

is generated as a $\mathbb{Z}$-module by the Hecke operators T_n for $n \leq r$.

Proof. For any ring R, let $S_k(N, R) = S_k(N; \mathbb{Z}) \otimes R$, where $S_k(N; \mathbb{Z}) \subset \mathbb{Z}[[q]]$ is the submodule of cusp forms with integer Fourier expansion at the cusp ∞, and let $\mathbb{T}_R = \mathbb{T} \otimes_{\mathbb{Z}} R$. For any ring R, there is a perfect pairing

$$S_k(N, R) \otimes_R \mathbb{T}_R \to R$$

given by $\langle f, T\rangle \mapsto a_1(T(f))$ (this is true for $R = \mathbb{Z}$, hence for any R).

Let M be the submodule of $\mathbb{T}$ generated by $T_1, T_2, \ldots, T_r$, where r is the largest integer $\leq \frac{kN}{12} \cdot [\mathrm{SL}_2(\mathbb{Z}) : \Gamma]$. Consider the exact sequence of additive abelian groups

$$0 \to M \overset{i}{\to} \mathbb{T} \to \mathbb{T}/M \to 0.$$

Let p be a prime and use the fact that tensor product is right exact to obtain an exact sequence

$$M \otimes \mathbb{F}_p \xrightarrow{\bar{i}} \mathbb{T} \otimes \mathbb{F}_p \to (\mathbb{T}/M) \otimes \mathbb{F}_p \to 0.$$

Suppose that $f \in S_k(N, \mathbb{F}_p)$ pairs to 0 with each of $T_1, \ldots, T_r$. Then

$$a_m(f) = a_1(T_m f) = \langle f, T_m \rangle = 0$$

in $\mathbb{F}_p$ for each $m \leq r$. By Theorem 9.18, it follows that $f = 0$. Thus the pairing restricted to the image of $M \otimes \mathbb{F}_p$ in $\mathbb{T}_{\mathbb{F}_p}$ is nondegenerate, so because (9.4.5) is perfect, it follows that

$$\dim_{\mathbb{F}_p} \bar{i}(M \otimes \mathbb{F}_p) = \dim_{\mathbb{F}_p} S_k(N, \mathbb{F}_p).$$

Thus $(\mathbb{T}/M) \otimes \mathbb{F}_p = 0$. Repeating the argument for all primes p shows that $\mathbb{T}/M = 0$, as claimed. □

Remark 9.24. In general, the conclusion of Theorem 9.23 is not true if one considers only T_n where n runs over the primes less than the bound. Consider, for example, $S_2(11)$, where the bound is 1 and there are no primes ≤ 1. However, the Hecke algebra is generated as an algebra by operators T_p with $p \leq r$.

9.5. Exercises

9.1 Prove that the group $\Gamma_1(N)$ is a normal subgroup of $\Gamma_0(N)$ and that the quotient $\Gamma_0(N)/\Gamma_1(N)$ is isomorphic to $(\mathbb{Z}/N\mathbb{Z})^*$.

9.2 Prove that the operators $\langle d \rangle$ are elements of $\mathbb{Z}[\ldots, T_n, \ldots]$. [Hint: Use Dirichlet's theorem on primes in arithmetic progression.]

9.3 Find an example like Example 9.6 but in which the new subspace is nonzero. More precisely, find an integer N such that the Hecke ring on $S_2(\Gamma_0(N))$ is not equal to the ring generated by Hecke operators T_n with $\gcd(n, N) = 1$ and $S_2(\Gamma_0(N))_{\text{new}} \neq 0$.

9.4 (a) Following Example 9.15, compute a basis for $S_2(\Gamma_0(31))$.
(b) Use Algorithm 9.12 to compute a basis for $S_2(\Gamma_0(31))$.

Chapter 10

Computing Periods

This chapter is about computing period maps associated to newforms. We assume you have read Chapters 8 and 9 and that you are familiar with abelian varieties at the level of [**Ros86**].

In Section 10.1 we introduce the period map and give some examples of situations in which computing it is relevant. Section 10.2 is about how to use the period mapping to attach an abelian variety to any newform. In Section 10.3, we introduce extended modular symbols, which are the key computational tool for quickly computing periods of modular symbols. We turn to numerical computation of period integrals in Section 10.4, and in Section 10.5 we explain how to use Atkin-Lehner operators to speed convergence. In Section 10.6 we explain how to compute the full period map with a minimum amount of work.

Section 10.7 briefly sketches three approaches to computing all elliptic curves of a given conductor.

This chapter was inspired by [**Cre97a**], which contains similar algorithms in the special case of a newform $f = \sum a_n q^n \in S_2(\Gamma_0(N))$ with $a_n \in \mathbb{Z}$.

See also [**Dok04**] for algorithmic methods to compute special values of very general L-functions, which can be used for approximating $L(f, s)$ for arbitrary s.

10.1. The Period Map

Let Γ be a subgroup of $\mathrm{SL}_2(\mathbb{Z})$ that contains $\Gamma_1(N)$ for some N, and suppose

$$f = \sum_{n\geq 1} a_n q^n \in S_k(\Gamma)$$

is a newform (see Definition 9.9). In this chapter we describe how to approximately compute the complex period mapping

$$\Phi_f : \mathbb{M}_k(\Gamma) \to \mathbb{C},$$

given by

$$\Phi_f(P\{\alpha,\beta\}) = \langle f, P\{\alpha,\beta\}\rangle = \int_\alpha^\beta f(z)P(z,1)dz,$$

as in Section 8.5. As an application, we can approximate the special values $L(f,j)$, for $j = 1, 2, \ldots, k-1$ using (8.5.5). We can also compute the period lattice attached to a modular abelian variety, which is an important step, e.g., in enumeration of $\mathbb{Q}$-curves (see, e.g., [**GLQ04**]) or computation of a curve whose Jacobian is a modular abelian variety A_f (see, e.g., [**Wan95**]).

10.2. Abelian Varieties Attached to Newforms

Fix a newform $f \in S_k(\Gamma)$, where $\Gamma_1(N) \subset \Gamma$ for some N. Let $f_1, \ldots, f_d$ be the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f, where $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts via its action on the Fourier coefficients, which are algebraic integers (since they are the eigenvalues of matrices with integer entries). Let

$$V_f = \mathbb{C}f_1 \oplus \cdots \oplus \mathbb{C}f_d \subset S_k(\Gamma) \tag{10.2.1}$$

be the subspace of cusp forms spanned by the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f. One can show using the results discussed in Section 9.2 that the above sum is direct, i.e., that V_f has dimension d.

The integration pairing induces a $\mathbb{T}$-equivariant homomorphism

$$\Phi_f : \mathbb{M}_k(\Gamma) \to V_f^* = \mathrm{Hom}_{\mathbb{C}}(V_f, \mathbb{C})$$

from modular symbols to the $\mathbb{C}$-linear dual V_f^* of V_f. Here $\mathbb{T}$ acts on V_f^* via $(\varphi t)(x) = \varphi(tx)$, and this homomorphism is $\mathbb{T}$-stable by Theorem 8.21. The *abelian variety attached to* f is the quotient

$$A_f(\mathbb{C}) = V_f^*/\Phi_f(\mathbb{S}_k(\Gamma;\mathbb{Z})).$$

Here $\mathbb{S}_k(\Gamma;\mathbb{Z}) = \mathbb{S}_k(\Gamma)$, and we include the $\mathbb{Z}$ in the notation to emphasize that these are integral modular symbols. See [**Shi59**] for a proof that $A_f(\mathbb{C})$ is an abelian variety (in particular, $\Phi_f(\mathbb{S}_k(\Gamma;\mathbb{Z}))$ is a lattice, and V_f^* is equipped with a nondegenerate Riemann form).

When $k = 2$, we can also construct A_f as a quotient of the modular Jacobian $\mathrm{Jac}(X_\Gamma)$, so A_f is an abelian variety canonically defined over $\mathbb{Q}$.

In general, we have an exact sequence

$$0 \to \mathrm{Ker}(\Phi_f) \to \mathbb{S}_k(\Gamma) \to V_f^* \to A_f(\mathbb{C}) \to 0.$$

Remark 10.1. When $k = 2$, the abelian variety A_f has a canonical structure of abelian variety over $\mathbb{Q}$. Moreover, there is a conjecture of Ribet and Serre in [**Rib92**] that describes the simple abelian varieties A over $\mathbb{Q}$ that should arise via this construction. In particular, the conjecture is that A is isogenous to some abelian variety A_f if and only if $\mathrm{End}(A/\mathbb{Q}) \otimes \mathbb{Q}$ is a number field of degree $\dim(A)$. The abelian varieties A_f have this property since $\mathbb{Q}(\ldots, a_n(f), \ldots)$ embeds in $\mathrm{End}(A/\mathbb{Q})\otimes\mathbb{Q}$ and the endomorphism ring over $\mathbb{Q}$ has degree at most $\dim(A)$ (see [**Rib92**] for details). Ribet proves that his conjecture is a consequence of Serre's conjecture [**Ser87**] on modularity of mod p odd irreducible Galois representations (see Section 1.5). Much of Serre's conjecture has been proved by Khare and Wintenberger (not published). In particular, it is a theorem that if A is a simple abelian variety over $\mathbb{Q}$ with $\mathrm{End}(A/\mathbb{Q}) \otimes \mathbb{Q}$ a number field of degree $\dim(A)$ and if A has good reduction at 2, then A is isogenous to some abelian variety A_f.

Remark 10.2. When $k > 2$, there is an object called a *Grothendieck motive* that is attached to f and has a canonical "structure over $\mathbb{Q}$". See [**Sch90**].

10.3. Extended Modular Symbols

In this section, we extend the notion of modular symbols to allows symbols of the form $P\{w, z\}$ where w and z are arbitrary elements of $\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q})$.

Definition 10.3 (Extended Modular Symbols)**.** The abelian group $\overline{\mathbb{M}}_k$ of *extended modular symbols* of weight k is the $\mathbb{Z}$-span of symbols $P\{w, z\}$, with $P \in V_{k-2}$ a homogeneous polynomial of degree $k-2$ with integer coefficients, modulo the relations

$$P \cdot (\{w, y\} + \{y, z\} + \{z, w\}) = 0$$

and modulo any torsion.

Fix a finite index subgroup $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$. Just as for usual modular symbols, $\overline{\mathbb{M}}_k$ is equipped with an action of Γ, and we define the space of *extended modular symbols* of weight k for Γ to be the quotient

$$\overline{\mathbb{M}}_k(\Gamma) = (\overline{\mathbb{M}}_k / \langle \gamma x - x : \gamma \in \Gamma, x \in \overline{\mathbb{M}}_k \rangle)/\,\mathrm{tor}\,.$$

The quotient $\overline{\mathbb{M}}_k(\Gamma)$ is torsion-free and fixed by Γ.

The integration pairing extends naturally to a pairing

$$\big(S_k(\Gamma) \oplus \overline{S}_k(\Gamma)\big) \times \overline{\mathbb{M}}_k(\Gamma) \to \mathbb{C}, \tag{10.3.1}$$

where we recall from (8.5.1) that $\overline{S}_k(\Gamma)$ denotes the space of antiholomorphic cusp forms. Moreover, if

$$\iota : \mathbb{M}_k(\Gamma) \to \overline{\mathbb{M}}_k(\Gamma)$$

is the natural map, then ι respects (10.3.1) in the sense that for all $f \in S_k(\Gamma) \oplus \overline{S}_k(\Gamma)$ and $x \in \mathbb{M}_k(\Gamma)$, we have

$$\langle f, x\rangle = \langle f, \iota(x)\rangle.$$

As we will see soon, it is often useful to replace $x \in \mathbb{M}_k(\Gamma)$ first by $\iota(x)$ and then by an equivalent sum $\sum y_i$ of symbols $y_i \in \overline{\mathbb{M}}_k(N, \varepsilon)$ such that $\langle f, \sum y_i\rangle$ is easier to compute numerically than $\langle f, x\rangle$.

Let ε be a Dirichlet character of modulus N. If $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, let $\varepsilon(\gamma) = \varepsilon(d)$. Let $\overline{\mathbb{M}}_k(N, \varepsilon)$ be the quotient of $\overline{\mathbb{M}}_k(N, \mathbb{Z}[\varepsilon])$ by the relations $\gamma(x) - \varepsilon(\gamma)x$, for all $x \in \mathbb{M}_k(N, \mathbb{Z}[\varepsilon])$, $\gamma \in \Gamma_0(N)$, and modulo any torsion.

10.4. Approximating Period Integrals

In this section we assume Γ is a congruence subgroup of $\mathrm{SL}_2(\mathbb{Z})$ that contains $\Gamma_1(N)$ for some N. Suppose $\alpha \in \mathfrak{h}$, so $\mathrm{Im}(\alpha) > 0$ and m is an integer such that $0 \le m \le k-2$, and consider the extended modular symbol $X^mY^{k-2-m}\{\alpha, \infty\}$. Let $\langle \cdot, \cdot \rangle$ denote the integration pairing from Section 8.5. Given an arbitrary cusp form $f = \sum_{n=1}^{\infty} a_n q^n \in S_k(\Gamma)$, we have

$$\Phi_f(X^mY^{k-2-m}\{\alpha,\infty\}) = \left\langle f,\, X^mY^{k-2-m}\{\alpha,\infty\}\right\rangle \tag{10.4.1}$$

$$= \int_{\alpha}^{\infty} f(z) z^m dz \tag{10.4.2}$$

$$= \sum_{n=1}^{\infty} a_n \int_{\alpha}^{\infty} e^{2\pi i n z} z^m dz. \tag{10.4.3}$$

The reversal of summation and integration is justified because the imaginary part of α is positive so that the sum converges absolutely. The following lemma is useful for computing the above infinite sum.

Lemma 10.4.

$$\int_{\alpha}^{\infty} e^{2\pi i n z} z^m dz \;=\; e^{2\pi i n \alpha} \sum_{s=0}^{m} \left(\frac{(-1)^s \alpha^{m-s}}{(2\pi i n)^{s+1}} \prod_{j=(m+1)-s}^{m} j \right). \tag{10.4.4}$$

Proof. See Exercise 10.1 □

In practice we will usually be interested in computing the period map Φ_f when $f \in S_k(\Gamma)$ is a newform. Since f is a newform, there is a Dirichlet character ε such that $f \in S_k(N, \varepsilon)$. The period map $\Phi_f : \mathbb{M}_k(\Gamma) \to \mathbb{C}$ then factors through the quotient $\mathbb{M}_k(N,\varepsilon)$, so it suffices to compute the period map on modular symbols in $\mathbb{M}_k(N,\varepsilon)$.

The following proposition is an analogue of [**Cre97a**, Prop. 2.1.1(5)].

Proposition 10.5. *For any $\gamma \in \Gamma_0(N)$, $P \in V_{k-2}$ and $\alpha \in \mathfrak{h}^*$, we have the following relation in $\overline{\mathbb{M}}_k(N,\varepsilon)$:*

$$\begin{aligned} P\{\infty,\gamma(\infty)\} &= P\{\alpha,\gamma(\alpha)\} + (P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\} && (10.4.5)\\ &= \varepsilon(\gamma)(\gamma^{-1}P)\{\alpha,\infty\} - P\{\gamma(\alpha),\infty\}. && (10.4.6)\end{aligned}$$

Proof. By definition, if $x \in \mathbb{M}_k(N,\varepsilon)$ is a modular symbol and $\gamma \in \Gamma_0(N)$, then $\gamma x = \varepsilon(\gamma)x$. Thus $\varepsilon(\gamma)\gamma^{-1}x = x$, so

$$\begin{aligned} P\{\infty,\gamma(\infty)\} &= P\{\infty,\alpha\} + P\{\alpha,\gamma(\alpha)\} + P\{\gamma(\alpha),\gamma(\infty)\}\\ &= P\{\infty,\alpha\} + P\{\alpha,\gamma(\alpha)\} + \varepsilon(\gamma)\gamma^{-1}(P\{\gamma(\alpha),\gamma(\infty)\})\\ &= P\{\infty,\alpha\} + P\{\alpha,\gamma(\alpha)\} + \varepsilon(\gamma)(\gamma^{-1}P)\{\alpha,\infty\}\\ &= P\{\alpha,\gamma(\alpha)\} + P\{\infty,\alpha\} - \varepsilon(\gamma)(\gamma^{-1}P)\{\infty,\alpha\}\\ &= P\{\alpha,\gamma(\alpha)\} + (P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\}.\end{aligned}$$

The second equality in the statement of the proposition now follows easily. □

In the case of weight 2 and trivial character, the "error term"

$$(P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\} \tag{10.4.7}$$

vanishes since P is constant and $\varepsilon(\gamma)=1$. In general this term does not vanish. However, we can suitably modify the formulas found in [**Cre97a**, 2.10] and still obtain an algorithm for computing period integrals.

Algorithm 10.6 (Period Integrals)**.** *Given $\gamma \in \Gamma_0(N)$, $P \in V_{k-2}$ and $f \in S_k(N,\varepsilon)$ presented as a q-expansion to some precision, this algorithm outputs an approximation to the period integral $\langle f,\, P\{\infty,\gamma(\infty)\}\rangle$.*

(1) Write $\gamma = \left(\begin{smallmatrix} a & b \\ cN & d\end{smallmatrix}\right) \in \Gamma_0(N)$, with $a,b,c,d \in \mathbb{Z}$, and set $\alpha = \frac{-d+i}{cN}$ in Proposition 10.5.
(2) Replacing γ by $-\gamma$ if necessary, we find that the imaginary parts of α and $\gamma(\alpha) = \frac{a+i}{cN}$ are both equal to the positive number $\frac{1}{cN}$.
(3) Use (10.4.3) and Lemma 10.4 to compute the integrals that appear in Proposition 10.5.

It would be nice if the modular symbols of the form $P\{\infty,\gamma(\infty)\}$ for $P \in V_{k-2}$ and $\gamma \in \Gamma_0(N)$ were to generate a large subspace of $\mathbb{M}_k(N,\varepsilon)\otimes\mathbb{Q}$. When $k=2$ and $\varepsilon=1$, Manin proved in [**Man72**] that the map $\Gamma_0(N) \to H_1(X_0(N),\mathbb{Z})$ sending γ to $\{0,\gamma(0)\}$ is a surjective group homomorphism. When $k>2$, the author does not know a similar group-theoretic statement. However, we have the following theorem.

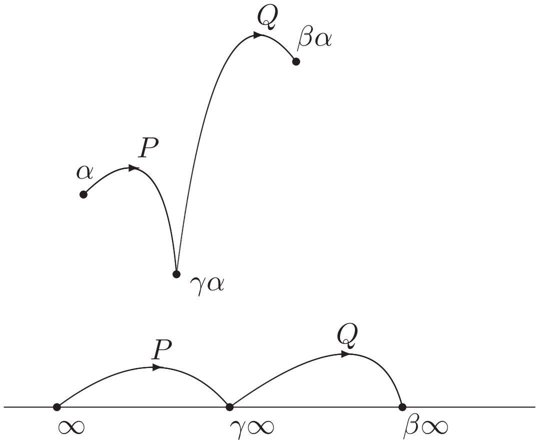

Figure 10.4.1. “Transporting” a transportable modular symbol.

Theorem 10.7. *Any element of* $\mathbb{S}_k(N,\varepsilon)$ *can be written in the form*

$$\sum_{i=1}^{n} P_i\{\infty,\gamma_i(\infty)\}$$

for some $P_i \in V_{k-2}$ *and* $\gamma_i \in \Gamma_0(N)$. *Moreover,* P_i *and* γ_i *can be chosen so that* $\sum P_i = \sum \varepsilon(\gamma_i)\gamma_i^{-1}(P_i)$, *so the error term* (10.4.7) *vanishes.*

The author and Helena Verrill prove this theorem in [**SV01**]. The condition that the error term vanishes means that one can replace ∞ by any α in the expression for the modular symbol and obtain an equivalent modular symbol. For this reason, we call such modular symbols *transportable*, as illustrated in Figure 10.4.1.

Note that in general not every element of the form $P\{\infty,\gamma(\infty)\}$ must lie in $\mathbb{S}_k(N,\varepsilon)$. However, if $\gamma P = P$, then $P\{\infty,\gamma(\infty)\}$ does lie in $\mathbb{S}_k(N,\varepsilon)$. It would be interesting to know under what circumstances $\mathbb{S}_k(N,\varepsilon)$ is generated by symbols of the form $P\{\infty,\gamma(\infty)\}$ with $\gamma P = P$. This sometimes fails for k odd; for example, when $k = 3$, the condition $\gamma P = P$ implies that $\gamma \in \Gamma_0(N)$ has an eigenvector with eigenvalue 1, and hence is of finite order. When k is even, the author can see no obstruction to generating $\mathbb{S}_k(N,\varepsilon)$ using such symbols.

10.5. Speeding Convergence Using Atkin-Lehner

Let $w_N = \left(\begin{smallmatrix} 0 & -1 \\ N & 0 \end{smallmatrix}\right) \in \mathrm{Mat}_2(\mathbb{Z})$. Consider the Atkin-Lehner involution W_N on $M_k(\Gamma_1(N))$, which is defined by

$$\begin{aligned} W_N(f) &= N^{(2-k)/2} \cdot f|_{[w_N]_k} \\ &= N^{(2-k)/2} \cdot f\left(-\frac{1}{Nz}\right) \cdot N^{k-1} \cdot (Nz)^{-k} \\ &= N^{-k/2} \cdot z^{-k} \cdot f\left(-\frac{1}{Nz}\right). \end{aligned}$$

Here we take the positive square root if k is odd. Then $W_N^2 = (-1)^k$ is an involution when k is even.

There is an operator on modular symbols, which we also denote W_N, which is given by

$$\begin{aligned} W_N(P\{\alpha,\beta\}) &= N^{(2-k)/2} \cdot w_N(P)\{w_N(\alpha), w_N(\beta)\} \\ &= N^{(2-k)/2} \cdot P(-Y, NX)\left\{-\frac{1}{\alpha N}, -\frac{1}{\beta N}\right\}, \end{aligned}$$

and one has that if $f \in S_k(\Gamma_1(N))$ and $x \in \mathbb{M}_k(\Gamma_1(N))$, then

$$\langle W_N(f), x\rangle = \langle f, W_N(x)\rangle.$$

If ε is a Dirichlet character of modulus N, then the operator W_N sends $S_k(N,\varepsilon)$ to $S_k(\Gamma_1(N),\overline{\varepsilon})$. Thus if $\varepsilon^2 = 1$, then W_N preserves $S_k(N,\varepsilon)$. In particular, W_N acts on $S_k(\Gamma_0(N))$.

The next proposition shows how to compute the pairing $\langle f, P\{\infty,\gamma(\infty)\}\rangle$ under certain restrictive assumptions. It generalizes a result of [**Cre97b**] to higher weight.

Proposition 10.8. *Let $f \in S_k(N,\varepsilon)$ be a cusp form which is an eigenform for the Atkin-Lehner operator W_N having eigenvalue $w \in \{\pm 1\}$ (thus $\varepsilon^2 = 1$ and k is even). Then for any $\gamma \in \Gamma_0(N)$ and any $P \in V_{k-2}$, with the property that $\gamma P = \varepsilon(\gamma) P$, we have the following formula, valid for any $\alpha \in \mathfrak{h}$:*

$$\begin{aligned} \langle f, P\{\infty,\gamma(\infty)\}\rangle = \Big\langle f, \quad & w\frac{P(Y,-NX)}{N^{k/2-1}}\{w_N(\alpha),\infty\} \\ &+ \left(P - w\frac{P(Y,-NX)}{N^{k/2-1}}\right)\left\{i/\sqrt{N},\infty\right\} - P\left\{\gamma(\alpha),\infty\right\}\Big\rangle. \end{aligned}$$

Here $w_N(\alpha) = -\dfrac{1}{N\alpha}$.

Proof. By Proposition 10.5 our condition on P implies that $P\{\infty,\gamma(\infty)\} = P\{\alpha,\gamma(\alpha)\}$. We describe the steps of the following computation below.

$$\begin{aligned}&\Big\langle f,\quad P\{\alpha,\gamma(\alpha)\}\Big\rangle\\&=\Big\langle f,\quad P\{\alpha,i/\sqrt{N}\}+P\{i/\sqrt{N},W(\alpha)\}+P\{W(\alpha),\gamma(\alpha)\}\Big\rangle\\&=\Big\langle f,\quad w\frac{W(P)}{N^{k/2-1}}\{W(\alpha),i/\sqrt{N}\}+P\{i/\sqrt{N},W(\alpha)\}+P\{W(\alpha),\gamma(\alpha)\}\Big\rangle.\end{aligned}$$

For the first equality, we break the path into three paths, and in the second, we apply the W-involution to the first term and use that the action of W is compatible with the pairing $\langle\, ,\,\rangle$ and that f is an eigenvector with eigenvalue w. In the following sequence of equalities we combine the first two terms and break up the third; then we replace $\{W(\alpha),i/\sqrt{N}\}$ by $\{W(\alpha),\infty\}+\{\infty,i/\sqrt{N}\}$ and regroup:

$$\begin{aligned}&w\frac{W(P)}{N^{k/2-1}}\{W(\alpha),i/\sqrt{N}\}+P\{i/\sqrt{N},W(\alpha)\}+P\{W(\alpha),\gamma(\alpha)\}\\&=\left(w\frac{W(P)}{N^{k/2-1}}-P\right)\{W(\alpha),i/\sqrt{N}\}+P\{W(\alpha),\infty\}-P\{\gamma(\alpha),\infty\}\\&=w\frac{W(P)}{N^{k/2-1}}\{W(\alpha),\infty\}+\left(P-w\frac{W(P)}{N^{k/2-1}}\right)\{i/\sqrt{N},\infty\}-P\{\gamma(\alpha),\infty\}.\end{aligned}$$

□

A good choice for α is $\alpha=\gamma^{-1}\left(\frac{b}{d}+\frac{i}{d\sqrt{N}}\right)$, so that $W(\alpha)=\frac{c}{d}+\frac{i}{d\sqrt{N}}$. This maximizes the minimum of the imaginary parts of α and $W(\alpha)$, which results in series that converge more quickly.

Let $\gamma=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in\Gamma_0(N)$. The polynomial

$$P(X,Y)=(cX^2+(d-a)XY-bY^2)^{\frac{k-2}{2}}$$

satisfies $\gamma(P)=P$. We obtained this formula by viewing V_{k-2} as the $(k-2)$th symmetric product of the 2-dimensional space on which $\Gamma_0(N)$ acts naturally. For example, observe that since $\det(\gamma)=1$, the symmetric product of two eigenvectors for γ is an eigenvector in V_2 having eigenvalue 1. For the same reason, if $\varepsilon(\gamma)\neq 1$, there need not be a polynomial $P(X,Y)$ such that $\gamma(P)=\varepsilon(\gamma)P$. One remedy is to choose another γ so that $\varepsilon(\gamma)=1$.

Since the imaginary parts of the terms $i/\sqrt{N}$, α and $W(\alpha)$ in the proposition are all relatively large, the sums appearing at the beginning of Section 10.4 converge quickly if d is small. It is *important* to choose γ in Proposition 10.8 with d small; otherwise the series will converge very slowly.

Remark 10.9. Is there a generalization of Proposition 10.8 without the restrictions that $\varepsilon^2=1$ and k is even?

10.5.1. Another Atkin-Lehner Trick. Suppose E is an elliptic curve and let $L(E,s)$ be the corresponding L-function. Let $\varepsilon \in \{\pm 1\}$ be the root number of E, i.e., the sign of the functional equation for $L(E,s)$, so $\Lambda(E,s) = \varepsilon\Lambda(E,2-s)$, where $\Lambda(E,s) = N^{s/2}(2\pi)^{-s}\Gamma(s)L(E,s)$. Let $f = f_E$ be the modular form associated to E (which exists by [**Wil95, BCDT01**]). If $W_N(f) = wf$, then $\varepsilon = -w$ (see Exercise 10.2). We have

$$\begin{aligned} L(E,1) &= -2\pi \int_0^\infty f(z)\,dz \\ &= -2\pi i\,\langle f,\,\{0,\infty\}\rangle \\ &= -2\pi i\,\left\langle f, \{0, i/\sqrt{N}\} + \{i/\sqrt{N},\infty\}\right\rangle \\ &= -2\pi i\,\left\langle wf, \{w_N(0), w_N(i/\sqrt{N})\} + \{i/\sqrt{N},\infty\}\right\rangle \\ &= -2\pi i\,\left\langle wf, \{\infty, i/\sqrt{N}\} + \{i/\sqrt{N},\infty\}\right\rangle \\ &= -2\pi i\,(w-1)\left\langle f, \{\infty, i/\sqrt{N}\}\right\rangle. \end{aligned}$$

If $w = 1$, then $L(E,1) = 0$. If $w = -1$, then

$$L(E,1) = 4\pi i \left\langle f, \{\infty, i/\sqrt{N}\}\right\rangle = 2\sum_{n=1}^{\infty} \frac{a_n}{n} e^{-2\pi n/\sqrt{N}}. \tag{10.5.1}$$

For more about computing with L-functions of elliptic curves, including a trick for computing ε quickly without directly computing W_N, see [**Coh93**, §7.5] and [**Cre97a**, §2.11]. One can also find higher derivatives $L^{(r)}(E,1)$ by a formula similar to (10.5.1) (see [**Cre97a**, §2.13]). The methods in this chapter for obtaining rapidly converging series are not just of computational interest; see, e.g., [**Gre83**] for a nontrivial theoretical application to the Birch and Swinnerton-Dyer conjecture.

10.6. Computing the Period Mapping

Fix a newform $f = \sum a_n q^n \in S_k(\Gamma)$, where $\Gamma_1(N) \subset \Gamma$ for some N. Let V_f be as in (10.2.1).

Let $\Theta_f : M_k(\Gamma;\mathbb{Q}) \to V$ be *any* $\mathbb{Q}$-linear map with the same kernel as Φ_f; we call any such map a *rational period mapping* associated to f. Let Φ_f be the period mapping associated to the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f. We have a commutative diagram

$$\begin{tikzcd}
\mathbb{M}_k(\Gamma;\mathbb{Q}) \arrow[rr, "\Phi_f"] \arrow[dr, "\Theta_f"'] & & \mathrm{Hom}_{\mathbb{C}}(V_f,\mathbb{C}) \\
& V \arrow[ur, hook, "i_f"] &
\end{tikzcd}$$

Recall from Section 10.2 that the cokernel of Φ_f is the abelian variety $A_f(\mathbb{C})$.

The Hecke algebra $\mathbb{T}$ acts on the linear dual

$$\mathbb{M}_k(\Gamma;\mathbb{Q})^* = \mathrm{Hom}(\mathbb{M}_k(\Gamma),\mathbb{Q})$$

by $(t\varphi)(x) = \varphi(tx)$. Let $I = I_f \subset \mathbb{T}$ be the kernel of the ring homomorphism $\mathbb{T} \to \mathbb{Z}[a_2, a_3, \ldots]$ that sends T_n to a_n. Let

$$\mathbb{M}_k(\Gamma;\mathbb{Q})^*[I] = \{\varphi \in \mathbb{M}_k(\Gamma;\mathbb{Q})^* : t\varphi = 0 \text{ all } t \in I\}.$$

Since f is a newform, one can show that $\mathbb{M}_k(\Gamma;\mathbb{Q})^*[I]$ has dimension d. Let $\theta_1, \ldots, \theta_d$ be a basis for $\mathbb{M}_k(\Gamma;\mathbb{Q})^*[I]$, so

$$\mathrm{Ker}(\Phi_f) = \mathrm{Ker}(\theta_1) \oplus \cdots \oplus \mathrm{Ker}(\theta_d).$$

We can thus compute $\mathrm{Ker}(\Phi_f)$, hence a choice of Θ_f. To compute Φ_f, it remains to compute i_f.

Let $S_k(\Gamma;\mathbb{Q})$ denote the space of cusp forms with q-expansion in $\mathbb{Q}[[q]]$. By Exercise 10.3

$$S_k(\Gamma;\mathbb{Q})[I] = S_k(\Gamma)[I] \cap \mathbb{Q}[[q]]$$

is a $\mathbb{Q}$-vector space of dimension d. Let $g_1, \ldots, g_d$ be a basis for this $\mathbb{Q}$-vector space. We will compute Φ_f with respect to the basis of $\mathrm{Hom}_{\mathbb{Q}}(S_k(\Gamma;\mathbb{Q})[I];\mathbb{C})$ dual to this basis. Choose elements $x_1, \ldots, x_d \in \mathbb{M}_k(\Gamma)$ with the following properties:

(1) Using Proposition 10.5 or Proposition 10.8, it is possible to compute the period integrals $\langle g_i, x_j\rangle$, $i, j \in \{1, \ldots, d\}$, efficiently.

(2) The $2d$ elements $v + \eta(v)$ and $v - \eta(v)$ for $v = \Theta_f(x_1), \ldots, \Theta_f(x_d)$ span a space of dimension $2d$ (i.e., they span $\mathbb{M}_k(\Gamma)/\operatorname{Ker}(\Phi_f)$).

Given this data, we can compute

$$i_f(v + \eta(v)) = 2\mathrm{Re}(\langle g_1, x_i\rangle, \ldots, \langle g_d, x_i\rangle)$$

and

$$i_f(v - \eta(v)) = 2i\mathrm{Im}(\langle g_1, x_i\rangle, \ldots, \langle g_d, x_i\rangle).$$

We break the integrals into real and imaginary parts because this increases the precision of our answers. Since the vectors $v_n + \eta(v_n)$ and $v_n - \eta(v_n)$, $n = 1, \ldots, d$, span $\mathbb{M}_k(N, \varepsilon;\mathbb{Q})/\operatorname{Ker}(\Phi_f)$, we have computed i_f.

Remark 10.10. We want to find symbols x_i satisfying the conditions of Proposition 10.8. This is usually possible when d is very small, but in practice it is difficult when d is large.

Remark 10.11. The above strategy was motivated by [**Cre97a**, §2.10].

10.7. All Elliptic Curves of Given Conductor

Using modular symbols and the period map, we can compute all elliptic curves over $\mathbb{Q}$ of conductor N, up to isogeny. The algorithm in this section gives all *modular elliptic curves* (up to isogeny), i.e., elliptic curves attached to modular forms, of conductor N. Fortunately, it is now known by [**Wil95, BCDT01, TW95**] that every elliptic curve over $\mathbb{Q}$ is modular, so the procedure of this section gives all elliptic curves (up to isogeny) of given conductor. See [**Cre06**] for a nice historical discussion of this problem.

Algorithm 10.12 (Elliptic Curves of Conductor N)**.** *Given $N > 0$, this algorithm outputs equations for all elliptic curves of conductor N, up to isogeny.*

(1) [Modular Symbols] Compute $\mathbb{M}_2(\Gamma_0(N))$ using Section 8.7.

(2) [Find Rational Eigenspaces] Find the 2-dimensional eigenspaces V in $\mathbb{M}_2(\Gamma_0(N))_{\mathrm{new}}$ that correspond to elliptic curves. Do *not* use the algorithm for decomposition from Section 7.5, which is too complicated and gives more information than we need. Instead, for the first few primes $p \nmid N$, compute all eigenspaces $\mathrm{Ker}(T_p - a)$, where a runs through integers with $-2\sqrt{p} < a < 2\sqrt{p}$. Intersect these eigenspaces to find the eigenspaces that correspond to elliptic curves. To find just the new ones, either compute the degeneracy maps to lower level or find all the rational eigenspaces of all levels that strictly divide N and exclude them.

(3) [Find Newforms] Use Algorithm 9.14 to compute to some precision each newform $f = \sum_{n=1}^{\infty} a_n q^n \in \mathbb{Z}[[q]]$ associated to each eigenspace V found in step (2).

(4) [Find Each Curve] For each newform f found in step (3), do the following:

   (a) [Period Lattice] Compute the corresponding period lattice $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ by computing the image of Φ_f, as described in Section 10.6.

   (b) [Compute τ] Let $\tau = \omega_1/\omega_2$. If $\mathrm{Im}(\tau) < 0$, swap ω_1 and ω_2, so $\mathrm{Im}(\tau) > 0$. By successively applying generators of $\mathrm{SL}_2(\mathbb{Z})$, we find an $\mathrm{SL}_2(\mathbb{Z})$ equivalent element τ' in $\mathcal{F}$, i.e., $|\mathrm{Re}(\tau')| \leq 1/2$ and $|\tau| \geq 1$.

(c) [c-invariants] Compute the invariants c_4 and c_6 of the lattice Λ using the following rapidly convergent series:

$$c_4 = \left(\frac{2\pi}{\omega_2}\right)^4 \cdot \left(1 + 240\sum_{n=1}^{\infty} \frac{n^3 q^n}{1-q^n}\right),$$
$$c_6 = \left(\frac{2\pi}{\omega_2}\right)^6 \cdot \left(1 - 504\sum_{n=1}^{\infty} \frac{n^5 q^n}{1-q^n}\right),$$

where $q = e^{2\pi i \tau'}$, where τ' is as in step (4b). A theorem of Edixhoven (that the Manin constant is an integer) implies that the invariants c_4 and c_6 of Λ are integers, so it is only necessary to compute Λ to large precision to completely determine them.

(d) [Elliptic Curve] An elliptic curve with invariants c_4 and c_6 is

$$E: \quad y^2 = x^3 - \frac{c_4}{48}x - \frac{c_6}{864}.$$

(e) [Prove Correctness] Using Tate's algorithm, find the conductor of E. If the conductor is not N, then recompute c_4 and c_6 using more terms of f and real numbers to larger precision, etc. If the conductor is N, compute the coefficients b_p of the modular form $g = g_E$ attached to the elliptic curve E, for $p \leq \#\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})/6$. Verify that $a_p = b_p$, where a_p are the coefficients of f. If this equality holds, then E must be isogenous to the elliptic curve attached to f, by the Sturm bound (Theorem 9.18) and Faltings's isogeny theorem. If the equality fails for some p, recompute c_4 and c_6 to larger precision.

There are numerous tricks to optimize the above algorithm. For example, often one can work separately with $\mathbb{M}_k(\Gamma_0(N))^+_{\text{new}}$ and $\mathbb{M}_k(\Gamma_0(N))^-_{\text{new}}$ and get enough information to find E, up to isogeny (see [**Cre97b**]).

Once we have one curve from each isogeny class of curves of conductor N, we find each curve in each isogeny class (which is another interesting problem discussed in [**Cre97a**]), hence all curves of conductor N. If $E/\mathbb{Q}$ is an elliptic curve, then any curve isogenous to E is isogenous via a chain of isogenies of prime degree. There is an *a priori* bound on the degrees of these isogenies due to Mazur. Also, there are various methods for finding all isogenies of a given degree with domain E. See [**Cre97a**, §3.8] for more details.

10.7.1. Finding Curves: S-Integral Points.

In this section we briefly survey an alternative approach to finding curves of a given conductor by finding integral points on other elliptic curves.

Cremona and others have developed a complementary approach to the problem of computing all elliptic curves of given conductor (see [**CL04**]).

Instead of computing all curves of given conductor, we instead consider the seemingly more difficult problem of finding all curves with good reduction outside a finite set S of primes. Since one can compute the conductor of a curve using Tate's algorithm [**Tat75, Cre97a**, §3.2], if we know all curves with good reduction outside S, we can find all curves of conductor N by letting S be the set of prime divisors of N.

There is a strategy for finding all curves with good reduction outside S. It is not an algorithm, in the sense that it is always guaranteed to terminate (the modular symbols method above *is* an algorithm), but in practice it often works. Also, this strategy makes sense over any number field, whereas the modular symbols method does not (there are generalizations of modular symbols to other number fields).

Fix a finite set S of primes of a number field K. It is a theorem of Shafarevich that there are only finitely many elliptic curves with good reduction outside S (see [**Sil92**, Section IX.6]). His proof uses that the group of S-units in K is finite and Siegel's theorem that there are only finitely many S-integral points on an elliptic curve. One can make all this explicit, and sometimes in practice one can compute all these S-integral points.

The problem of finding all elliptic curves with good reduction outside of S can be broken into several subproblems, the main ones being

(1) determine the following finite subgroup of $K^*/(K^*)^m$:

$$K(S,m) = \{x \in K^*/(K^*)^m \,:\, m \mid \mathrm{ord}_{\mathfrak{p}}(x) \text{ all } \mathfrak{p} \notin S\};$$

(2) find all S-integral points on certain elliptic curves $y^2 = x^3 + k$.

In [**CL04**], there is one example, where they find all curves of conductor $N = 2^8 \cdot 17^2 = 73984$ by finding all curves with good reduction outside $\{2, 17\}$. They finds 32 curves of conductor 73984 that divide into 16 isogeny classes. (Note that $\dim S_2(\Gamma_0(N)) = 9577$.)

10.7.2. Finding Curves: Enumeration.

One can also find curves by simply enumerating Weierstrass equations. For example, the paper [**SW02**] discusses a database that the author and Watkins created that contains hundreds of millions of elliptic curves. It was constructed by enumerating Weierstrass equations of a certain form. This database does not contain *every* curve of each conductor included in the database. It is, however, fairly complete in some cases. For example, using the Mestre method of graphs [**Mes86**], we verified in [**JBS03**] that the database contains all elliptic curve of prime conductor < 234446, which implies that the smallest conductor rank 4 curve is composite.

10.8. Exercises

10.1 Prove Lemma 10.4.

10.2 Suppose $f \in S_2(\Gamma_0(N))$ is a newform and that $W_N(f) = wf$. Let $\Lambda(E, s) = N^{s/2}(2\pi)^{-s}\Gamma(s)L(E, s)$. Prove that

$$\Lambda(E, s) = -w\Lambda(E, 2 - s).$$

[Hint: Show that $\Lambda(f, s) = \int_{0,\infty} f(iy/\sqrt{N})y^{s-1}\,dy$. Then substitute $1/y$ for y.]

10.3 Let $f = \sum a_n q^n \in \mathbb{C}[[q]]$ be a power series whose coefficients a_n together generate a number field K of degree d over $\mathbb{Q}$. Let V_f be the complex vector space spanned by the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f.

(a) Give an example to show that V_f need not have dimension d.

(b) Suppose V_f has dimension d. Prove that $V_f \cap \mathbb{Q}[[q]]$ is a $\mathbb{Q}$-vector space of dimension d.

10.4 Find an elliptic curve of conductor 11 using Section 10.7.

Chapter 11

Solutions to Selected Exercises

11.1. Chapter 1

(1) Exercise 1.1. Suppose $\gamma = \left(\begin{smallmatrix} a & nb \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{R})$ is a matrix with positive determinant. Then γ is a linear fractional transformation that fixes the real line, so it must either fix or swap the upper and lower half planes. Now

$$\gamma(i) = \frac{ai+b}{ci+d} = \frac{ac+bd+(ad-bc)i}{d^2+c^2},$$

so since $\det\gamma = ad-bc > 0$, the imaginary part of $\gamma(i)$ is positive; hence γ sends the upper half plane to itself.

(2) Exercise 1.2. Avoiding poles, the quotient rule for differentiation goes through exactly as in the real case, so any rational function $f(z) = p(z)/q(z)$ $(p, q \in \mathbb{C}[z])$ is holomorphic on $\mathbb{C} - \{\alpha : q(\alpha) = 0\}$. By the fundamental theorem of algebra, this set of poles is finite, and hence it is discrete. Write $q(z) = a_n(z-\alpha_1)^{r_1} \cdots (z-\alpha_k)^{r_k}$ for each α_i and let $q_i(z) = q(z)/(z-\alpha_i)^{r_i}$ which is a polynomial nonzero at α_i. Thus for each i we have $(z-\alpha_i)^{r_i} f(z) = p(z)/q'(z)$ is holomorphic at α_i and hence $f(z)$ is meromorphic on $\mathbb{C}$.

(3) Exercise 1.3.

(a) The product fg of two meromorphic functions on the upper half plane is itself meromorphic. Also, for all $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ we have

$$(fg)^{[\gamma]_{k+j}} = \frac{1}{(cz+d)^{k+j}}((fg)\circ\gamma)$$
$$= \frac{1}{(cz+d)^{k}}(f\circ\gamma)\frac{1}{(cz+d)^{j}}(g\circ\gamma) = fg,$$

so fg is weakly modular.

(b) If f is meromorphic on the upper half plane, then so is $1/f$. Now

$$\frac{1}{f} = \frac{1}{(cz+d)^{-k}f\circ\gamma} = (cz+d)^{k}((1/f)\circ\gamma) = \frac{1}{f}^{[\gamma]_{-k}},$$

so $1/f$ is a weakly modular form of weight $-k$.

(c) Let f and g be modular functions. Then, as above, fg is a weakly modular function. Let $\sum_{n=m}^{\infty} a_n q^n$ and $\sum_{n=m'}^{\infty} b_n q^n$ be their q-expansions around any $\alpha \in \mathbb{P}^1(\mathbb{Q})$; then their formal product is the q-expansion of fg. But the formal product of two Laurent series about the same point is itself a Laurent series with convergence in the intersection of the convergent domains of the original series, so fg has a meromorphic q-expansion at each $\alpha \in \mathbb{P}^1(\mathbb{Q})$ and hence at each cusp.

(d) We are in exactly the same case as in part (c), but because f and g are modular functions, $m, m' \geq 0$ and hence the function is holomorphic at each of its cusps.

(4) Exercise 1.4. Let f be a weakly modular function of odd weight k. Since $\gamma = \left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, we have $f(z) = (-1)^{-k}f(\gamma(z)) = -f(z)$ so $f = 0$.

(5) Exercise 1.5. Because $\mathrm{SL}_2(\mathbb{Z}/1\mathbb{Z})$ is the trivial group, $\Gamma(1) = \ker(\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/1\mathbb{Z}))$ must be all of $\mathrm{SL}_2(\mathbb{Z})$. As $\mathrm{SL}_2(\mathbb{Z}) = \Gamma(1) \subset \Gamma_1(1) \subset \Gamma_0(1) \subset \mathrm{SL}_2(\mathbb{Z})$, we must have $\Gamma(1) = \Gamma_1(1) = \Gamma_0(1) = \mathrm{SL}_2(\mathbb{Z})$.

(6) Exercise 1.6.

(a) The group $\Gamma_1(N)$ is the inverse image of the subgroup of $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ generated by $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, and the inverse image of a group (under a group homomorphism) is a group.

(b) The group contains the kernel of the homomorphism $\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$, and that kernel has finite index since the quotient is contained in $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$, which is finite.

(c) Same argument as previous part.

(d) The level is at most N since both groups contain $\Gamma(N)$. It can be no greater than N since $\left(\begin{smallmatrix} 1 & N \\ 0 & 1 \end{smallmatrix}\right)$ is in both groups.

(7) Exercise 1.7. See [**DS05**, Lemma 1.2.2].

(8) Exercise 1.8. Let $\alpha = p/q \in \mathbb{Q}$, where p and q are relatively prime. By the Euclidean algorithm, we can find $x, y \in \mathbb{Z}$ such that $px + qy = 1$. Let $\gamma_\alpha = \left(\begin{smallmatrix} p & -y \\ q & x \end{smallmatrix}\right)$. Note that $\gamma_\alpha \in \mathrm{SL}_2(\mathbb{Z})$ and $\gamma_\alpha(\infty) = \alpha$. Also let γ_∞ be the identity map on $\mathbb{P}^1(\mathbb{Q})$. Now γ_β^{-1} sends β to ∞ so we have $\gamma_\alpha \circ \gamma_\beta^{-1}$ which sends α to β.

11.2. Chapter 2

(1) Exercise 2.1. We have

$$\zeta(26) = \frac{1315862 \cdot \pi^{26}}{11094481976030578125}.$$

Variation: Compute $\zeta(28)$.

(2) Exercise 2.2. Omitted.

(3) Exercise 2.3.

$$\begin{aligned} E_8 &= -\frac{B_8}{16} + q + \sum_{n=2}^{\infty} \sigma_7(n) q^n \\ &= \frac{1}{480} + q + 129q^2 + 2188q^3 + \cdots . \end{aligned}$$

Variation: Compute E_{10}.

(4) Exercise 2.4. Omitted.

(5) Exercise 2.5. We have $d = \dim S_{28} = 2$. A choice of a, b with $4a + 6b \leq 14$ and $4a + 6b \equiv 4 \pmod{12}$ is $a = 1, b = 0$. A basis for S_{28} is then

$$\begin{aligned} g_1 &= \Delta F_6^{2(2-1)+0} F_4 = q - 792q^2 - 324q^3 + 67590208q^4 + \cdots , \\ g_2 &= \Delta^2 F_6^{2(2-2)+0} F_4 = q^2 + 192q^3 - 8280q^4 + \cdots . \end{aligned}$$

The Victor Miller basis is then

$$\begin{aligned} f_1 &= g_1 + 729 g_2 = q + 151740q^3 + 61032448q^4 + \cdots , \\ f_2 &= g_2 = q^2 + 192q^3 - 8280q^4 + \cdots . \end{aligned}$$

Variation: Compute the Victor Miller basis for S_{30}.

(6) Exercise 2.6. From the previous exercise we have $f = \Delta^2 F_4$. Then

$$\begin{aligned} f = \Delta^2 F_4 &= \left(\frac{F_4^3 - F_6^2}{-1728}\right)^2 \cdot F_4 \\ &= \left(\frac{\left(-\frac{8}{B_4}E_4\right)^3 - \left(-\frac{12}{B_6}E_6\right)^2}{-1728}\right)^2 \cdot \left(-\frac{8}{B_4}E_4\right) \\ &= 5186160 E_4 E_6^4 - 564480000 E_4^4 E_6^2 + 15360000000 E_4^7. \end{aligned}$$

(7) Exercise 2.7. No, it is not always integral. For example, for $k = 12$, the coefficient of q is $-2 \cdot 12/B_{12} = 65520/691 \notin \mathbb{Z}$. Variation: Find, with proof, the set of all k such that the normalized series F_k *is* integral (use that B_k is eventually very large compared to $2k$).

(8) Exercise 2.8. We compute the Victor Miller basis to precision great enough to determine T_2. This means we need up to $O(q^5)$.

$$\begin{aligned} f_0 &= 1 + 2611200q^3 + 19524758400q^4 + \cdots, \\ f_1 &= q + 50220q^3 + 87866368q^4 + \cdots, \\ f_2 &= q^2 + 432q^3 + 39960q^4 + \cdots. \end{aligned}$$

Then the matrix of T_2 on this basis is

$$\begin{pmatrix} 2147483649 & 0 & 19524758400 \\ 0 & 0 & 2235350016 \\ 0 & 1 & 39960 \end{pmatrix}.$$

(The rows of this matrix are the linear combinations that give the images of the f_i under T_2.) This matrix has characteristic polynomial

$$(x - 2147483649) \cdot (x^2 - 39960x - 2235350016).$$

11.3. Chapter 3

(1) Exercise 3.1. Write $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, so $\lambda' = \frac{a\lambda+b}{c\lambda+d}$. Let f be the isomorphism $\mathbb{C}/\Lambda \to \mathbb{C}/\Lambda'$ given by $f(z) = z/(c\lambda + d)$. We have

$$f\left(\frac{1}{N}\right) = \frac{1}{N(c\lambda+d)} = \frac{a}{N} - \frac{c}{N} \cdot \frac{a\lambda+b}{c\lambda+d} \cong \frac{a}{N} \pmod{\mathbb{Z} + \mathbb{Z}\lambda'},$$

where the second equality can be verified easily by expanding out each side, and for the congruence we use that $N \mid c$. Thus the subgroup of $\mathbb{C}/\Lambda$ generated by $\frac{1}{N}$ is taken isomorphically to the subgroup of $\mathbb{C}/\Lambda'$ generated by $\frac{1}{N}$.

(2) Exercise 3.2. For any integer r, we have $\left(\begin{smallmatrix} 1 & r \\ 0 & 1 \end{smallmatrix}\right) \in \Gamma_0(N)$, so $\{0, \infty\} = \{r, \infty\}$. Thus

$$0 = \{0,\infty\} - \{0,\infty\} = \{n,\infty\} - \{m,\infty\} = \{n,\infty\} + \{\infty, m\} = \{n, m\}.$$

(3) Exercise 3.3.
   (a) $(0 : 1), (1 : 0), (1 : 1), \dots, (1, p-1)$.
   (b) $p + 1$.
   (c) See [**Cre97a**, Prop. 2.2.1].

(4) Exercise 3.4. We start with $b = 4$, $a = 7$. Then $4 \cdot 2 \equiv 1 \pmod 7$. Let $\delta_1 = \left(\begin{smallmatrix} 4 & 1 \\ 7 & 2 \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$. Since $\delta_1 \in \Gamma_0(7)$, we use the right coset representative $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ and see that

$$\{0, 4/7\} = \{0, 1/2\} + \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \{0, \infty\}.$$

Repeating the process, we have $\delta_2 = \left(\begin{smallmatrix} 1 & 1 \\ 2 & 0 \end{smallmatrix}\right)$, which is in the same coset at $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Thus

$$\{0, 1/2\} = \left(\begin{smallmatrix} 0 & 6 \\ 1 & 0 \end{smallmatrix}\right) \{0, \infty\} + \{0, 0\}.$$

Putting it together gives

$$\{0, 4/7\} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \{0, \infty\} + \left(\begin{smallmatrix} 0 & 6 \\ 1 & 0 \end{smallmatrix}\right) \{0, \infty\} = [(0, 1)] + [(1, 0)].$$

(5) Exercise 3.5.
   (a) Coset representatives for $\Gamma_0(3)$ in $\mathrm{SL}_2(\mathbb{Z})$ are

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

   which we refer to below as $[r_0], [r_1], [r_2]$, and $[r_3]$, respectively.
   (b) In terms of representatives we have

$$\begin{aligned} [r_0] + [r_3] &= 0, & [r_0] + [r_3] + [r_2] &= 0, \\ [r_1] + [r_2] &= 0, & [r_1] + [r_1] + [r_1] &= 0, \\ [r_2] + [r_1] &= 0, & [r_2] + [r_0] + [r_3] &= 0, \\ [r_3] + [r_0] &= 0, & [r_3] + [r_2] + [r_0] &= 0. \end{aligned}$$

   (c) By the first three relations we have $[r_2] = [r_1] = 0 = 0[r_0]$ and $[r_3] = -1[r_0]$.
   (d)

$$\begin{aligned} T_2([r_0]) &= [r_0] \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2 \end{smallmatrix}\right) + [r_0] \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1 \end{smallmatrix}\right) + [r_0] \left(\begin{smallmatrix} 2 & 1 \\ 0 & 1 \end{smallmatrix}\right) + [r_0] \left(\begin{smallmatrix} 1 & 0 \\ 1 & 2 \end{smallmatrix}\right) \\ &= [\left(\begin{smallmatrix} 1 & 0 \\ 0 & 2 \end{smallmatrix}\right)] + [\left(\begin{smallmatrix} 2 & 0 \\ 0 & 1 \end{smallmatrix}\right)] + [\left(\begin{smallmatrix} 2 & 1 \\ 0 & 1 \end{smallmatrix}\right)] + [\left(\begin{smallmatrix} 1 & 0 \\ 1 & 2 \end{smallmatrix}\right)] \\ &= [r_0] + [r_0] + [r_0] + [r_2] \\ &= 3[r_0]. \end{aligned}$$

11.4. Chapter 4

(1) Exercise 4.1. Suppose f is a Dirichlet character with modulus N. Then $-1 = f(-1) = f(-1+N) = 1$, a contradiction.

(2) Exercise 4.2.

(a) Any finite subgroup of the multiplicative group of a field is cyclic (since the number of roots of a polynomial over a field is at most its degree), so $(\mathbb{Z}/p\mathbb{Z})^*$ is cyclic. Let g be an integer that reduces to a generator of $(\mathbb{Z}/p\mathbb{Z})^*$. Let $x = 1 + p \in (\mathbb{Z}/p^n\mathbb{Z})^*$; by the binomial theorem

$$x^{p^{n-2}} = 1 + p^{n-2} \cdot p + \cdots \equiv 1 + p^{n-1} \not\equiv 0 \pmod{p^n},$$

so x has order p^{n-1}. Since p is odd, $\gcd(p^{n-1}, p-1) = 1$, so xg has order $p^{n-1} \cdot (p-1) = \varphi(p^n)$; hence $(\mathbb{Z}/p^n\mathbb{Z})^*$ is cyclic.

(b) By the binomial theorem $(1+2^2)^{2^{n-3}} \not\equiv 1 \pmod{2^n}$, so 5 has order 2^{n-2} in $(\mathbb{Z}/2^n\mathbb{Z})^*$, and clearly -1 has order 2. Since $5 \equiv 1 \pmod 4$, -1 is not a power of 5 in $(\mathbb{Z}/2^n\mathbb{Z})^*$. Thus the subgroups $\langle -1 \rangle$ and $\langle 5 \rangle$ have trivial intersection. The product of their orders is $2^{n-1} = \varphi(2^n) = \#(\mathbb{Z}/2^n\mathbb{Z})^*$, so the claim follows.

(3) Exercise 4.3. Write $n = \prod p_i^{e_i}$. The order of g divides n, so the condition implies that $p_i^{e_i}$ divides the order of g for each i. Thus the order of g is divisible by the least common multiple of the $p_i^{e_i}$, i.e., by n.

(4) Exercise 4.4.

(a) The bijection given by $1 + p^{n-1}a \pmod{p^n} \mapsto a \pmod p$ is a homomorphism since

$$(1 + p^{n-1}a)(1 + p^{n-1}b) \equiv 1 + p^{n-1}(a+b) \pmod{p^n}.$$

(b) We have an exact sequence

$$1 \to 1 + p\mathbb{Z}/p^n\mathbb{Z} \to (\mathbb{Z}/p^n\mathbb{Z})^* \to (\mathbb{Z}/p\mathbb{Z})^* \to 1,$$

so it suffices to solve the discrete log problem in the kernel and cokernel. We prove by induction on n that we can solve the discrete log problem in the kernel easily (compared to known methods for solving the discrete log problem in $(\mathbb{Z}/p\mathbb{Z})^*$). We have an exact sequence

$$1 \to 1 + p^{n-1}\mathbb{Z}/p^n\mathbb{Z} \to (\mathbb{Z}/p^n\mathbb{Z})^* \to (\mathbb{Z}/p^{n-1}\mathbb{Z})^* \to 1.$$

The first part of this problem shows that we can solve the discrete log problem in the kernel, and by induction we can solve it in the cokernel. This completes the proof.

(5) Exercise 4.5. If $\varepsilon(5) = 1$, then since ε is nontrivial, Exercise 4.2 implies that ε factors through $(\mathbb{Z}/4\mathbb{Z})^*$, hence has conductor $4 = 2^{1+1}$, as claimed. If $\varepsilon(5) \neq 1$, then again from Exercise 4.2 we see that if ε has order r, then ε factors through $(\mathbb{Z}/2^{r+2}\mathbb{Z})^*$ but nothing smaller.

(6) Exercise 4.6.
   (a) Take $f = x^2 + 2$.
   (b) The element 2 has order 4.
   (c) A minimal generator for $(\mathbb{Z}/25\mathbb{Z})^*$ is 2, and the characters are [1], [2], [3], [4].
   (d) Each of the four Galois orbits has size 1.

11.5. Chapter 5

(1) Exercise 5.1. The eigenspace E_λ of A with eigenvalue λ is preserved by B, since if $v \in E_\lambda$, then

$$ABv = BAv = B(\lambda v) = \lambda Bv.$$

Because B is diagonalizable, its minimal polynomial equals its characteristic polynomial; hence the same is true for the restriction of B to E_λ, i.e., the restriction of B is diagonalizable. Choose basis for all E_λ so that the restrictions of B to these eigenspaces is diagonal with respect to these bases. Then the concatenation of these bases is a basis that simultaneously diagonalizes A and B.

(2) Exercise 5.2. When ε is the trivial character, the $B_{k,\varepsilon}$ are defined by

$$\sum_{a=1}^{1} \frac{\varepsilon(a)xe^{ax}}{e^x - 1} = \frac{xe^x}{e^x - 1} = x + \frac{x}{e^x - 1} = \sum_{k=0}^{\infty} B_{k,\varepsilon}\frac{x^k}{k!}.$$

Thus $B_{1,\varepsilon} = 1 + B_1 = \frac{1}{2}$, and for $k > 1$, we have $B_{k,\varepsilon} = B_k$.

(3) Exercise 5.3. Omitted.

(4) Exercise 5.4. The Eisenstein series in our basis for $E_3(\Gamma_1(13))$ are of the form $E_{3,1,\varepsilon}$ or $E_{3,\varepsilon,1}$ with $\varepsilon(-1) = (-1)^3 = -1$. There are six characters ε with modulus 13 such that $\varepsilon(-1) = -1$, and we have the two series $E_{3,1,\varepsilon}$ and $E_{3,\varepsilon,1}$ associated to each of these. This gives a dimension of 12.

11.6. Chapter 6

(1) Exercise 6.1.

(a) By Proposition 3.10, we have $[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)] = \#\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. By the Chinese Remainder Theorem,
$$\#\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z}) = \prod_{p|N} \#\mathbb{P}^1(\mathbb{Z}/p^{\mathrm{ord}_p(N)}\mathbb{Z}).$$
So we are reduced to computing $\#\mathbb{P}^1(\mathbb{Z}/p^{\mathrm{ord}_p(N)}\mathbb{Z})$. We have $(a,b) \in (\mathbb{Z}/p^n\mathbb{Z})^2$ with $\gcd(a,b,p) = 1$ if and only if $(a,b) \notin (p\mathbb{Z}/p^n\mathbb{Z})^2$, so there are $p^{2n} - p^{2(n-1)}$ such pairs. The unit group $(\mathbb{Z}/p^n\mathbb{Z})^*$ has order $\varphi(p^n) = p^n - p^{n-1}$. It follows that
$$\#\mathbb{P}^1(\mathbb{Z}/N\mathbb{Z}) = \frac{p^{2n} - p^{2(n-1)}}{p^n - p^{n-1}} = p^n + p^{n-1}.$$

(b) Omitted.

(2) Exercise 6.2. Omitted.

(3) Exercise 6.3. Omitted.

(4) Exercise 6.4. Omitted.

(5) Exercise 6.5. See the source code to SAGE.

11.7. Chapter 7

(1) Exercise 7.1. Take a basis of W and let G be the matrix whose rows are these basis elements. Let B be the row echelon form of G. After a permutation p of columns, we may write $B = p_i(I|C)$, where I is the identity matrix. The matrix $A = p^{-1}(-C^t|I)$, where I is a different sized identity matrix, has the property that $W = \mathrm{Ker}(A)$.

(2) Exercise 7.2. The answer is no. For example if $A = nI$ is n times the identity matrix and if $p \mid n$, then $\mathrm{rref}(A \pmod{p}) = 0$ but $\mathrm{rref}(A) \pmod{p} = I$.

(3) Exercise 7.3. Let $T = \prod E_i$ be an invertible matrix such that $TA = E$ is in (reduced) echelon form and the E_i are elementary matrices, i.e., the result of applying an elementary row operation to the identity matrix. If p is a prime that does not divide any of the nonzero numerators or denominators of the entries of A and any E_i, then $\mathrm{rref}(A \pmod{p}) = \mathrm{rref}(A) \pmod{p}$. This is because $E \pmod{p}$ is in echelon form and $A \pmod{p}$ can be transformed to $E \pmod{p}$ via a series of elementary row operations modulo p.

(4) Exercise 7.4.

(a) The echelon form (over $\mathbb{Q}$) is
$$\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

  - (b) The kernel is the 1-dimensional span of $(1, -2, 1)$.
  - (c) The characteristic polynomial is $x \cdot (x^2 - 15x - 18)$.

(5) Exercise 7.5.
  - (a) The answer is given in the problem.
  - (b) See [**Coh93**, §2.4].

11.8. Chapter 8

(1) Exercise 8.1. Using the Chinese Remainder Theorem we immediately reduce to proving the statement when both $M = p^r$ and $N = p^s$ are powers of a prime p. Then $[a] \in (\mathbb{Z}/p^s\mathbb{Z})^*$ is represented by an integer a with $\gcd(a, p) = 1$. That same integer a defines an element of $(\mathbb{Z}/p^r\mathbb{Z})^*$ that reduces modulo p^s to $[a]$.

(2) Exercise 8.2. See [**Shi94**, Lemma 1.38].

(3) Exercise 8.3. Coset representatives for $\Gamma_1(3)$ are in bijection with (c, d) where $c, d \in \mathbb{Z}/3\mathbb{Z}$ and $\gcd(c, d, N) = 1$, so the following are representatives:

$$\left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right), \left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right), \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right), \left(\begin{smallmatrix} 2 & 0 \\ 1 & 2 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 1 \\ 2 & 0 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 0 \\ 2 & 1 \end{smallmatrix}\right), \left(\begin{smallmatrix} 2 & 0 \\ 2 & 2 \end{smallmatrix}\right),$$

which we call $r_1, \ldots, r_8$, respectively. Now our Manin symbols are of the form $[X, r_i]$ and $[Y, r_i]$ for $1 \leq i \leq 8$ modulo the relations

$$x + x\sigma = 0, \quad x + x\tau + x\tau^2 = 0, \quad \text{and } x - xJ = 0.$$

First, note that J acts trivially on Manin symbols of odd weight because it sends X to $-X$, Y to $-Y$ and r_i to $-r_i$, so

$$[z, g]J = [-z, -g] = [z, g].$$

Thus the last relation is trivially true.

Now $\sigma^{-1}X = -Y$ and $\sigma^{-1}Y = X$. Also $\tau^{-1}X = -Y, \tau^{-1}Y = X - Y, \tau^{-2}X = -X + Y$ and $\tau^{-2}Y = -X$.

The first relation on the first symbol says that

$$[X, r_1] = -[-Y, r_3] = [Y, r_3]$$

and the second relation tells us that

$$[X, r_1] + [-Y, r_5] + [-X + Y, r_6] = 0.$$

(4) Exercise 8.4. Let $f \in S_k(\Gamma)$ and $g \in \Gamma$. All that remains to be shown is that this pairing respects the relation $x = xg$ for all modular symbols x. By linearity it suffices to show the invariance

of $\langle f, X^{k-i-2}Y^i\{\alpha,\beta\}\rangle$. We have

$$\begin{aligned}
&\left\langle f, (X^{k-2-i}Y^i\{\alpha,\beta\})g^{-1}\right\rangle \\
&= \left\langle f, (aX+bY)^{k-i-2}(cX+dY)^i\{g^{-1}(\alpha), g^{-1}(\beta)\}\right\rangle \\
&= \int_{g^{-1}(\alpha)}^{g^{-1}(\beta)} f(z)(az+b)^{k-i-2}(cz+d)^i\,dz \\
&= \int_{g^{-1}(\alpha)}^{g^{-1}(\beta)} f(z)\frac{(az+b)^{k-i-2}}{(cz+d)^{k-i-2}}(cz+d)^{k-2}\,dz \\
&= \int_{g^{-1}(\alpha)}^{g^{-1}(\beta)} f(z)\,g(z)^{k-i-2}(cz+d)^{k-2}\,dz \\
&= \int_{\alpha}^{\beta} f(g^{-1}(z))\,g(g^{-1}(z))^{k-i-2}(cg^{-1}(z)+d)^{k-2}\,d(g^{-1}(z)) \\
&= \int_{\alpha}^{\beta} f(g^{-1}(z))\,z^{k-i-2}(cg^{-1}(z)+d)^{k-2}\,(cg^{-1}(z)+d)^2\,dz \\
&= \int_{\alpha}^{\beta} f(z)\,z^{k-i-2}\,dz \\
&= \left\langle f, X^{k-i-2}Y^i\{\alpha,\beta\}\right\rangle,
\end{aligned}$$

where the second to last simplification is due to invariance under $[g]_k$, i.e.,

$$f(g^{-1}(z)) = f^{[g]_k}(g^{-1}(z)) = (cg^{-1}(z)+d)^{-k}f(g(g^{-1}(z))).$$

(The proof for $f \in \overline{S}_k(\Gamma)$ works in exactly the same way.)

(5) Exercise 8.5.

(a) Let $\eta = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$. For any $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ we have

$$\gamma\eta = \begin{pmatrix} -a & b \\ -c & d \end{pmatrix},\ \eta\gamma = \begin{pmatrix} -a & -b \\ c & d \end{pmatrix},\ \text{and } \eta\gamma\eta = \begin{pmatrix} a & -b \\ -c & d \end{pmatrix}.$$

First, if $\gamma \in SL_2(\mathbb{Z})$, then $\eta\gamma\eta \in GL_2(\mathbb{Z})$ and

$$\det(\eta\gamma\eta) = \det\eta\det\gamma\det\eta = (-1)(1)(-1) = 1$$

so $\eta\gamma\eta \in SL_2(\mathbb{Z})$. As $\eta^2 = 1$, conjugation by η is self-inverse, so it must be a bijection.

Now if $\gamma \in \Gamma_0(N)$, then $c \equiv 0 \pmod N$, so $-c \equiv 0 \pmod N$, and so $\eta\gamma\eta \in \Gamma_0(N)$. Thus $\eta\Gamma_0(N)\eta = \Gamma_0(N)$.

If $\gamma \in \Gamma_1(N)$, then $-c \equiv 0 \pmod N$ as before and also $a \equiv d \equiv 1 \pmod N$, so $\eta\gamma\eta \in \Gamma_1(N)$. Thus $\eta\Gamma_1(N)\eta = \Gamma_1(N)$.

(b) Omitted.

11.9. Chapter 9

(1) Exercise 9.1. Consider the surjective homomorphism

$$r : \mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z}).$$

Notice that $\Gamma_1(N)$ is the exact inverse image of the subgroup H of matrices of the form $\left(\begin{smallmatrix}1 & * \\ 0 & 1\end{smallmatrix}\right)$ and $\Gamma_0(N)$ is the inverse image of the subgroup T of upper triangular matrices. It thus suffices to observe that H is normal in T, which is clear. Finally, the quotient T/H is isomorphic to the group of diagonal matrices in $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})^*$, which is isomorphic to $(\mathbb{Z}/N\mathbb{Z})^*$.

(2) Exercise 9.2. It is enough to show $\langle p\rangle \in \mathbb{Z}[\ldots, T_n, \ldots]$ for primes p, since each $\langle d\rangle$ can be written in terms of the $\langle p\rangle$. Since $p \nmid N$, we have that

$$T_{p^2} = T_p^2 - \langle p\rangle p^{k-1},$$

so

$$\langle p\rangle p^{k-1} = T_p^2 - T_{p^2}.$$

By Dirichlet's theorem on primes in arithmetic progression, there is a prime $q \neq p$ congruent to p mod N. Since p^{k-1} and q^{k-1} are relatively prime, there exist integers a and b such that $ap^{k-1} + bq^{k-1} = 1$. Then

$$\langle p\rangle = \langle p\rangle(ap^{k-1} + bq^{k-1}) = a({T_p}^2 - T_{p^2}) + b({T_q}^2 - T_{q^2}) \in \mathbb{Z}[\ldots, T_n, \ldots].$$

(3) Exercise 9.3. Take $N = 33$. The space $S_2(\Gamma_0(33))$ is a direct sum of the two old subspaces coming from $S_2(\Gamma_0(11))$ and the new subspace, which has dimension 1. If f is a basis for $S_2(\Gamma_0(11))$ and g is a basis for $S_2(\Gamma_0(33))_{\mathrm{new}}$, then $\alpha_1(f), \alpha_3(f), g$ is a basis for $S_2(\Gamma_0(33))$ on which all Hecke operators T_n, with $\gcd(n, 33) = 1$, have diagonal matrix. However, the operator T_3 on $S_2(\Gamma_0(33))$ does not act as a scalar on $\alpha_1(f)$, so it cannot be in the ring generated by all operators T_n with $\gcd(n, 33) = 1$.

(4) Exercise 9.4. Omitted.

11.10. Chapter 10

(1) Exercise 10.1. Hint: Use either repeated integration by parts or a change of variables that relates the integral to the Γ function.

(2) Exercise 10.2. See [**Cre97a**, §2.8].

(3) Exercise 10.3.

   (a) Let $f = \sqrt{-1}\sum q^n$. Then $d = 2$, but the nontrivial conjugate of f is $-f$, so V_f has dimension 1.

(b) Choose $\alpha \in K$ such that $K = \mathbb{Q}(\alpha)$. Write

$$f = \sum_{i=0}^{d-1} \alpha^i g_i \tag{11.10.1}$$

with $g_i \in \mathbb{Q}[[q]]$. Let W_g be the $\mathbb{Q}$-span of the g_i, and let $W_f = V_f \cap \mathbb{Q}[[q]]$. By considering the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ conjugates of (11.10.1), we see that the Galois conjugates of f are in the $\mathbb{C}$-span of the g_i, so

$$d = \dim_{\mathbb{C}} V_f \leq \dim_{\mathbb{Q}} W_g. \tag{11.10.2}$$

Likewise, taking the above modulo $O(q^n)$ for any n, we obtain a matrix equation

$$F = AG,$$

where the columns of F are the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f, the matrix A is the Vandermonde matrix corresponding to α (and its $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ conjugates), and G has columns g_i. Since A is a Vandermonde matrix, it is invertible, so $A^{-1}F = G$. Taking the limit as n goes to infinity, we see that each g_i is a linear combination of the f_i, hence an element of V_f. Thus $W_g \subset W_f$, so (11.10.2) implies that $\dim_{\mathbb{Q}} W_f \geq d$. But $W_f \otimes_{\mathbb{Q}} \mathbb{C} \subset V_f$ so finally

$$d \leq \dim_{\mathbb{Q}} W_f = \dim_{\mathbb{C}}(W_f \otimes_{\mathbb{Q}} \mathbb{C}) \leq \dim_{\mathbb{C}} V_f = d.$$

(4) Exercise 10.4. See the appendix to Chapter II in [**Cre97a**], where this example is worked out in complete detail.

Appendix A

Computing in Higher Rank

by Paul E. Gunnells

A.1. Introduction

This book has addressed the theoretical and practical problems of performing computations with modular forms. Modular forms are the simplest examples of the general theory of automorphic forms attached to a reductive algebraic group G with an arithmetic subgroup Γ; they are the case $G = \mathrm{SL}_2(\mathbb{R})$ with Γ a congruence subgroup of $\mathrm{SL}_2(\mathbb{Z})$. For such pairs (G, Γ) the Langlands philosophy asserts that there should be deep connections between automorphic forms and arithmetic, connections that are revealed through the action of the Hecke operators on spaces of automorphic forms. There have been many profound advances in recent years in our understanding of these phenomena, for example:

- the establishment of the modularity of elliptic curves defined over $\mathbb{Q}$ [**Wil95, TW95, Dia96, CDT99, BCDT01**],
- the proof by Harris–Taylor of the local Langlands correspondence [**HT01**], and
- Lafforgue's proof of the global Langlands correspondence for function fields [**Laf02**].

Nevertheless, we are still far from seeing that the links between automorphic forms and arithmetic hold in the broad scope in which they are generally believed. Hence one has the natural problem of studying spaces of automorphic forms computationally.

The goal of this appendix is to describe some computational techniques for automorphic forms. We focus on the case $G = \mathrm{SL}_n(\mathbb{R})$ and $\Gamma \subset \mathrm{SL}_n(\mathbb{Z})$, since the automorphic forms that arise are one natural generalization of modular forms, and since this is the setting for which we have the most tools available. In fact, we do not work directly with automorphic forms, but rather with the cohomology of the arithmetic group Γ with certain coefficient modules. This is the most natural generalization of the tools developed in previous chapters.

Here is a brief overview of the contents. Section A.2 gives background on automorphic forms and the cohomology of arithmetic groups and explains why the two are related. In Section A.3 we describe the basic topological tools used to compute the cohomology of Γ explicitly. Section A.4 defines the Hecke operators, describes the generalization of the modular symbols from Chapter 8 to higher rank, and explains how to compute the action of the Hecke operators on the top degree cohomology group. Section A.5 discusses computation of the Hecke action on cohomology groups below the top degree. Finally, Section A.6 briefly discusses some related material and presents some open problems.

A.1.1. The theory of automorphic forms is notorious for the difficulty of its prerequisites. Even if one is only interested in the cohomology of arithmetic groups—a small part of the full theory—one needs considerable background in algebraic groups, algebraic topology, and representation theory. This is somewhat reflected in our presentation, which falls far short of being self-contained. Indeed, a complete account would require a long book of its own. We have chosen to sketch the foundational material and to provide many pointers to the literature; good general references are [**BW00, Harb, LS90, Vog97**]. We hope that the energetic reader will follow the references and fill many gaps on his/her own.

The choice of topics presented here is heavily influenced (as usual) by the author's interests and expertise. There are many computational topics in the cohomology of arithmetic groups we have completely omitted, including the trace formula in its many incarnations [**GP05**], the explicit Jacquet–Langlands correspondence [**Dem04, SW05**], and moduli space techniques [**FvdG, vdG**]. We encourage the reader to investigate these extremely interesting and useful techniques.

A.1.2. Acknowledgements. I thank Avner Ash, John Cremona, Mark McConnell, and Dan Yasaki for helpful comments. I also thank the NSF for support.

A.2. Automorphic Forms and Arithmetic Groups

A.2.1. Let $\Gamma = \Gamma_0(N) \subset \mathrm{SL}_2(\mathbb{Z})$ be the usual Hecke congruence subgroup of matrices upper-triangular mod N. Let $Y_0(N)$ be the modular curve $\Gamma \backslash \mathfrak{h}$, and let $X_0(N)$ be its canonical compactification obtained by adjoining cusps. For any integer $k \geq 2$, let $S_k(N)$ be the space of weight k holomorphic cuspidal modular forms on Γ. According to Eichler–Shimura [**Shi94**, Chapter 8], we have the isomorphism

$$H^1(X_0(N); \mathbb{C}) \xrightarrow{\sim} S_2(N) \oplus \overline{S_2(N)}, \tag{A.2.1}$$

where the bar denotes complex conjugation and where the isomorphism is one of Hecke modules.

More generally, for any integer $n \geq 0$, let $M_n \subset \mathbb{C}[x, y]$ be the subspace of degree n homogeneous polynomials. The space M_n admits a representation of Γ by the "change of variables" map

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot p(x, y) = p(dx - by, -cx + ay). \tag{A.2.2}$$

This induces a local system $\widetilde{M}_n$ on the curve $X_0(N)$.[1] Then the analogue of (A.2.1) for higher-weight modular forms is the isomorphism

$$H^1(X_0(N); \widetilde{M}_{k-2}) \xrightarrow{\sim} S_k(N) \oplus \overline{S_k(N)}. \tag{A.2.3}$$

Note that (A.2.3) reduces to (A.2.1) when $k = 2$.

Similar considerations apply if we work with the open curve $Y_0(N)$ instead, except that Eisenstein series also contribute to the cohomology. More precisely, let $E_k(N)$ be the space of weight k Eisenstein series on $\Gamma_0(N)$. Then (A.2.3) becomes

$$H^1(Y_0(N); \widetilde{M}_{k-2}) \xrightarrow{\sim} S_k(N) \oplus \overline{S_k(N)} \oplus E_k(N). \tag{A.2.4}$$

These isomorphisms lie at the heart of the modular symbols method.

A.2.2. The first step on the path to general automorphic forms is a reinterpretation of modular forms in terms of functions on $\mathrm{SL}_2(\mathbb{R})$. Let $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$ be a congruence subgroup. A weight k modular form on Γ is a holomorphic function $f \colon \mathfrak{h} \to \mathbb{C}$ satisfying the transformation property

$$f((az + b)/(cz + d)) = j(\gamma, z)^k f(z), \quad \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma, \quad z \in \mathfrak{h}.$$

[1] The classic references for cohomology with local systems are [**Ste99a**, Section 31] and [**Eil47**, Ch. V]. A more recent exposition (in the language of Čech cohomology and locally constant sheaves) can be found in [**BT82**, II.13]. For an exposition tailored to our needs, see [**Harb**, Section 2.9].

Here $j(\gamma, z)$ is the *automorphy factor* $cz + d$. There are some additional conditions f must satisfy at the cusps of $\mathfrak{h}$, but these are not so important for our discussion.

The group $G = \mathrm{SL}_2(\mathbb{R})$ acts transitively on $\mathfrak{h}$, with the subgroup $K = \mathrm{SO}(2)$ fixing i. Thus $\mathfrak{h}$ can be written as the quotient G/K. From this, we see that f can be viewed as a function $G \to \mathbb{C}$ that is K-*invariant on the right* and that satisfies a certain symmetry condition with respect to the Γ-*action on the left*. Of course not every f with these properties is a modular form: some extra data is needed to take the role of holomorphicity and to handle the behavior at the cusps. Again, this can be ignored right now.

We can turn this interpretation around as follows. Suppose φ is a function $G \to \mathbb{C}$ that is Γ-*invariant on the left*, that is, $\varphi(\gamma g) = \varphi(g)$ for all $\gamma \in \Gamma$. Hence φ can be thought of as a function $\varphi\colon \Gamma\backslash G \to \mathbb{C}$. We further suppose that φ satisfies a certain symmetry condition with respect to the K-*action on the right.* In particular, any matrix $m \in K$ can be written

$$m = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}, \quad \theta \in \mathbb{R}, \tag{A.2.5}$$

with θ uniquely determined modulo 2π. Let ζ_m be the complex number $e^{i\theta}$. Then the K-symmetry we require is

$$\varphi(gm) = \zeta_m^{-k}\varphi(z), \quad m \in K,$$

where k is some fixed nonnegative integer.

It turns out that such functions φ are very closely related to modular forms: *any* $f \in S_k(\Gamma)$ uniquely determines such a function $\varphi_f\colon \Gamma\backslash G \to \mathbb{C}$. The correspondence is very simple. Given a weight k modular form f, define

$$\varphi_f(g) := f(g \cdot i) j(g, i)^{-k}. \tag{A.2.6}$$

We claim φ_f is left Γ-invariant and satisfies the desired K-symmetry on the right. Indeed, since j satisfies the cocycle property

$$j(gh, z) = j(g, h \cdot z) j(h, z),$$

we have

$$\varphi_f(\gamma g) = f((\gamma g)\cdot i) j(\gamma g, i)^{-k} = j(\gamma, g\cdot i)^k f(g\cdot i) j(\gamma, g\cdot i)^{-k} j(g, i)^{-k} = \varphi_f(g).$$

Moreover, any $m \in K$ stabilizes i. Hence

$$\varphi_f(gm) = f((gm) \cdot i) j(gm, i)^{-k} = f(g \cdot i) j(m, i)^{-k} j(g, m \cdot i)^{-k}.$$

From (A.2.5) we have $j(m, i)^{-k} = (\cos\theta + i\sin\theta)^{-k} = \zeta_m^{-k}$, and thus $\varphi_f(gm) = \zeta_m^{-k}\varphi_f(g)$.

Hence in (A.2.6) the weight and the automorphy factor "untwist" the Γ-action to make φ_f left Γ-invariant. The upshot is that we can study modular forms by studying the spaces of functions that arise through the construction (A.2.6).

Of course, not every $\varphi\colon \Gamma\backslash G \to \mathbb{C}$ will arise as φ_f for some $f \in S_K(\Gamma)$: after all, f is holomorphic and satisfies rather stringent growth conditions. Pinning down all the requirements is somewhat technical and is (mostly) done in the sequel.

A.2.3. Before we define automorphic forms, we need to find the correct generalizations of our groups $\mathrm{SL}_2(\mathbb{R})$ and $\Gamma_0(N)$. The correct setup is rather technical, but this really reflects the power of the general theory, which handles so many different situations (e.g., Maass forms, Hilbert modular forms, Siegel modular forms, etc.).

Let G be a connected Lie group, and let $K \subset G$ be a maximal compact subgroup. We assume that G is the set of real points of a connected semisimple algebraic group $\mathbf{G}$ defined over $\mathbb{Q}$. These conditions mean the following [**PR94**, §2.1.1]:

(1) The group $\mathbf{G}$ has the structure of an affine algebraic variety given by an ideal I in the ring $R = \mathbb{C}[x_{ij}, D^{-1}]$, where the variables $\{x_{ij} \mid 1 \leq i, j \leq n\}$ should be interpreted as the entries of an "indeterminate matrix," and D is the polynomial $\det(x_{ij})$. Both the group multiplication $\mathbf{G} \times \mathbf{G} \to \mathbf{G}$ and inversion $\mathbf{G} \to \mathbf{G}$ are required to be morphisms of algebraic varieties.

The ring R is the coordinate ring of the algebraic group GL_n. Hence this condition means that $\mathbf{G}$ can be essentially viewed as a subgroup of $\mathrm{GL}_n(\mathbb{C})$ defined by polynomial equations in the matrix entries of the latter.

(2) *Defined over* $\mathbb{Q}$ means that I is generated by polynomials with rational coefficients.

(3) *Connected* means that $\mathbf{G}$ is connected as an algebraic variety.

(4) *Set of real points* means that G is the set of real solutions to the equations determined by I. We write $G = \mathbf{G}(\mathbb{R})$.

(5) *Semisimple* means that the maximal connected solvable normal subgroup of $\mathbf{G}$ is trivial.

Example A.1. The most important example for our purposes is the *split form of* SL_n. For this choice we have

$$G = \mathrm{SL}_n(\mathbb{R}) \text{ and } K = \mathrm{SO}(n).$$

Example A.2. Let $F/\mathbb{Q}$ be a number field. Then there is a $\mathbb{Q}$-group $\mathbf{G}$ such that $\mathbf{G}(\mathbb{Q}) = \mathrm{SL}_n(F)$. The group $\mathbf{G}$ is constructed as $\mathbf{R}_{F/\mathbb{Q}}(\mathrm{SL}_n)$, where $\mathbf{R}_{F/\mathbb{Q}}$ denotes the *restriction of scalars* from F to $\mathbb{Q}$ [**PR94**, §2.1.2]. For example, if F is totally real, the group $\mathbf{R}_{F/\mathbb{Q}}(\mathrm{SL}_2)$ appears when one studies Hilbert modular forms.

Let (r, s) be the signature of the field F, so that $F \otimes \mathbb{R} \simeq \mathbb{R}^r \times \mathbb{C}^s$. Then $G = \mathrm{SL}_n(\mathbb{R})^r \times \mathrm{SL}_n(\mathbb{C})^s$ and $K = \mathrm{SO}(n)^r \times \mathrm{SU}(n)^s$.

Example A.3. Another important example is the *split symplectic group* Sp_{2n}. This is the group that arises when one studies Siegel modular forms. The group of real points $\mathrm{Sp}_{2n}(\mathbb{R})$ is the subgroup of $\mathrm{SL}_{2n}(\mathbb{R})$ preserving a fixed nondegenerate alternating bilinear form on $\mathbb{R}^{2n}$. We have $K = \mathrm{U}(n)$.

A.2.4. To generalize $\Gamma_0(N)$, we need the notion of an *arithmetic group*. This is a discrete subgroup Γ of the group of rational points $\mathbf{G}(\mathbb{Q})$ that is commensurable with the set of integral points $\mathbf{G}(\mathbb{Z})$. Here commensurable simply means that $\Gamma \cap \mathbf{G}(\mathbb{Z})$ is a finite index subgroup of both Γ and $\mathbf{G}(\mathbb{Z})$; in particular $\mathbf{G}(\mathbb{Z})$ itself is an arithmetic group.

Example A.4. For the split form of SL_n we have $\mathbf{G}(\mathbb{Z}) = \mathrm{SL}_n(\mathbb{Z}) \subset \mathbf{G}(\mathbb{Q}) = \mathrm{SL}_n(\mathbb{Q})$. A trivial way to obtain other arithmetic groups is by conjugation: if $g \in \mathrm{SL}_n(\mathbb{Q})$, then $g \cdot \mathrm{SL}_n(\mathbb{Z}) \cdot g^{-1}$ is also arithmetic.

A more interesting collection of examples is given by the congruence subgroups. The *principal congruence subgroup* $\Gamma(N)$ is the group of matrices congruent to the identity modulo N for some fixed integer $N \geq 1$. A *congruence subgroup* is a group containing $\Gamma(N)$ for some N.

In higher dimensions there are many candidates to generalize the Hecke subgroup $\Gamma_0(N)$. For example, one can take the subgroup of $\mathrm{SL}_n(\mathbb{Z})$ that is upper-triangular mod N. From a computational perspective, this choice is not so good since its index in $\mathrm{SL}_n(\mathbb{Z})$ is large. A better choice, and the one that usually appears in the literature, is to define $\Gamma_0(N)$ to be the subgroup of $\mathrm{SL}_n(\mathbb{Z})$ with bottom row congruent to $(0, \ldots, 0, *) \mod N$.

A.2.5. We are almost ready to define automorphic forms. Let $\mathfrak{g}$ be the Lie algebra of G, and let $U(\mathfrak{g})$ be its universal enveloping algebra over $\mathbb{C}$. Geometrically, $\mathfrak{g}$ is just the tangent space at the identity of the smooth manifold G. The algebra $U(\mathfrak{g})$ is a certain complex associative algebra canonically built from $\mathfrak{g}$. The usual definition would lead us a bit far afield, so we will settle for an equivalent characterization: $U(\mathfrak{g})$ can be realized as a certain subalgebra of the ring of differential operators on $C^\infty(G)$, the space of smooth functions on G.

In particular, G acts on $C^\infty(G)$ by *left translations*: given $g \in G$ and $f \in C^\infty(G)$, we define

$$L_g(f)(x) := f(g^{-1}x).$$

Then $U(\mathfrak{g})$ can be identified with the ring of all differential operators on $C^\infty(G)$ that are invariant under left translation. For our purposes the most important part of $U(\mathfrak{g})$ is its center $Z(\mathfrak{g})$. In terms of differential operators, $Z(\mathfrak{g})$ consists of those operators that are also invariant under *right translation*:

$$R_g(f)(x) := f(xg).$$

Definition A.5. An *automorphic form* on G with respect to Γ is a function $\varphi\colon G \to \mathbb{C}$ satisfying

(1) $\varphi(\gamma g) = \varphi(g)$ for all $\gamma \in \Gamma$,

(2) the right translates $\{\varphi(gk) \mid k \in K\}$ span a finite-dimensional space ξ of functions,

(3) there exists an ideal $J \subset Z(\mathfrak{g})$ of finite codimension such that J annihilates φ, and

(4) φ satisfies a certain growth condition that we do not wish to make precise. (In the literature, φ is said to be *slowly increasing*.)

For fixed ξ and J, we denote by $\mathscr{A}(\Gamma, \xi, J, K)$ the space of all functions satisfying the above four conditions. It is a basic theorem, due to Harish-Chandra [**HC68**], that $\mathscr{A}(\Gamma, \xi, J, K)$ is finite-dimensional.

Example A.6. We can identify the cuspidal modular forms $S_k(N)$ in the language of Definition A.5. Given a modular form f, let $\varphi_f \in C^\infty(\mathrm{SL}_2(\mathbb{R}))$ be the function from (A.2.6). Then the map $f \mapsto \varphi_f$ identifies $S_k(N)$ with the subspace $\mathscr{A}_k(N)$ of functions φ satisfying

(1) $\varphi(\gamma g) = \varphi(g)$ for all $\gamma \in \Gamma_0(N)$,

(2) $\varphi(gm) = \zeta_m^{-k}\varphi(g)$ for all $m \in \mathrm{SO}(2)$,

(3) $(\Delta + \lambda_k)\varphi = 0$, where $\Delta \in Z(\mathfrak{g})$ is the *Laplace–Beltrami–Casimir operator* and

$$\lambda_k = \frac{k}{2}\left(\frac{k}{2} - 1\right),$$

(4) φ is slowly increasing, and

(5) φ is *cuspidal*.

The first four conditions parallel Definition A.5. Item (1) is the Γ-invariance. Item (2) implies that the right translates of φ by SO(2) lie in a fixed finite-dimensional representation of SO(2). Item (3) is how holomorphicity appears, namely that φ is killed by a certain differential operator. Finally, item (4) is the usual growth condition.

The only condition missing from the general definition is (5), which is an extra constraint placed on φ to ensure that it comes from a cusp form. This condition can be expressed by the vanishing of certain integrals ("constant terms"); for details we refer to [**Bum97, Gel75**].

Example A.7. Another important example appears when we set $k = 0$ in (2) in Example A.6 and relax (3) by requiring only that $(\Delta - \lambda)\varphi = 0$ for *some* nonzero $\lambda \in \mathbb{R}$. Such automorphic forms cannot possibly arise from modular forms, since there are no nontrivial cusp forms of weight 0. However, there are plenty of solutions to these conditions: they correspond to *real-analytic* cuspidal modular forms of weight 0 and are known as *Maass forms*. Traditionally one writes $\lambda = (1 - s^2)/4$. The positivity of Δ implies that $s \in (-1, 1)$ or is purely imaginary.

Maass forms are highly elusive objects. Selberg proved that there are infinitely many linearly independent Maass forms of full level (i.e., on $\mathrm{SL}_2(\mathbb{Z})$), but to this date no explicit construction of a single one is known. (Selberg's argument is indirect and relies on the trace formula; for an exposition see [**Sar03**].) For higher levels some explicit examples can be constructed using theta series attached to indefinite quadratic forms [**Vig77**]. Numerically Maass forms have been well studied; see for example [**FL**].

In general the arithmetic nature of the eigenvalues λ that correspond to Maass forms is unknown, although a famous conjecture of Selberg states that for congruence subgroups they satisfy the inequality $\lambda \geq 1/4$ (in other words, only purely imaginary s appear above). The truth of this conjecture would have far-reaching consequences, from analytic number theory to graph theory [**Lub94**].

A.2.6. As Example A.6 indicates, there is a notion of *cuspidal automorphic form*. The exact definition is too technical to state here, but it involves an appropriate generalization of the notion of constant term familiar from modular forms.

There are also *Eisenstein series* [**Lan66, Art79**]. Again the complete definition is technical; we only mention that there are different types of Eisenstein series corresponding to certain subgroups of G. The Eisenstein series that are easiest to understand are those built from cusp forms on lower rank groups. Very explicit formulas for Eisenstein series on GL_3 can be seen in [**Bum84**]. For a down-to-earth exposition of some of the Eisenstein series on GL_n, we refer to [**Gol05**].

The decomposition of $M_k(\Gamma_0(N))$ into cusp forms and Eisenstein series also generalizes to a general group G, although the statement is much more complicated. The result is a theorem of Langlands [**Lan76**] known as the *spectral decomposition of* $L^2(\Gamma\backslash G)$. A thorough recent presentation of this can be found in [**MW94**].

A.2.7. Let $\mathscr{A} = \mathscr{A}(\Gamma, K)$ be the space of all automorphic forms, where ξ and J range over all possibilities. The space $\mathscr{A}$ is huge, and the arithmetic significance of much of it is unknown. This is already apparent for $G =$

$\mathrm{SL}_2(\mathbb{R})$. The automorphic forms directly connected with arithmetic are the holomorphic modular forms, not the Maass forms[2]. Thus the question arises: which automorphic forms in $\mathscr{A}$ are the most natural generalization of the modular forms?

One answer is provided by the isomorphisms (A.2.1), (A.2.3), (A.2.4). These show that modular forms appear naturally in the cohomology of modular curves. Hence a reasonable approach is to generalize the *left* of (A.2.1), (A.2.3), (A.2.4), and to study the resulting cohomology groups. This is the approach we will take. One drawback is that it is not obvious that our generalization has anything to do with automorphic forms, but we will see eventually that it certainly does. So we begin by looking for an appropriate generalization of the modular curve $Y_0(N)$.

Let G and K be as in Section A.2.3, and let X be the quotient G/K. This is a global Riemannian symmetric space [**Hel01**]. One can prove that X is contractible. Any arithmetic group $\Gamma \subset G$ acts on X properly discontinuously. In particular, if Γ is torsion-free, then the quotient $\Gamma\backslash X$ is a smooth manifold.

Unlike the modular curves, $\Gamma\backslash X$ will not have a complex structure in general[3]; nevertheless, $\Gamma\backslash X$ is a very nice space. In particular, if Γ is torsion-free, it is an *Eilenberg–Mac Lane* space for Γ, otherwise known as a $K(\Gamma, 1)$. This means that the only nontrivial homotopy group of $\Gamma\backslash X$ is its fundamental group, which is isomorphic to Γ, and that the universal cover of $\Gamma\backslash X$ is contractible. Hence $\Gamma\backslash X$ is in some sense a "topological incarnation"[4] of Γ.

This leads us to the notion of the *group cohomology* $H^*(\Gamma;\mathbb{C})$ of Γ with trivial complex coefficients. In the early days of algebraic topology, this was defined to be the complex cohomology of an Eilenberg–Mac Lane space for Γ [**Bro94**, Introduction, I.4]:

$$H^*(\Gamma;\mathbb{C}) = H^*(\Gamma\backslash X;\mathbb{C}). \tag{A.2.7}$$

Today there are purely algebraic approaches to $H^*(\Gamma;\mathbb{C})$ [**Bro94**, III.1], but for our purposes (A.2.7) is exactly what we need. In fact, the group cohomology $H^*(\Gamma;\mathbb{C})$ can be identified with the cohomology of the quotient $\Gamma\backslash X$ even if Γ has torsion, since we are working with complex coefficients. The cohomology groups $H^*(\Gamma;\mathbb{C})$, where Γ is an arithmetic group, are our proposed generalization for the weight 2 modular forms.

What about higher weights? For this we must replace the trivial coefficient module $\mathbb{C}$ with local systems, just as we did in (A.2.3). For our

[2] However, Maass forms play a very important *indirect* role in arithmetic.

[3] The symmetric spaces that have a complex structure are known as *bounded domains*, or *Hermitian symmetric spaces* [**Hel01**].

[4] This apt phrase is due to Vogan [**Vog97**].

purposes it is enough to let $\mathscr{M}$ be a rational finite-dimensional representation of G over the complex numbers. Any such $\mathscr{M}$ gives a representation of $\Gamma \subset G$ and thus induces a local system $\widetilde{\mathscr{M}}$ on $\Gamma\backslash X$. As before, the group cohomology $H^*(\Gamma;\mathscr{M})$ is the cohomology $H^*(\Gamma\backslash X;\widetilde{\mathscr{M}})$. In (A.2.3) we took $\mathscr{M} = M_n$, the nth symmetric power of the standard representation. For a general group G there are many kinds of representations to consider. In any case, we contend that the cohomology spaces

$$H^*(\Gamma;\mathscr{M}) = H^*(\Gamma\backslash X;\widetilde{\mathscr{M}})$$

are a good generalization of the spaces of modular forms.

A.2.8. It is certainly not obvious that the cohomology groups $H^*(\Gamma;\mathscr{M})$ have *anything* to do with automorphic forms, although the isomorphisms (A.2.1), (A.2.3), (A.2.4) look promising.

The connection is provided by a deep theorem of Franke [**Fra98**], which asserts that

(1) the cohomology groups $H^*(\Gamma;\mathscr{M})$ can be directly computed in terms of certain automorphic forms (the automorphic forms of "cohomological type," also known as those with "nonvanishing $(\mathfrak{g}, K)$ cohomology" [**VZ84**]); and

(2) there is a direct sum decomposition

$$H^*(\Gamma;\mathscr{M}) = H^*_{\mathrm{cusp}}(\Gamma;\mathscr{M}) \oplus \bigoplus_{\{P\}} H^*_{\{P\}}(\Gamma;\mathscr{M}), \tag{A.2.8}$$

where the sum is taken over the set of classes of *associate proper* $\mathbb{Q}$*-parabolic subgroups of* G.

The precise version of statement (1) is known in the literature as the *Borel conjecture*. Statement (2) parallels Langlands's spectral decomposition of $L^2(\Gamma\backslash G)$.

Example A.8. For $\Gamma = \Gamma_0(N) \subset \mathrm{SL}_2(\mathbb{Z})$, the decomposition (A.2.8) is exactly (A.2.4). The cusp forms $S_k(N) \oplus \overline{S_k(N)}$ correspond to the summand $H^1_{\mathrm{cusp}}(\Gamma;\mathscr{M})$. There is one class of proper $\mathbb{Q}$-parabolic subgroups in $\mathrm{SL}_2(\mathbb{R})$, represented by the Borel subgroup of upper-triangular matrices. Hence only one term appears in big direct sum on the right of (A.2.8), which is the Eisenstein term E_k.

The summand $H^*_{\mathrm{cusp}}(\Gamma;\mathscr{M})$ of (A.2.8) is called the *cuspidal cohomology*; this is the subspace of classes represented by cuspidal automorphic forms. The remaining summands constitute the *Eisenstein cohomology* of Γ [**Har91**]. In particular the summand indexed by $\{P\}$ is constructed using Eisenstein series attached to certain cuspidal automorphic forms on lower rank groups. Hence $H^*_{\mathrm{cusp}}(\Gamma;\mathscr{M})$ is in some sense the most important part of the cohomology: all the rest can be built systematically from cuspidal cohomology on lower rank groups[5]. This leads us to our basic computational problem:

Problem A.9. Develop tools to compute explicitly the cohomology spaces $H^*(\Gamma;\mathscr{M})$ and to identify the cuspidal subspace $H^*_{\mathrm{cusp}}(\Gamma;\mathscr{M})$.

A.3. Combinatorial Models for Group Cohomology

A.3.1. In this section, we restrict attention to $G = \mathrm{SL}_n(\mathbb{R})$ and Γ, a congruence subgroup of $\mathrm{SL}_n(\mathbb{Z})$. By the previous section, we can study the group cohomology $H^*(\Gamma;\mathscr{M})$ by studying the cohomology $H^*(\Gamma\backslash X;\widetilde{\mathscr{M}})$. The latter spaces can be studied using standard topological techniques, such as taking the cohomology of complexes associated to cellular decompositions of $\Gamma\backslash X$. For $\mathrm{SL}_n(\mathbb{R})$, one can construct such decompositions using a version of explicit reduction theory of real positive-definite quadratic forms due to Voronoĭ [**Vor08**]. The goal of this section is to explain how this is done. We also discuss how the cohomology can be explicitly studied for congruence subgroups of $\mathrm{SL}_3(\mathbb{Z})$.

A.3.2. Let V be the $\mathbb{R}$-vector space of all symmetric $n \times n$ matrices, and let $C \subset V$ be the subset of positive-definite matrices. The space C can be identified with the space of all real positive-definite quadratic forms in n variables: in coordinates, if $x = (x_1, \ldots, x_n)^t \in \mathbb{R}^n$ (column vector), then the matrix $A \in C$ induces the quadratic form

$$x \longmapsto x^t A x,$$

and it is well known that any positive-definite quadratic form arises in this way. The space C is a cone, in that it is preserved by homotheties: if $x \in C$, then $\lambda x \in C$ for all $\lambda \in \mathbb{R}_{>0}$. It is also convex: if $x_1, x_2 \in C$, then $tx_1 + (1-t)x_2 \in C$ for $t \in [0,1]$. Let D be the quotient of C by homotheties.

Example A.10. The case $n = 2$ is illustrative. We can take coordinates on $V \simeq \mathbb{R}^3$ by representing any matrix in V as

$$\begin{pmatrix} x & y \\ y & z \end{pmatrix}, \quad x, y, z \in \mathbb{R}.$$

The subset of singular matrices $Q = \{xz - y^2 = 0\}$ is a quadric cone in V dividing the complement $V \smallsetminus Q$ into three connected components. The component containing the identity matrix is the cone C of positive-definite matrices. The quotient D can be identified with an open 2-disk.

[5] This is a bit of an oversimplification, since it is a highly nontrivial problem to decide when cusp cohomology from lower rank groups appears in Γ. However, many results are known; as a selection we mention [**Har91, Har87, LS04**]

The group G acts on C on the left by

$$(g, c) \longmapsto gcg^t.$$

This action commutes with that of the homotheties and thus descends to a G-action on D. One can show that G acts transitively on D and that the stabilizer of the image of the identity matrix is $K = \mathrm{SO}(n)$. Hence we may identify D with our symmetric space $X = \mathrm{SL}_n(\mathbb{R})/\mathrm{SO}(n)$. We will do this in the sequel, using the notation D when we want to emphasize the coordinates coming from the linear structure of $C \subset V$ and using the notation X for the quotient G/K.

We can make the identification $D \simeq X$ more explicit. If $g \in \mathrm{SL}_n(\mathbb{R})$, then the map

$$g \longmapsto gg^t \tag{A.3.1}$$

takes g to a symmetric positive-definite matrix. Any coset gK is taken to the same matrix since $KK^t = \mathrm{Id}$. Thus (A.3.1) identifies G/K with a subset C_1 of C, namely those positive-definite symmetric matrices with determinant 1. It is easy to see that C_1 maps diffeomorphically onto D.

The inverse map $C_1 \to G/K$ is more complicated. Given a determinant 1 positive-definite symmetric matrix A, one must find $g \in \mathrm{SL}_n(\mathbb{R})$ such that $gg^t = A$. Such a representation always exists, with g determined uniquely up to right multiplication by an element of K. In computational linear algebra, such a g can be constructed through *Cholesky decomposition* of A.

The group $\mathrm{SL}_n(\mathbb{Z})$ acts on C via the G-action and does so properly discontinuously. This is the "unimodular change of variables" action on quadratic forms [**Ser73**, V.1.1]. Under our identification of D with X, this is the usual action of $\mathrm{SL}_n(\mathbb{Z})$ by left translation from Section A.2.7.

A.3.3. Now consider the group cohomology $H^*(\Gamma; \mathscr{M}) = H^*(\Gamma\backslash X; \widetilde{\mathscr{M}})$. The identification $D \simeq X$ shows that the dimension of X is $n(n+1)/2 - 1$. Hence $H^i(\Gamma; \mathscr{M})$ vanishes if $i > n(n+1)/2 - 1$. Since $\dim X$ grows quadratically in n, there are many potentially interesting cohomology groups to study.

However, it turns out that there is some additional vanishing of the cohomology for deeper (topological) reasons. For $n = 2$, this is easy to see. The quotient $\Gamma\backslash\mathfrak{h}$ is homeomorphic to a topological surface with punctures, corresponding to the cusps of Γ. Any such surface S can be retracted onto a finite graph simply by "stretching" S along its punctures. Thus $H^2(\Gamma; \mathscr{M}) = 0$, even though $\dim \Gamma\backslash\mathfrak{h} = 2$.

For $\Gamma \subset \mathrm{SL}_n(\mathbb{Z})$, a theorem of Borel–Serre implies that $H^i(\Gamma; \mathscr{M})$ vanishes if $i > \dim X - n + 1 = n(n-1)/2$ [**BS73**, Theorem 11.4.4]. The number $\nu = n(n-1)/2$ is called the *virtual cohomological dimension* of Γ

and is denoted $\operatorname{vcd}\Gamma$. Thus we only need to consider cohomology in degrees $i \leq \nu$.

Moreover we know from Section A.2.8 that the most interesting part of the cohomology is the cuspidal cohomology. In what degrees can it live? For $n = 2$, there is only one interesting cohomology group $H^1(\Gamma; \mathscr{M})$, and it contains the cuspidal cohomology. For higher dimensions, the situation is quite different: for most i, the subspace $H^i_{\mathrm{cusp}}(\Gamma; \mathscr{M})$ vanishes! In fact in the late 1970's Borel, Wallach, and Zuckerman observed that the cuspidal cohomology can only live in the cohomological degrees lying in an interval around $(\dim X)/2$ of size linear in n. An explicit description of this interval is given in [**Sch86**, Proposition 3.5]; one can also look at Table A.3.1, from which the precise statement is easy to determine.

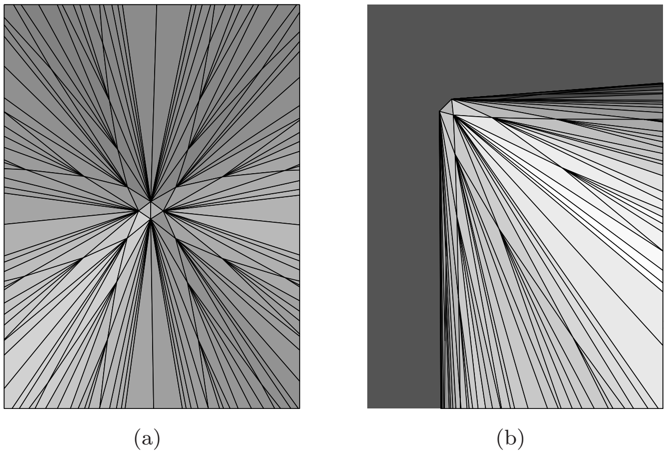
Another feature of Table A.3.1 deserves to be mentioned. There are exactly two values of n, namely $n = 2, 3$, such that virtual cohomological dimension equals the upper limit of the cuspidal range. This will have implications later, when we study the action of the Hecke operators on the cohomology.

n	2	3	4	5	6	7	8	9
$\dim X$	2	5	9	14	20	27	35	44
$\operatorname{vcd}\Gamma$	1	3	6	10	15	21	28	36
top degree of H^*_{cusp}	1	3	5	8	11	15	19	24
bottom degree of H^*_{cusp}	1	2	4	6	9	12	16	20

Table A.3.1. The virtual cohomological dimension and the cuspidal range for subgroups of $\mathrm{SL}_n(\mathbb{Z})$.

A.3.4. Recall that a point in $\mathbb{Z}^n$ is said to be *primitive* if the greatest common divisor of its coordinates is 1. In particular, a primitive point is nonzero. Let $\mathscr{P} \subset \mathbb{Z}^n$ be the set of primitive points. Any $v \in \mathscr{P}$, written as a column vector, determines a rank-1 symmetric matrix $q(v)$ in the closure $\bar{C}$ via $q(v) = vv^t$. The *Voronoĭ polyhedron* Π is defined to be the closed convex hull in $\bar{C}$ of the points $q(v)$, as v ranges over $\mathscr{P}$. Note that by construction, $\mathrm{SL}_n(\mathbb{Z})$ acts on Π, since $\mathrm{SL}_n(\mathbb{Z})$ preserves the set $\{q(v)\}$ and acts linearly on V.

Example A.11. Figure A.3.1 represents a crude attempt to show what Π looks like for $n = 2$. These images were constructed by computing a large subset of the points $q(v)$ and taking the convex hull (we took all points $v \in \mathscr{P}$ such that $\operatorname{Trace} q(v) < N$ for some large integer N). From a distance, the polyhedron Π looks almost indistinguishable from the cone C; this is somewhat conveyed by the right of Figure A.3.1. Unfortunately Π is not locally finite, so we really cannot produce an accurate picture. To get a more accurate image, the reader should imagine that each vertex meets infinitely many edges. On the other hand, Π is not hopelessly complex: each maximal face is a triangle, as the pictures suggest.



(a)

(b)

Figure A.3.1. The polyhedron Π for $\mathrm{SL}_2(\mathbb{Z})$. In (a) we see Π from the origin, in (b) from the side. The small triangle at the right center of (a) is the facet with vertices $\{q(e_1), q(e_2), q(e_1+e_2)\}$, where $\{e_1, e_2\}$ is the standard basis of $\mathbb{Z}^2$. In (b) the x-axis runs along the top from left to right, and the z-axis runs down the left side. The facet from (a) is the little triangle at the top left corner of (b).

A.3.5. The polyhedron Π is quite complicated: it has infinitely many faces and is not locally finite. However, one of Voronoĭ's great insights is that Π is actually not as complicated as it seems.

For any $A \in C$, let $\mu(A)$ be the minimum value attained by A on $\mathscr{P}$ and let $M(A) \subset \mathscr{P}$ be the set on which A attains $\mu(A)$. Note that $\mu(A) > 0$ and $M(A)$ is finite since A is positive-definite. Then A is called *perfect* if it is recoverable from the knowledge of the pair $(\mu(A), M(A))$. In other words, given $(\mu(A), M(A))$, we can write a system of linear equations

$$mZm^t = \mu(A), \quad m \in M(A), \tag{A.3.2}$$

where $Z = (z_{ij})$ is a symmetric matrix of variables. Then A is perfect if and only if A is the unique solution to the system (A.3.2).

Example A.12. The quadratic form $Q(x, y) = x^2 - xy + y^2$ is perfect. The smallest nontrivial value it attains on $\mathbb{Z}^2$ is $\mu(Q) = 1$, and it does so on the columns of

$$M(Q) = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

and their negatives. Letting $\alpha x^2+\beta xy+\gamma y^2$ be an undetermined quadratic form and applying the data $(\mu(Q), M(Q))$, we are led to the system of linear equations

$$\alpha = 1, \quad \gamma = 1, \quad \alpha+\beta+\gamma = 1.$$

From this we recover $Q(x,y)$.

Example A.13. The quadratic form $Q'(x,y) = x^2+y^2$ is not perfect. Again the smallest nontrivial value of Q' on $\mathbb{Z}^2$ is $m(Q') = 1$, attained on the columns of

$$M(Q') = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

and their negatives. But every member of the one-parameter family of quadratic forms

$$x^2+\alpha xy+y^2, \quad \alpha \in (-1,1) \tag{A.3.3}$$

has the same set of minimal vectors, and so Q' cannot be recovered from the knowledge of $m(Q'), M(Q')$.

Example A.14. Example A.12 generalizes to all n. Define

$$A_n(x) := \sum_{i=1}^{n} x_i^2 - \sum_{1\le i<j\le n} x_i x_j. \tag{A.3.4}$$

Then A_n is perfect for all n. We have $\mu(A_n) = 1$, and $M(A_n)$ consists of all points of the form

$$\pm(e_i+e_{i+1}+\cdots+e_{i+k}), \quad 1\le i\le n, \quad i\le i+k\le n,$$

where $\{e_i\}$ is the standard basis of $\mathbb{Z}^n$. This quadratic form is closely related to the A_n root lattice [**FH91**], which explains its name. It is one of two infinite families of perfect forms studied by Voronoĭ (the other is related to the D_n root lattice).

We can now summarize Voronoĭ's main results:

(1) There are finitely many equivalence classes of perfect forms modulo the action of $\mathrm{SL}_n(\mathbb{Z})$. Voronoĭ even gave an explicit algorithm to determine all the perfect forms of a given dimension.

(2) The facets of Π, in other words the codimension 1 faces, are in bijection with the rank n perfect quadratic forms. Under this correspondence the minimal vectors $M(A)$ determine a facet F_A by taking the convex hull in $\bar{C}$ of the finite point set $\{q(m) \mid m \in M(A)\}$. Hence there are finitely many faces of Π modulo $\mathrm{SL}_n(\mathbb{Z})$ and thus finitely many modulo any finite index subgroup Γ.

(3) Let $\mathscr{V}$ be the set of cones over the faces of Π. Then $\mathscr{V}$ is a *fan*, which means (i) if $\sigma \in \mathscr{V}$, then any face of σ is also in $\mathscr{V}$; and (ii) if $\sigma, \sigma' \in \mathscr{V}$, then $\sigma \cap \sigma'$ is a common face of each[6]. The fan $\mathscr{V}$ provides a reduction theory for C in the following sense: any point $x \in C$ is contained in a unique $\sigma(x) \in \mathscr{V}$, and the set $\{\gamma \in \mathrm{SL}_n(\mathbb{Z}) \mid \gamma \cdot \sigma(x) = \sigma(x)\}$ is finite. Voronoĭ also gave an explicit algorithm to determine $\sigma(x)$ given x, the *Voronoĭ reduction algorithm.*

The number N_{perf} of equivalence classes of perfect forms modulo the action of $\mathrm{GL}_n(\mathbb{Z})$ grows rapidly with n (Table A.3.2); the complete classification is known only for $n \leq 8$. For a list of perfect forms up to $n = 7$, see [**CS88**]. For a recent comprehensive treatment of perfect forms, with many historical remarks, see [**Mar03**].

A.3.6. Our goal now is to describe how the Voronoĭ fan $\mathscr{V}$ can be used to compute the cohomology $H^*(\Gamma; \mathscr{M})$. The idea is to use the cones in $\mathscr{V}$ to chop the quotient D into pieces.

For any $\sigma \in \mathscr{V}$, let σ° be the open cone obtained by taking the complement in σ of its proper faces. Then after taking the quotient by homotheties, the cones $\{\sigma^\circ \cap C \mid \sigma \in \mathscr{V}\}$ pass to locally closed subsets of D. Let $\mathscr{C}$ be the set of these images.

Any $c \in \mathscr{C}$ is a *topological cell*, i.e., it is homeomorphic to an open ball, since c is homeomorphic to a face of Π. Because $\mathscr{C}$ comes from the fan $\mathscr{V}$, the cells in $\mathscr{C}$ have good incidence properties: the closure in D of any $c \in \mathscr{C}$ can be written as a finite disjoint union of elements of $\mathscr{C}$. Moreover, $\mathscr{C}$ is locally finite: by taking quotients of all the σ° meeting C, we have eliminated the open cones lying in $\bar{C}$, and it is these cones that are responsible for the failure of local finiteness of $\mathscr{V}$. We summarize these properties by saying

[6] Strictly speaking, Voronoĭ actually showed that every codimension 1 cone is contained in two top-dimensional cones.

that $\mathscr{C}$ gives a *cellular decomposition* of D. Clearly $\mathrm{SL}_n(\mathbb{Z})$ acts on $\mathscr{C}$, since $\mathscr{C}$ is constructed using the fan $\mathscr{V}$. Thus we obtain a cellular decomposition[7] of $\Gamma\backslash D$ for any torsion-free Γ. We call $\mathscr{C}$ the *Voronoĭ decomposition* of D.

Some care must be taken in using these cells to perform topological computations. The problem is that even though the individual pieces are homeomorphic to balls and are glued together nicely, the boundaries of the closures of the pieces are not homeomorphic to spheres in general. (If they were, then the Voronoĭ decomposition would give rise to a *regular* cell complex [**CF67**], which can be used as a substitute for a simplicial or CW complex in homology computations.) Nevertheless, there is a way to remedy this.

Recall that a subspace A of a topological space B is a *strong deformation retract* if there is a continuous map $f\colon B \times [0,1] \to B$ such that $f(b,0) = b$, $f(b,1) \in A$, and $f(a,t) = a$ for all $a \in A$. For such pairs $A \subset B$ we have $H^*(A) = H^*(B)$. One can show that there is a strong deformation retraction from C to itself equivariant under the actions of both $\mathrm{SL}_n(\mathbb{Z})$ and the homotheties and that the image of the retraction modulo homotheties, denoted W, is naturally a locally finite regular cell complex of dimension ν. Moreover, the cells in W are in bijective, inclusion-reversing correspondence with the cells in $\mathscr{C}$. In particular, if a cell in $\mathscr{C}$ has *codimension* d, the corresponding cell in W has *dimension* d. Thus, for example, the vertices of W modulo $\mathrm{SL}_n(\mathbb{Z})$ are in bijection with the top-dimensional cells in $\mathscr{C}$, which are in bijection with equivalence classes of perfect forms.

In the literature W is called the *well-rounded retract*. The subspace $W \subset D \simeq X$ has a beautiful geometric interpretation. The quotient

$$\mathrm{SL}_n(\mathbb{Z})\backslash X = \mathrm{SL}_n(\mathbb{Z})\backslash \mathrm{SL}_n(\mathbb{R})/\,\mathrm{SO}(n)$$

can be interpreted as the moduli space of lattices in $\mathbb{R}^n$ modulo the equivalence relation of rotation and positive scaling (cf. [**AG00**]; for $n = 2$ one can also see [**Ser73**, VII, Proposition 3]). Then W corresponds to those lattices whose shortest nonzero vectors span $\mathbb{R}^n$. This is the origin of the name: the shortest vectors of such a lattice are "more round" than those of a generic lattice.

The space W was known classically for $n = 2$ and was constructed for $n \geq 3$ by Lannes and Soulé, although Soulé only published the case $n = 3$ [**Sou75**]. The construction for all n appears in work of Ash [**Ash80, Ash84**], who also generalized W to a much larger class of groups. Explicit computations of the cell structure of W have only been performed up to

[7] If Γ has torsion, then cells in $\mathscr{C}$ can have nontrivial stabilizers in Γ, and thus $\Gamma\backslash\mathscr{C}$ should be considered as an "orbifold" cellular decomposition.

$n = 6$ [**EVGS02**]. Certainly computing W explicitly for $n = 8$ seems very difficult, as Table A.3.2 indicates.

Example A.15. Figure A.3.2 illustrates $\mathscr{C}$ and W for $\mathrm{SL}_2(\mathbb{Z})$. As in Example A.11, the polyhedron Π is 3-dimensional, and so the Voronoĭ fan $\mathscr{V}$ has cones of dimensions $0, 1, 2, 3$. The 1-cones of $\mathscr{V}$, which correspond to the vertices of Π, pass to infinitely many points on the boundary $\partial\bar{D} = \bar{D} \smallsetminus D$. The 3-cones become triangles in $\bar{D}$ with vertices on $\partial\bar{D}$. In fact, the identifications $D \simeq \mathrm{SL}_2(\mathbb{R})/\,\mathrm{SO}(2) \simeq \mathfrak{h}$ realize D as the Klein model for the hyperbolic plane, in which geodesics are represented by Euclidean line segments. Hence, the images of the 1-cones of $\mathscr{V}$ are none other than the usual cusps of $\mathfrak{h}$, and the triangles are the $\mathrm{SL}_2(\mathbb{Z})$-translates of the ideal triangle with vertices $\{0, 1, \infty\}$. These triangles form a tessellation of $\mathfrak{h}$ sometimes known as the *Farey tessellation*. The edges of the Voronoĭ are the $\mathrm{SL}_2(\mathbb{Z})$-translates of the ideal geodesic between 0 and ∞. After adjoining cusps and passing to the quotient $X_0(N)$, these edges become the supports of the Manin symbols from Section 8.2 (cf. Figure 3.2.1). This example also shows how the Voronoĭ decomposition fails to be a regular cell complex: the boundaries of the closures of the triangles in D do not contain the vertices and thus are not homeomorphic to circles.

The virtual cohomological dimension of $\mathrm{SL}_2(\mathbb{Z})$ is 1. Hence the well-rounded retract W is a graph (Figures A.3.2 and A.3.3). Note that W is not a manifold. The vertices of W are in bijection with the Farey triangles—each vertex lies at the center of the corresponding triangle—and the edges are in bijection with the Manin symbols. Under the map $D \to \mathfrak{h}$, the graph W becomes the familiar "PSL_2-tree" embedded in $\mathfrak{h}$, with vertices at the order 3 elliptic points (Figure A.3.3).

A.3.7. We now discuss the example $\mathrm{SL}_3(\mathbb{Z})$ in some detail. This example gives a good feeling for how the general situation compares to the case $n = 2$.

We begin with the Voronoĭ fan $\mathscr{V}$. The cone C is 6-dimensional, and the quotient D is 5-dimensional. There is one equivalence class of perfect forms modulo the action of $\mathrm{SL}_3(\mathbb{Z})$, represented by the form (A.3.4). Hence there are 12 minimal vectors; six are the columns of the matrix

$$\begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & 1 & 1 \end{pmatrix}, \tag{A.3.5}$$

and the remaining six are the negatives of these. This implies that the cone σ corresponding to this form is 6-dimensional and simplicial. The latter implies that the faces of σ are the cones generated by $\{q(v) \mid v \in S\}$, where S ranges over all subsets of (A.3.5). To get the full structure of the fan, one

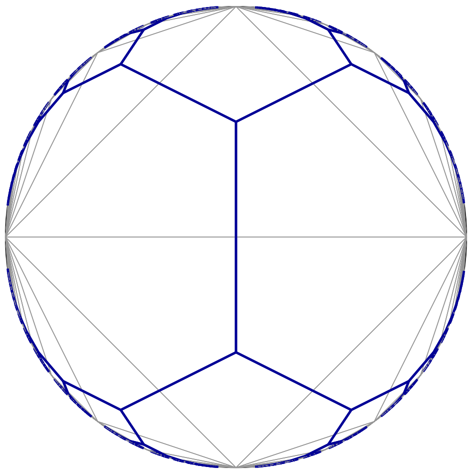

Figure A.3.2. The Voronoĭ decomposition and the retract in D.

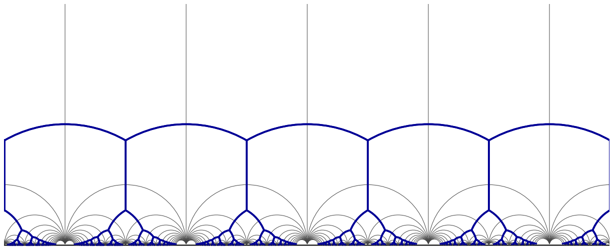

Figure A.3.3. The Voronoĭ decomposition and the retract in $\mathfrak{h}$.

must determine the $\mathrm{SL}_3(\mathbb{Z})$ orbits of faces, as well as which faces lie in the boundary $\partial\bar{C} = \bar{C} \smallsetminus C$. After some pleasant computation, one finds:

(1) There is one equivalence class modulo $\mathrm{SL}_3(\mathbb{Z})$ for each of the 6-, 5-, 2-, and 1-dimensional cones.

(2) There are two equivalence classes of the 4-dimensional cones, represented by the sets of minimal vectors

$$\begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

(3) There are two equivalence classes of the 3-dimensional cones, represented by the sets of minimal vectors

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

The second type of 3-cone lies in $\partial\bar{C}$ and thus does not determine a cell in $\mathscr{C}$.

(4) The 2- and 1-dimensional cones lie entirely in $\partial\bar{C}$ and do not determine cells in $\mathscr{C}$.

After passing from C to D, the cones of dimension k determine cells of dimension $k-1$. Therefore, modulo the action of $\mathrm{SL}_3(\mathbb{Z})$ there are five types of cells in the Voronoĭ decomposition $\mathscr{C}$, with dimensions from 5 to 2. We denote these cell types by c_5, c_4, c_{3a}, c_{3b}, and c_2. Here c_{3a} corresponds to the first type of 4-cone in item (2) above, and c_{3b} to the second. For a beautiful way to index the cells of $\mathscr{C}$ using configurations in projective spaces, see [**McC91**].

The virtual cohomological dimension of $\mathrm{SL}_3(\mathbb{Z})$ is 3, which means that the retract W is a 3-dimensional cell complex. The closures of the top-dimensional cells in W, which are in bijection with the Voronoĭ cells of type c_2, are homeomorphic to solid cubes truncated along two pairs of opposite corners (Figure A.3.4). To compute this, one must see how many Voronoĭ cells of a given type contain a fixed cell of type c_2 (since the inclusions of cells in W are the *opposite* of those in $\mathscr{C}$).

A table of the incidence relations between the cells of $\mathscr{C}$ and W is given in Table A.3.3. To interpret the table, let $m = m(X, Y)$ be the integer in row X and column Y.

- If m is below the diagonal, then the boundary of a cell of type Y contains m cells of type X.
- If m is above the diagonal, then a cell of type Y appears in the boundary of m cells of type X.

For instance, the entry 16 in row c_5 and column c_2 means that a Voronoĭ cell of type c_2 meets the boundaries of 16 cells of type c_5. This is the same as the number of vertices in the Soulé cube (Figure A.3.4). Investigation of the table shows that the triangular (respectively, hexagonal) faces of the Soulé cube correspond to the Voronoĭ cells of type c_{3a} (resp., c_{3b}).

Figure A.3.5 shows a Schlegel diagram for the Soulé cube. One vertex is at infinity; this is indicated by the arrows on three of the edges. This Soulé cube is dual to the Voronoĭ cell C of type c_2 with minimal vectors given by the columns of the identity matrix. The labels on the 2-faces are additional minimal vectors that show which Voronoĭ cells contain C. For example, the central triangle labelled with $(1,1,1)^t$ is dual to the Voronoĭ cell of type c_{3a} with minimal vectors given by those of C together with $(1,1,1)^t$. Cells of type c_4 containing C in their closure correspond to the edges of the figure; the minimal vectors for a given edge are those of C together with the two vectors on the 2-faces containing the edge. Similarly, one can read off the minimal vectors of the top-dimensional Voronoĭ cells containing C, which correspond to the vertices of Figure A.3.5.

	c_5	c_4	c_{3a}	c_{3b}	c_2
c_5	•	2	3	6	16
c_4	6	•	3	6	24
c_{3a}	3	1	•	•	4
c_{3b}	12	4	•	•	6
c_2	12	8	4	3	•

Table A.3.3. Incidence relations in the Voronoĭ decomposition and the retract for $\mathrm{SL}_3(\mathbb{Z})$.

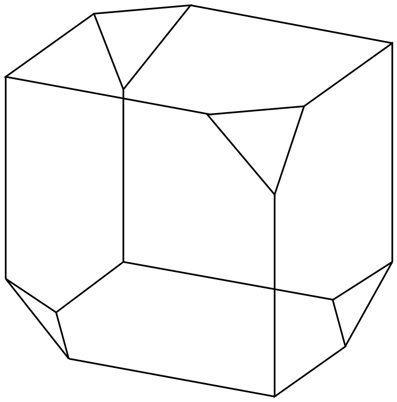

Figure A.3.4. The Soulé cube.

A.3.8. Now let p be a prime, and let $\Gamma = \Gamma_0(p) \subset \mathrm{SL}_3(\mathbb{Z})$ be the Hecke subgroup of matrices with bottom row congruent to $(0, 0, *) \mod p$ (Example A.4). The virtual cohomological dimension of Γ is 3, and the cusp cohomology with constant coefficients can appear in degrees 2 and 3. One can show that the cusp cohomology in degree 2 is dual to that in degree 3, so for computational purposes it suffices to focus on degree 3.

In terms of W, these will be cochains supported on the 3-cells. Unfortunately we cannot work directly with the quotient $\Gamma\backslash W$ since Γ has torsion: there will be cells taken to themselves by the Γ-action, and thus the cells of W need to be subdivided to induce the structure of a cell complex on $\Gamma\backslash W$. Thus when Γ has torsion, the "set of 3-cells modulo Γ" unfortunately makes no sense.

To circumvent this problem, one can mimic the idea of Manin symbols. The quotient $\Gamma\backslash \mathrm{SL}_3(\mathbb{Z})$ is in bijection with the finite projective plane $\mathbb{P}^2(\mathbb{F}_p)$,

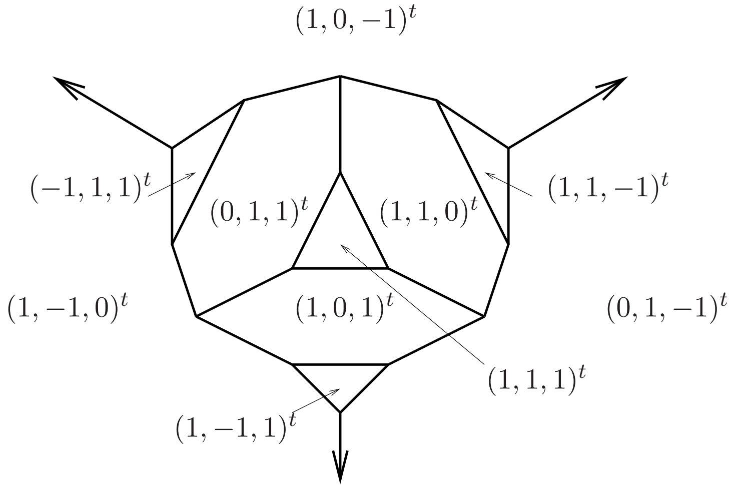

Figure A.3.5. A Schlegel diagram of a Soulé cube, showing the minimal vectors that correspond to the 2-faces.

where $\mathbb{F}_p$ is the field with p elements (cf. Proposition 3.10). The group $\mathrm{SL}_3(\mathbb{Z})$ acts transitively on the set of all 3-cells of W; if we fix one such cell w, its stabilizer $\mathrm{Stab}(w) = \{\gamma \in \mathrm{SL}_3(\mathbb{Z}) \mid \gamma w = w\}$ is a finite subgroup of $\mathrm{SL}_3(\mathbb{Z})$. Hence the set of 3-cells modulo Γ should be interpreted as the set of orbits in $\mathbb{P}^2(\mathbb{F}_p)$ of the finite group $\mathrm{Stab}(w)$. This suggests describing $H^3(\Gamma;\mathbb{C})$ in terms of the space $\mathscr{S}$ of complex-valued functions $f\colon \mathbb{P}^2(\mathbb{F}_p) \to \mathbb{C}$. To carry this out, there are two problems:

(1) How do we explicitly describe $H^3(\Gamma;\mathbb{C})$ in terms of $\mathscr{S}$?

(2) How can we isolate the cuspidal subspace $H^3_{\mathrm{cusp}}(\Gamma;\mathbb{C}) \subset H^3(\Gamma;\mathbb{C})$ in terms of our description?

Fully describing the solutions to these problems is rather complicated. We content ourselves with presenting the following theorem, which collects together several statements in [**AGG84**]. This result should be compared to Theorems 3.13 and 8.4.

Theorem A.16 (Theorem 3.19 and Summary 3.23 of [**AGG84**])**.** *We have*

$$\dim H^3(\Gamma_0(p);\mathbb{C}) = \dim H^3_{cusp}(\Gamma_0(p);\mathbb{C}) + 2S_p,$$

where S_p is the dimension of the space of weight 2 holomorphic cusp forms on $\Gamma_0(p) \subset \mathrm{SL}_2(\mathbb{Z})$. Moreover, the cuspidal cohomology $H^3_{cusp}(\Gamma_0(p);\mathbb{C})$ is isomorphic to the vector space of functions $f\colon \mathbb{P}^2(\mathbb{F}_p) \to \mathbb{C}$ satisfying

(1) $f(x,y,z) = f(z,x,y) = f(-x,y,z) = -f(y,x,z)$,

(2) $f(x,y,z) + f(-y,x-y,z) + f(y-x,-x,z) = 0$,

(3) $f(x,y,0) = 0$, *and*

(4) $\sum_{z=1}^{p-1} f(x,y,z) = 0$.

Unlike subgroups of $\mathrm{SL}_2(\mathbb{Z})$, cuspidal cohomology is apparently much rarer for $\Gamma_0(p) \subset \mathrm{SL}_3(\mathbb{Z})$. The computations of [**AGG84, vGvdKTV97**] show that the only prime levels $p \leq 337$ with nonvanishing cusp cohomology are 53, 61, 79, 89, and 223. In all these examples, the cuspidal subspace is 2-dimensional.

For more details of how to implement such computations, we refer to [**AGG84, vGvdKTV97**]. For further details about the additional complications arising for higher rank groups, in particular subgroups of $\mathrm{SL}_4(\mathbb{Z})$, see [**AGM02**, Section 3].

A.4. Hecke Operators and Modular Symbols

A.4.1. There is one ingredient missing so far in our discussion of the cohomology of arithmetic groups, namely the Hecke operators. These are an essential tool in the study of modular forms. Indeed, the forms with the most arithmetic significance are the Hecke eigenforms, and the connection with arithmetic is revealed by the Hecke eigenvalues.

In higher rank the situation is similar. There is an algebra of Hecke operators acting on the cohomology spaces $H^*(\Gamma; \mathscr{M})$. The eigenvalues of these operators are conjecturally related to certain representations of the Galois group. Just as in the case $G = \mathrm{SL}_2(\mathbb{R})$, we need tools to compute the Hecke action.

In this section we discuss this problem. We begin with a general description of the Hecke operators and how they act on cohomology. Then we focus on one particular cohomology group, namely the top degree $H^\nu(\Gamma; \mathbb{C})$, where $\nu = \mathrm{vcd}(\Gamma)$ and Γ has finite index in $\mathrm{SL}_n(\mathbb{Z})$. This is the setting that generalizes the modular symbols method from Chapter 8. We conclude by giving examples of Hecke eigenclasses in the cuspidal cohomology of $\Gamma_0(p) \subset \mathrm{SL}_3(\mathbb{Z})$.

A.4.2. Let $g \in \mathrm{SL}_n(\mathbb{Q})$. The group $\Gamma' = \Gamma \cap g^{-1}\Gamma g$ has finite index in both Γ and $g^{-1}\Gamma g$. The element g determines a diagram $C(g)$

$$\begin{tikzcd}
 & \Gamma'\backslash X \arrow[dl, "s"'] \arrow[dr, "t"] & \\
\Gamma\backslash X & & \Gamma\backslash X
\end{tikzcd}$$

called a *Hecke correspondence*. The map s is induced by the inclusion $\Gamma' \subset \Gamma$, while t is induced by the inclusion $\Gamma' \subset g^{-1}\Gamma g$ followed by the diffeomorphism $g^{-1}\Gamma g\backslash X \to \Gamma\backslash X$ given by left multiplication by g. Specifically,

$$s(\Gamma' x) = \Gamma x, \quad t(\Gamma' x) = \Gamma g x, \quad x \in X.$$

The maps s and t are finite-to-one, since the indices $[\Gamma' : \Gamma]$ and $[\Gamma' : g^{-1}\Gamma g]$ are finite. This implies that we obtain maps on cohomology

$$s^*\colon H^*(\Gamma\backslash X) \to H^*(\Gamma'\backslash X), \quad t_*\colon H^*(\Gamma'\backslash X) \to H^*(\Gamma\backslash X).$$

Here the map s^* is the usual induced map on cohomology, while the "wrong-way" map[8] t_* is given by summing a class over the finite fibers of t. These maps can be composed to give a map

$$T_g := t_* s^*\colon H^*(\Gamma\backslash X; \widetilde{\mathscr{M}}) \longrightarrow H^*(\Gamma\backslash X; \widetilde{\mathscr{M}}).$$

This is called the *Hecke operator* associated to g. There is an obvious notion of isomorphism of Hecke correspondences. One can show that up to isomorphism, the correspondence $C(g)$ and thus the Hecke operator T_g depend only on the double coset $\Gamma g \Gamma$. One can compose Hecke correspondences, and thus we obtain an algebra of operators acting on the cohomology, just as in the classical case.

Example A.17. Let $n = 2$, and let $\Gamma = \mathrm{SL}_2(\mathbb{Z})$. If we take $g = \mathrm{diag}(1, p)$, where p is a prime, then the action of T_g on $H^1(\Gamma; M_{k-2})$ is the same as the action of the classical Hecke operator T_p on the weight k holomorphic modular forms. If we take $\Gamma = \Gamma_0(N)$, we obtain an operator $T(p)$ for all p prime to N, and the algebra of Hecke operators coincides with the (semisimple) Hecke algebra generated by the T_p, $(p, N) = 1$. For $p|N$, one can also describe the U_p operators in this language.

Example A.18. Now let $n > 2$ and let $\Gamma = \mathrm{SL}_n(\mathbb{Z})$. The picture is very similar, except that now there are several Hecke operators attached to any prime p. In fact there are $n - 1$ operators $T(p, k)$, $k = 1, \ldots, n - 1$. The operator $T(p, k)$ is associated to the correspondence $C(g)$, where $g = \mathrm{diag}(1, \ldots, 1, p, \ldots, p)$ and where p occurs k times. If we consider the congruence subgroups $\Gamma_0(N)$, we have operators $T(p, k)$ for $(p, N) = 1$ and analogues of the U_p operators for $p|N$.

Just as in the classical case, any double coset $\Gamma g \Gamma$ can be written as a disjoint union of left cosets

$$\Gamma g \Gamma = \coprod_{h \in \Omega} \Gamma h$$

[8] Under the identification $H^*(\Gamma\backslash X; \widetilde{\mathscr{M}}) \simeq H^*(\Gamma; \mathscr{M})$, the map t_* becomes the transfer map in group cohomology [**Bro94**, III.9].

for a certain finite set of $n \times n$ integral matrices Ω. For the operator $T(p,k)$, the set Ω can be taken to be all upper-triangular matrices of the form [**Kri90**, Proposition 7.2]

$$\begin{pmatrix} p^{e_1} & & a_{ij} \\ & \ddots & \\ & & p^{e_n} \end{pmatrix},$$

where

- $e_i \in \{0,1\}$ and exactly k of the e_i are equal to 1 and
- $a_{ij} = 0$ unless $e_i = 0$ and $e_j = 1$, in which case a_{ij} satisfies $0 \le a_{ij} < p$.

Remark A.19. The number of coset representatives for the operator $T(p,k)$ is the same as the number of points in the finite Grassmannian $G(k,n)(\mathbb{F}_p)$. A similar phenomenon is true for the Hecke operators for any group G, although there are some subtleties [**Gro98**].

A.4.3. Recall that in Section A.3.6 we constructed the Voronoĭ decomposition $\mathscr{C}$ and the well-rounded retract W and that we can use them to compute the cohomology $H^*(\Gamma;\mathscr{M})$. Unfortunately, we cannot directly use them to compute the action of the Hecke operators on cohomology, since the Hecke operators do not act cellularly on $\mathscr{C}$ or W. The problem is that the Hecke image of a cell in $\mathscr{C}$ (or W) is usually not a union of cells in $\mathscr{C}$ (or W). This is already apparent for $n = 2$. The edges of $\mathscr{C}$ are the $\mathrm{SL}_2(\mathbb{Z})$-translates of the ideal geodesic τ from 0 to ∞ (Example A.15). Applying a Hecke operator takes such an edge to a union of ideal geodesics, each with vertices at a pair of cusps. In general such geodesics are not an $\mathrm{SL}_2(\mathbb{Z})$-translate of τ.

For $n = 2$, one solution is to work with all possible ideal geodesics with vertices at the cusps, in other words the space of modular symbols $\mathbb{M}_2$ from Section 3.2. Manin's trick (Proposition 3.11) shows how to write any modular symbol as a linear combination of unimodular symbols, by which we mean modular symbols supported on the edges of $\mathscr{C}$. These are the ideas we now generalize to all n.

Definition A.20. Let S_0 be the $\mathbb{Q}$-vector space spanned by the symbols $\mathbf{v} = [v_1,\dots,v_n]$, where $v_i \in \mathbb{Q}^n \smallsetminus \{0\}$, modulo the following relations:

(1) If τ is a permutation on n letters, then

$$[v_1,\dots,v_n] = \mathrm{sign}(\tau)[\tau(v_1),\dots,\tau(v_n)],$$

where $\mathrm{sign}(\tau)$ is the sign of τ.

(2) If $q \in \mathbb{Q}^\times$, then

$$[qv_1, v_2 \dots, v_n] = [v_1,\dots,v_n].$$

(3) If the points $v_1, \ldots, v_n$ are linearly dependent, then $\mathbf{v} = 0$.

Let $B \subset S_0$ be the subspace generated by linear combinations of the form

$$\sum_{i=0}^{n} (-1)^i [v_0, \ldots, \hat{v}_i, \ldots, v_n], \tag{A.4.1}$$

where $v_0, \ldots, v_n \in \mathbb{Q}^n \smallsetminus \{0\}$ and where $\hat{v}_i$ means to omit v_i.

We call S_0 the space of *modular symbols*. We caution the reader that there are some differences in what we call modular symbols and those found in Section 3.2 and Definition 8.2; we compare them in Section A.4.4. The group $\mathrm{SL}_n(\mathbb{Q})$ acts on S_0 by left multiplication: $g \cdot \mathbf{v} = [gv_1, \ldots, gv_n]$. This action preserves the subspace B and thus induces an action on the quotient $M = S_0/B$. For $\Gamma \subset \mathrm{SL}_n(\mathbb{Z})$ a finite index subgroup, let M_Γ be the space of Γ-coinvariants in M. In other words, M_Γ is the quotient of M by the subspace generated by $\{m - \gamma \cdot m \mid \gamma \in \Gamma\}$.

The relationship between modular symbols and the cohomology of Γ is given by the following theorem, first proved for SL_n by Ash and Rudolph [**AR79**] and by Ash for general G [**Ash86**]:

Theorem A.21 ([**Ash86, AR79**]). *Let $\Gamma \subset \mathrm{SL}_n(\mathbb{Z})$ be a finite index subgroup. There is an isomorphism*

$$M_\Gamma \xrightarrow{\sim} H^\nu(\Gamma; \mathbb{Q}), \tag{A.4.2}$$

where Γ acts trivially on $\mathbb{Q}$ and where $\nu = \mathrm{vcd}(\Gamma)$.

We remark that Theorem A.21 remains true if $\mathbb{Q}$ is replaced with nontrivial coefficients as in Section A.2.7. Moreover, if Γ is assumed to be torsion-free then we can replace $\mathbb{Q}$ with $\mathbb{Z}$.

The great virtue of M_Γ is that it admits an action of the Hecke operators. Given a Hecke operator T_g, write the double coset $\Gamma g \Gamma$ as a disjoint union of left cosets

$$\Gamma g \Gamma = \coprod_{h \in \Omega} \Gamma h \tag{A.4.3}$$

as in Example A.18. Any class in M_Γ can be lifted to a representative $\eta = \sum q(\mathbf{v})\mathbf{v} \in S_0$, where $q(\mathbf{v}) \in \mathbb{Q}$ and almost all $q(\mathbf{v})$ vanish. Then we define

$$T_g(\mathbf{v}) = \sum_{h \in \Omega} h \cdot \mathbf{v} \tag{A.4.4}$$

and extend to η by linearity. The right side of (A.4.4) depends on the choices of η and Ω, but after taking quotients and coinvariants, we obtain a well-defined action on cohomology via (A.4.2).

A.4.4. The space S_0 is closely related to the space $\mathbb{M}_2$ from Section 3.2 and Section 8.1. Indeed, $\mathbb{M}_2$ was defined to be the quotient $(F/R)/(F/R)_{\mathrm{tor}}$, where F is the free abelian group generated by ordered pairs

$$\{\alpha, \beta\}, \quad \alpha, \beta \in \mathbb{P}^1(\mathbb{Q}), \tag{A.4.5}$$

and R is the subgroup generated by elements of the form

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\}, \quad \alpha, \beta, \gamma \in \mathbb{P}^1(\mathbb{Q}). \tag{A.4.6}$$

The only new feature in Definition A.20 is item (3). For $n = 2$ this corresponds to the condition $\{\alpha, \alpha\} = 0$, which follows from (A.4.6). We have

$$S_0/B \simeq \mathbb{M}_2 \otimes \mathbb{Q}.$$

Hence there are two differences between S_0 and $\mathbb{M}_2$: our notion of modular symbols uses rational coefficients instead of integral coefficients and is the space of symbols *before* dividing out by the subspace of relations B; we further caution the reader that this is somewhat at odds with the literature.

We also remark that the general arbitrary weight definition of modular symbols for a subgroup $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$ given in Section 8.1 also includes taking Γ-coinvariants, as well as extra data for a coefficient system. We have not included the latter data since our emphasis is trivial coefficients, although it would be easy to do so in the spirit of Section 8.1.

Elements of $\mathbb{M}_2$ also have a geometric interpretation: the symbol $\{\alpha, \beta\}$ corresponds to the ideal geodesic in $\mathfrak{h}$ with endpoints at the cusps α and β. We have a similar picture for the symbols $\mathbf{v} = [v_1, \ldots, v_n]$. We can assume that each v_i is primitive, which means that each v_i determines a vertex of the Voronoĭ polyhedron Π. The rational cone generated by these vertices determines a subset $\Delta(\mathbf{v}) \subset D$, where D is the linear model of the symmetric space $X = \mathrm{SL}_n(\mathbb{R})/\mathrm{SO}(n)$ from Section A.3.2. This subset $\Delta(\mathbf{v})$ is then an "ideal simplex" in X. There is also a connection between $\Delta(\mathbf{v})$ and torus orbits in X; we refer to [**Ash86**] for a related discussion.

A.4.5. Now we need a generalization of the Manin trick (Section 3.3.1). This is known in the literature as the *modular symbols algorithm.*

We can define a kind of norm function on S_0 as follows. Let $\mathbf{v} = [v_1, \ldots, v_n]$ be a modular symbol. For each v_i, choose $\lambda_i \in \mathbb{Q}^\times$ such that $\lambda_i v_i$ is primitive. Then we define

$$\|\mathbf{v}\| := |\det(\lambda_1 v_1, \ldots, \lambda_n v_n)| \in \mathbb{Z}.$$

Note that $\|\mathbf{v}\|$ is well defined, since the λ_i are unique up to sign, and permuting the v_i only changes the determinant by a sign. We extend $\|\ \|$ to all of S_0 by taking the maximum of $\|\ \|$ over the support of any $\eta \in S_0$: if

$\eta = \sum q(\mathbf{v})\mathbf{v}$, where $q(\mathbf{v}) \in \mathbb{Q}$ and almost all $q(\mathbf{v})$ vanish, then we put

$$\|\eta\| = \operatorname*{Max}_{q(\mathbf{v})\neq 0} \|\mathbf{v}\|.$$

We say a modular symbol η is *unimodular* if $\|\eta\| = 1$. It is clear that the images of the unimodular symbols generate a finite-dimensional subspace of M_Γ. The next theorem shows that this subspace is actually *all* of M_Γ.

Theorem A.22 ([**AR79, Bar94**]). *The space M_Γ is spanned by the images of the unimodular symbols. More precisely, given any symbol $\mathbf{v} \in S_0$ with $\|\mathbf{v}\| > 1$,*

(1) *in S_0/B we may write*

$$\mathbf{v} = \sum q(\mathbf{w})\mathbf{w}, \quad q(\mathbf{w}) \in \mathbb{Z}, \tag{A.4.7}$$

where if $q(\mathbf{w}) \neq 0$, then $\|\mathbf{w}\| = 1$, and

(2) *the number of terms on the right side of* (A.4.7) *is bounded by a polynomial in* $\log \|\mathbf{v}\|$ *that depends only on the dimension n.*

Proof. (Sketch) Given a modular symbol $\mathbf{v} = [v_1, \dots, v_n]$, we may assume that the points v_i are primitive. We will show that if $\|\mathbf{v}\| > 1$, we can find a point u such that when we apply the relation (A.4.1) using the points $u, v_1, \dots, v_n$, all terms other than $\mathbf{v}$ have norm less than $\|\mathbf{v}\|$. We call such a point a *reducing point* for $\mathbf{v}$.

Let $P \subset \mathbb{R}^n$ be the open parallelotope

$$P := \left\{ \sum \lambda_i v_i \;\middle|\; |\lambda_i| < \|\mathbf{v}\|^{-1/n} \right\}.$$

Then P is an n-dimensional centrally symmetric convex body with volume 2^n. By Minkowski's theorem from the geometry of numbers (cf. [**FT93**, IV.2.6]), $P \cap \mathbb{Z}^n$ contains a nonzero point u. Using (A.4.1), we find

$$\mathbf{v} = \sum_{i=1}^{n} (-1)^{i-1} \mathbf{v}_i(u), \tag{A.4.8}$$

where $\mathbf{v}_i(u)$ is the symbol

$$\mathbf{v}_i(u) = [v_1, \dots, v_{i-1}, u, v_{i+1}, \dots, v_n].$$

Moreover, it is easy to see that the new symbols satisfy

$$0 \leq \|\mathbf{v}_i(u)\| < \|\mathbf{v}\|^{(n-1)/n}, \quad i = 1, \dots, n. \tag{A.4.9}$$

This completes the proof of the first statement.

To prove the second statement, we must estimate how many times relations of the form (A.4.8) need to be applied to obtain (A.4.7). A nonunimodular symbol produces at most n new modular symbols after (A.4.8) is performed; we potentially have to apply (A.4.8) again to each of the symbols that result, which in turn could produce as many as n new symbols for each. Hence we can visualize the process of constructing (A.4.7) as building a rooted tree, where the root is $\mathbf{v}$, the leaves are the symbols $\mathbf{w}$, and where each node has at most n children. It is not hard to see that the bound (A.4.9) implies that the depth of this tree (i.e., the longest length of a path from the root to a leaf) is $O(\log\log\|\mathbf{v}\|)$. From this the second statement follows easily. □

Statement (1) of Theorem A.22 is due to Ash and Rudolph [**AR79**]. Instead of P, they used the larger parallelotope P' defined by

$$P' := \Big\{ \sum \lambda_i v_i \;\Big|\; |\lambda_i| < 1 \Big\},$$

which has volume $2^n\|\mathbf{v}\|$. The observation that P' can be replaced by P and the proof of (2) are both due to Barvinok [**Bar94**].

A.4.6. The relationship between Theorem A.22 and Manin's trick should be clear. For $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$, the Manin symbols correspond exactly to the unimodular symbols mod Γ. So Theorem A.22 implies that every modular symbol (in the language of Section 8.1) is a linear combination of Manin symbols. This is exactly the conclusion of Proposition 8.3.

In higher rank the relationship between Manin symbols and unimodular symbols is more subtle. In fact there are two possible notions of "Manin symbol," which agree for $\mathrm{SL}_2(\mathbb{Z})$ but not in general. One possibility is the obvious one: a Manin symbol is a unimodular symbol.

The other possibility is to define a Manin symbol to be a modular symbol corresponding to a top-dimensional cell of the retract W. But for $n \geq 5$, such modular symbols need not be unimodular. In particular, for $n = 5$ there are two equivalence classes of top-dimensional cells. One class corresponds to the unimodular symbols, the other to a set of modular symbols of norm 2. However, Theorems A.21 and A.22 show that $H^\nu(\Gamma;\mathbb{Q})$ is spanned by unimodular symbols. Thus as far as this cohomology group is concerned, the second class of symbols is in some sense unnecessary.

A.4.7. We return to the setting of Section A.3.8 and give examples of Hecke eigenclasses in the cusp cohomology of $\Gamma = \Gamma_0(p) \subset \mathrm{SL}_3(\mathbb{Z})$. We closely follow [**AGG84, vGvdKTV97**]. Note that since the top of the cuspidal range for SL_3 is the same as the virtual cohomological dimension ν, we can use modular symbols to compute the Hecke action on cuspidal classes.

Given a prime l coprime to p, there are two Hecke operators of interest $T(l,1)$ and $T(l,2)$. We can compute the action of these operators on

$H^3_{\mathrm{cusp}}(\Gamma;\mathbb{C})$ as follows. Recall that $H^3_{\mathrm{cusp}}(\Gamma;\mathbb{C})$ can be identified with a certain space of functions $f\colon \mathbb{P}^2(\mathbb{F}_p)\to\mathbb{C}$ (Theorem A.16). Given $x\in\mathbb{P}^2(\mathbb{F}_p)$, let $Q_x\in\mathrm{SL}_3(\mathbb{Z})$ be a matrix such that $Q_x\mapsto x$ under the identification $\mathbb{P}^2(\mathbb{F}_p)\xrightarrow{\sim}\Gamma\backslash\mathrm{SL}_3(\mathbb{Z})$. Then Q_x determines a unimodular symbol $[Q_x]$ by taking the v_i to be the columns of Q_x. Given any Hecke operator T_g, we can find coset representatives h_i such that $\Gamma g\Gamma=\coprod\Gamma h_i$ (explicit representatives for $\Gamma=\Gamma_0(p)$ and $T_g=T(l,k)$ are given in [**AGG84, vGvdKTV97**]). The modular symbols $[h_iQ_x]$ are no longer unimodular in general, but we can apply Theorem A.22 to write

$$[h_iQ_x]=\sum_j[R_{ij}],\quad R_{ij}\in\mathrm{SL}_3(\mathbb{Z}).$$

Then for $f\colon\mathbb{P}^2(\mathbb{F}_p)\to\mathbb{C}$ as in Theorem A.16, we have

$$(T_gf)(x)=\sum_{i,j}f(\overline{R_{ij}}),$$

where $\overline{R_{ij}}$ is the class of R_{ij} in $\mathbb{P}^2(\mathbb{F}_p)$.

Now let $\xi\in H^3_{\mathrm{cusp}}(\Gamma;\mathbb{C})$ be a simultaneous eigenclass for all the Hecke operators $T(l,1)$, $T(l,2)$, as l ranges over all primes coprime with p. General considerations from the theory of automorphic forms imply that the eigenvalues $a(l,1)$, $a(l,2)$ are complex conjugates of one other. Hence it suffices to compute $a(l,1)$. We give two examples of cuspidal eigenclasses for two different prime levels.

Example A.23. Let $p=53$. Then $H^3_{\mathrm{cusp}}(\Gamma_0(53);\mathbb{C})$ is 2-dimensional. Let $\eta=(1+\sqrt{-11})/2$. One eigenclass is given by the data

l	2	3	5	7	11	13
$a(l,1)$	$-1-2\eta$	$-2+2\eta$	1	-3	1	$-2-12\eta$

and the other is obtained by complex conjugation.

Example A.24. Let $p=61$. Then $H^3_{\mathrm{cusp}}(\Gamma_0(61);\mathbb{C})$ is 2-dimensional. Let $\omega=(1+\sqrt{-3})/2$. One eigenclass is given by the data

l	2	3	5	7	11	13
$a(l,1)$	$1-2\omega$	$-5+4\omega$	$-2+4\omega$	-6ω	$-2+2\omega$	$-2-4\omega$

and the other is obtained by complex conjugation.

A.5. Other Cohomology Groups

A.5.1. In Section A.4 we saw how to compute the Hecke action on the top cohomology group $H^\nu(\Gamma;\mathbb{C})$. Unfortunately for $n\geq 4$, this cohomology group does not contain any cuspidal cohomology. The first case is $\Gamma\subset\mathrm{SL}_4(\mathbb{Z})$; we have $\mathrm{vcd}(\Gamma)=6$, and the cusp cohomology lives in degrees 4 and 5. One can show that the cusp cohomology in degree 4 is dual to that in degree 5, so for computational purposes it suffices to be able to compute the Hecke action on $H^5(\Gamma;\mathbb{C})$. But modular symbols do not help us here.

In this section we describe a technique to compute the Hecke action on $H^{\nu-1}(\Gamma;\mathbb{C})$, following [**Gun00a**]. The technique is an extension of the modular symbol algorithm to these cohomology groups. In principle the ideas in this section can be modified to compute the Hecke action on other cohomology groups $H^{\nu-k}(\Gamma;\mathbb{C})$, $k>1$, although this has not been investigated[9]. For $n=4$, we have applied the algorithm in joint work with Ash and McConnell to investigate computationally the cohomology $H^5(\Gamma;\mathbb{C})$, where $\Gamma_0(N)\subset \mathrm{SL}_4(\mathbb{Z})$ [**AGM02**].

A.5.2. To begin, we need an analogue of Theorem A.21 for lower degree cohomology groups. In other words, we need a generalization of the modular symbols for other cohomology groups. This is achieved by the *sharbly complex* S_*:

Definition A.25 ([**Ash94**])**.** Let $\{S_*,\partial\}$ be the chain complex given by the following data:

(1) For $k\geq 0$, S_k is the $\mathbb{Q}$-vector space generated by the symbols $\mathbf{u}=[v_1,\dots,v_{n+k}]$, where $v_i\in\mathbb{Q}^n\smallsetminus\{0\}$, modulo the relations:
   (a) If τ is a permutation on $(n+k)$ letters, then

$$[v_1,\dots,v_{n+k}]=\operatorname{sign}(\tau)[\tau(v_1),\dots,\tau(v_{n+k})],$$

   where $\operatorname{sign}(\tau)$ is the sign of τ.
   (b) If $q\in\mathbb{Q}^\times$, then

$$[qv_1,v_2\dots,v_{n+k}]=[v_1,\dots,v_{n+k}].$$

   (c) If the rank of the matrix $(v_1,\dots,v_{n+k})$ is less than n, then $\mathbf{u}=0$.

(2) For $k>0$, the boundary map $\partial\colon S_k\to S_{k-1}$ is

$$[v_1,\dots,v_{n+k}]\longmapsto\sum_{i=1}^{n+k}(-1)^i[v_1,\dots,\hat{v}_i,\dots,v_{n+k}].$$

We define ∂ to be identically zero on S_0.

The elements

$$\mathbf{u}=[v_1,\dots,v_{n+k}]$$

[9] The first interesting case is $n=5$, for which the cuspidal cohomology lives in $H^{\nu-2}$.

are called *k-sharblies*[10]. The 0-sharblies are exactly the modular symbols from Definition A.20, and the subspace $B \subset S_0$ is the image of the boundary map $\partial\colon S_1 \to S_0$.

There is an obvious left action of Γ on S_* commuting with ∂. For any $k \geq 0$, let $S_{k,\Gamma}$ be the space of Γ-coinvariants. Since the boundary map ∂ commutes with the Γ-action, we obtain a complex $(S_{*,\Gamma}, \partial_\Gamma)$. The following theorem shows that this complex computes the cohomology of Γ:

Theorem A.26 ([**Ash94**])**.** *There is a natural isomorphism*

$$H^{\nu-k}(\Gamma; \mathbb{C}) \xrightarrow{\sim} H_k(S_{*,\Gamma} \otimes \mathbb{C}).$$

A.5.3. We can extend our norm function $\|\ \|$ from modular symbols to all of S_k as follows. Let $\mathbf{u} = [v_1, \ldots, v_{n+k}]$ be a k-sharbly, and let $Z(\mathbf{u})$ be the set of all submodular symbols determined by $\mathbf{u}$. In other words, $Z(\mathbf{u})$ consists of the modular symbols of the form $[v_{i_1}, \ldots, v_{i_n}]$, where $\{i_1, \ldots, i_n\}$ ranges over all n-fold subsets of $\{1, \ldots, n+k\}$. Define $\|\mathbf{u}\|$ by

$$\|\mathbf{u}\| = \operatorname*{Max}_{\mathbf{v} \in Z(\mathbf{u})} \|\mathbf{v}\|.$$

Note that $\|\mathbf{u}\|$ is well defined modulo the relations in Definition A.25. As for modular symbols, we extend the norm to sharbly chains $\xi = \sum q(\mathbf{u})\mathbf{u}$ taking the maximum norm over the support. Formally, we let $\operatorname{supp}(\xi) = \{\mathbf{u} \mid q(\mathbf{u}) \neq 0\}$ and $Z(\xi) = \bigcup_{\mathbf{u} \in \operatorname{supp}(\xi)} Z(\mathbf{u})$, and then we define $\|\xi\|$ by

$$\|\xi\| = \operatorname*{Max}_{\mathbf{v} \in Z(\xi)} \|\mathbf{v}\|.$$

We say that ξ is *reduced* if $\|\xi\| = 1$. Hence ξ is reduced if and only if all its submodular symbols are unimodular or have determinant 0. Clearly there are only finitely many reduced k-sharblies modulo Γ for any k.

In general the cohomology groups $H^*(\Gamma; \mathbb{C})$ are *not* spanned by reduced sharblies. However, it is known (cf. [**McC91**]) that for $\Gamma \subset \mathrm{SL}_4(\mathbb{Z})$, the group $H^5(\Gamma; \mathbb{C})$ is spanned by reduced 1-sharbly cycles. The best one can say in general is that for each pair n, k, there is an integer $N = N(n,k)$ such that for $\Gamma \subset \mathrm{SL}_n(\mathbb{Z})$, $H^{\nu-k}(\Gamma; \mathbb{C})$ is spanned by k-sharblies of norm $\leq N$. This set of sharblies is also finite modulo Γ, although it is not known how large N must be for any given pair n, k.

A.5.4. Recall that the cells of the well-rounded retract W are indexed by sets of primitive vectors in $\mathbb{Z}^n$. Since any primitive vector determines a point in $\mathbb{Q}^n \smallsetminus \{0\}$ and since sets of such points index sharblies, it is clear that there is a close relationship between S_* and the chain complex associated to W,

[10] The terminology for S_* is due to Lee Rudolph, in honor of Lee and Szczarba. They introduced a very similar complex in [**LS76**] for $\mathrm{SL}_3(\mathbb{Z})$.

although of course S_* is much bigger. In any case, both complexes compute $H^*(\Gamma;\mathbb{C})$.

The main benefit of using the sharbly complex to compute cohomology is that it admits a Hecke action. Suppose $\xi = \sum q(\mathbf{u})\mathbf{u}$ is a sharbly cycle mod Γ, and consider a Hecke operator T_g. Then we have

$$T_g(\xi) = \sum_{h\in\Omega,\mathbf{u}} n(\mathbf{u})h\cdot\mathbf{u}, \tag{A.5.1}$$

where Ω is a set of coset representatives as in (A.4.3). Since $\Omega \not\subset \mathrm{SL}_n(\mathbb{Z})$ in general, the Hecke image of a reduced sharbly is not usually reduced.

A.5.5. We are now ready to describe our algorithm for the computation of the Hecke operators on $H^{\nu-1}(\Gamma;\mathbb{C})$. It suffices to describe an algorithm that takes as input a 1-sharbly cycle ξ and produces as output a cycle ξ' with

(a) the classes of ξ and ξ' in $H^{\nu-1}(\Gamma;\mathbb{C})$ the same, and

(b) $\|\xi'\| < \|\xi\|$ if $\|\xi\| > 1$.

Below, we will present an algorithm satisfying (a). In [**Gun00a**], we conjectured (and presented evidence) that the algorithm satisfies (b) for $n \le 4$. Further evidence is provided by the computations in [**AGM02**], which relied on the algorithm to compute the Hecke action on $H^5(\Gamma;\mathbb{C})$, where $\Gamma = \Gamma_0(N) \subset \mathrm{SL}_4(\mathbb{Z})$.

The idea behind the algorithm is simple: given a 1-sharbly cycle ξ that is not reduced, (i) simultaneously apply the modular symbol algorithm (Theorem A.22) to each of its submodular symbols, and then (ii) package the resulting data into a new 1-sharbly cycle. Our experience in presenting this algorithm is that most people find the geometry involved in (ii) daunting. Hence we will give details only for $n = 2$ and will provide a sketch for $n > 2$. Full details are contained in [**Gun00a**]. Note that $n = 2$ is topologically and arithmetically uninteresting, since we are computing the Hecke action on $H^0(\Gamma;\mathbb{C})$; nevertheless, the geometry faithfully represents the situation for all n.

A.5.6. Fix $n = 2$, let $\xi \in S_1$ be a 1-sharbly cycle mod Γ for some $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$, and suppose ξ is not reduced. Assume Γ is torsion-free to simplify the presentation.

Suppose first that all submodular symbols $\mathbf{v} \in Z(\xi)$ are nonunimodular. Select reducing points for each $\mathbf{v} \in Z(\xi)$ and make these choices Γ-equivariantly. This means the following. Suppose $\mathbf{u}, \mathbf{u}' \in \operatorname{supp}\xi$ and $\mathbf{v} \in \operatorname{supp}(\partial\mathbf{u})$ and $\mathbf{v}' \in \operatorname{supp}(\partial\mathbf{u}')$ are modular symbols such that $\mathbf{v} = \gamma\cdot\mathbf{v}'$ for some $\gamma \in \Gamma$. Then we select reducing points w for $\mathbf{v}$ and w' for $\mathbf{v}'$ such that $w = \gamma \cdot w'$. (Note that since Γ is torsion-free, no modular symbol can be identified to itself by an element of Γ; hence $\mathbf{v} \neq \mathbf{v}'$.) This is possible since if $\mathbf{v}$ is a modular symbol and w is a reducing point for $\mathbf{v}$, then $\gamma \cdot w$ is a reducing point for $\gamma \cdot \mathbf{v}$ for any $\gamma \in \Gamma$. Because there are only finitely many Γ-orbits in $Z(\xi)$, we can choose reducing points Γ-equivariantly by selecting them for some set of orbit representatives.

It is important to note that Γ-equivariance is the only global criterion we use when selecting reducing. In particular, there is a priori no relationship among the three reducing points chosen for any $\mathbf{u} \in \operatorname{supp} \xi$.

A.5.7. Now we want to use the reducing points and the 1-sharblies in ξ to build ξ'. Choose $\mathbf{u} = [v_1, v_2, v_3] \in \operatorname{supp} \xi$, and denote the reducing point for $[v_i, v_j]$ by w_k, where $\{i, j, k\} = \{1, 2, 3\}$. We use the v_i and the w_i to build a 2-sharbly chain $\eta(\mathbf{u})$ as follows.

Let P be an octahedron in $\mathbb{R}^3$. Label the vertices of P with the v_i and w_i such that the vertex labeled v_i is opposite the vertex labeled w_i (Figure A.5.1). Subdivide P into four tetrahedra by connecting two opposite vertices, say v_1 and w_1, with an edge (Figure A.5.2). For each tetrahedron T, take the labels of four vertices and arrange them into a quadruple. If we orient P, then we can use the induced orientation on T to order the four primitive points. In this way, each T determines a 2-sharbly, and $\eta(\mathbf{u})$ is defined to be the sum. For example, if we use the decomposition in Figure A.5.2, we have

(A.5.2)
$$\eta(\mathbf{u}) = [v_1, v_3, v_2, w_1] + [v_1, w_2, v_3, w_1] + [v_1, w_3, w_2, w_1] + [v_1, v_2, w_3, w_1].$$

Repeat this construction for all $\mathbf{u} \in \operatorname{supp} \xi$, and let $\eta = \sum q(\mathbf{u})\eta(\mathbf{u})$. Finally, let $\xi' = \xi + \partial\eta$.

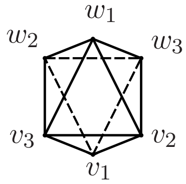

Figure A.5.1.

A.5.8. By construction, ξ' is a cycle mod Γ in the same class as ξ. We claim in addition that no submodular symbol from ξ appears in ξ'. To see this, consider $\partial\eta(\mathbf{u})$. From (A.5.2), we have

$$\begin{aligned}(\text{A.5.3}) \quad \partial\eta(\mathbf{u}) = &-[v_1, v_2, v_3] + [v_1, v_2, w_3] + [v_1, w_2, v_3] + [w_1, v_2, v_3] \\ &- [v_1, w_2, w_3] - [w_1, v_2, w_3] - [w_1, w_2, v_3] + [w_1, w_2, w_3].\end{aligned}$$

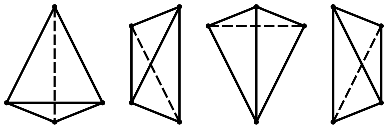

Figure A.5.2.

Note that this is the boundary in S_*, not in $S_{*,\Gamma}$. Furthermore, $\partial\eta(\mathbf{u})$ is independent of which pair of opposite vertices of P we connected to build $\eta(\mathbf{u})$.

From (A.5.3), we see that in $\xi + \partial\eta$ the 1-sharbly $-[v_1, v_2, v_3]$ is canceled by $\mathbf{u} \in \operatorname{supp}\xi$. We also claim that 1-sharblies in (A.5.3) of the form $[v_i, v_j, w_k]$ vanish in $\partial_\Gamma\eta$.

To see this, let $\mathbf{u}$,$\mathbf{u}' \in \operatorname{supp}\xi$, and suppose $\mathbf{v} = [v_1, v_2] \in \operatorname{supp}\partial\mathbf{u}$ equals $\gamma \cdot \mathbf{v}'$ for some $\mathbf{v}' = [v_1', v_2'] \in \operatorname{supp}\partial\mathbf{u}'$. Since the reducing points were chosen Γ-equivariantly, we have $w = \gamma \cdot w'$. This means that the 1-sharbly $[v_1, v_2, w] \in \partial\eta(\mathbf{u})$ will be canceled mod Γ by $[v_1', v_2', w'] \in \partial\eta(\mathbf{u}')$. Hence, in passing from ξ to ξ', the effect in $(S_*)_\Gamma$ is to replace $\mathbf{u}$ with *four* 1-sharblies in $\operatorname{supp}\xi'$:

$$[v_1, v_2, v_3] \longmapsto -[v_1, w_2, w_3] - [w_1, v_2, w_3] - [w_1, w_2, v_3] + [w_1, w_2, w_3]. \tag{A.5.4}$$

Note that in (A.5.4), there are no 1-sharblies of the form $[v_i, v_j, w_k]$.

Remark A.27. For implementation purposes, it is not necessary to explicitly construct η. Rather, one may work directly with (A.5.4).

A.5.9. Why do we expect ξ' to satisfy $\|\xi'\| < \|\xi\|$? First of all, in the right hand side of (A.5.4) there are no submodular symbols of the form $[v_i, v_j]$. In fact, any submodular symbol involving a point v_i also includes a reducing point for $[v_i, v_j]$.

On the other hand, consider the submodular symbols in (A.5.4) of the form $[w_i, w_j]$. Since there is no relationship among the w_i, one has no reason to believe that these modular symbols are closer to unimodularity than those in $\mathbf{u}$. Indeed, for certain choices of reducing points it can happen that $\|[w_i, w_j]\| \geq \|\mathbf{u}\|$.

The upshot is that some care must be taken in choosing reducing points. In [**Gun00a**, Conjectures 3.5 and 3.6] we describe two methods for finding reducing points for modular symbols, one using Voronoĭ reduction and one using LLL-reduction. Our experience is that if one selects reducing points using either of these conjectures, then $\|[w_i, w_j]\| < \|\mathbf{u}\|$ for each of the new modular symbols $[w_i, w_j]$. In fact, in practice these symbols are trivial or satisfy $\|[w_i, w_j]\| = 1$.

A.5.10. In the previous discussion we assumed that no submodular symbols of any $\mathbf{u} \in \operatorname{supp} \xi$ were unimodular. Now we say what to do if some are. There are three cases to consider.

First, all submodular symbols of $\mathbf{u}$ may be unimodular. In this case there are no reducing points, and (A.5.4) becomes

$$[v_1, v_2, v_3] \longmapsto [v_1, v_2, v_3]. \tag{A.5.5}$$

Second, one submodular symbol of $\mathbf{u}$ may be nonunimodular, say the symbol $[v_1, v_2]$. In this case, to build η, we use a tetrahedron P' and put $\eta(\mathbf{u}) = [v_1, v_2, v_3, w_3]$ (Figure A.5.3). Since $[v_1, v_2, w_3]$ vanishes in the boundary of η mod Γ, (A.5.4) becomes

$$[v_1, v_2, v_3] \mapsto -[v_1, v_3, w_3] + [v_2, v_3, w_3]. \tag{A.5.6}$$

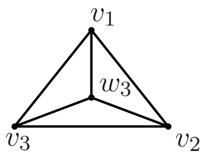

Figure A.5.3.

Finally, two submodular symbols of $\mathbf{u}$ may be nonunimodular, say $[v_1, v_2]$ and $[v_1, v_3]$. In this case we use the cone on a square P'' (Figure A.5.4). To construct $\eta(\mathbf{u})$, we must choose a decomposition of P'' into tetrahedra. Since P'' has a nonsimplicial face, this choice affects ξ' (in contrast to the previous cases). If we subdivide P'' by connecting the vertex labelled v_2 with the vertex labelled w_2, we obtain

$$[v_1, v_2, v_3] \longmapsto [v_2, w_2, w_3] + [v_2, v_3, w_2] + [v_1, v_3, w_2]. \tag{A.5.7}$$

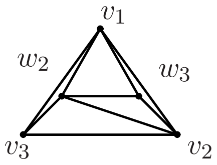

Figure A.5.4.

A.5.11. Now consider general n. The basic technique is the same, but the combinatorics become more complicated. Suppose $\mathbf{u} = [v_1, \ldots, v_{n+1}]$ satisfies $q(\mathbf{u}) \neq 0$ in a 1-sharbly cycle ξ, and for $i = 1, \ldots, n+1$ let $\mathbf{v}_i$ be the submodular symbol $[v_1, \ldots, \widehat{v_i}, \ldots, v_{n+1}]$. Assume that all $\mathbf{v}_i$ are nonunimodular, and for each i let w_i be a reducing point for $\mathbf{v}_i$.

For any subset $I \subset \{1, \dots, n+1\}$, let $\mathbf{u}_I$ be the 1-sharbly $[u_1, \dots, u_{n+1}]$, where $u_i = w_i$ if $i \in I$, and $u_i = v_i$ otherwise. The polytope P used to build $\eta(\mathbf{u})$ is the *cross polytope*, which is the higher-dimensional analogue of the octahedron [**Gun00a**, §4.4]. We suppress the details and give the final answer: (A.5.4) becomes

$$\mathbf{u} \longmapsto -\sum_I (-1)^{\#I} \mathbf{u}_I, \tag{A.5.8}$$

where the sum is taken over all subsets $I \subset \{1, \dots, n+1\}$ of cardinality *at least* 2.

More generally, if some $\mathbf{v}_i$ happen to be unimodular, then the polytope used to build η is an iterated cone on a lower-dimensional cross polytope. This is already visible for $n = 2$:

- The 2-dimensional cross polytope is a square, and the polytope P'' is a cone on a square.
- The 1-dimensional cross polytope is an interval, and the polytope P' is a double cone on an interval.

Altogether there are $n+1$ relations generalizing (A.5.5)–(A.5.7).

A.5.12. Now we describe how these computations are carried out in practice, focusing on $\Gamma = \Gamma_0(N) \subset \mathrm{SL}_4(\mathbb{Z})$ and $H^5(\Gamma; \mathbb{C})$. Besides discussing technical details, we also have to slightly modify some aspects of the construction in Section A.5.6, since Γ is not torsion-free.

Let W be the well-rounded retract. We can represent a cohomology class $\beta \in H^5(\Gamma; \mathbb{C})$ as $\beta = \sum q(\sigma)\sigma$, where σ denotes a codimension 1 cell in W. In this case there are three types of codimension 1 cells in W. Under the bijection $W \leftrightarrow \mathscr{C}$, these cells correspond to the Voronoĭ cells indexed by the columns of the matrices

(A.5.9)
$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{pmatrix}.$$

Thus each σ in W modulo Γ corresponds to an $\mathrm{SL}_4(\mathbb{Z})$-translate of one of the matrices in (A.5.9). These translates determine basis 1-sharblies $\mathbf{u}$ (by taking the points u_i to be the columns), and hence we can represent β by a 1-sharbly chain $\xi = \sum q(\mathbf{u})\mathbf{u} \in S_1$ that is a cycle in the complex of coinvariants $(S_{*,\Gamma}, \partial_\Gamma)$.

To make later computations more efficient, we precompute more data attached to ξ. Given a 1-sharbly $\mathbf{u} = [u_1, \dots, u_{n+1}]$, a *lift* $M(\mathbf{u})$ of $\mathbf{u}$ is defined to be an integral matrix with primitive columns M_i such that $\mathbf{u} =$

$[M_1, \dots, M_{n+1}]$. Then we encode ξ, once and for all, by a finite collection Φ of 4-tuples

$$(\mathbf{u}, n(\mathbf{u}), \{\mathbf{v}\}, \{M(\mathbf{v})\}),$$

where

(1) $\mathbf{u}$ ranges over the support of ξ,

(2) $n(\mathbf{u}) \in \mathbb{C}$ is the coefficient of $\mathbf{u}$ in ξ,

(3) $\{\mathbf{v}\}$ is the set of submodular symbols appearing in the boundary of $\mathbf{u}$, and

(4) $\{M(\mathbf{v})\}$ is a set of lifts for $\{\mathbf{v}\}$.

Moreover, the lifts in (4) are chosen to satisfy the following Γ-equivariance condition. Suppose that for $\mathbf{u}, \mathbf{u}' \in \operatorname{supp} \xi$ we have $\mathbf{v} \in \operatorname{supp}(\partial \mathbf{u})$ and $\mathbf{v}' \in \operatorname{supp}(\partial \mathbf{u}')$ satisfying $\mathbf{v} = \gamma \cdot \mathbf{v}'$ for some $\gamma \in \Gamma$. Then we require $M(\mathbf{v}) = \gamma M(\mathbf{v}')$. This is possible since ξ is a cycle modulo Γ, although there is one complication since Γ has torsion: it can happen that some submodular symbol $\mathbf{v}$ of a 1-sharbly $\mathbf{u}$ is identified to *itself* by an element of Γ. This means that in constructing $\{M(\mathbf{v})\}$ for $\mathbf{u}$, we must somehow choose more than one lift for $\mathbf{v}$. To deal with this, let $M(\mathbf{v})$ be any lift of $\mathbf{v}$, and let $\Gamma(\mathbf{v}) \subset \Gamma$ be the stabilizer of $\mathbf{v}$. Then in ξ, we replace $q(\mathbf{u})\mathbf{u}$ by

$$\frac{1}{\#\Gamma(\mathbf{v})} \sum_{\gamma \in \Gamma(\mathbf{v})} q(\mathbf{u}) \mathbf{u}_\gamma,$$

where $\mathbf{u}_\gamma$ has the same data as $\mathbf{u}$, except[11] that we give $\mathbf{v}$ the lift $\gamma M(\mathbf{v})$.

Next we compute and store the 1-sharbly transformation laws generalizing (A.5.5)–(A.5.7). As a part of this we fix triangulations of certain cross polytopes as in (A.5.7).

We are now ready to begin the actual reduction algorithm. We take a Hecke operator $T(l, k)$ and build the coset representatives Ω as in (A.5.1). For each $h \in \Omega$ and each 1-sharbly $\mathbf{u}$ in the support of ξ, we obtain a nonreduced 1-sharbly $\mathbf{u}_h := h \cdot \mathbf{u}$. Here h acts on all the data attached to $\mathbf{u}$ in the list Φ. In particular, we replace each lift $M(\mathbf{v})$ with $h \cdot M(\mathbf{v})$, where the dot means matrix multiplication.

Now we check the submodular symbols of $\mathbf{u}_h$ and choose reducing points for the nonunimodular symbols. This is where the lifts come in handy. Recall that reduction points must be chosen Γ-equivariantly over the entire cycle. Instead of explicitly keeping track of the identifications between modular symbols, we do the following trick:

[11] In fact, we can be slightly more clever than this and only introduce denominators that are powers of 2.

(1) Construct the *Hermite normal form* $M_{\mathrm{her}}(\mathbf{v})$ of the lift $M(\mathbf{v})$ (see [**Coh93**, §2.4] and Exercise 7.5). Record the transformation matrix $U \in \mathrm{GL}_4(\mathbb{Z})$ such that $UM(\mathbf{v}) = M_{\mathrm{her}}(\mathbf{v})$.

(2) Choose a reducing point u for $M_{\mathrm{her}}(\mathbf{v})$.

(3) Then the reducing point for $M(\mathbf{v})$ is $U^{-1}u$.

This guarantees Γ-equivariance: if $\mathbf{v}$, $\mathbf{v}'$ are submodular symbols of ξ with $\gamma\cdot\mathbf{v} = \mathbf{v}'$ and with reducing points u, u', we have $\gamma u = u'$. The reason is that the Hermite normal form $M_{\mathrm{her}}(\mathbf{v})$ is a *uniquely determined* representative of the $\mathrm{GL}_4(\mathbb{Z})$-orbit of $M(\mathbf{v})$ [**Coh93**]. Hence if $\gamma M(\mathbf{v}) = M(\mathbf{v}')$, then $M_{\mathrm{her}}(\mathbf{v}) = M_{\mathrm{her}}(\mathbf{v}')$.

After computing all reducing points, we apply the appropriate transformation law. The result will be a chain of 1-sharblies, each of which has (conjecturally) smaller norm than the original 1-sharbly $\mathbf{u}$. We output these 1-sharblies if they are reduced; otherwise they are fed into the reduction algorithm again. Eventually we obtain a reduced 1-sharbly cycle ξ' homologous to the original cycle ξ.

The final step of the algorithm is to rewrite ξ' as a cocycle on W. This is easy to do since the relevant cells of W are in bijection with the reduced 1-sharblies. There are some nuisances in keeping orientations straight, but the computation is not difficult. We refer to [**AGM02**] for details.

A.5.13. We now give some examples, taken from [**AGM02**], of Hecke eigenclasses in $H^5(\Gamma_0(N);\mathbb{C})$ for various levels N. Instead of giving a table of eigenvalues, we give the *Hecke polynomials*. If β is an eigenclass with $T(l,k)(\beta) = a(l,k)\beta$, then we define

$$H(\beta, l) = \sum_k (-1)^k l^{k(k-1)/2} a(l,k) X^k \in \mathbb{C}[X].$$

For almost all l, after putting $X = l^{-s}$ where s is a complex variable, the function $H(\beta, s)$ is the inverse of the local factor at l of the automorphic representation attached to β.

Example A.28. Suppose $N = 11$. Then the cohomology $H^5(\Gamma_0(11);\mathbb{C})$ is 2-dimensional. There are two Hecke eigenclasses u_1, u_2, each with rational Hecke eigenvalues.

u_1	T_2	$(1-4X)(1-8X)(1+2X+2X^2)$
	T_3	$(1-9X)(1-27X)(1+X+3X^2)$
	T_5	$(1-25X)(1-125X)(1-X+5X^2)$
	T_7	$(1-49X)(1-343X)(1+2X+7X^2)$
u_2	T_2	$(1-X)(1-2X)(1+8X+32X^2)$
	T_3	$(1-X)(1-3X)(1+9X+243X^2)$
	T_5	$(1-X)(1-5X)(1-25X+3125X^2)$
	T_7	$(1-X)(1-7X)(1+98X+16807X^2)$

Example A.29. Suppose $N = 19$. Then the cohomology $H^5(\Gamma_0(19);\mathbb{C})$ is 3-dimensional. There are three Hecke eigenclasses u_1, u_2, u_3, each with rational Hecke eigenvalues.

u_1	T_2	$(1-4X)(1-8X)(1+2X^2)$
	T_3	$(1-9X)(1-27X)(1+2X+3X^2)$
	T_5	$(1-25X)(1-125X)(1-3X+5X^2)$
u_2	T_2	$(1-X)(1-2X)(1+32X^2)$
	T_3	$(1-X)(1-3X)(1+18X+243X^2)$
	T_5	$(1-X)(1-5X)(1-75X+3125X^2)$
u_3	T_2	$(1-2X)(1-4X)(1+3X+8X^2)$
	T_3	$(1-3X)(1-9X)(1+5X+27X^2)$
	T_5	$(1-5X)(1-25X)(1+12X+125X^2)$

In these examples, the cohomology is completely accounted for by the Eisenstein summand of (A.2.8). In fact, let $\Gamma_0'(N) \subset \mathrm{SL}_2(\mathbb{Z})$ be the usual Hecke congruence subgroup of matrices upper-triangular modulo N. Then the cohomology classes above actually come from classes in $H^1(\Gamma_0'(N))$, that is from holomorphic modular forms of level N.

For $N = 11$, the space of weight two cusp forms $S_2(11)$ is 1-dimensional. This cusp form f lifts in two different ways to $H^5(\Gamma_0(11);\mathbb{C})$, which can be seen from the quadratic part of the Hecke polynomials for the u_i. Indeed, for u_i the quadratic part is exactly the inverse of the local factor for the L-function attached to f, after the substitution $X = l^{-s}$. For u_2, we see that the lift is also twisted by the square of the cyclotomic character. (In fact the linear terms of the Hecke polynomials come from powers of the cyclotomic character.)

For $N = 19$, the space of weight two cusp forms $S_2(19)$ is again 1-dimensional. The classes u_1 and u_2 are lifts of this form, exactly as for $N = 11$. The class u_3, on the other hand, comes from $S_4(19)$, the space of weight 4 cusp forms on $\Gamma_0'(19)$. In fact, $\dim S_4(19) = 4$, with one Hecke eigenform defined over $\mathbb{Q}$ and another defined over a totally real cubic extension of $\mathbb{Q}$. Only the rational weight four eigenform contributes to $H^5(\Gamma_0(19);\mathbb{C})$. One can show that whether or not a weight four cuspidal eigenform f contributes to the cohomology of $\Gamma_0(N)$ depends only on the sign of the functional equation of $L(f, s)$ [**Wes**]. This phenomenon is typical of what one encounters when studying Eisenstein cohomology.

In addition to the lifts of weight 2 and weight 4 cusp forms, for other levels one finds lifts of Eisenstein series of weights 2 and 4 and lifts of cuspidal cohomology classes from subgroups of $\mathrm{SL}_3(\mathbb{Z})$. For some levels one finds cuspidal classes that appear to be lifts from the group of symplectic similitudes GSp(4). More details can be found in [**AGM02, AGM**].

A.5.14. Here are some notes on the reduction algorithm and its implementation:

- Some additional care must be taken when selecting reducing points for the submodular symbols of $\mathbf{u}$. In particular, in practice one should choose w for $\mathbf{v}$ such that $\sum \|\mathbf{v}_i(w)\|$ is minimized. Similar remarks apply when choosing a subdivision of the crosspolytopes in Section A.5.10.
- In practice, the reduction algorithm has *always* terminated with a reduced 1-sharbly cycle ξ' homologous to ξ. However, at the moment we cannot prove that this will always happen.
- Experimentally, the efficiency of the reduction step appears to be comparable to that of Theorem A.22. In other words the depth of the "reduction tree" associated to a given 1-sharbly $\mathbf{u}$ seems to be bounded by a polynomial in $\log\log \|\mathbf{u}\|$. Hence computing the Hecke action using this algorithm is extremely efficient.

  On the other hand, computing Hecke operators on SL_4 is still a much bigger computation—relative to the level—than on SL_2 and SL_3. For example, the size of the full retract W modulo $\Gamma_0(p)$ is roughly $O(p^6)$, which grows rapidly with p. The portion of the retract corresponding to H^5 is much smaller, around $p^3/10$, but this still grows quite quickly. This makes computing with $p > 100$ out of reach at the moment.

  The number of Hecke cosets grows rapidly as well, e.g., the number of coset representatives of $T(l, 2)$ is $l^4 + l^3 + 2l^2 + l + 1$. Hence it is only feasible to compute Hecke operators for small l; for large levels only $l = 2$ is possible.

  Here are some numbers to give an idea of the size of these computations. For level 73, the rank of H^5 is 20. There are 39504 cells of codimension 1 and 4128 top-dimensional cells in W modulo $\Gamma_0(73)$. The computational techniques in [**AGM02**] used at this level (a Lanczos scheme over a large finite field) tend to produce sharbly cycles supported on almost all the cells. Computing $T(2, 1)$

requires a reduction tree of depth 1 and produces as many as 26 reduced 1-sharblies for each of the 15 nonreduced Hecke images. Thus one cycle produces a cycle supported on as many as 15406560 1-sharblies, all of which must be converted to an appropriate cell of W modulo Γ. Also this is just what needs to be done for *one* cycle; do not forget that the rank of H^5 is 20.

In practice the numbers are slightly better, since the reduction step produces fewer 1-sharblies on average and since the support of the initial cycle has size less than 39504. Nevertheless the orders of magnitude are correct.

- Using lifts is a convenient way to encode the global Γ-identifications in the cycle ξ, since it means we do not have to maintain a big data structure keeping track of the identifications on $\partial\xi$. However, there is a certain expense in computing the Hermite normal form. This is balanced by the benefit that working with the data Φ associated to ξ allows us to reduce the supporting 1-sharblies $\mathbf{u}$ *independently.* This means we can cheaply parallelize our computation: each 1-sharbly, encoded as a 4-tuple $(\mathbf{u}, n(\mathbf{u}), \{\mathbf{v}\}, \{M(\mathbf{v})\})$, can be handled by a separate computer. The results of all these individual computations can then be collated at the end, when producing a W-cocycle.

A.6. Complements and Open Problems

A.6.1. We conclude this appendix by giving some complements and describing some possible directions for future work, both theoretical and computational. Since a full explanation of the material in this section would involve many more pages, we will be brief and will provide many references.

A.6.2. Perfect Quadratic Forms over Number Fields and Retracts. Since Voronoĭ's pioneering work [**Vor08**], it has been the goal of many to extend his results from $\mathbb{Q}$ to a general algebraic number field F. Recently Coulangeon [**Cou01**], building on work of Icaza and Baeza [**Ica97, BI97**], has found a good notion of *perfection* for quadratic forms over number fields[12]. One of the key ideas in [**Cou01**] is that the correct notion of equivalence between Humbert forms involves not only the action of $\mathrm{GL}_n(\mathscr{O}_F)$, where $\mathscr{O}_F$ is the ring of integers of F, but also the action of a certain continuous group U related to the units $\mathscr{O}_F^\times$. One of Coulangeon's basic results is that there are finitely many equivalence classes of perfect Humbert forms modulo these actions.

[12] Such forms are called *Humbert forms* in the literature.

On the other hand, Ash's original construction of retracts [**Ash77**] introduces a geometric notion of perfection. Namely he generalizes the Voronoĭ polyhedron Π and defines a quadratic form to be perfect if it naturally indexes a facet of Π. What is the connection between these two notions? Can one use Coulangeon's results to construct cell complexes to be used in cohomology computations? One tempting possibility is to try to use the group U to collapse the Voronoĭ cells of [**Ash77**] into a cell decomposition of the symmetric space associated to $\mathrm{SL}_n(F)$.

A.6.3. The Modular Complex. In his study of multiple ζ-values, Goncharov has recently defined the *modular complex* M^* [**Gon97, Gon98**]. This is an n-step complex of $\mathrm{GL}_n(\mathbb{Z})$-modules closely related both to the properties of multiple polylogarithms evaluated at μ_N, the Nth roots of unity, and to the action of $G_{\mathbb{Q}}$ on $\pi_{1,N} = \pi_1^l(\mathbb{P}^1 \smallsetminus \{0, \infty, \mu_N\})$, the pro-$l$ completion of the algebraic fundamental group of $\mathbb{P}^1 \smallsetminus \{0, \infty, \mu_N\}$.

Remarkably, the modular complex is very closely related to the Voronoĭ decomposition $\mathscr{V}$. In fact, one can succinctly describe the modular complex by saying that it is the chain complex of the cells coming from the top-dimensional Voronoĭ cone of type A_n. This is all of the Voronoĭ decomposition for $n = 2, 3$, and Goncharov showed that the modular complex is quasi-isomorphic to the full Voronoĭ complex for $n = 4$. Hence there is a precise relationship among multiple polylogarithms, the Galois action on $\pi_{1,N}$, and the cohomology of level N congruence subgroups of $\mathrm{SL}_n(\mathbb{Z})$.

The question then arises, how much of the cohomology of congruence subgroups is captured by the modular complex for all n? Table A.3.2 indicates that asymptotically very little of the Voronoĭ decomposition comes from the A_n cone, but this says nothing about the cohomology. The first interesting case to consider is $n = 5$.

A.6.4. Retracts for Other Groups. The most general construction of retracts W known [**Ash84**] applies only to *linear* symmetric spaces. The most familiar example of such a space is $\mathrm{SL}_n(\mathbb{R})/\mathrm{SO}(n)$; other examples are the symmetric spaces associated to SL_n over number fields and division algebras.

Now let $\Gamma \subset \mathbf{G}(\mathbb{Q})$ be an arithmetic group, and let $X = G/K$ be the associated symmetric space. What can one say about cell complexes that can be used to compute $H^*(\Gamma; \mathscr{M})$? The theorem of Borel–Serre mentioned in Section A.3.3 implies the vanishing of $H^k(\Gamma; \mathscr{M})$ for $k > \nu := \dim X - q$, where q is the $\mathbb{Q}$-*rank* of Γ. For example, for the split form of SL_n, the $\mathbb{Q}$-rank is $n - 1$. For the split symplectic group Sp_{2n}, the $\mathbb{Q}$-rank is n. Moreover, this bound is sharp: there will be coefficient modules $\mathscr{M}$ for which $H^{\nu}(\Gamma; \mathscr{M}) \neq 0$. Hence any minimal cell complex used to compute the cohomology of Γ should have dimension ν.

Ideally one would like to see such a complex realized as a subspace of X and would like to be able to treat all finite index subgroups of Γ simultaneously. This leads to the following question: is there a Γ-equivariant deformation retraction of X onto a regular cell complex W of dimension ν?

For $\mathbf{G} = \mathrm{Sp}_4$, McConnell and MacPherson showed that the answer is yes. Their construction begins by realizing the symplectic symmetric space X_{Sp} as a subspace of the special linear symmetric space X_{SL}. They then construct subsets of X_{Sp} by intersecting the Voronoĭ cells in X_{SL} with X_{Sp}. Through explicit computations in coordinates they prove that these intersections are cells and give a cell decomposition of X_{Sp}. By taking an appropriate dual complex (as suggested by Figures A.3.2 and A.3.3 and as done in [**Ash77**]), they construct the desired cell complex W.

Other progress has been recently made by Bullock [**Bul00**], Bullock and Connell [**BC06**], and Yasaki [**Yas05b, Yas05a**] in the case of groups of $\mathbb{Q}$-rank 1. In particular, Yasaki uses the *tilings* of Saper [**Sap97**] to construct an explicit retract for the unitary group $\mathrm{SU}(2,1)$ over the Gaussian integers. His method also works for Hilbert modular groups, although further refinement may be needed to produce a regular cell complex. Can one generalize these techniques to construct retracts for groups of arbitrary $\mathbb{Q}$-rank? Is there an analogue of the Voronoĭ decomposition for these retracts (i.e., a dual cell decomposition of the symmetric space)? If so, can one generalize ideas in Sections A.4–A.5 and use that generalization to compute the action of the Hecke operators on the cohomology?

A.6.5. Deeper Cohomology Groups. The algorithm in Section A.5 can be used to compute the Hecke action on $H^{\nu-1}(\Gamma)$. For $n > 4$, this group no longer contains cuspidal cohomology classes. Can one generalize this algorithm to compute the Hecke action on deeper cohomology groups? The first practical case is $n = 5$. Here $\nu = 10$, and the highest degree in which cuspidal cohomology can live is 8. This case is also interesting since the cohomology of full level has been studied [**EVGS02**].

Here are some indications of what one can expect. The general strategy is the same: for a k-sharbly ξ representing a class in $H^{\nu-k}(\Gamma)$, begin by Γ-equivariantly choosing reducing points for the nonunimodular submodular symbols of ξ. This data can be packaged into a new k-sharbly cycle as in Section A.5.7ff, but the crosspolytopes must be replaced with *hypersimplices*. By definition, the hypersimplex $\Delta(n,k)$ is the convex hull in $\mathbb{R}^n$ of the points $\{\sum_{i\in I} e_i\}$, where I ranges over all order k subsets of $\{1,\dots,n\}$ and $e_1,\dots,e_n$ denotes the standard basis of $\mathbb{R}^n$.

The simplest example is $n = 2$, $k = 2$. From the point of view of cohomology, this is even less interesting than $n = 2$, $k = 1$, since now we are computing the Hecke action on $H^{-1}(\Gamma)$! Nevertheless, the geometry here illustrates what one can expect in general.

Each 2-sharbly in the support of ξ can be written as $[v_1, v_2, v_3, v_4]$ and determines six submodular symbols, of the form $[v_i, v_j]$, $i \neq j$. Assume for simplicity that all these submodular symbols are nonunimodular. Let w_{ij} be the reducing point for $[v_i, v_j]$. Then use the ten points v_i, w_{ij} to label the vertices of the hypersimplex $\Delta(5, 2)$ as in Figure A.6.1 (note that $\Delta(5, 2)$ is 4-dimensional).

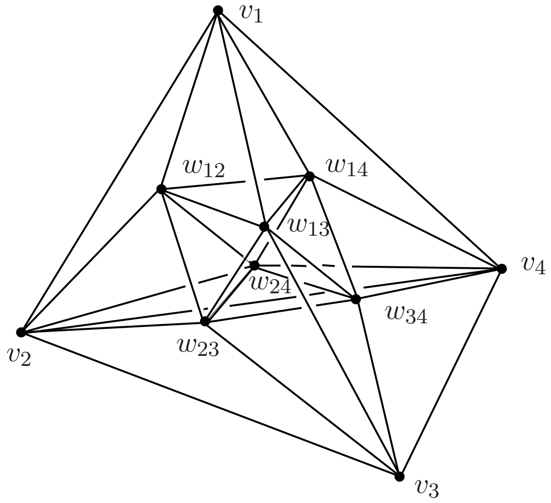

Figure A.6.1.

The boundary of this hypersimplex gives the analogue of (A.5.4). Which 2-sharblies will appear in ξ'? The boundary $\partial\Delta(5, 2)$ is a union of five tetrahedra and five octahedra. The outer tetrahedron will not appear in ξ', since that is the analogue of the left side of (A.5.4). The four octahedra sharing a triangular face with the outer tetrahedron also will not appear, since they disappear when considering ξ' modulo Γ. The remaining four tetrahedra and the central octahedron survive to ξ' and constitute the right side of the analogue of (A.5.4). Note that we must choose a simplicial subdivision of the central octahedron to write the result as a 2-sharbly cycle and that this must be done with care since it introduces a new submodular symbol.

If some submodular symbols are unimodular, then again one must consider iterated cones on hypersimplices, just as in Section A.5.10. The analogues of these steps become more complicated, since there are now many simplicial subdivisions of a hypersimplex[13]. There is one final complication: in general we cannot use reduced k-sharblies alone to represent cohomology classes. Thus one must terminate the algorithm when $\|\xi\|$ is less than some predetermined bound.

A.6.6. Other Linear Groups. Let F be a number field, and let $\mathbf{G} = \mathbf{R}_{F/\mathbb{Q}}(\mathrm{SL}_n)$ (Example A.2). Let $\Gamma \subset \mathbf{G}(\mathbb{Q})$ be an arithmetic subgroup. Can one compute the action of the Hecke operators on $H^*(\Gamma)$?

There are two completely different approaches to this problem. The first involves the generalization of the modular symbols method. One can define the analogue of the sharbly complex, and can try to extend the techniques of Sections A.4–A.5.

This technique has been extensively used when F is *imaginary quadratic* and $n = 2$. We have $X = \mathrm{SL}_2(\mathbb{C})/\,\mathrm{SU}(2)$, which is isomorphic to 3-dimensional hyperbolic space $\mathfrak{h}_3$. The arithmetic groups $\Gamma \subset \mathrm{SL}_2(\mathscr{O}_F)$ are known as *Bianchi groups*. The retracts and cohomology of these groups have been well studied; as a representative sample of works we mention [**Men79, EGM98, Vog85, GS81**].

Such groups have $\mathbb{Q}$-rank 1 and thus have cohomological dimension 2. One can show that the cuspidal classes live in degrees 1 and 2. This means that we can use modular symbols to investigate the Hecke action on cuspidal cohomology. This was done by Cremona [**Cre84**] for *euclidean* fields F. In that case Theorem A.22 works with no trouble (the euclidean algorithm is needed to construct reducing points). For noneuclidean fields further work has been done by Whitley [**Whi90**], Cremona and Whitely [**CW94**] (both for principal ideal domains), Bygott [**Byg99**] (for $F = \mathbb{Q}(\sqrt{-5})$ and any field with class group an elementary abelian 2-group), and Lingham [**Lin05**] (any field with odd class number). Putting all these ideas together allows one to generalize the modular symbols method to *any* imaginary quadratic field [**Cre**].

For F imaginary quadratic and $n > 2$, very little has been studied. The only related work to the best of our knowledge is that of Staffeldt [**Sta79**]. He determined the structure of the Voronoĭ polyhedron in detail for $\mathbf{R}_{F/\mathbb{Q}}(\mathrm{SL}_3)$, where $F = \mathbb{Q}(\sqrt{-1})$. We have $\dim X = 8$ and $\nu = 6$. The cuspidal cohomology appears in degrees $3, 4, 5$, so one could try to use the techniques of Section A.5 to investigate it.

Similar remarks apply to F *real quadratic* and $n = 2$. The symmetric space $X \simeq \mathfrak{h} \times \mathfrak{h}$ has dimension 4 and the $\mathbb{Q}$-rank is 1, which means $\nu = 3$. Unfortunately the cuspidal cohomology appears only in degree 2, which

[13] Indeed, computing all simplicial subdivisions of $\Delta(n, k)$ is a difficult problem in convex geometry.

means modular symbols cannot see it. On the other hand, 1-sharblies can see it, and so one can try to use ideas in Section A.5 here to compute the Hecke operators. The data needed to build the retract W already (essentially) appears in the literature for certain fields; see for example [**Ong86**].

The second approach shifts the emphasis from modular symbols and the sharbly complex to the Voronoĭ fan and its cones. For this approach we must assume that the group Γ is associated to a *self-adjoint homogeneous cone* over $\mathbb{Q}$. (cf. [**Ash77**]). This class of groups includes arithmetic subgroups of $\mathbf{R}_{F/\mathbb{Q}}(\mathrm{SL}_n)$, where F is a totally real or CM field. Such groups have all the nice structures in Section A.3.2. For example, we have a cone C with a G-action. We also have an analogue of the Voronoĭ polyhedron Π. There is a natural compactification $\tilde{C}$ of C obtained by adjoining certain self-adjoint homogeneous cones of lower rank. The quotient $\Gamma\backslash\tilde{C}$ is singular in general, but it can still be used to compute $H^*(\Gamma;\mathbb{C})$. The polyhedron Π can be used to construct a fan $\mathscr{V}$ that gives a Γ-equivariant decomposition of all of $\tilde{C}$. But the most important structure we have is the Voronoĭ reduction algorithm: given any point $x \in \tilde{C}$, we can determine the unique Voronoĭ cone containing x.

Here is how this setup can be used to compute the Hecke action. Full details are in [**Gun99, GM03**]. We define two chain complexes $\mathbf{C}_*^V$ and $\mathbf{C}_*^R$. The latter is essentially the chain complex generated by all simplicial rational polyhedral cones in $\tilde{C}$; the former is the subcomplex generated by the Voronoĭ cones. These are the analogues of the sharbly complex and the chain complex associated to the retract W, and one can show that either can be used to compute $H^*(\Gamma;\mathbb{C})$. Take a cycle $\xi \in \mathbf{C}_*^V$ representing a cohomology class in $H^*(\Gamma;\mathbb{C})$ and act on it by a Hecke operator T. We have $T(\xi) \in \mathbf{C}_*^R$, and we must push $T(\xi)$ back to $\mathbf{C}_*^V$.

To do this, we use the linear structure on $\tilde{C}$ to subdivide $T(\xi)$ very finely into a chain ξ'. For each 1-cone τ in $\operatorname{supp}\xi'$, we choose a 1-cone $\rho_\tau \in \tilde{C} \smallsetminus C$ and assemble them using the combinatorics of ξ' into a polyhedral chain ξ'' homologous to ξ'. Under certain conditions involved in the construction of ξ', this chain ξ'' will lie in $\mathbf{C}_*^V$.

We illustrate this process for the split group SL_2; more details can be found in [**Gun99**]. We work modulo homotheties, so that the three-dimensional cone $\tilde{C}$ becomes the extended upper half plane $\mathfrak{h}^* := \mathfrak{h}\cup\mathbb{Q}\cup\{\infty\}$, with $\partial\tilde{C}$ passing to the cusps $\mathfrak{h}^* \smallsetminus \mathfrak{h}$. As usual top-dimensional Voronoĭ cones become the triangles of the Farey tessellation, and the cones ρ_τ become cusps. Given any $x \in \mathfrak{h}$, let $R(x)$ be the set of cusps of the unique triangle or edge containing x (this can be computed using the Voronoĭ reduction algorithm). Extend R to a function on $\mathfrak{h}^*$ by putting $R(u) = \{u\}$ for any cusp u.

In $\mathfrak{h}$, the support of $T(\xi)$ becomes a geodesic μ between two cusps u, u', in other words the support of a modular symbol $[u, u']$ (Figure A.6.2). Subdivide μ by choosing points $x_0, \ldots, x_n$ such that $x_0 = u$, $x_n = u'$, and $R(x_i) \cap R(x_{i+1}) \neq \varnothing$. (This is easily done, for example by repeatedly barycentrically subdividing μ.) For each $i < n$ choose a cusp $q_i \in R(x_i) \cap R(x_{i+1})$, and put $q_n = u'$. Then we have a relation in H^1:

$$[u, u'] = [q_0, q_1] + \cdots + [q_{n-1}, q_n]. \tag{A.6.1}$$

Moreover, each $[q_i, q_{i+1}]$ is unimodular, since q_i and q_{i+1} are both vertices of a triangle containing x_{i+1}. Upon lifting (A.6.1) back to $\mathbf{C}_*^R$, the cusps q_i become the 1-cones ρ_τ and give us a relation $T(\xi) = \xi'' \in \mathbf{C}_*^V$.

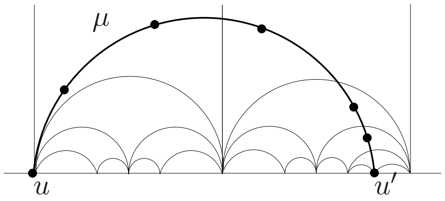

Figure A.6.2. A subdivision of μ; the solid dots are the x_i. Since the x_i lie in the same or adjacent Voronoĭ cells, we can assign cusps to them to construct a homology to a cycle in $\mathbf{C}_*^V$.

A.6.7. The Sharbly Complex for General Groups. In [**Gun00b**] we generalized Theorem A.22 (without the complexity statement) to the symplectic group Sp_{2n}. Using this algorithm and the symplectic retract [**MM93, MM89**], one can compute the action of the Hecke operators on the top-degree cohomology of subgroups of $\mathrm{Sp}_4(\mathbb{Z})$.

More recently, Toth has investigated modular symbols for other groups. He showed that the unimodular symbols generate the top-degree cohomology groups for Γ an arithmetic subgroup of a split classical group or a split group of type E_6 or E_7 [**Tot05**]. His technique of proof is completely different from that of [**Gun00b**]. In particular he does not give an analogue of the Manin trick. Can one extract an algorithm from Toth's proof that can be used to explicitly compute the action of the Hecke operators on cohomology?

The proof of the main result of [**Gun00b**] uses a description of the relations among the modular symbols. These relations were motivated by the structure of the cell complex in [**MM93, MM89**]. The modular symbols and these relations are analogues of the groups S_0 and S_1 in the sharbly complex. Can one extend these combinatorial constructions to form a *symplectic sharbly complex*? What about for general groups $\mathbf{G}$?

Already for Sp_4, resolution of this question would have immediate arithmetic applications. Indeed, Harder has a beautiful conjecture about certain congruences between holomorphic modular forms and Siegel modular forms of full level [**Hara**]. Examples of these congruences were checked numerically in [**Hara**] using techniques of [**FvdG**] to compute the Hecke action.

However, to investigate higher levels, one needs a different technique. The relevant cohomology classes live in $H^{\nu-1}(\Gamma;\mathscr{M})$, so one only needs to understand the first three terms of the complex $S_0 \leftarrow S_1 \leftarrow S_2$. We understand S_0, S_1 from [**Gun00b**]; the key is understanding S_2, which should encode relations among elements of S_1. If one could do this and then could generalize the techniques of [**Gun00a**], one would have a way to investigate Harder's conjecture.

A.6.8. Generalized Modular Symbols. We conclude this appendix by discussing a geometric approach to modular symbols. This complements the algebraic approaches presented in this book and leads to many new interesting phenomena and problems.

Suppose $\mathbf{H}$ and $\mathbf{G}$ are connected semisimple algebraic groups over $\mathbb{Q}$ with an injective map $f\colon \mathbf{H} \to \mathbf{G}$. Let K_H be a maximal compact subgroup of $H = \mathbf{H}(\mathbb{R})$, and suppose $K \subset G$ is a maximal compact subgroup containing $f(K_H)$. Let $X = G/K$ and $Y = H/K_H$.

Now let $\Gamma \subset \mathbf{G}(\mathbb{Q})$ be a torsion-free arithmetic subgroup. Let $\Gamma_H = f^{-1}(\Gamma)$. We get a map $\Gamma_H\backslash Y \to \Gamma\backslash X$, and we denote the image by $S(H,\Gamma)$. Any compactly supported cohomology class $\xi \in H_c^{\dim Y}(\Gamma\backslash X;\mathbb{C})$ can be pulled back via f to $\Gamma_H\backslash Y$ and integrated to obtain a complex number. Hence $S(H,\Gamma)$ defines a linear form on $H_c^{\dim Y}(\Gamma\backslash X;\mathbb{C})$. By Poincaré duality, this linear form determines a class $[S(H,\Gamma)] \in H^{\dim X-\dim Y}(\Gamma\backslash X;\mathbb{C})$, called a *generalized modular symbol*. Such classes have been considered by many authors, for example [**AB90, SV03, Har05, AGR93**].

As an example, we can take $\mathbf{G}$ to be the split form of SL_2, and we can take $f\colon \mathbf{H} \to \mathbf{G}$ to be the inclusion of connected component of the diagonal subgroup. Hence $H \simeq \mathbb{R}_{>0}$. In this case K_H is trivial. The image of Y in X is the ideal geodesic from 0 to ∞. One way to vary f is by taking an $\mathrm{SL}_2(\mathbb{Q})$-translate of this geodesic, which gives a geodesic between two cusps. Hence we can obtain the support of any modular symbol this way. This example generalizes to SL_n to yield the modular symbols in Section A.4. Here $H \simeq (\mathbb{R} > 0)^{n-1}$. Note that $\dim Y = n-1$, so the cohomology classes we have constructed live in the top degree $H^{\nu}(\Gamma\backslash X;\mathbb{C})$.

Another family of examples is provided by taking $\mathbf{H}$ to be a Levi factor of a parabolic subgroup; these are the modular symbols studied in [**AB90**].

There are many natural questions to study for such objects. Here are two:

- Under what conditions on $\mathbf{G}, \mathbf{H}, \Gamma$ is $[S(H,\Gamma)]$ nonzero? This question is connected to relations between periods of automorphic forms and functoriality lifting. There are a variety of partial results known; see for example [**SV03, AGR93**].
- We know the usual modular symbols span the top-degree cohomology for any arithmetic group Γ. Fix a class of generalized modular symbols by fixing the pair $\mathbf{G}, \mathbf{H}$ and fixing some class of maps f. How much of the cohomology can one span for a general arithmetic group $\Gamma \subset \mathbf{G}(\mathbb{Q})$?

  A simple example is given by the Ash–Borel construction for $\mathbf{G} = \mathrm{SL}_3$ and $\mathbf{H}$ a Levi factor of a rational parabolic subgroup $\mathbf{P}$ of type $(2,1)$. In this case $H \simeq \mathrm{SL}_2(\mathbb{R}) \times \mathbb{R}_{>0}$ and sits inside G via

$$g \begin{pmatrix} \alpha^{-1}M & 0 \\ 0 & \alpha \end{pmatrix} g^{-1}, \quad M \in \mathrm{SL}_2(\mathbb{R}), \quad \alpha \in \mathbb{R}_{>0}, \quad g \in \mathrm{SL}_3(\mathbb{Q}).$$

  For $\Gamma \subset \mathrm{SL}_3(\mathbb{Z})$ these symbols define a subspace

$$S_{(2,1)} \subset H^2(\Gamma\backslash X; \mathbb{C}).$$

  Are there Γ for which $S_{(2,1)}$ equals the full cohomology space? For general Γ how much is captured? Is there a nice combinatorial way to write down the relations among these classes? Can one cook up a generalization of Theorem A.22 for these classes and use it to compute Hecke eigenvalues?

Explicit Heegner points: Kolyvagin's conjecture and non-trivial elements in the Shafarevich-Tate group

Dimitar Jetchev, Kristin Lauter and William Stein

Abstract

Kolyvagin used Heegner points to associate a system of cohomology classes to an elliptic curve over $\mathbb{Q}$ and conjectured that the system contains a nontrivial class. His conjecture has profound implications on the structure of Selmer groups. We provide new computational and theoretical evidence for Kolyvagin's conjecture. More precisely, we apply results of Zhang and others to deduce that Kolyvagin classes are computable, then explicitly study Heegner points over ring class fields and Kolyvagin's conjecture for specific elliptic curves of rank two. We explain how Kolyvagin's conjecture implies that if the analytic rank of an elliptic curve is at least two then the $\mathbb{Z}_p$-corank of the corresponding Selmer group is at least two as well. We also use explicitly computed Heegner points to produce non-trivial classes in the Shafarevich-Tate group.

1. Introduction

Let $E_{/F}$ be an elliptic curve over a number field F. The analytic rank $r_{\mathrm{an}}(E/F)$ of E is the order of vanishing of the L-function $L(E_{/F}, s)$ at $s = 1$. The Mordell-Weil rank $r_{\mathrm{MW}}(E/F)$ is the rank of the Mordell-Weil group $E(F)$. The conjecture of Birch and Swinnerton-Dyer asserts that $r_{\mathrm{an}}(E/F) = r_{\mathrm{MW}}(E/F)$.

Kolyvagin constructed explicit cohomology classes from Heegner points over certain abelian extensions of quadratic imaginary fields and used these classes to bound the size of the Selmer groups for elliptic curves over $\mathbb{Q}$ of analytic rank at most one (see [Kol90], [Kol91b] and [Gro91]). His results, together with the Gross-Zagier formula (see [GZ86]), imply the following theorem:

Theorem 1.1 (Gross-Zagier, Kolyvagin). *Let $E_{/\mathbb{Q}}$ be an elliptic curve which satisfies $r_{\mathrm{an}}(E/\mathbb{Q}) \leqslant 1$. Then the Shafarevich-Tate group $Ш(E/\mathbb{Q})$ is finite and $r_{\mathrm{an}}(E/\mathbb{Q}) = r_{\mathrm{MW}}(E/\mathbb{Q})$.*

Unfortunately, very little is known about the Birch and Swinnerton-Dyer conjecture for elliptic curves $E_{/\mathbb{Q}}$ with $r_{\mathrm{an}}(E/\mathbb{Q}) \geqslant 2$. Still, it implies the following conjecture:

Conjecture 1. If $r_{\mathrm{an}}(E/\mathbb{Q}) \geqslant 2$ then $r_{\mathrm{MW}}(E/\mathbb{Q}) \geqslant 2$.

As far as we know, nothing has been proved towards the above assertion. A weaker conjecture can be formulated in the language of Selmer coranks. The Selmer corank $r_p(E/F)$ of $E_{/F}$ is the $\mathbb{Z}_p$-corank of the Selmer group $\mathrm{Sel}_{p^\infty}(E/F)$. Using Kummer theory, one shows that $r_p(E/\mathbb{Q}) \geqslant r_{\mathrm{MW}}(E/\mathbb{Q})$ with an equality occuring if and only if the p-primary part of the Shafarevich-Tate group $Ш(E/\mathbb{Q})$ is finite. Thus, one obtains the following weaker conjecture:

2000 Mathematics Subject Classification 11G05
Keywords: Elliptic curves, Heegner points, Selmer groups
The first author was supported by summer internships at Microsoft Research as well as by graduate fellowships from Microsoft Research and University of California at Berkeley. The third author was partially supported by NSF grant 0555776.

Conjecture 2. If $r_{\mathrm{an}}(E/\mathbb{Q}) \geqslant 2$ then $r_p(E/\mathbb{Q}) \geqslant 2$.

For elliptic curves E of arbitrary analytic rank, Kolyvagin was able to explain the exact structure of the Selmer group $\mathrm{Sel}_{p^\infty}(E/\mathbb{Q})$ in terms of Heegner points and the associated cohomology classes under a conjecture about the non-triviality of these classes (see [Kol91a, Conj.A]). Unfortunately, Kolyvagin's conjecture appears to be extremely difficult to prove. Until the present paper, there has been no example of an elliptic curve over $\mathbb{Q}$ of rank at least two for which the conjecture has been verified.

In this paper, we present a complete algorithm to compute Kolyvagin's cohomology classes by explicitly computing the corresponding Heegner points over ring class fields. We use this algorithm to verify Kolyvagin's conjecture for the first time for elliptic curves of analytic rank two. We also explain (see Corollary 3.3) how Kolyvagin's conjecture implies Conjecture 2. In addition, we use methods of Cornut (see [Cor02]) to provide theoretical evidence for Kolyvagin's conjecture. As a separate application of the explicit computation of Heegner points, we construct nontrivial cohomology classes in the Shafarevich-Tate group $\text{Ш}(E/K)$ of elliptic curves E over certain quadratic imaginary fields. One of the main contributions of this paper is that by establishing certain height bounds, we prove that there exists an algorithm which *provably* computes the correct Heegner points over ring class fields.

The paper is organized as follows. Section 2 introduces Heegner points over ring class fields and Kolyvagin cohomology classes. We explain the methods of computation and illustrate them with several examples. In Section 3 we state Kolyvagin's conjecture, discuss Kolyvagin's work on Selmer groups and establish Conjecture 2 as a corollary. Moreover, we present a proof of the theoretical evidence following closely Cornut's arguments. Section 3.6 contains the essential examples for which we manage to explicitly verify the conjecture. Finally, in Section 4 we apply our computational techniques to produce explicit non-trivial elements in the Shafarevich-Tate groups for specific elliptic curves. Finally, the appendix establishes certain bounds on the logarithmic heights of the Heegner points over ring class fields.

2. Heegner points over ring class fields

We discuss Heegner points over ring class fields in Section 2.1 and describe a method for computing them in Section 2.2. Height estimates for these points are given in the appendix. We illustrate the method with some examples in Section 2.3. The standard references are [Gro91], [Kol90] and [McC91].

2.1 Heegner points over ring class fields

Let E be an elliptic curve over $\mathbb{Q}$ of conductor N and let $K = \mathbb{Q}(\sqrt{-D})$ for some fundamental discriminant $D > 0$, $D \neq 3, 4$, such that all prime factors of N are split in K. We refer to such a discriminant as a *Heegner discriminant* for $E/\mathbb{Q}$. Let $\mathcal{O}_K$ be the ring of integers of K. It follows that $N\mathcal{O}_K = \mathcal{N}\bar{\mathcal{N}}$ for an ideal $\mathcal{N}$ of $\mathcal{O}_K$ with $\mathcal{O}_K/\mathcal{N} \simeq \mathbb{Z}/N\mathbb{Z}$.

By the modularity theorem (see [BCDT01]), there exists an optimal (having minimal degree) modular parameterization $\varphi : X_0(N) \to E$. Let $\mathcal{N}^{-1}$ be the fractional ideal of $\mathcal{O}_K$ for which $\mathcal{N}\mathcal{N}^{-1} = \mathcal{O}_K$. We view $\mathcal{O}_K$ and $\mathcal{N}$ as $\mathbb{Z}$-lattices of rank two in $\mathbb{C}$ and observe that $\mathbb{C}/\mathcal{O}_K \to \mathbb{C}/\mathcal{N}^{-1}$ is a cyclic isogeny of degree N between the elliptic curves $\mathbb{C}/\mathcal{O}_K$ and $\mathbb{C}/\mathcal{N}^{-1}$. This isogeny corresponds to a complex point $x_1 \in X_0(N)(\mathbb{C})$. According to the theory of complex multiplication [Sil94, Ch.II], the point x_1 is defined over the Hilbert class field H_K of K.

More generally, for an integer c, let $\mathcal{O}_c = \mathbb{Z} + c\mathcal{O}_K$ be the order of conductor c in $\mathcal{O}_K$ and let $\mathcal{N}_c = \mathcal{N} \cap \mathcal{O}_c$, which is an invertible ideal of $\mathcal{O}_c$. Then $\mathcal{O}_c/\mathcal{N}_c \simeq \mathbb{Z}/N\mathbb{Z}$ and the map $\mathbb{C}/\mathcal{O}_c \to \mathbb{C}/\mathcal{N}_c^{-1}$

is a cyclic isogeny of degree N. Thus, it defines a point $x_c \in X_0(N)(\mathbb{C})$. By the theory of complex multiplication, this point is defined over the ring class field $K[c]$ of conductor c over K (that is, the unique abelian extension of K corresponding to the norm subgroup $\widehat{\mathcal{O}_c}^{\times} K^\times \subset \widehat{K}^\times$; e.g., if $c = 1$ then $K[1] = H_K$).

We use the parameterization $\varphi : X_0(N) \to E$ to obtain points

$$y_c = \varphi(x_c) \in E(K[c]).$$

Let $y_K = \mathrm{Tr}_{H_K/K}(y_1)$. We refer to y_K as the *Heegner point* for the discriminant D, even though it is only well defined up to sign and torsion (if $\mathcal{N}'$ is another ideal with $\mathcal{O}/\mathcal{N}' \simeq \mathbb{Z}/N\mathbb{Z}$ then the new Heegner point differs from y_K by at most a sign change and a rational torsion point).

2.2 Explicit computation of the points y_c

Significant work has been done on explicit calculations of Heegner points on elliptic curves (see [Coh07], [Del02], [Elk94], [Wat04]). Yet, all of these only compute the points y_1 and y_K. In [EJL06] explicit computations of the points y_c were considered in several examples and some difficulties were outlined. However, there has been no algorithm which provably computes the points y_c. One of the main contributions of this paper is the description of such an algorithm.

To compute the point $y_c = [\mathbb{C}/\mathcal{O}_c \to \mathbb{C}/\mathcal{N}_c^{-1}] \in E(K[c])$ we let $f \in S_2(\Gamma_0(N))$ be the newform corresponding to the elliptic curve E and Λ be the complex lattice (defined up to homothety), such that $E \cong \mathbb{C}/\Lambda$. Let $\mathfrak{h}^\times = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q}) \cup \{i\infty\}$, where $\mathfrak{h} = \{z \in \mathbb{C} : \Im(z) > 0\}$ is the upper-half plane equipped with the action of $\Gamma_0(N)$ by linear fractional transformations. The modular parametrization $\varphi : X_0(N) \to E$ is then given by the function $\varphi : \mathfrak{h}^\times \to \mathbb{C}/\Lambda$

$$\varphi(\tau) = \int_\tau^{i\infty} f(z)dz = \sum_{n \geqslant 1} \frac{a_n}{n} e^{2\pi i n \tau}, \tag{1}$$

where $f = \sum_{n=1}^{\infty} a_n q^n$ is the Fourier expansion of the modular form f.

We first compute ideal class representatives $\mathfrak{a}_1, \mathfrak{a}_2, \dots, \mathfrak{a}_{h_c}$ for the Picard group $\mathrm{Pic}(\mathcal{O}_c) \cong \mathrm{Gal}(K[c]/K)$, where $h_c = \#\,\mathrm{Pic}(\mathcal{O}_c)$. Let $\sigma_i \in \mathrm{Gal}(K[c]/K)$ be the image of the ideal class of $\mathfrak{a}_i$ under the Artin map. We use the ideal $\mathfrak{a}_i$ to compute a complex number (a *quadratic surd*)$\tau_i \in \mathfrak{h}$ representing the CM point $\sigma_i(x_c)$ for each $i = 1, \dots, h_c$ (since $X_0(N) = \Gamma_0(N)\backslash\mathfrak{h}^\times$). Explicitly, the Galois conjugates of x_c are

$$\sigma_i(x_c) = [\mathbb{C}/\mathfrak{a}_i^{-1} \to \mathbb{C}/\mathfrak{a}_i^{-1}\mathcal{N}_c^{-1}],\ i = 1, \dots, h_c.$$

Next, we use (1) to approximate $\varphi(\sigma_i(x_c))$ as an element of $\mathbb{C}/\Lambda$ by truncating the infinite series up to sufficiently many terms whose number is determined precisely by the results of the appendix. Finally, the image of $\varphi(\tau_i) + \Lambda$ under the Weierstrass $\wp$-function gives us an approximation of the x-coordinate of the point y_c on the Weierstrass model of the elliptic curve E. On the other hand, this coordinate is $K[c]$-rational. Thus, if we compute the map (1) with sufficiently many terms and up to high enough floating point accuracy, we must be able to recognize the correct x-coordinate of y_c on the Weierstrass model as an element of $K[c]$.

To implement the last step, we use the upper bound established in the appendix on the logarithmic height of the Heegner point y_c. The bound on the logarithmic height comes from a bound on the canonical height combined with bounds on the height difference (see the appendix for complete details). Once we have a height bound, we estimate the floating point accuracy required for the computation. Finally, we estimate the number of terms of (1) necessary to compute the point y_c up to the corresponding accuracy (see [Coh07, p.591] for more details).

Remark 1. In practice, there are two ways to implement the above algorithm. The first approach is to compute an approximation x_i of the x-coordinates of $y_c^{\sigma_i}$ for every $i = 1, \dots, c$ and form the polynomial $F(z) = \prod_{i=1}^{h_c}(z - x_i)$. The coefficients of this polynomial are very close to the rational coefficients of the minimal polynomial of the actual x-coordinate of y_c. Thus, one can try to recognize the coefficients of $F(z)$ by using the continued fractions method. The second approach is to search for the τ_i with the largest imaginary part (which will make the convergence of the corresponding series (1) defining the modular parametrization fast) and then try to search for an algebraic dependence of degree $[K[c] : K]$ using standard algorithms implemented in PARI/GP. Indeed, computing a conjugate with a smaller imaginary part might be significantly harder since the infinite series in (1) will converge slower and one will need more terms to compute the image up to the required accuracy.

Remark 2. We did *not* actually implement an algorithm for computing bounds on heights of Heegner points as described in the appendix of this paper. Thus, the computations in the specific examples below are not provably correct, though we did many consistency checks and we are convinced that our computational observations are correct. The primary goal of the examples and practical implementation of our algorithm is to provide tools and data for improving our theoretical understanding of Kolyvagin's conjecture, and not making the computations below provably correct does not detract from either of these goals.

2.3 Examples

We compute the Heegner points y_c for specific elliptic curves and choices of quadratic imaginary fields.

53a1: Let $E_{/\mathbb{Q}}$ be the elliptic curve with label **53a1** in Cremona's database (see [Cre]). Explicitly, E is the curve $y^2 + xy + y = x^3 - x^2$. Let $D = 43$ and $c = 5$. The conductor of E is 53 which is split in $K = \mathbb{Q}(\sqrt{-D})$, so D is a Heegner discriminant for E. The modular form associated to E is $f_E(q) = q - q^2 - 3q^3 - q^4 + 3q^6 - 4q^7 + 3q^8 + 6q^9 + \cdots$. One applies the methods from Section 2.2 to compute the minimal polynomial of the x-coordinate of y_5 for the above model

$$F(x) = x^6 - 12x^5 + 1980x^4 - 5855x^3 + 6930x^2 - 3852x + 864.$$

Since $F(x)$ is an irreducible polynomial over K, it generates the ring class field $K[5]/K$, i.e., $K[5] = K[\alpha] \cong K[x]/\langle F(x)\rangle$, where α is one of the roots. To find the y-coordinate of y_5 we substitute α into the equation of E and factor the resulting quadratic polynomial over $K[5]$ to obtain that the point y_5 is equal to

$$\big(\alpha, -4/315\alpha^5 + 43/315\alpha^4 - 7897/315\alpha^3 + 2167/35\alpha^2 - 372/7\alpha + 544/35\big) \in E(K[5]).$$

389a1: The elliptic curve with label **389a1** is $y^2 + y = x^3 + x^2 - 2x$ and the associated modular form is $f_E(q) = q - 2q^2 - 2q^3 + 2q^4 - 3q^5 + 4q^6 - 5q^7 + q^9 + 6q^{10} + \cdots$. Let $D = 7$ (which is a Heegner discriminant for E) and $c = 5$. As above, we compute the minimal polynomial of the x-coordinate of y_5:

$$F(x) = x^6 + \frac{10}{7}x^5 - \frac{867}{49}x^4 - \frac{76}{245}x^3 + \frac{3148}{35}x^2 - \frac{25944}{245}x + \frac{48771}{1225}.$$

If α is a root of $F(x)$ then $y_5 = (\alpha, \beta)$ where

$$\beta = \frac{280}{7761}\sqrt{-7}\alpha^5 + \frac{1030}{7761}\sqrt{-7}\alpha^4 - \frac{12305}{36218}\sqrt{-7}\alpha^3 - \frac{10099}{15522}\sqrt{-7}\alpha^2 + \frac{70565}{54327}\sqrt{-7}\alpha + \frac{-18109 - 33814\sqrt{-7}}{36218}.$$

709a1: The elliptic curve **709a1** with equation $y^2 + y = x^3 - x^2 - 2x$ has an associated modular form $f_E(q) = q - 2q^2 - q^3 + 2q^4 - 3q^5 + 2q^6 - 4q^7 - 2q^9 + \cdots$. Let $D = 7$ (a Heegner discriminant for E) and $c = 5$. The minimal polynomial of the x-coordinate of y_5 is

$$F(x) = \frac{1}{5^2 \cdot 7^2 \cdot 19^2}\left(442225x^6 - 161350x^5 - 2082625x^4 - 387380x^3 + 2627410x^2 + 18136030x + 339921\right),$$

and if α is a root of x then $y_5 = (\alpha, \beta)$ for

$$\beta = \frac{341145}{62822}\sqrt{-7}\alpha^5 - \frac{138045}{31411}\sqrt{-7}\alpha^4 - \frac{31161685}{1319262}\sqrt{-7}\alpha^3 + \frac{7109897}{1319262}\sqrt{-7}\alpha^2 + \\ + \frac{39756589}{1319262}\sqrt{-7}\alpha + \frac{-219877 + 4423733\sqrt{-7}}{439754}.$$

718b1: The curve **718b1** has equation $y^2 + xy + y = x^3 - 5x$ with associated modular form $f_E(q) = q - q^2 - 2q^3 + q^4 - 3q^5 + 2q^6 - 5q^7 - q^8 + q^9 + 3q^{10} + \dots$. Again, for $D = 7$ and $c = 5$ we find $F(x) = \frac{1}{3^4 \cdot 5^2}\left(2025x^6 + 12400x^5 + 32200x^4 + 78960x^3 + 289120x^2 + 622560x + 472896\right)$ and $y_5 = (\alpha, \beta)$ with

$$\beta = \frac{16335}{12271}\sqrt{-7}\alpha^5 + \frac{206525}{36813}\sqrt{-7}\alpha^4 + \frac{54995}{5259}\sqrt{-7}\alpha^3 + \frac{390532}{12271}\sqrt{-7}\alpha^2 + \\ + \frac{-36813 + 9538687\sqrt{-7}}{73626}\alpha + \frac{-12271 + 4018835\sqrt{-7}}{24542}.$$

3. Kolyvagin's conjecture: consequences and evidence

We recall Kolyvagin's construction of the cohomology classes in Section 3.2 and state Kolyvagin's conjecture in Section 3.3. Section 3.4 is devoted to the proof of the promised consequence regarding the $\mathbb{Z}_p$-corank of the Selmer group of an elliptic curve with large analytic rank. In Section 3.5 we provide Cornut's arguments for the theoretical evidence for Kolyvagin's conjecture and finally, in Section 3.6 we verify Kolyvagin's conjecture for particular elliptic curves. Throughout the entire section we assume that $E_{/\mathbb{Q}}$ is an elliptic curve of conductor N, D is a Heegner discriminant for E and $p \nmid ND$ is a prime such that the mod p Galois representation $\overline{\rho}_{E,p} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(E[p])$ is surjective.

3.1 Preliminaries

Most of this section follows the exposition in [Gro91], [McC91] and [Kol91c].

1. Kolyvagin primes. We refer to a prime number ℓ as a *Kolyvagin prime* if ℓ is inert in K and p divides both a_ℓ and $\ell + 1$). For a Kolyvagin prime ℓ let

$$M(\ell) = \mathrm{ord}_p(\gcd(a_\ell, \ell + 1)).$$

We denote by Λ^r the set of all square-free products of exactly r Kolyvagin primes and let $\Lambda = \bigcup_r \Lambda^r$. For any $c \in \Lambda$, let $M(c) = \min_{\ell \mid c} M(\ell)$. Finally, let

$$\Lambda^r_m = \{c \in \Lambda^r : M(c) \geqslant m\}$$

and let $\Lambda_m = \bigcup_r \Lambda^r_m$.

2. Kolyvagin derivative operators. Let $\mathcal{G}_c = \mathrm{Gal}(K[c]/K)$ and $G_c = \mathrm{Gal}(K[c]/K[1])$. For each $\ell \in \Lambda^1$, the group G_ℓ is cyclic of order $\ell + 1$. Indeed,

$$G_\ell \simeq (\mathcal{O}_K/\ell\mathcal{O}_K)^\times/(\mathbb{Z}/\ell\mathbb{Z})^\times \simeq \mathbb{F}_\lambda^\times/\mathbb{F}_\ell^\times.$$

Moreover, $G_c \cong \prod_{\ell | c} G_\ell$ (since $\mathrm{Gal}(K[c]/K[c/\ell]) \cong G_\ell$). Next, fix a generator σ_ℓ of G_ℓ for each $\ell \in \Lambda^1$. Define $D_\ell = \sum_{i=1}^{\ell} i\sigma_\ell^i \in \mathbb{Z}[G_\ell]$ and let

$$D_c = \prod_{\ell | c} D_\ell \in \mathbb{Z}[G_c].$$

Note that $(\sigma_\ell - 1)D_\ell = 1 + \ell - \mathrm{Tr}_{K[\ell]/K[1]}$.

We refer to D_c as the *Kolyvagin derivative operators.* Finally, let S be a set of coset representatives for the subgroup $G_c \subseteq \mathcal{G}_c$. Define

$$P_c = \sum_{s \in S} s D_c y_c \in E(K[c]).$$

The points P_c are derived from the points y_c, so we will refer to them as *derived Heegner points.*

3. The function $m : \Lambda \to \mathbb{Z}$ and the sequence $\{m_r\}_{r \geqslant 0}$. For any $c \in \Lambda$ let $m'(c)$ be the largest positive integer such that $P_c \in p^{m'(c)}E(K[c])$ (if P_c is torsion then $m'(c) = \infty$). Define a function $m : \Lambda \to \mathbb{Z}$ by

$$m(c) = \begin{cases} m'(c) & \text{if } m'(c) \leqslant M(c), \\ \infty & \text{otherwise.} \end{cases}$$

Finally, let $m_r = \min_{c \in \Lambda^r} m(c)$.

Proposition 3.1. *The sequence $\{m_r\}_{r \geqslant 0}$ is non-increasing, i.e., $m_r \geqslant m_{r+1}$ for every $r \geqslant 0$.*

Proof. This is proved in [Kol91c, Thm.C]. □

3.2 Kolyvagin cohomology classes

Kolyvagin uses the points P_c to construct classes $\kappa_{c,m} \in \mathrm{H}^1(K, E[p^m])$ for any $c \in \Lambda_m$. For the details of the construction, we refer to [Gro91, pp.241-242]) and [McC91, §4]. The class $\kappa_{c,m}$ is explicit, in the sense that it is represented by the 1-cocycle

$$\sigma \mapsto \sigma\left(\frac{P_c}{p^m}\right) - \frac{P_c}{p^m} - \frac{(\sigma - 1)P_c}{p^m}, \tag{2}$$

where $\dfrac{(\sigma-1)P_c}{p^m}$ is the unique p^m-division point of $(\sigma - 1)P_c$ in $E(K[c])$ (see [McC91, Lem. 4.1]). The class $\kappa_{c,m}$ is non-trivial if and only if $P_c \notin p^m E(K[c])$ (which is equivalent to $m > m(c)$).

Finally, let $-\varepsilon$ be the sign of the functional equation corresponding to E. For each $c \in \Lambda_m$, let $\varepsilon(c) = \varepsilon \cdot (-1)^{f_c}$ where $f_c = \#\{\ell : \ell \mid c\}$ (e.g., $f_1 = 0$). It follows from [Gro91, Prop.5.4(ii)] that $\kappa_{c,m}$ lies in the $\varepsilon(c)$-eigenspace for the action of complex conjugation on $\mathrm{H}^1(K, E[p^m])$.

3.3 Statement of the conjecture

We are interested in $m_\infty = \min_{c \in \Lambda} m(c) = \lim_{r \to \infty} m_r$. In the case when the Heegner point $P_1 = y_K$ has infinite order in $E(K)$, the Gross-Zagier formula (see [GZ86]) implies that $r_{\mathrm{an}}(E/K) = 1$, so (by the results of Kolyvagin) $r_{\mathrm{MW}}(E/K) = 1$. This means that $m_0 = \mathrm{ord}_p([E(K) : \mathbb{Z}y_K]) < \infty$. In particular, $m_\infty < \infty$ which is equivalent to the system of cohomology classes

$$T = \{\kappa_{c,m} : m \leqslant M(c)\}$$

containing at least one non-zero class. A much more interesting and subtle is the case of an elliptic curves E over K of analytic rank at least two. In this case, Kolyvagin conjectured (see [Kol91a, Conj.C]) that T contains a non-trivial class as well.

Conjecture 3 (Kolyvagin's conjecture). We have $m_\infty < \infty$, i.e., T contains at least one class $\kappa_{c,m} \neq 0$.

Remark 3. Although Kolyvagin's conjecture is obvious in the case of elliptic curves of analytic rank one over K, the number m_∞ is still interesting. Indeed, the p-part of the Birch and Swinnerton-Dyer conjectural formula for $E_{/K}$ is equivalent to $m_\infty = \mathrm{ord}_p \left(\prod_{q \mid N} c_q \right)$, where c_q is the Tamagawa number of $E_{/\mathbb{Q}}$ at q. See [Jet07] for some new results related to this question which imply (in many cases) the exact upper bound on the order of the p-primary part of the Shafarevich-Tate group as predicted by the conjectural formula.

3.4 A consequence on the structure of Selmer groups

Let $r_p^{\pm}(E/K) = \mathrm{corank}_{\mathbb{Z}_p} \mathrm{Sel}_{p^\infty}(E/K)^{\pm}$. Kolyvagin (see [Kol91a]) proved the following:

Theorem 3.2 (Kolyvagin). *Assume Conjecture 3 and let f be the smallest nonnegative integer for which $m_f < \infty$. Then*

$$\mathrm{Sel}_{p^\infty}(E/K)^{\varepsilon(-1)^{f+1}} \cong (\mathbb{Q}_p/\mathbb{Z}_p)^{f+1} \oplus \textit{(a finite group)}$$

and

$$\mathrm{Sel}_{p^\infty}(E/K)^{\varepsilon(-1)^{f}} \cong (\mathbb{Q}_p/\mathbb{Z}_p)^{r} \oplus \textit{(a finite group)}$$

where $r \leqslant f$ and $f - r$ is even. In other words, $r_p^{\varepsilon(-1)^f}(E/K) = r$ and $r_p^{\varepsilon(-1)^{f+1}}(E/K) = f + 1$.

The above structure theorem of Kolyvagin has the following consequence which strongly supports Conjecture 2.

Corollary 3.3. *Assume Conjecture 3. Then (i) If $r_{\mathrm{an}}(E/\mathbb{Q})$ is even and nonzero then*

$$r_p(E/\mathbb{Q}) \geqslant 2.$$

(ii) If $r_{\mathrm{an}}(E/\mathbb{Q})$ is odd and strictly larger than one then

$$r_p(E/\mathbb{Q}) \geqslant 3.$$

Proof. (i) By [BFH90] or [MM97], one can choose a quadratic imaginary field $K = \mathbb{Q}(\sqrt{-D})$ with Heegner discriminant D, such that $L'(E^D_{/\mathbb{Q}}, 1) \neq 0$, where E^D is the twist of E by the quadratic character associated to K (note that D is a Heegner discriminant, so the sign of the functional equation of E^D is always odd since E has even sign). Hence, by Theorem 1.1, the Selmer group $\mathrm{Sel}_{p^\infty}(E^D/\mathbb{Q})$ has $\mathbb{Z}_p$-corank one, i.e., $r_p^-(E/K) = r_p(E^D/\mathbb{Q}) = 1$. We want to prove $r_p^+(E/K) = r_p(E/\mathbb{Q}) \geqslant 2$. Assume the contrary, i.e., $r_p^+(E/K) = r_p(E/\mathbb{Q}) \leqslant 1$. This means (by Theorem 3.2) that $r = f = 0$ (here, r and f are as in Theorem 3.2). Therefore, $m_0 < \infty$ which means that the Heegner point y_K has infinite order in $E(K)$ and hence (by the Gross-Zagier formula), $L'(E_{/K}, 1) \neq 0$. But this is a contradiction since

$$L'(E_{/K}, s) = L'(E_{/\mathbb{Q}}, s) L(E^D_{/\mathbb{Q}}, s) + L(E_{/\mathbb{Q}}, s) L'(E^D_{/\mathbb{Q}}, s),$$

which vanishes at $s = 1$ since $L(E_{/\mathbb{Q}}, 1) = L'(E_{/\mathbb{Q}}, 1) = 0$. Thus, $r_p(E/\mathbb{Q}) = r_p^+(E/K) \geqslant 2$.

(ii) It follows from the work of Waldspurger (see also [BFH90, pp.543-44]) that one can choose a quadratic imaginary field $K = \mathbb{Q}(\sqrt{-D})$ with a Heegner discriminant D, such that $L(E^D_{/\mathbb{Q}}, 1) \neq 0$ (this uses the fact that $r_{\mathrm{an}}(E/\mathbb{Q})$ is odd). Therefore, by Theorem 1.1, $r_p(E^D/\mathbb{Q}) = 0$, i.e., $r_p^-(E/K) = 0$. By Theorem 3.2, $r = 0$ and f is even. If $f \geqslant 2$ we are done since $r_p(E/\mathbb{Q}) = r_p^+(E/K) = f + 1 \geqslant 3$. If $f = 0$, we use the same argument as in (i) to arrive at a contradiction. Therefore, $r_p(E/\mathbb{Q}) = r_p^+(E/K) \geqslant 3$. □

Remark 4. The parity conjecture proved by Nekovář (see [Nek01]) implies that

$$r_p(E/\mathbb{Q}) \equiv r_{\mathrm{an}}(E/\mathbb{Q}) \mod 2.$$

Yet, Nekovář's result does not imply in any obvious way the statements of the above proposition.

3.5 Cornut's theoretical evidence for Kolyvagin's conjecture

The following evidence for Conjecture 3 was proven by Cornut.

Proposition 3.4. *For all but finitely many $c \in \Lambda$ there exists a set R of liftings for the elements of $\mathrm{Gal}(K[1]/K)$ into $\mathrm{Gal}(K^{\mathrm{ab}}/K)$, such that if $P_c = D_0 D_c y_c$ is the derived Heegner point defined in terms of this choice of liftings (i.e, if $D_0 = \sum_{\sigma \in R} \sigma$), then P_c is non-torsion.*

Remark 5. For a non-torsion point P_c, let $m'(c)$ be the function defined in Section 3.1. Proposition 3.4 provides little evidence towards Kolyvagin's conjecture. The reason is that even if one gets non-torsion points P_c, it might still happen that for each such c we have $m'(c) > M(c)$ (i.e., $m(c) = \infty$) in which case all classes $\kappa_{c,m}$ with $m \leqslant M(c)$ will be trivial.

Let $K[\infty] = \bigcup_{c \in \Lambda} K[c]$. The proof of the proposition depends on the following two lemmas:

Lemma 3.5. *The group $E(K[\infty])_{\mathrm{tors}}$ is finite.*

Proof. Let q be any prime which is a prime of good reduction for E, which is inert in K and which is different from the primes in Λ^1 (there are infinitely many such primes according to Čebotarev density theorem). Let $\mathfrak{q}$ be the unique prime of K over q. It follows from class field theory that the prime $\mathfrak{q}$ splits completely in $K[\infty]$ since it splits completely in each of the finite extensions $K[c]$. Thus, the completion of $K[\infty]$ at any prime which lies over $\mathfrak{q}$ is isomorphic to $K_{\mathfrak{q}}$ and therefore, $E(K[\infty])_{\mathrm{tors}} \hookrightarrow E(K_{\mathfrak{q}})_{\mathrm{tors}}$. The last group is finite since it is isomorphic to an extension of $\mathbb{Z}_q^2$ by a finite group (see [Mil86, Lem.I.3.3] or [Tat67, p.168-169]). Therefore, $E(K[\infty]_{\mathrm{tors}})$ is finite. □

Let $|E(K[\infty])_{\mathrm{tors}}| = M < \infty$ and let $d(c) = [K[c] : K[1]] = \prod_{\ell | c} (\ell + 1)$ for any $c \in \Lambda$. Let m_E be the modular degree of E, i.e., the degree of the fixed optimal modular parametrization $\varphi : X_0(N) \to E$.

Lemma 3.6. *Suppose that $c \in \Lambda$ satisfies $d(c) > m_E M$. There exists a set of lifting R of $\mathrm{Gal}(K[1]/K)$ into $\mathrm{Gal}(K[c]/K)$, such that $D_0 y_c \notin E(K[c])_{\mathrm{tors}}$, where $D_0 = \sum_{\sigma \in R} \sigma$.*

Proof. The $\mathrm{Gal}(K[c]/K[1])$-orbit of the point $x_c \in X_0(N)(K[c])$ consists of $d(c)$ distinct points (since $K[c] = K(j(\mathcal{O}_c)))$, so there are at least $d(c)/m_E$ distinct points in the orbit $\mathrm{Gal}(K[c]/K[1])y_c$. Choose a set of representatives R of $\mathrm{Gal}(K[c]/K)/\mathrm{Gal}(K[c]/K[1])$ which contains the identity element $1 \in \mathrm{Gal}(K[c]/K)$. For $\tau \in \mathrm{Gal}(K[c]/K[1])$ define

$$R_\tau = (R - \{1\}) \cup \{\tau\}.$$

Let $S = \sum_{\sigma \in R} \sigma y_c$ and $S_\tau = \sum_{\sigma \in R_\tau} \sigma y_c$. Then

$$S_\tau - S = \tau y_c - y_c,$$

which takes at least $d(c)/m_E > M$ distinct values. Therefore, there exists an automorphism $\tau \in \mathrm{Gal}(K[c]/K[1])$, for which $S_\tau \notin E(K[c])_{\mathrm{tors}}$, which proves the lemma. □

Proof of Proposition 3.4. Suppose that $c \in \Lambda$ satisfies the statement of Lemma 3.6 for some choice of liftings R and the corresponding $D_0 = \sum_{\sigma \in R}$, i.e., $D_0 y_c \notin E(K[c])_{\mathrm{tors}}$. For any ring class character $\chi : \mathrm{Gal}(K[c]/K) \to \mathbb{C}^\times$, let $e_\chi \in \mathbb{C}[\mathrm{Gal}(K[c]/K)]$ be the eidempotent projector corresponding to χ. Explicitly,

$$e_\chi = \frac{1}{\# \mathrm{Gal}(K[c]/K)} \sum_{\sigma \in \mathrm{Gal}(K[c]/K)} \chi^{-1}(\sigma)\sigma \in \mathbb{C}[\mathrm{Gal}(K[c]/K)].$$

Consider $V = E(K[c]) \otimes \mathbb{C}$ as a complex representation of $\mathrm{Gal}(K[c]/K)$. The representation V decomposes as

$$V = \bigoplus_{\chi : \mathrm{Gal}(K[c]/K) \to \mathbb{C}^\times} V_\chi,$$

where V_χ is the one-dimensional subspace on which $\mathrm{Gal}(K[c]/K[1])$ acts via the character χ. Since the vector $D_0 y_c \otimes 1 \in V$ is non-zero, there exists a ring class character χ, such that $e_\chi(D_0 y_c \otimes 1) \neq 0$.

Next, we consider the point $D_0 D_c y_c \in E(K[c])$ and claim that $D_0 D_c y_c \otimes 1 \in E(K[c]) \otimes \mathbb{C}$ is non-zero, which is sufficient to conclude that $P_c = D_0 D_c y_c \notin E(K[c])_{\mathrm{tors}}$. We will prove that $e_\chi(D_0 D_c y_c \otimes 1) \neq 0$. Indeed,

$$e_\chi(D_0 D_c y_c \otimes 1) = e_\chi D_c (D_0 y_c \otimes 1) = \prod_{\ell \mid c} \left(\sum_{i=1}^{\ell} i \sigma_\ell^i \right) e_\chi (D_0 y_c \otimes 1) =$$

$$= \prod_{\ell \mid c} \left(\sum_{i=1}^{\ell} i \chi(\sigma_\ell)^i \right) e_\chi (D_0 y_c \otimes 1),$$

the last equality holding since $\tau e_\chi = \chi(\tau) e_\chi$ in $\mathbb{C}[\mathrm{Gal}(K[c]/K)]$ for all $\tau \in \mathrm{Gal}(K[c]/K)$. Thus, it remains to compute $\sum_{i=1}^{\ell} i\chi(\sigma_\ell)^i$ for every $\ell \mid c$. It is not hard to show that

$$\sum_{i=1}^{\ell} i\chi(\sigma_\ell)^i = \begin{cases} \frac{\ell+1}{\chi(\sigma_\ell)-1} & \text{if } \chi(\sigma_\ell) \neq 1 \\ \frac{\ell(\ell+1)}{2} & \text{if } \chi(\sigma_\ell) = 1. \end{cases}$$

Thus, $e_\chi(D_0 D_c y_c \otimes 1) \neq 0$ which means that $P_c = D_0 D_c y_c \notin E(K[c])_{\mathrm{tors}}$ for any c satisfying $D_0 y_c \notin E(K[c])_{\mathrm{tors}}$. To complete the proof, notice that for all, but finitely many $c \in \Lambda$, the hypothesis of Lemma 3.6 will be satisfied. □

3.6 Computational evidence for Kolyvagin's conjecture

Consider the example $E =$ **389a1** with equation $y^2 + y = x^3 + x^2 - 2x$. As in Section 2.3, let $D = 7$, $\ell = 5$, and $p = 3$. Using the algorithm of [GJP$^+$05, §2.1] we verify that the mod p Galois representation $\overline{\rho}_{E,p}$ is surjective. Next, we observe that $\ell = 5$ is a Kolyvagin prime for E, p and D. Let $c = 5$ and consider the class $\kappa_{5,1} \in \mathrm{H}^1(K, E[3])$. We claim that $\kappa_{5,1} \neq 0$, which will verify Kolyvagin's conjecture.

Proposition 3.7. *The class $\kappa_{5,1} \neq 0$. In other words, Kolyvagin's conjecture holds for $E =$* **389a1**, *$D = 7$ and $p = 3$.*

Before proving the proposition, we recall some standard facts about division polynomials (see, e.g., [Sil92, Ex.3.7]). For an elliptic curve given in Weierstrass form over any field of characteristic different from 2 and 3, $y^2 = x^3 + Ax + B$, one defines a sequence of polynomials $\psi_m \in \mathbb{Z}[A, B, x, y]$

inductively as follows:

$$\begin{aligned}
&\psi_1 = 1,\ \psi_2 = 2y,\\
&\psi_3 = 3x^4 + 6Ax^2 + 12Bx - A^2,\\
&\psi_4 = 4y(x^6 + 5Ax^4 + 20Bx^3 - 5A^2x^2 - 4ABx - 8B^2 - A^3),\\
&\psi_{2m+1} = \psi_{m+2}\psi_m^3 - \psi_{m-1}\psi_{m+1}^3 \ \text{ for } m \geqslant 2,\\
&2y\psi_{2m} = \psi_m(\psi_{m+2}\psi_{m-1}^2 - \psi_{m-2}\psi_{m+1}^2) \ \text{ for } m \geqslant 3.
\end{aligned}$$

Define also polynomials ϕ_m and ω_m by

$$\phi_m = x\psi_m^2 - \psi_{m+1}\psi_{m-1},\ 4y\omega_m = \psi_{m+2}\psi_{m-1}^2 - \psi_{m-2}\psi_{m+1}^2.$$

After replacing y^2 by $x^3 + Ax + B$, the polynomials ϕ_m and ψ_m^2 can be viewed as polynomials in x with leading terms x^{m^2} and $m^2x^{m^2-1}$, respectively. Finally, multiplication-by-m is given by

$$mP = \left(\frac{\phi_m(P)}{\psi_m(P)^2}, \frac{\omega_m(P)}{\psi_m(P)^3}\right).$$

Proof of Proposition 3.7. We already computed the Heegner point y_5 on the model $y^2 + y = x^3 + x^2 - 2x$ in Section 2.3. The Weierstrass model for E is $y^2 = x^3 - 7/3x + 107/108$, so $A = -7/3$ and $B = 107/108$. We now compute the point $P_5 = \sum_{i=1}^{5} i\sigma^i(y_5) \in E(K[5])$ on the Weierstrass model, where σ is a generator of $\mathrm{Gal}(K[5]/K)$. To show that $\kappa_{5,1} \neq 0$ we need to check that there is no point $Q = (x, y)$, such that $3Q = P_5$. For the verification of this fact, we use the division polynomial ψ_3 and the polynomial ϕ_3. Indeed, it follows from the recursive definitions that

$$\begin{aligned}
\phi_3(x) = {} & x^9 - 12Ax^7 - 168Bx^6 + (30A^2 + 72B)x^5 - 168ABx^4 +\\
& + (36A^3 + 144AB - 96B^2)x^3 + 72A^2Bx^2 +\\
& + (9A^4 - 24A^2B + 96AB^2 + 144B^2)x + 8A^3B + 64B^3.
\end{aligned}$$

Consider the polynomial $g(x) = \phi_3(x) - X(P_5)\psi_3(x)^2$, where $X(P_5)$ is the x-coordinate of the point P_5 on the Weierstrass model. We factor $g(x)$ (which has degree 9) over the number field $K[5]$ and check that it is irreducible. In particular, there is no root of $g(x)$ in $K[5]$, i.e., there is no $Q \in E(K[5])$, such that $3Q = P_5$. Thus, $\kappa_{5,1} \neq 0$. □

Remark 6. Using exactly the same method as above, we verify Kolyvagin's conjecture for the other two elliptic curves of rank two from Section 2.3. For both $E =$ **709a1** and $E =$ **718b1** we use $D = 7$, $p = 3$ and $\ell = 5$ (which are valid parameters), and verify that $\kappa_{5,1} \neq 0$ in the two cases. For completeness, we provide all the data of each computation in the three examples in the files `389a1.txt`, `709a1.txt` and `718a1.txt`.

4. Non-trivial elements in the Shafarevich-Tate group

Throughout the entire section, let $E_{/\mathbb{Q}}$ be a non-CM elliptic curve, $K = \mathbb{Q}(\sqrt{-D})$, where D is a Heegner discriminant for E such that the Heegner point y_K has infinite order in $E(K)$ (which, by the Gross-Zagier formula and Kolyvagin's result, means that $E(K)$ has Mordell-Weil rank one) and let p be a prime, such that $p \nmid DN$ and the mod p Galois representation $\overline{\rho}_{E,p}$ is surjective.

4.1 Non-triviality in Kolyvagin classes.

Under the above assumptions, the next proposition provides a criterion which guarantees that an explicit class in the Shafarevich-Tate group $\text{Ш}(E/K)$ is non-zero.

Proposition 4.1. *Let $c \in \Lambda_m$. Assume that the following hypotheses are satisfied:*

i) *[Selmer hypothesis]: The class* $\kappa_{c,m} \in \mathrm{H}^1(K, E[p^m])$ *is an element of the Selmer group* $\mathrm{Sel}_{p^m}(E/K)$.

ii) *[Non-divisibility]: The derived Heegner point* P_c *is not divisible by* p^m *in* $E(K[c])$*, i.e.,* $P_c \notin p^m E(K[c])$.

iii) *[Parity]: The number* $f_c = \#\{\ell : \ell \mid c\}$ *is odd.*

Then the image $\kappa'_{c,m} \in \mathrm{H}^1(K, E)[p^m]$ *of* $\kappa_{c,m}$ *is a non-zero element of* $\text{Ш}(E/K)[p^m]$.

Proof. The first hypothesis implies that the image $\kappa'_{c,m}$ of $\kappa_{c,m}$ in $\mathrm{H}^1(K, E)[p^m]$ is an element of the Shafarevich-Tate group $\text{Ш}(E/K)$. The second one implies that $\kappa_{c,m} \neq 0$. To show that $\kappa'_{c,m} \neq 0$ we use the exact sequence

$$0 \to E(K)/p^m E(K) \to \mathrm{Sel}_{p^m}(E/K) \to \text{Ш}(E/K)[p^m] \to 0$$

which splits under the action of complex conjugation as

$$0 \to (E(K)/p^m E(K))^{\pm} \to \mathrm{Sel}_{p^m}(E/K)^{\pm} \to \text{Ш}(E/K)^{\pm}[p^m] \to 0.$$

According to [Gro91, Prop.5.4(2)], the class $\kappa_{c,m}$ lies in the ε_c-eigenspace of the Selmer group $\mathrm{Sel}_{p^m}(E/K)$ for the action of complex conjugation, where $\varepsilon_c = \varepsilon(-1)^{f_c} = -1$ (f_c is odd by the third hypothesis and $\varepsilon = 1$ since $-\varepsilon$ is the sign of the functional equation for $E_{/K}$ which is -1 by Gross-Zagier). On the other hand, the Heegner point $y_K = P_1$ lies in the ε_1-eigenspace of complex conjugation (again, by [Gro91, Prop.5.4(2)]) where $\varepsilon_1 = \varepsilon(-1)^{f_1} = 1$. Since $E(K)$ has rank one, the group $E(K)^-$ is torsion and since $E(K)[p] = 0$, we obtain that $(E(K)/p^m E(K))^- = 0$. Therefore,

$$\mathrm{Sel}_{p^m}(E/K)^- \cong \text{Ш}(E/K)^-[p^m],$$

which implies $\kappa'_{c,m} \neq 0$. □

4.2 The example $E =$ 53a1.

The Weierstrass equation for the curve $E =$**53a1** is $y^2 = x^3 + 405x + 16038$ and E has rank one over $\mathbb{Q}$. The Fourier coefficient $a_5(f) \equiv 5 + 1 \equiv 0 \mod 3$, so $\ell = 5$ is a Kolyvagin prime for E, the discriminant $D = 43$ and the prime $p = 3$. Kolyvagin's construction exhibits a class $\kappa_{5,1} \in \mathrm{H}^1(K, E[3])$. We will prove the following proposition:

Proposition 4.2. *The cohomology class* $\kappa_{5,1} \in \mathrm{H}^1(K, E[3])$ *lies in the Selmer group* $\mathrm{Sel}_3(E/K)$ *and its image* $\kappa'_{5,1}$ *in the Shafarevich-Tate group* $\text{Ш}(E/K)$ *is a nonzero* 3*-torsion element.*

Remark 7. Since E/K has analytic rank one, Kolyvagin's conjecture is automatic (since $m_0 < \infty$ by Gross-Zagier's formula) and one knows (see [McC91, Thm. 5.8]) that there exist Kolyvagin classes $\kappa'_{c,m}$ which generate $\text{Ш}(E/K)[p^\infty]$. Yet, this result is not explicit in the sense that one does not know any particular Kolyvagin class which is non-trivial. The above proposition exhibits an explicit non-zero cohomology class in the p-primary part of the Shafarevich-Tate group $\text{Ш}(E/K)$.

Proof. Using the data computed in Section 2.3 for this curve, we apply the Kolyvagin derivative to compute the point P_5. In order to do this, one needs a generator of the Galois group $\mathrm{Gal}(K[5]/K)$. Such a generator is determined by the image of α, which will be another root of $f(x)$ in $K[5]$. We check that the automorphism σ defined by

$$\begin{aligned} \alpha \mapsto\ & \frac{1}{1601320}(47343 + 54795\sqrt{-43})\alpha^5 + \frac{1}{2401980}(-614771 - 936861\sqrt{-43})\alpha^4 + \\ & + \frac{1}{600495}(34507457 + 40541607\sqrt{-43})\alpha^3 + \frac{1}{4803960}(102487877 - 767102463\sqrt{-43})\alpha^2 + \\ & + \frac{1}{400330}(-61171198 + 52833377\sqrt{-43})\alpha + \frac{1}{200165}(18971815 - 7453713\sqrt{-43}) \end{aligned}$$

is a generator (we found this automorphism by factoring the defining polynomial of the number field over the number field $K[5]$). Thus, we can compute $P_5 = \sum_{i=1}^{5} i\sigma^i(y_5)$.

Note that we are computing the point on the Weierstrass model of E rather than on the original model. The cohomology class $\kappa_{5,1}$ is trivial if and only if $P_5 \in 3E(K[5])$. To show that $P_5 \notin 3E(K[5])$, we repeat the argument from Proposition 3.7 and verify (using any factorization algorithm for polynomials over number fields) that the polynomial $g(x) = \phi_3(x) - X(P_5)\psi_3(x)^2$ has no linear factors over $K[5]$ (here, $X(P_5)$ is the x-coordinate of P_5). This means that there is no point $Q = (x, y) \in E(K[5])$, such that $3Q = P_5$, i.e., $\kappa_{5,1} \neq 0$. Finally, using Proposition 4.1 we conclude that the class $\kappa'_{5,1} \in Ш(E/K)[3]$ is non-trivial. □

Remark 8. For completeness, all the computational data is provided (with the appropriate explanations) in the file `53a1.txt`. We verified the irreducibility of $g(x)$ using MAGMA and PARI/GP independently.

Appendix A. Upper bounds on the logarithmic heights of the Heegner points y_c

We explain how to compute an upper bound on the logarithmic height $h(y_c)$. The method first relates the canonical height $\widehat{h}(y_c)$ to special values of the first derivatives of certain automorphic L-functions via Zhang's generalization of the Gross-Zagier formula. Then we either compute the special values up to arbitrary precision using a well-known algorithm (recently implemented by Dokchitser) or use effective asymptotic upper bounds (convexity bounds) on the special values and Cauchy's integral formula. Finally, using some known bounds on the difference between the canonical and the logarithmic heights, we obtain explicit upper bounds on the logarithmic height $h(y_c)$. We provide a summary of the asymptotic bounds in Section A.4 and refer the reader to [Jet] for complete details.

A.1 The automorphic L-functions $L(f, \chi, s)$ and $L(\pi_{f\otimes\theta_\chi}, s)$

Let $d_c = c^2 D$ and let $f = \sum_{n\geqslant 1} a_n q^n$ be the new eigenform of level N and weight two corresponding to E. Let $\chi : \mathrm{Gal}(K[c]/K) \to \mathbb{C}^\times$ be a ring class character.

1. The theta series θ_χ. Recall that ideal classes for $\mathrm{Pic}(\mathcal{O}_c)$ correspond to primitive, reduced binary quadratic forms of discriminants d_c. To each ideal class $\mathcal{A}$ we consider the corresponding binary quadratic form $Q_\mathcal{A}$ and the theta series $\theta_{Q_\mathcal{A}}$ associated to it via

$$\theta_{Q_\mathcal{A}} = \sum_M e^{2\pi i z Q_\mathcal{A}(M)}$$

which is a modular form for $\Gamma_0(d_c)$ of weight one with character ε (the quadratic character of K) according to Weil's converse theorem (see [Shi71] for details). This allows us to define a cusp form

$$\theta_\chi = \sum_{\mathcal{A}\in \mathrm{Pic}(\mathcal{O}_c)} \chi^{-1}(\mathcal{A})\theta_{Q_\mathcal{A}} \in S_1(\Gamma_0(d_c), \varepsilon).$$

Here, we view χ^{-1} as a character of $\mathrm{Pic}(\mathcal{O}_c)$ via the isomorphism $\mathrm{Pic}(\mathcal{O}_c) \cong \mathrm{Gal}(K[c]/K)$. Let $\theta_\chi = \sum_{m\geqslant 0} b_m q^m$ be the Fourier expansion. By $L(f, \chi, s)$ we will always mean the Rankin L-function $L(f \otimes \theta_\chi, s)$ (equivalently, the L-function associated to the automorphic representation $\pi = f \otimes \theta_\chi$ of GL_4).

2. The functional equation of $L(f, \chi, s)$. We recall some basic facts about the Rankin L-series $L(f \otimes \theta_\chi, s)$ following [Gro84, §III]. Since $(N, D) = 1$, the *conductor* of $L(f \otimes \theta_\chi, s)$ is $Q = N^2 d_c^2$.

The Euler factor at infinity (the gamma factor) is $L_\infty(f \otimes \theta_\chi, s) = \Gamma_{\mathbb{C}}(s)^2$. If we set

$$\Lambda(f \otimes \theta_\chi, s) = Q^{s/2} L_\infty(f \otimes \theta_\chi, s) L(f \otimes \theta_\chi, s)$$

then the function Λ has a holomorphic continuation to the entire complex plane and satisfies the functional equation

$$\Lambda(f \otimes \theta_\chi, s) = -\Lambda(f \otimes \theta_\chi, 2 - s).$$

In particular, the order of vanishing of $L(f \otimes \theta_\chi, s)$ at $s = 1$ is non-negative and odd, i.e., $L(f \otimes \theta_\chi, 1) = 0$.

3. The automorphic L-function $L(\pi_{f\otimes\theta_\chi}, s)$. In order to center the critical line at $\mathrm{Re}(s) = \frac{1}{2}$ instead of $\mathrm{Re}(s) = 1$ (which is consistent with Langlands convention), we consider the L-function $L(\pi_{f\otimes\theta_\chi}, s)$ corresponding to the automorphic representation attached to $f \otimes \theta_\chi$ for GL_4. This function satisfies

$$L(\pi_{f\otimes\theta_\chi}, s) = L\left(f \otimes \theta_\chi, s + \frac{1}{2}\right)$$

The function $L(\pi_{f\otimes\theta_\chi}, s)$ then satisfies a functional equation relating the values at s and $1 - s$. For a general automorphic L-function $L(\pi, s)$, we consider the corresponding Dirichlet series and Euler product

$$L(\pi, s) = \sum_{n \geqslant 1} \frac{\lambda_\pi(n)}{n^s} = \prod_p (1 - \alpha_{\pi,1}(p)p^{-s})^{-1} \ldots (1 - \alpha_{\pi,d}(p)p^{-s})^{-1},$$

which are absolutely convergent for $\mathrm{Re}(s) > 1$.

A.2 Zhang's formula

For a character χ of $\mathrm{Gal}(K[c]/K)$, let

$$e_\chi = \frac{1}{\#\,\mathrm{Gal}(K[c]/K)} \sum_{\sigma \in \mathrm{Gal}(K[c]/K)} \chi^{-1}(\sigma)\sigma \in \mathbb{C}[\mathrm{Gal}(K[c]/K)]$$

be the associated eidempotent (see also Section 3.5). The canonical height $\widehat{h}(e_\chi y_c)$ is related via the generalized Gross-Zagier formula of Zhang to a special value of the derivative of the Rankin-Selberg L-function $L(f, \chi, s)$ at $s = 1$ (see [Zha01, Thm.1.2.1]). More precisely,

Theorem A.1 (Zhang). *If $(\,,)$ denotes the Petersson inner product on $S_2(\Gamma_0(N))$ then*

$$L'(f, \chi, 1) = \frac{4}{\sqrt{D}}(f, f)\widehat{h}(e_\chi y_c).$$

Since $\langle e_{\chi'} y_c, e_{\chi''} y_c \rangle = 0$ whenever $\chi' \neq \chi''$ (here, $\langle\,,\rangle$ denotes the Néron-Tate height pairing for E) and since $\widehat{h}(x) = \langle x, x \rangle$ then

$$\widehat{h}(y_c) = \widehat{h}\left(\sum_\chi e_\chi y_c\right) = \sum_\chi \widehat{h}(e_\chi y_c). \tag{3}$$

Thus, we will have an upper bound on the canonical height $\widehat{h}(y_c)$ if we obtain upper bounds on the special values $L'(f, \chi, 1)$ for every character χ of $\mathrm{Gal}(K[c]/K)$.

A.3 Computing special values of derivatives of automorphic L-functions

For simplicity, let $\gamma(s) = L_\infty(f \otimes \theta_\chi, s + 1/2)$ be the gamma factor of the L-function $L(\pi, s)$. This means that if $\Lambda(\pi, s) = Q^{s/2}\gamma(s)L(\pi, s)$ then $\Lambda(\pi, s)$ satisfies the functional equation $\Lambda(\pi, s) = \Lambda(\pi, 1 - s)$. We will describe a classical algorithm to compute the value of $L^{(k)}(\pi, s)$ at $s = s_0$ up to arbitrary precision. The algorithm and its implementation is discussed in a greater generality in [Dok04]. The main idea is to express $\Lambda(\pi, s)$ as an infinite series with rapid convergence which is usually done in the following sequence of steps:

i) Consider the inverse Mellin transform of the gamma factor $\gamma(s)$, i.e., the function $\phi(t)$ which satisfies
$$\gamma(s) = \int_0^\infty \phi(t) t^s \frac{dt}{t}.$$
One can show (see [Dok04, §3]) that $\phi(t)$ decays exponentially for large t. Hence, the sum
$$\Theta(t) = \sum_{n=1}^\infty \lambda_\pi(n) \phi\left(\frac{nt}{\sqrt{Q}}\right)$$
converges exponentially fast. The function $\phi(t)$ can be computed numerically as explained in [Dok04, §3-5].

ii) The Mellin transform of $\Theta(t)$ is exactly the function $\Lambda(\pi, s)$. Indeed,
$$\int_0^\infty \Theta(t) t^s \frac{dt}{t} = \int_0^\infty \sum_{n=1}^\infty \lambda_\pi(n) \phi\left(\frac{nt}{\sqrt{Q}}\right) t^s \frac{dt}{t} = \sum_{n=1}^\infty \lambda_\pi(n) \int_0^\infty \phi\left(\frac{nt}{\sqrt{Q}}\right) t^s \frac{dt}{t} =$$
$$= \sum_{n=1}^\infty \lambda_\pi(n) \left(\frac{\sqrt{Q}}{n}\right)^s \int_0^\infty \phi(t') t'^s \frac{dt'}{t'} = Q^{s/2} \gamma(s) L(\pi, s) = \Lambda(\pi, s).$$

iii) Next, we obtain a functional equation for $\Theta(t)$ which relates $\Theta(t)$ to $\Theta(1/t)$. Indeed, since $\Lambda(\pi, s)$ is holomorphic, Mellin's inversion formula implies that
$$\Theta(t) = \int_{c-i\infty}^{c+i\infty} \Lambda(\pi, s) t^{-s} ds, \ \forall c.$$
Therefore,
$$\Theta(1/t) = \int_{c-i\infty}^{c+i\infty} \Lambda(\pi, s)(1/t)^{-s} ds = -t \int_{c-i\infty}^{c+i\infty} \Lambda(\pi, 1-s) t^{-(1-s)} ds =$$
$$= -t \int_{c-i\infty}^{c+i\infty} \Lambda(\pi, s') t^{-s'} ds' = -t\Theta(t).$$
Thus, $\Theta(t)$ satisfies the functional equation $\Theta(1/t) = -t\Theta(t)$.

iv) Next, we consider the incomplete Mellin transform
$$G_s(t) = t^{-s} \int_t^\infty \phi(x) x^s \frac{dx}{x}, \ t > 0$$
of $\phi(t)$. The function $G_s(t)$ satisfies $\lim_{t \to 0} t^s G_s(t) = \gamma(s)$ and it decays exponentially. Moreover, it can be computed numerically (see [Dok04, §4-5]).

v) Finally, we use the functional equation for $\Theta(t)$ to obtain
$$\Lambda(\pi, s) = \int_0^\infty \Theta(t) t^s \frac{dt}{t} = \int_0^1 \Theta(t) t^s \frac{dt}{t} + \int_1^\infty \Theta(t) t^s \frac{dt}{t} =$$
$$= \int_1^\infty \Theta(1/t') t'^{-s} \frac{dt'}{t'} + \int_1^\infty \Theta(t) t^s \frac{dt}{t} =$$
$$= -\int_1^\infty \Theta(t') t'^{1-s} \frac{dt'}{t'} + \int_1^\infty \Theta(t) t^s \frac{dt}{t}.$$

vi) Finally, we compute

$$\int_1^\infty \Theta(t)t^s\frac{dt}{t} = \int_1^\infty \sum_{n=1}^\infty \lambda_\pi(n)\phi\left(\frac{nt}{\sqrt{Q}}\right)t^s\frac{dt}{t} = \sum_{n=1}^\infty \lambda_\pi(n)\int_1^\infty \phi\left(\frac{nt}{\sqrt{Q}}\right)t^s\frac{dt}{t} =$$

$$= \sum_{n=1}^\infty \lambda_\pi(n)\int_{\frac{n}{\sqrt{Q}}}^\infty \phi\left(t'\right)\left(\frac{\sqrt{Q}t'}{n}\right)^s = \sum_{n=1}^\infty \lambda_\pi(n)G_s\left(\frac{n}{\sqrt{Q}}\right).$$

Thus,

$$\Lambda(\pi, s) = \sum_{n=1}^\infty \lambda_\pi(n)G_s\left(\frac{n}{\sqrt{Q}}\right) - \sum_{n=1}^\infty \lambda_\pi(n)G_{1-s}\left(\frac{n}{\sqrt{Q}}\right)$$

is the desired expansion. From here, we obtain a formula for the k-th derivative

$$\frac{\partial^k}{\partial s^k}\Lambda(\pi, s) = \sum_{n=1}^\infty \lambda_\pi(n)\frac{\partial^k}{\partial s^k}G_s\left(\frac{n}{\sqrt{Q}}\right) - \sum_{n=1}^\infty \lambda_\pi(n)\frac{\partial^k}{\partial s^k}G_{1-s}\left(\frac{n}{\sqrt{Q}}\right).$$

The computation of the derivatives of $G_s(x)$ is explained in [Dok04, §3-5].

A.4 Asymptotic estimates on the canonical heights $\widehat{h}(y_c)$

In this section we provide an asymptotic bound on the canonical height $\widehat{h}(y_c)$ by using convexity bounds on the special values of the automorphic L-functions $L(\pi, s)$ defined in Section A.1. We only outline the basic techniques used to prove the asymptotic bounds and refer the reader to [Jet] for the complete details. Asymptotic bounds on heights of Heegner points are obtained in [RV], but these bounds are of significantly different type than ours. In our case, we fix the elliptic curve E and let the fundamental discriminant D and the conductor c of the ring class field both vary. We obtain the following:

Proposition A.2. *Fix the elliptic curve E and let the fundamental discriminant D and the conductor c vary. For any $\varepsilon > 0$ the following asymptotic bound holds*

$$\widehat{h}(y_c) \ll_{\varepsilon,f} h_D D^\varepsilon c^{2+\varepsilon},$$

where h_D is the class number of the quadratic imaginary field $K = \mathbb{Q}(\sqrt{-D})$. Moreover, the implied constant depends only on ε and the cusp form f.

One proves the proposition by combining the formula of Zhang with convexity bounds on special values of automorphic L-functions. The latter are conveniently expressed in terms of a quantity known as the *analytic conductor* associated to the automorphic representation π (see [Mic02, p.12]). It is a function $Q_\pi(t)$ over the real line, which is defined as

$$Q_\pi(t) = Q \cdot \prod_{i=1}^d (1 + |it - \mu_{\pi,i}|), \ \forall t \in \mathbb{R},$$

where $\mu_{\pi,i}$ are obtained from the gamma factor

$$L_\infty(\pi, s) = \prod_{i=1}^d \Gamma_\mathbb{R}(s - \mu_{\pi,i}), \ \Gamma_\mathbb{R}(s) = \pi^{-s/2}\Gamma(s/2).$$

In our situation for $\pi = \pi_{f\otimes\theta_\chi}$, $d = 4$ and $\mu_{\pi,1} = \mu_{\pi,2} = 0$, $\mu_{\pi,3} = \mu_{\pi,4} = 1$ (see [Mic02, §1.1.1] and [Ser70, §3] for discussions of local factors at archimedian places). Moreover, we let $Q_\pi = Q_\pi(0)$.

The main idea is to prove that for a fixed f, $|L'(\pi_{f\otimes\theta_\chi}, 1/2)| \ll_{\varepsilon,f} Q_{\pi_{f\otimes\theta_\chi}}^{1/4+\varepsilon}$, where the implied constant only depends on f and ε (and is independent of χ and the discriminant D). To establish the bound, we first prove an asymptotic bound for the L-function $L(\pi_{f\otimes\theta_\chi}, s)$ on the vertical line $\mathrm{Re}(s) =$

$1+\varepsilon$ by either using the Ramanujan-Petersson conjecture or a method of Iwaniec (see [Mic02, p.26]). This gives us the estimate $|L(\pi_{f\otimes\theta_\chi}, 1+\varepsilon+it)| \ll_{\varepsilon,f} Q_{\pi_{f\otimes\theta_\chi}}(t)^{\varepsilon}$. Then, by the functional equation for $L(\pi_{f\otimes\theta_\chi}, s)$ and Stirling's approximation formula, we deduce an upper bound for the L-function on the vertical line $\mathrm{Re}(s) = -\varepsilon$, i.e., $|L(\pi_{f\otimes\theta_\chi}, -\varepsilon+t)| \ll_{\varepsilon,f} Q_{\pi_{f\otimes\theta_\chi}}(t)^{1/2+\varepsilon}$. Next, we apply Phragmen-Lindelöf's convexity principle (see [IK04, Thm.5.53]) to obtain the bound $|L(\pi_{f\otimes\theta_\chi}, 1/2+it)| \ll_{\varepsilon,f} Q_{\pi}(t)^{1/4+\varepsilon}$ (also known as *convexity bound*). Finally, by applying Cauchy's integral formula for a small circle centered at $s = 1/2$, we obtain the asymptotic estimate $|L'(\pi_{f\otimes\theta_\chi}, 1/2)| \ll_{\varepsilon,f} Q_{\pi_{f\otimes\theta_\chi}}^{1/4+\varepsilon}$. Since $Q = N^2 d_c^2 = N^2 D^2 c^4$ in our situation and since $[K[c] : K] = h_D \prod_{\ell|c}(\ell+1)$, Zhang's formula (Theorem A.1) and equation (3) imply that for any $\varepsilon > 0$,

$$\widehat{h}(y_c) \ll_{\varepsilon,f} h_D D^{\varepsilon} c^{2+\varepsilon}.$$

Remark 9. In the above situation (the Rankin-Selberg L-function of two cusp forms of levels N and $d_c = c^2 D$), one can even prove a subconvexity bound $|L'(\pi_{f\otimes\theta_\chi}, 1/2)| \ll_f D^{1/2-1/1057} c^{1-2/1057}$, where the implied constant depends only on f and is independent of χ (see [Mic04, Thm.2]). Yet, the proof relies on much more involved analytic number theory techniques than the convexity principle, so we do not discuss it here.

A.5 Height difference bounds and the main estimates

To estimate $h(y_c)$ we need a bound on the difference between the canonical and the logarithmic heights. Such a bound has been established in [Sil90] and [CPS06] and is effective.

Let F be a number field. For any non-archimedian place v of K, let $E^0(F_v)$ denote the points of $E(F_v)$ which specialize to the identity component of the Néron model of E over the ring of integers $\mathcal{O}_v$ of F_v. Moreover, let $n_v = [F_v : \mathbb{Q}_v]$ and let M_F^∞ denote the set of all archimedian places of F. A slightly weakened (but easier to compute) bounds on the height difference are provided by the following result of [CPS06, Thm.2]

Theorem A.3 (Cremona-Prickett-Siksek). *Let $P \in E(F)$ and suppose that $P \in E^0(F_v)$ for every non-archimedian place v of F. Then*

$$\frac{1}{3[F:\mathbb{Q}]} \sum_{v\in M_F^\infty} n_v \log \delta_v \leqslant h(P) - \widehat{h}(P) \leqslant \frac{1}{3[F:\mathbb{Q}]} \sum_{v\in M_F^\infty} n_v \log \varepsilon_v,$$

where ε_v and δ_v are defined in [CPS06, §2].

Remark 10. All of the points y_c in our particular examples satisfies the condition $y_c \in E^0(K[c]_v)$ for all non-archimedian places v of $K[c]$. Indeed, according to [GZ86, §III.3] (see also [Jet07, Cor.3.2]) the point y_c lies in $E^0(K[c]_v)$ up to a rational torsion point. Since $E(\mathbb{Q})_{\mathrm{tors}}$ is trivial for all the curves that we are considering, the above proposition is applicable. In general, one does not need this assumption in order to compute height difference bounds (see [CPS06, Thm.1] for the general case).

Remark 11. A method for computing ε_v and δ_v up to arbitrary precision for real and complex archimedian places is provided in [CPS06, §7-9].

Acknowledgements

We are indebted to Christophe Cornut for sharing his thoughts on the Kolyvagin's conjecture. We would like to thank Jan Nekovář for his helpful discussions on height bounds, Stephen D. Miller and Mark Watkins for pointing out analytic methods for estimating special values of derivatives of automorphic L-functions, Henri Darmon and David Jao for useful conversations on Heegner points computations, and Ken Ribet for reading the preliminary draft and for useful conversations.

Chapter 1

The BSD Rank Conjecture

This chapter explains the conjecture that Birch and Swinnerton-Dyer made about ranks of elliptic curves (the BSD rank conjecture).

1.1. Statement of the BSD Rank Conjecture

An excellent reference for this section is Andrew Wiles's Clay Math Institute paper [**Wil00**]. The reader is also strongly encouraged to look Birch's original paper [**Bir71**] to get a better sense of the excitement surrounding this conjecture, as exemplified in the following quote:

> "I want to describe some computations undertaken by myself and Swinnerton-Dyer on EDSAC by which we have calculated the zeta-functions of certain elliptic curves. As a result of these computations we have found an analogue for an elliptic curve of the Tamagawa number of an algebraic group; and conjectures (due to ourselves, due to Tate, and due to others) have proliferated."

An *elliptic curve* E over a field K is the projective closure of the zero locus of a nonsingular affine curve

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \tag{1.1.1}$$

where $a_1, a_2, a_3, a_4, a_6 \in K$. There is a simple algebraic condition on the a_i that ensures that (1.1.1) defines a nonsingular curve (see, e.g., [**Sil92**]).

An elliptic curve E has genus 1, and the set of points on E has a natural structure of *abelian group*, with identity element the one extra projective point at ∞. Again, there are simple algebraic formulas that, given two points P and Q on an elliptic curve, produce a third point $P+Q$ on the elliptic curve. Moreover, if P and Q both have coordinates in K, then so does $P+Q$. The *Mordell-Weil group*

$$E(K) = \{ \text{ points on } E \text{ with coordinates in } K \ \}$$

of E over K plays a central role in this book.

In the 1920s, Mordell proved that if $K=\mathbb{Q}$, then $E(\mathbb{Q})$ is finitely generated, and soon after Weil proved that $E(K)$ is finitely generated for any number field K, so

$$E(K) \approx \mathbb{Z}^r \oplus T, \tag{1.1.2}$$

where T is a finite group. Perhaps the chief invariant of an elliptic curve E over a number field K is the *rank*, which is the number r in (1.1.2).

Fix an elliptic curve E over $\mathbb{Q}$. For all but finitely many prime numbers p, the equation (1.1.1) reduces modulo p to define an elliptic curve over the finite field $\mathbb{F}_p$. The primes that must be excluded are exactly the primes that divide the discriminant Δ of (1.1.1).

As above, the set of points $E(\mathbb{F}_p)$ is an abelian group. This group is finite, because it is contained in the set $\mathbb{P}^2(\mathbb{F}_p)$ of rational points in the projective plane. Moreover, since it is the set of points on a (genus 1) curve, a theorem of Hasse implies that

$$|p+1-\#E(\mathbb{F}_p)| \leq 2\sqrt{p}.$$

The error terms

$$a_p = p+1-\#E(\mathbb{F}_p)$$

play a central role in almost everything in this book. We next gather together the error terms into a single "generating function":

$$\tilde{L}(E,s) = \prod_{p\nmid\Delta}\left(\frac{1}{1-a_pp^{-s}+p^{1-2s}}\right).$$

The function $\tilde{L}(E,s)$ defines a complex analytic function on some right half plane $\mathrm{Re}(s) > \frac{3}{2}$.

A deep theorem of Wiles et al. [**Wil95, BCDT01**], which many consider the crowning achievement of 1990s number theory, implies that $\tilde{L}(E,s)$ can be analytically continued to an analytic function on all $\mathbb{C}$. This implies that $\tilde{L}(E,s)$ has a Taylor series expansion about $s=1$:

$$\tilde{L}(E,s) = c_0 + c_1(s-1) + c_2(s-1)^2 + \cdots$$

Define the *analytic rank* r_{an} of E to be the order of vanishing of $\tilde{L}(E,s)$ as $s=1$, so

$$\tilde{L}(E,s) = c_{r_{\mathrm{an}}}(s-1)^{r_{\mathrm{an}}} + \cdots .$$

The definitions of the analytic and Mordell-Weil ranks could not be more different – one is completely analytic and the other is purely algebraic.

Conjecture 1.1 (Birch and Swinnerton-Dyer Rank Conjecture)**.** *Let E be an elliptic curve over $\mathbb{Q}$. Then the algebraic and analytic ranks of E are the same.*

This problem is extremely difficult. The conjecture was made in the 1960s, and hundreds of people have thought about it for over 4 decades. The work of Wiles et al. on modularity in late 1999, combined with earlier work of Gross, Zagier, and Kolyvagin, and many others proves the following partial result toward the conjecture.

Theorem 1.2. *Suppose E is an elliptic curve over $\mathbb{Q}$ and that $r_{\mathrm{an}} \leq 1$. Then the algebraic and analytic ranks of E are the same.*

In 2000, Conjecture 1.1 was declared a million dollar millenium prize problem by the Clay Mathematics Institute, which motivated even more work, conferences, etc., on the conjecture. Since then, to the best of my knowledge, not a single new result directly about Conjecture 1.1 has been proved[1]. The class of curves for which we know the conjecture is still the set of curves over $\mathbb{Q}$ with $r_{\mathrm{an}} \leq 1$, along with a finite set of individual curves on which further computer calculations have been performed (by Cremona, Watkins, myself, and others).

> *"A new idea is needed."*
> – Nick Katz on BSD, at a 2001 Arizona Winter School

And another quote from Bertolini-Darmon (2001):

> "The following question stands as the ultimate challenge concerning the Birch and Swinnerton-Dyer conjecture for elliptic curves over $\mathbb{Q}$: *Provide evidence for the Birch and Swinnerton-Dyer conjecture in cases where* $\mathrm{ord}_{s=1} L(E,s) > 1$."

1.2. The BSD Rank Conjecture Implies that $E(\mathbb{Q})$ is Computable

Proposition 1.3. *Let E be an elliptic curve over $\mathbb{Q}$. If Conjecture 1.1 is true, then there is an algorithm to compute the rank of E.*

Proof. By naively searching for points in $E(\mathbb{Q})$ we obtain a lower bound on r, which is closer and closer to the true rank r, the longer we run the search. At some point this lower bound will equal r, but without using further information we do not know when that will occur.

[1] Much interesting new work has been done on related conjectures and problems.

As explained, e.g., in [**Cre97**] (see also [**Dok04**]), we can for any k compute $L^{(k)}(E,1)$ to any desired precision. Such computations yield upper bounds on r_{an}. In particular, if we compute $L^{(k)}(E,1)$ and it is nonzero (to the precision of our computation), then $r_{\mathrm{an}} \leq k$. Eventually this method will also converge to give an upper bound on r_{an}, though again without further information we do not know when our computed upper bound on r_{an} equals to the true value of r_{an}.

Since we are assuming that Conjecture 1.1 is true, we know that $r = r_{\mathrm{an}}$, hence at some point the lower bound on r computed using point searches will equal the upper bound on r_{an} computed using the L-series. At this point, by Conjecture 1.1, we know the true value of r. □

Next we show that given the rank r, the full group $E(\mathbb{Q})$ is computable. The issue is that what we did above might have only computed a subgroup of finite index. The argument below follows [**Cre97**, §3.5] closely.

The *naive height* $h(P)$ of a point $P = (x,y) \in E(\mathbb{Q})$ is

$$h(P) = \log(\max(\mathrm{numer}(x), \mathrm{denom}(x))).$$

The *Néron-Tate canonical height* of P is

$$\hat{h}(P) = \lim_{n\to\infty} \frac{h(2^n P)}{4^n}.$$

Note that if P has finite order then $\hat{h}(P) = 0$. Also, a standard result is that the *height pairing*

$$\langle P, Q\rangle = \frac{1}{2}\left(\hat{h}(P+Q) - \hat{h}(P) - \hat{h}(Q)\right)$$

defines a nondegenerate real-valued quadratic form on $E(\mathbb{Q})/_{\mathrm{tor}}$ with discrete image.

Lemma 1.4. *Let $B > 0$ be a positive real number such that*

$$S = \{P \in E(\mathbb{Q}) \,:\, \hat{h}(P) \leq B\}$$

contains a set of generators for $E(\mathbb{Q})/2E(\mathbb{Q})$. Then S generates $E(\mathbb{Q})$.

Proof. Let A be the subgroup of $E(\mathbb{Q})/_{\mathrm{tor}}$ generated by the points in S. Suppose for the sake of contradiction that A is a proper subgroup. Then there is $Q \in E(\mathbb{Q}) \setminus A$ with $\hat{h}(Q)$ minimal, since $\hat{h}$ takes a discrete set of values. Since S contains generators for $E(\mathbb{Q})/2E(\mathbb{Q})$, there is an element $P \in S$ that is congruent to Q modulo $2E(\mathbb{Q})$, i.e., so that

$$Q = P + 2R,$$

for some $R \in E(\mathbb{Q})$. We have $R \notin A$ (since otherwise Q would be in A), so $\hat{h}(R) \geq \hat{h}(Q)$ by minimality. Finally, since $\hat{h}$ is quadratic and nonnegative, we have

$$\begin{aligned}\hat{h}(P) &= \frac{1}{2}\left(\hat{h}(Q+P) + \hat{h}(Q-P) - \hat{h}(Q)\right)\\ &\geq \frac{1}{2}\hat{h}(2R) - \hat{h}(Q)\\ &= 2\hat{h}(R) - \hat{h}(Q) \geq \hat{h}(Q) > B.\end{aligned}$$

(Here we use that $\hat{h}(P) = \langle P, P\rangle$ and use properties of a bilinear form.) □

Proposition 1.5. *Let E be an elliptic curve over $\mathbb{Q}$. If Conjecture 1.1 is true, then there is an algorithm to compute $E(\mathbb{Q})$.*

Proof. By Proposition 1.3 we can compute the rank r of $E(\mathbb{Q})$. Note that we can also trivially compute the subgroup $E(\mathbb{Q})[2]$ of elements of order 2 in $E(\mathbb{Q})$, since if E is given by $y^2 = x^3+ax+b$, then this subgroup is generated by points (α, β), where α is a rational root of $x^3 + ax + b$. Thus we can compute $s = \dim_{\mathbb{F}_2} E(\mathbb{Q})/2E(\mathbb{Q})$, since it is equal to $r + \dim E(\mathbb{Q})[2]$.

Run any search for points in $E(\mathbb{Q})$ and use that $\hat{h}$ is a nondegenerate quadratic form to find independent points $P_1, \ldots, P_r$ of infinite order. It is easy to check whether a point P is twice another point (just solve a relatively simple algebraic equation). Run through all subsets of the points P_i, and if any subset of the P_i sums to $2Q$ for some point $Q \in E(\mathbb{Q})$, then we replace one of the P_i by Q and decrease the index of our subgroup in $E(\mathbb{Q})$ by a factor of 2. Because $E(\mathbb{Q})$ is a finitely generated group, after a finite number of steps (and including the 2-torsion points found above) we obtain independent points $P_1, \ldots, P_s$ that generate $E(\mathbb{Q})/2E(\mathbb{Q})$.

Let C the the explicit bound of Cremona-Pricket-Siksek on the difference between the naive and canonical height (i.e., for any $P \in E(\mathbb{Q})$, we have $|h(P) - \hat{h}(P)| < C$). Let

$$B = \max\{\hat{h}(P_1), \ldots, \hat{h}(P_s)\}.$$

Then by a point search up to naive height $B + C$, we compute a set that contains the set S in Lemma 1.4. This set then contains generators for $E(\mathbb{Q})$, hence we have computed $E(\mathbb{Q})$.

□

1.3. The Complex L-series $L(E, s)$

In Section 1.1 we defined a function $\tilde{L}(E, s)$, which encoded information about $E(\mathbb{F}_p)$ for all but finitely many primes p. In this section we define the function $L(E, s)$, which includes information about all primes, and the function $\Lambda(E, s)$ that also includes information "at infinity".

Let E be an elliptic curve over $\mathbb{Q}$ defined by *a minimal Weierstrass equation*

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6. \tag{1.3.1}$$

A minimal Weierstrass equation in one for which the a_i are all integers and the discriminant $\Delta \in \mathbb{Z}$ is minimal amongs all discriminants of Weierstrass equations for E (again, see [**Sil92**] for the definition of the discriminant of a Weierstrass equation, and also for an explicit description of the allowed transformations of a Weierstrass equation).

For each prime number $p \nmid \Delta$, the equation (1.3.1) reduces modulo p to define an elliptic $E_{\mathbb{F}_p}$ over the finite field $\mathbb{F}_p$. Let

$$a_p = p + 1 - \#E(\mathbb{F}_p).$$

For each prime $p \mid \Delta$, we use the following recipe to define a_p. If the *singular* curve $E_{\mathbb{F}_p}$ has a cuspidal singularity, e.g., is $y^2 = x^3$, then let $a_p = 0$. If it has a a nodal singularity, e.g., like $y^2 = x^3 + x^2$, let $a_p = 1$ if the slope of the tangent line at the singular point is in $\mathbb{F}_p$ and let $a_p = -1$ if the slope is not in $\mathbb{F}_p$. Summarizing:

$$a_p = \begin{cases} 0 & \text{if the reduction is cuspidal (``additive''),} \\ 1 & \text{if the reduction is nodal and tangent line is } \mathbb{F}_p\text{-rational (``split multiplicative'')} \\ -1 & \text{if the reduction is nodal and tangent line is not } \mathbb{F}_p\text{-rational (``non-split multiplicative'} \end{cases}$$

Even in the cases when $p \mid \Delta$, we still have

$$a_p = p + 1 - \#E(\mathbb{F}_p).$$

When E has additive reduction, the nonsingular points form a group isomorphic to $(\mathbb{F}_p, +)$, and there is one singular point, hence $p+1$ points, so

$$a_p = p + 1 - (p + 1))) = 0.$$

When E has split multiplicative reduction, there is 1 singular point plus the number of elements of a group isomorphic to $(\mathbb{F}_p^*, \times)$, so $1 + (p - 1) = p$ points, and

$$a_p = p + 1 - p = 1.$$

When E has non-split multiplicative reduction, there is 1 singular point plus the number of elements of a group isomorphic $(\mathbb{F}_{p^2}^*/\mathbb{F}_p^*, \times)$, i.e., $p+2$ points, and

$$a_p = p + 1 - (p + 2) = -1.$$

The definition of the full L-function of E is then

$$L(E, s) = \prod_{p \mid \Delta} \frac{1}{1 - a_p p^{-s}} \cdot \prod_{p \nmid \Delta} \frac{1}{1 - a_p p^{-s} + p \cdot p^{-2s}}. = \sum_{n=1}^{\infty} \frac{a_n}{n^s}.$$

If in addition we add in a few more analytic factors to the L-function we obtain a function $\Lambda(E, s)$ that satisfies a remarkably simple functional equation. Let

$$\Gamma(z) = \int_0^\infty t^{z-1}e^{-t}dt$$

be the Γ-*function* (e.g., $\Gamma(n) = (n-1)!$), which defines a meromorphic function on $\mathbb{C}$, with poles at the non-positive integers.

Theorem 1.6 (Hecke, Wiles et al.). *There is a unique positive integer $N = N_E$ and sign $\varepsilon = \varepsilon_E \in \{\pm 1\}$ such that the function*

$$\Lambda(E, s) = N^{s/2} \cdot (2\pi)^{-s} \cdot \Gamma(s) \cdot L(E, s)$$

extends to a complex analytic function on all $\mathbb{C}$ that satisfies the functional equation

$$\Lambda(E, 2-s) = \varepsilon \cdot \Lambda(E, s), \tag{1.3.2}$$

for all $s \in \mathbb{C}$.

Proof. Wiles et al. prove that $L(E, s)$ is the L-series attached to a modular form (see Section **??** below), and Hecke proved that the L-series of a modular form analytically continues and satisfies the given functional equation. □

The integer $N = N_E$ is called the *conductor* of E and $\varepsilon = \varepsilon_E$ is called the *sign in the functional equation* for E or the *root number* of E. One can prove that the primes that divide N are the same as the primes that divide Δ. Moreover, for $p \geq 5$, we have that

$$\mathrm{ord}_p(N) = \begin{cases} 0, & \text{if } p \nmid \Delta, \\ 1, & \text{if } E \text{ has multiplicative reduction at } p, \text{ and} \\ 2, & \text{if } E \text{ has additive reduction at } p. \end{cases}$$

There is a geometric algorithm called Tate's algorithm that computes N in all cases and ε.

Example 1.7. Consider the elliptic curve E defined by

$$y^2 + y = x^3 + 50x + 31.$$

The above Weierstrass equation is minimal and has discriminant

$$-1 \cdot 5^6 \cdot 7^2 \cdot 11.$$

```
sage: e = EllipticCurve('1925d'); e
Elliptic Curve defined by y^2 + y = x^3 + 50*x + 31 over Rational Field
sage: e.is_minimal()
True
sage: factor(e.discriminant())
-1 * 5^6 * 7^2 * 11
```

At 5 the curve has additive reduction so $a_5 = 0$. At 7 the curve has split multiplicative reduction so $a_7 = 1$. At 11 the curve has nonsplit multiplicative reduction, so $a_{11} = -1$. Counting points for $p = 2, 3$, we find that

$$L(E, s) = \frac{1}{1^{-s}} + \frac{3}{3^{-s}} + \frac{-2}{4^{-s}} + \frac{1}{7^{-s}} + \frac{6}{9^{-s}} + \frac{-1}{11^{-s}} + \frac{-6}{12^{-s}} + \cdots$$

```
sage: [e.ap(p) for p in primes(14)]
[0, 3, 0, 1, -1, 4]
```

Corollary 1.8. *Let E be an elliptic curve over $\mathbb{Q}$, let $\varepsilon \in \{1, -1\}$ be the sign in the functional equation* (1.3.2)*, and let $r_{E,\mathrm{an}} = \mathrm{ord}_{s=1} L(E, s)$. Then*

$$\varepsilon = (-1)^{r_{E,\mathrm{an}}}.$$

Proof. Because $\Gamma(1) = 1$, we have $\mathrm{ord}_{s=1} L(E, s) = \mathrm{ord}_{s=1} \Lambda(E, s)$. It thus sufficies to prove the corollary with $L(E, s)$ replaced by $\Lambda(E, s)$. Note that $r = r_{E,\mathrm{an}}$ is the minimal integer $r \geq 0$ such that $\Lambda^{(r)}(E, 1) \neq 0$. By repeated differentiation, we see that for any integer $k \geq 0$, we have

$$(-1)^k \Lambda^{(k)}(E, 2 - s) = \varepsilon \cdot \Lambda^{(k)}(s). \tag{1.3.3}$$

Setting $s = 1$ and $k = r$, and using that $\Lambda^{(r)}(E, 1) \neq 0$, shows that $(-1)^r = \varepsilon$, as claimed. □

Conjecture 1.9 (The Parity Conjecture)**.** *Let E be an elliptic curve over $\mathbb{Q}$, let $r_{E,\mathrm{an}}$ be the analytic rank and $r_{E,\mathrm{alg}}$ be the algebraic rank. Then*

$$r_{E,\mathrm{alg}} \equiv r_{E,\mathrm{an}} \pmod 2.$$

Jan Nekovar has done a huge amount of work toward Conjecture 1.9; in particular, he proves it under the (as yet unproved) hypothesis that $Ш(E)$ is finite (see Section 2.2 below).

1.4. Computing $L(E, s)$

In this section we briefly describe one way to evaluate $L(E, s)$, for s real. See [**Dok04**] for a more sophisticated analysis of computing $L(E, s)$ and its Taylor expansion for any complex number s.

Theorem 1.10 (Lavrik). *We have the following rapidly-converging series expression for $L(E,s)$, for any complex number s:*

$$L(E,s) = N^{-s/2} \cdot (2\pi)^s \cdot \Gamma(s)^{-1} \cdot \sum_{n=1}^{\infty} a_n \cdot (F_n(s-1) - \varepsilon F_n(1-s))$$

where

$$F_n(t) = \Gamma\left(t+1, \frac{2\pi n}{\sqrt{N}}\right) \cdot \left(\frac{\sqrt{N}}{2\pi n}\right)^{t+1},$$

and

$$\Gamma(z,\alpha) = \int_{\alpha}^{\infty} t^{z-1} e^{-t} dt$$

is the incomplete Γ-function.

Theorem 1.10 above is a special case of a more general theorem that gives rapidly converging series that allow computation of any Dirichlet series $\sum a_n n^s$ that meromorphically continues to the whole complex plane and satisfies an appropriate functional equation. For more details, see [**Coh00**, §10.3], especially Exercise 24 on page 521 of [**Coh00**].

1.4.1. Approximating the Rank. Fix an elliptic curve E over $\mathbb{Q}$. The usual method to *approximate* the rank is to find a series that rapidly converges to $L^{(r)}(E,1)$ for $r = 0,1,2,3,\ldots$, then compute $L(E,1)$, $L'(E,1)$, $L^{(2)}(E,1)$, etc., until one appears to be nonzero. Note that half of the $L^{(k)}(E,1)$ are automatically 0 because of equation (1.3.3). For more details, see [**Cre97**, §2.13] and [**Dok04**].

In this section, we describe a slightly different method, which only uses Theorem 1.10 and the definition of the derivative.

Proposition 1.11. *Write*

$$L(E,s) = c_r(s-1)^r + c_{r+1}(s-1)^{r+1} + \cdots .$$

with $c_r \neq 0$. Then

$$\lim_{s\to 1} (s-1) \cdot \frac{L'(E,s)}{L(E,s)} = r.$$

Proof. Setting $L(s) = L(E,s)$, we have

$$\begin{aligned}\lim_{s\to 1} (s-1) \cdot \frac{L'(s)}{L(s)} &= \lim_{s\to 1} (s-1) \cdot \frac{rc_r(s-1)^{r-1} + (r+1)c_{r+1}(s-1)^r + \cdots}{c_r(s-1)^r + c_{r+1}(s-1)^{r+1} + \cdots} \\ &= r \cdot \lim_{s\to 1} \frac{c_r(s-1)^r + \frac{(r+1)}{r}c_{r+1}(s-1)^{r+1} + \cdots}{c_r(s-1)^r + c_{r+1}(s-1)^{r+1} + \cdots} \\ &= r.\end{aligned}$$

□

Thus the rank r is the limit as $s \to 1$ of a certain (smooth) function. We know this limit is an integer. But, for example, for the rank 4 curve

$$y^2 + xy = x^3 - x^2 - 79x + 289 \tag{1.4.1}$$

of conductor 234446 nobody has succeeded in proving that this integer limit is 4. (We can prove that the limit is either 2 or 4 by using the functionality equation (1.3.2) to show that the order of vanishing is even, then verifying by computation that $L^{(4)}(E,1) = 214.65233\ldots \neq 0$.)

Using the definition of derivative, we approximate $(s-1)\frac{L'(s)}{L(s)}$ as follows. For $|s-1|$ small, we have

$$\begin{aligned}(s-1)\frac{L'(s)}{L(s)} &= \frac{s-1}{L(s)} \cdot \lim_{h\to 0} \frac{L(s+h)-L(s)}{h} \\ &\approx \frac{s-1}{L(s)} \cdot \frac{L(s+(s-1)^2)-L(s)}{(s-1)^2} \\ &= \frac{L(s^2-s+1)-L(s)}{(s-1)L(s)}\end{aligned}$$

In fact, we have

$$\lim_{s\to 1}(s-1)\cdot\frac{L'(s)}{L(s)} = \lim_{s\to 1}\frac{L(s^2-s+1)-L(s)}{(s-1)L(s)}.$$

We can use this formula in SAGE to "approximate" r. First we start with a curve of rank 2.

```
sage: e = EllipticCurve('389a'); e.rank()
2
sage: L = e.Lseries_dokchitser()
sage: def r(e,s): L1=L(s); L2=L(s^2-s+1); return (L2-L1)/((s-1)*L1)
sage: r(e,1.01)
2.00413534247395
sage: r(e,1.001)
2.00043133754756
sage: r(e,1.00001)
2.00000433133371
```

Next consider the curve $y^2 + xy = x^3 - x^2 - 79x + 289$ of rank 4:

```
sage: e =  EllipticCurve([1, -1, 0, -79, 289])
sage: e.rank()
4
sage: L = e.Lseries_dokchitser(100)
sage: def r(e,s): L1=L(s); L2=L(s^2-s+1); return (L2-L1)/((s-1)*L1)
sage: R = RealField(100)
sage: r(e,R('1.01'))
4.0212949184444018810727106489
sage: r(e,R('1.001'))
4.0022223745190806421850637523
sage: r(e,R('1.00001'))
4.0000223250026401574120263050
sage: r(e,R('1.000001'))
4.0000022325922257758141597819
```

It certainly looks like $\lim_{s\to 1} r(s) = 4$. We know that $\lim_{s\to 1} r(s) \in \mathbb{Z}$, and if only there were a good way to bound the error we could conclude that the limit is 4. But this has stumped people for years, and probably it is nearly impossible without a deep result that somehow interprets $L''(E, 1)$ in a completely different way.

1.5. The p-adic $\mathcal{L}$-series

Fix[2] an elliptic curve E defined over $\mathbb{Q}$. We say a prime p is a prime of *good ordinary reduction* for E if $p \nmid N_E$ and $a_p \not\equiv 0 \pmod{p}$. The Hasse bound, i.e., that $|a_p| < 2\sqrt{p}$ on implies that if $p \geq 5$ then ordinary at p is the same as $a_p \neq 0$.

In this section, we define for each odd prime number p of good ordinary reduction for E a p-adic L-function $L_p(E, T)$. This is a p-adic analogue of the complex L-function $L(E, s)$ about which there are similar analogue of the BSD conjecture.

1.5.1. Hensel's lemma and the Teichmuller lift. The following standard lemma is proved by Newton iteration.

Lemma 1.12 (Hensel)**.** *If $f \in \mathbb{Z}_p[x]$ is a polynomial and $\beta \in \mathbb{Z}/p\mathbb{Z}$ is a multiplicity one root of $\overline{f}$, then there is a unique lift of β to a root of f.*

For example, consider the polynomial $f(x) = x^{p-1} - 1$. By Fermat's little theorem, it has $p-1$ distinct roots in $\mathbb{Z}/p\mathbb{Z}$, so by Lemma 1.12 there are $p-1$ roots of $f(x)$ in $\mathbb{Z}_p$, i.e., all the $p-1$st roots of unity are elements of $\mathbb{Z}_p$. The *Teichmuller lift* is the map that sends any $\beta \in (\mathbb{Z}/p\mathbb{Z})^*$ to the unique $(p-1)$st root of unity in $\mathbb{Z}_p^*$ that reduces to it.

The *Teichmuller character* is the homomorphism

$$\tau : \mathbb{Z}_p^* \to \mathbb{Z}_p^*$$

obtained by first reducing modulo p, then sending an element to its Teichmuller lift. The 1-*unit projection* character is the homomorphism

$$\langle \bullet \rangle : \mathbb{Z}_p^* \to 1 + p\mathbb{Z}_p$$

given by

$$\langle x \rangle = \frac{x}{\tau(x)}.$$

1.5.2. Modular Symbol and Measures. Let

$$f_E(z) = \sum_{n=1}^{\infty} a_n e^{2\pi i n z} \in S_2(\Gamma_0(N))$$

be the modular form associated to E, which is a holomorphic function on the extended upper half plane $\mathfrak{h} \cup \mathbb{Q} \cup \{\infty\}$. Let

$$\Omega_E = \int_{E(\mathbb{R})} \frac{dx}{2y + \underline{a}_1 x + \underline{a}_3} \in \mathbb{R}$$

[2] This section is based on correspondence with Robert Pollack and Koopa Koo.

be the real period associated to a minimal Weierstrass equation

$$y^2 + \underline{a}_1 xy + \underline{a}_3 y = x^3 + \underline{a}_2 x^2 + \underline{a}_4 x + \underline{a}_6$$

for E.

The *plus modular symbol map* associated to the elliptic curve E is the map $\mathbb{Q} \to \mathbb{Q}$ given by sending $r \in \mathbb{Q}$ to

$$[r] = [r]_E = \frac{2\pi i}{\Omega_E}\left(\int_r^{i\infty} f_E(z)dz + \int_{-r}^{i\infty} f_E(z)dz\right).$$

Question 1.13. Let E vary over all elliptic curve over $\mathbb{Q}$ and r over all rational numbers. Is the set of denominators of the rational numbers $[r]_E$ bounded? Thoughts: For a given curve E, the denominators are bounded by the order of the image in $E(\overline{\mathbb{Q}})$ of the cuspidal subgroup of $J_0(N)(\overline{\mathbb{Q}})$. It is likely one can show that if a prime ℓ divides the order of the image of this subgroup, then E admits a rational ℓ-isogeny. Mazur's theorem would then prove that the set of such ℓ is bounded, which would imply a "yes" answer to this question. Also, for any particular curve E, one can compute the cuspidal subgroup precisely, and hence bound the denominators of $[r]_E$.

Let a_p be the pth Fourier coefficient of E and note that the polynomial

$$x^2 - a_p x + p \equiv x(x - a_p) \pmod{p}$$

has distinct roots because p is an ordinary prime. Let α be the root of $x^2 - a_p x + p$ with $|\alpha|_p = 1$, i.e., the lift of the root a_p modulo p, which exists by Lemma 1.12.

Define a *measure on* $\mathbb{Z}_p^*$ by

$$\mu_E(a + p^n\mathbb{Z}_p) = \frac{1}{\alpha^n}\left[\frac{a}{p^n}\right] - \frac{1}{\alpha^{n+1}}\left[\frac{a}{p^{n-1}}\right].$$

That μ_E is a measure follows from the formula for the action of Hecke operators on modular symbols and that f_E is a Hecke eigenform. We will not prove this here[3].

1.5.3. The p-Adic L-function. Define the p-adic L-function as a function on characters

$$\chi \in \mathrm{Hom}(\mathbb{Z}_p^*, \mathbb{C}_p^*)$$

as follows. Send a character χ to

$$L_p(E, \chi) = \int_{\mathbb{Z}_p^*} \chi \, d\mu_E.$$

We will later make the integral on the right more precise, as a limit of Riemann sums (see Section 1.6).

[3] Add proof or good reference.

Remark 1.14. For any Dirichlet character $\chi : \mathbb{Z}/n\mathbb{Z} \to \mathbb{C}$, let $L(E, \chi, s)$ be the entire L-function defined by the Dirichlet series

$$\sum_{n=1}^{\infty} \frac{\chi(n)a_n}{n^s}.$$

The standard *interpolation property* of L_p is that for any primitive Dirichlet character χ of conductor p^n (for any n), we have[4]

$$L_p(E, \chi) = \begin{cases} p^n \cdot g(\chi) \cdot L(E, \bar{\chi}, 1)/\Omega_E & \text{for } \chi \neq 1, \\ (1 - \alpha^{-1})^2 L(E, 1)/\Omega_E & \text{if } \chi = 1, \end{cases} \tag{1.5.1}$$

where $g(\chi)$ is the Gauss sum:

$$g(\chi) = \sum_{a \mod p^n} \chi(a) e^{\frac{2\pi i a}{p^n}}.$$

Note, in particular, that $L(E, 1) \neq 0$ if and only if $L_p(E, 1) \neq 0$.

In order to obtain a Taylor series attached to L_p, we view L_p as a p-adic analytic function on the open disk

$$D = \{u \in \mathbb{C}_p : |u - 1|_p < 1\},$$

as follows. We have that $\gamma = 1 + p$ is a topological generator for $1 + p\mathbb{Z}_p$. For any $u \in D$, let $\psi_u : 1 + p\mathbb{Z}_p \to \mathbb{C}_p^*$ be the character given by sending γ to u and extending by using the group law and continuity. Extend ψ_u to a character $\chi_u : \mathbb{Z}_p^* \to \mathbb{C}_p^*$ by letting $\chi_u(x) = \psi_u(\langle x \rangle)$. Finally, overloading notation, let

$$L_p(E, u) = L_p(E, \chi_u).$$

Theorem 1.15. *The function $L_p(E, u)$ is a p-adic analytic function on D with Taylor series about $u = 1$ in the variable T*

$$\mathcal{L}_p(E, T) \in \mathbb{Q}_p[[T]].$$

that converges on $\{z \in \mathbb{C}_p : |z|_p < 1\}$. (Note that $L_p(E, u) = \mathcal{L}_p(E, u - 1)$.)

It is $\mathcal{L}_p(E, T)$ that we will compute explicitly.

Conjecture 1.16 (Mazur, Tate, Teitelbaum)**.**

$$\operatorname{ord}_T \mathcal{L}_p(E, T) = \operatorname{rank} E(\mathbb{Q}).$$

Proposition 1.17. *Conjecture 1.16 is true if* $\operatorname{ord}_T \mathcal{L}_p(E, T) \leq 1$.

[4] I copied this from Bertolini-Darmon, and I don't trust it exactly yet, especially because the line from Bertolini-Darmon for $\chi = 1$ was wrong.

Sketch of Proof. By Remark 1.14, we have $\mathrm{ord}_T(\mathcal{L}_p(E,T)) = 0$ if and only if

$$r_{E,\mathrm{an}} = \mathrm{ord}_{s=1} L(E,s) = 0.$$

Since the BSD rank conjecture (Conjecture 1.1) is a theorem when $r_{E,\mathrm{an}} = 0$, Conjecture 1.16 is also known under the hypothesis that $\mathrm{ord}_T(\mathcal{L}_p(E,T)) = 0$.

Recall that the BSD rank conjecture is also a theorem when $r_{E,\mathrm{an}} = 1$. It turns out that the same is true of Conjecture 1.16 above. If $\mathrm{ord}_T(\mathcal{L}_p(E,T)) = 1$, then a theorem of Perrin-Riou implies that a certain Heegner point has nonzero p-adic height, hence is non-torsion, so by the Gross-Zagier theorem $r_{E,\mathrm{an}} = 1$. Kolyvagin's theorem then implies that $\mathrm{rank}\, E(\mathbb{Q}) = 1$. □

Remark 1.18. Mazur, Tate, and Teitelbaum also define an analogue of $\mathcal{L}_p(E,T)$ for primes of bad multiplicative reduction and make a conjecture. A prime p is *supersingular* for E if $a_p \equiv 0 \pmod{p}$; it is a theorem of Elkies [**Elk87**] that for any elliptic curve E there are infinitely many supersingular primes p. Perrin-Riou, Pollack, Greenberg and others have studied $\mathcal{L}_p(E,T)$ at good supersingular primes. More works needs to be done on finding a definition of $\mathcal{L}_p(E,T)$ when p is a prime of bad additive reduction for E.

Remark 1.19. A theorem of Rohrlich implies that there is some character as in (1.5.1) such that $L(E,\chi,1) \neq 0$, so $\mathcal{L}_p(E,T)$ is not identically zero. Thus $\mathrm{ord}_T \mathcal{L}_p(T) < \infty$.

1.6. Computing $\mathcal{L}_p(E,T)$

Fix notation as in Section 1.5. In particular, E is an elliptic curve over $\mathbb{Q}$, p is an odd prime of good ordinary reduction for E, and α is the root of $x^2 - a_p x + p$ with $|\alpha|_p = 1$.

For each integer $n \geq 1$, define a polynomial

$$P_n(T) = \sum_{a=1}^{p-1} \left(\sum_{j=0}^{p^{n-1}-1} \mu_E \left(\tau(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot (1+T)^j \right) \in \mathbb{Q}_p[T].$$

Recall that $\tau(a) \in \mathbb{Z}_p^*$ is the Teichmuller lift of a.

Proposition 1.20. *We have that the p-adic limit of these polynomials is the p-adic L-series:*

$$\lim_{n\to\infty} P_n(T) = \mathcal{L}_p(E,T).$$

This convergence is coefficient-by-coefficient, in the sense that if $P_n(T) = \sum_j a_{n,j} T^j$ and $\mathcal{L}_p(E,T) = \sum_j a_j T^j$, then

$$\lim_{n\to\infty} a_{n,j} = a_j.$$

We now give a proof of this convergence and in doing so obtain an upper bound for $|a_j - a_{n,j}|$.

For any choice ζ_r of p^r-th root of unity in $\mathbb{C}_p$, let χ_r be the $\mathbb{C}_p$-valued character of $\mathbb{Z}_p^\times$ of order p^r which factors through $1 + p\mathbb{Z}_p$ and sends $1 + p$ to ζ_r. Note that the conductor of χ_r is p^{r+1}.

Lemma 1.21. *Let ζ_r be a p^r-th root of unity with $1 \leq r \leq n-1$, and let χ_r be the corresponding character of order p^{r+1}, as above. Then*

$$P_n(\zeta_r - 1) = \int_{\mathbb{Z}_p^\times} \chi_r \; d\mu_E$$

In particular, note that the right hand side does not depend on n.

Proof. Writing $\chi = \chi_r$, we have

$$\begin{aligned} P_n(\zeta_r - 1) &= \sum_{a=1}^{p-1} \sum_{j=0}^{p^{n-1}-1} \mu_E \left(\tau(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot \zeta_r^j \\ &= \sum_{a=1}^{p-1} \sum_{j=0}^{p^{n-1}-1} \mu_E \left(\tau(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot \chi\left((1+p)^j\right) \\ &= \sum_{b \in (\mathbb{Z}/p^n\mathbb{Z})^*} \mu_E\left(b + p^n\mathbb{Z}_p\right) \cdot \chi(b) \\ &= \int_{\mathbb{Z}_p^\times} \chi \; d\mu_E. \end{aligned}$$

In the second to the last equality, we use that

$$(\mathbb{Z}/p^n\mathbb{Z})^* \cong (\mathbb{Z}/p\mathbb{Z})^* \times (1 + p(\mathbb{Z}/p^n\mathbb{Z}))^*$$

to sum over lifts of $b \in (\mathbb{Z}/p^n\mathbb{Z})^*$ of the form $\tau(a)(1+p)^j$, i.e., a Teichmuller lift times a power of $(1+p)^j$. In the last equality, we use that χ has conductor p^n, so is constant on the residue classes modulo p^n, i.e., the last equality is just the Riemann sums definition of the given integral.

□

For each positive integer n, let $w_n(T) = (1+T)^{p^n} - 1$.

Corollary 1.22. *We have that*

$$w_{n-1}(T) \text{ divides } P_{n+1}(T) - P_n(T).$$

Proof. By Lemma 1.21, $P_{n+1}(T)$ and $P_n(T)$ agree on $\zeta_j - 1$ for $0 \leq j \leq n-1$ and any choice ζ_j of p^j-th root of unity, so their difference vanishes on every root of the polynomial $w_{n-1}(T) = (1+T)^{p^{n-1}} - 1$. The claimed divisibility follows, since $w_{n-1}(T)$ has distinct roots. □

Lemma 1.23. *Let $f(T)=\sum_j b_j T^j$ and $g(T)=\sum_j c_j T^j$ be in $\mathcal{O}[T]$ with $\mathcal{O}$ a finite extension of $\mathbb{Z}_p$. If $f(T)$ divides $g(T)$, then*

$$\operatorname{ord}_p(c_j) \geq \min_{0\leq i\leq j} \operatorname{ord}_p(b_i).$$

Proof. We have $f(T)k(T)=g(T)$. The lemma follows by using the definition of polynomial multiplication and the non-archimedean property of ord_p on each coefficient of $g(T)$. □

As above, let $a_{n,j}$ be the jth coefficient of the polynomial $P_n(T)$. Let

$$c_n = \max(0, -\min_j \operatorname{ord}_p(a_{n,j}))$$

so that $p^{c_n}P_n(T)\in\mathbb{Z}_p[T]$, i.e., c_n is the smallest power of p that clears the denominator. Note that c_n is an integer since $a_{n,j}\in\mathbb{Q}$. *Probably if $E[p]$ is irreducible then $c_n=0$ – see Question 1.13.* Also, for any $j>0$, let

$$e_{n,j} = \min_{1\leq i\leq j} \operatorname{ord}_p \binom{p^n}{i}.$$

be the min of the valuations of the coefficients of $w_n(T)$, as in Lemma 1.23.

Proposition 1.24. *For all $n\geq 0$, we have $a_{n+1,0}=a_{n,0}$, and for $j>0$,*

$$\operatorname{ord}_p(a_{n+1,j}-a_{n,j}) \geq e_{n-1,j} - \max(c_n, c_{n+1}).$$

Proof. Let $c=\max(c_n,c_{n+1})$. The divisibility of Corollary 1.8 implies that there is a polynomial $h(T)\in\mathbb{Z}_p[T]$ with

$$w_{n-1}(T)\cdot p^c h(T) = p^c P_{n+1}(T) - p^c P_n(T)$$

and thus (by Gauss' lemma) $p^c h(T)\in\mathbb{Z}_p[T]$ since the right hand side of the equation is integral and $w_{n-1}(T)$ is a primitive polynomial. Applying Lemma 1.23 and renormalizing by p^c gives the result. □

For j fixed, $e_{n-1,j}-\max(c_{n+1},c_n)$ goes to infinity as n grows since the c_k are uniformly bounded (they are bounded by the power of p that divides the order of the cuspidal subgroup of E). Thus, $\{a_{n,j}\}$ is a Cauchy and Proposition 1.24 implies that that

$$\operatorname{ord}_p(a_j - a_{n,j}) \geq e_{n-1,j} - \max(c_{n+1}, c_n).$$

Remark 1.25. Recall that presently there is not a single example where we can provably show that $\operatorname{ord}_{s=1} L(E,s)\geq 4$. Amazingly $\operatorname{ord}_T \mathcal{L}_p(E,T)$ is "computable in practice" because Kato has proved, using his Euler system in K_2, that $\operatorname{rank} E(\mathbb{Q}) \leq \operatorname{ord}_T \mathcal{L}_p(E,T)$ by proving a divisibility predicted by Iwasawa Theory. Thus computing elements of $E(\mathbb{Q})$ gives a provable lower bound, and approximating $\mathcal{L}_p(E,T)$ using Riemann sums gives a provable upper bound – in practice these meet.

Chapter 2

The Birch and Swinnerton-Dyer Formula

2.1. Galois Cohomology

Galois cohomology is the basic language used for much research into algebraic aspects of the BSD conjecture. It was introduced by Lang and Tate in 1958 in [**LT58**]. This section contains a survey of the basic facts we will need in order to define Shafarevich-Tate groups, discuss descent, and construct Kolyvagin's cohomology classes.

The best basic reference on Galois cohomology is chapters VII and X of Serre's *Local Fields* [**Ser79**] or the (very similar!) article by Atiyah and Wall in Cassels-Frohlich [**Cp86**, Ch. IV]. See also the article by Gruenberg in [**Cp86**, Ch. V] for an introduction to profinite groups such as $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$. Since this section is only a survey, you should read one of the above two references in detail, if you haven't already. You might also want to read Chapter 1 of [**CS00**] by Coates and Sujatha, which contains an excellent summary of more advanced topics in Galois cohomology, and Serre's book *Galois Cohomology* [**Ser97**] discusses many general advanced topics in depth. The original article [**LT58**] is also well worth reading.

2.1.1. Group Cohomology. If G is a multiplicative group, the *group ring* $\mathbb{Z}[G]$ is the ring of all finite formal sums of elements of G, with multiplication defined using distributivity and extending linearly. Let A be an additive group. We say that A is a *G-module* if A is equipped with a module structure over the group ring $\mathbb{Z}[G]$.

Let A^G be the submodule of elements of A that are fixed by G. Notice that if $A \to B$ is a homomorphism of G-modules, then restriction defines a homomorphism $A^G \to B^G$, so $A \mapsto A^G$ is a *functor*. In fact, it is a *left-exact* functor:

Proposition 2.1. *If $0 \to A \to B \to C$ is an exact sequence of G modules, then $0 \to A^G \to B^G \to C^G$ is also exact.*

Definition 2.2 (Group Cohomology)**.** The *group cohomology $H^n(G, A)$* is by definition the *right derived functors* of the left exact functor $A \to A^G$. These are the unique, up to canonical equivalence, functors H^n such that

- The sequence

$$0 \to A^G \to B^G \to C^G \xrightarrow{\delta} H^1(G, A) \to \cdots \to H^n(G, A) \to H^n(G, B) \to H^n(G, C) \xrightarrow{\delta} H^{n+1}(G, A) \to$$

  is exact.
- If A is *coinduced*, i.e., $A = \mathrm{Hom}(\mathbb{Z}[G], X)$ for X an abelian group, then

$$\mathrm{H}^n(G, A) = 0 \text{ for all } n \geq 1.$$

Remark 2.3. For those familiar with the Ext functor, we have

$$\mathrm{H}^n(G, A) = \mathrm{Ext}^n_{\mathbb{Z}[G]}(\mathbb{Z}, A).$$

We construct $\mathrm{H}^n(G, A)$ explicitly as follows. Consider $\mathbb{Z}$ as a G-module, equipped with the trivial G-action. Consider the following free resolution of $\mathbb{Z}$. Let P_i be the free $\mathbb{Z}$-module with basis the set of $i+1$ tuples $(g_0, \ldots, g_i) \in G^{i+1}$, and with G acting on P_i componentwise:

$$s(g_0, \ldots, g_i) = (sg_0, \ldots, sg_i).$$

The homomorphism $d : P_i \to P_{i+1}$ is given by

$$d(g_0, \ldots, g_i) = \sum_{j=0}^{i} (-1)^j (g_0, \ldots, g_{j-1}, g_{j+1}, \ldots g_i),$$

and $P_0 \to \mathbb{Z}$ is given by sending every element (g_0) to $1 \in \mathbb{Z}$.

The cohomology groups $\mathrm{H}^i(G, A)$ are then the cohomology groups of the complex $K_i = \mathrm{Hom}_{\mathbb{Z}[G]}(P_i, A)$. We identify an element of K_i with a function $f : G^{i+1} \to A$ such that the condition

$$f(sg_0, \ldots, sg_i) = sf(g_0, \ldots, g_i)$$

holds. Notice that such an $f \in K_i$ is uniquely determined by the function (of i inputs)

$$\varphi(g_1, \ldots, g_i) = f(1, g_1, g_1 g_2, \ldots, g_1 \cdots g_i).$$

The boundary map $d : K_i \to K_{i+1}$ on such functions $\varphi \in K_i$ is then given explicitly by the formula

$$\begin{aligned}(d\varphi)(g_1, \ldots, g_{i+1}) = g_1\varphi(g_2, \ldots, g_{i+1}) + \sum_{j=1}^{i}(-1)^j\varphi(g_2, \ldots, g_jg_{j+1}, \ldots, g_{i+1})\\ + (-1)^{i+1}\varphi(g_1, \ldots, g_i).\end{aligned}$$

The group of *n-cocycles* is the group of $\varphi \in K_n$, as above are functions of n variables such that $d\varphi = 0$. The subgroup of *n-coboundaries* is the image of K_{n+1} under d. Explicitly, the cohomology group $H^n(G, A)$ is the quotient of the group group of n-cocycles modulo the subgroup of n-coboundaries.

When $n = 1$, the 1-cocycles are the maps $G \to A$ such that

$$\varphi(gg') = g\varphi(g') + \varphi(g),$$

and φ is a coboundary if there exists $a \in A$ such that $\varphi(g) = ga - a$ for all $g \in G$. Notice that if G acts trivially on A, then

$$\mathrm{H}^1(G, A) = \mathrm{Hom}(G, A).$$

2.1.2. The inf-res Sequence. Suppose G is a group and H is a normal subgroup of G, and A is a G-module. Then for any $n \geq 0$, there are natural homomorphisms

$$\mathrm{res} : \mathrm{H}^n(G, A) \to \mathrm{H}^n(H, A)$$

and

$$\mathrm{inf} : \mathrm{H}^n(G/H, A^H) \to \mathrm{H}^n(G, A)$$

Require that we view n-cocycles as certain maps on the n-fold product of the group. On cocycles, the map res is obtained by simply restricting a cocycle, which is a map $G^i \to A$, to a map $H^i \to A$. The second map inf is obtained by precomposing a cocycle $(G/H)^i \to A^H$ with the natural map $G^i \to (G/H)^i$.

Proposition 2.4. *The* inf-res sequence

$$0 \to \mathrm{H}^1(G/H, A^H) \xrightarrow{\mathrm{inf}} \mathrm{H}^1(G, A) \xrightarrow{\mathrm{res}} \mathrm{H}^1(H, A)$$

is exact.

Proof. See [**Ser79**, §VII.6]. □

2.1.3. Galois Cohomology. Let K be a field and L a finite *Galois extension* of K, so the set of field automorphisms of L that fix K equals the dimension of L viewed as a K-vector space.

For any $\mathrm{Gal}(L/K)$-module A and any $n \geq 0$, let

$$\mathrm{H}^n(L/K, A) = \mathrm{H}^n(\mathrm{Gal}(L/K), A).$$

If $M/L/K$ is a tower of Galois extensions of K and suppose $\mathrm{Gal}(M/K)$ acts on A. Then inf defines a map

$$\mathrm{H}^n(L/K, A^L) \to \mathrm{H}^n(M/K, A). \tag{2.1.1}$$

Let K^{sep} denote a separable closure of K and suppose A is a (continuous) $\mathrm{Gal}(K^{\mathrm{sep}}/K)$-module. (Note – if K has characteristic 0, then a separable closure is the same thing as an algebraic closure.) For any subfield $L \subset K^{\mathrm{sep}}$ that contains K, let $A(L) = A^L$. Let

$$\mathrm{H}^n(K, A) = \varinjlim_{L/K \text{ finite Galois}} \mathrm{H}^n(L/K, A(L)),$$

where the direct limit is with respect to the maps (2.1.1). We can think of this direct limit as simply the union of all the groups, where we identify two elements if they are eventually equal under some map (2.1.1).

One can prove (see [**Cp86**, Ch. V]) that changing the choice of separable closure K^{sep} only changes $\mathrm{H}^n(K, A)$ by unique isomorphism, i.e., the construction is essentially independent of the choice of seperable closure.

2.2. The Shafarevich-Tate Group

In this section we discuss Galois cohomology of elliptic curves, introduce the Kummmer sequence, define the Selmer group, the Shafarevich-Tate group and dicuss descent and the Mordell-Weil theorem.

2.2.1. The Elliptic Curve Kummer Sequence. Let E be an elliptic curve over a number field K. Consider the abelian group $E(\overline{\mathbb{Q}})$ of all points on E defined over a fixed choice $\overline{\mathbb{Q}}$ of algebraic closure of $\mathbb{Q}$. Then A is a module over $\mathrm{Gal}(\overline{\mathbb{Q}}/K)$, and we may consider the Galois cohomology groups

$$\mathrm{H}^n(K, E), \qquad \text{for } n = 0, 1, 2, \ldots$$

which are of great interest in the study of elliptic curves, especially for $n = 0, 1$.

If L is a finite Galois extension of K, then the inf-res sequence, written in terms of Galois chomology, is

$$0 \to \mathrm{H}^1(L/K, E(L)) \to \mathrm{H}^1(K, E) \to \mathrm{H}^1(L, E).$$

For any positive integer n consider the homomorphism

$$[n] : E(\overline{\mathbb{Q}}) \to E(\overline{\mathbb{Q}}).$$

This is a surjective homomorphism of abelian groups, so we have an exact sequence

$$0 \to E[n] \to E \xrightarrow{[n]} E \to 0.$$

The associated long exact sequence of Galois cohomology is

$$0 \to E(K)[n] \to E(K) \xrightarrow{[n]} E(K) \to \mathrm{H}^1(K, E[n]) \to \mathrm{H}^1(K, E) \xrightarrow{[n]} \mathrm{H}^1(K, E) \to \cdots.$$

An interesting way to rewrite the begining part of this sequence is as

$$0 \to E(K)/nE(K) \to \mathrm{H}^1(K, E[n]) \to H^1(K, E)[n] \to 0. \tag{2.2.1}$$

The sequence (2.2.1) is called the *Kummer sequence* associated to the elliptic curve.

2.2.2. The Global-to-Local Restriction Maps. Let $\wp$ be a prime ideal of the ring $\mathcal{O}_K$ of integers of the number field K, and let $K_\wp$ be the completion of K with respect to $\wp$. Thus $K_\wp$ is a finite extension the field $\mathbb{Q}_p$ of p-adic numbers.

More explicitly, if $K = \mathbb{Q}(\alpha)$, with α a root of the irreducible polynomial $f(x)$, then the prime ideals $\wp$ correspond to the irreducible factors of $f(x)$ in $\mathbb{Z}_p[x]$. The fields $K_\wp$ then correspond to adjoing roots of each of these irreducible factors of $f(x)$ in $\mathbb{Z}_p[x]$. Note that for most p, a generalization of Hensel's lemma (see Section 1.5.1) asserts that we can factor $f(x)$ by factoring $f(x)$ modulo p and iteratively lifting the factorization.

We have a natural map $\mathrm{Gal}(\overline{\mathbb{Q}}_p/K_\wp) \to \mathrm{Gal}(\overline{\mathbb{Q}}/K)$ got by restriction; implicit in this is a *choice* of embedding of $\overline{\mathbb{Q}}$ in $\overline{\mathbb{Q}}_p$ that sends K into K_v. We may thus view $\mathrm{Gal}(\overline{\mathbb{Q}}_p/K_\wp)$ as a subgroup of $\mathrm{Gal}(\overline{\mathbb{Q}}/K)$.

Let A be any $\mathrm{Gal}(\overline{\mathbb{Q}}/K)$ module. Then this restriction map induces a restriction map on Galois cohomology

$$\mathrm{res}_\wp : \mathrm{H}^1(K, A) \to \mathrm{H}^1(K_\wp, A).$$

Recall that in terms of 1-cocycles this sends a set-theoretic map (a crossed-homomorphism) $f : \mathrm{Gal}(\overline{\mathbb{Q}}/K) \to A$ to a map $\mathrm{res}_\wp(f) : \mathrm{Gal}(\overline{\mathbb{Q}}_p/K_\wp) \to A$.

Likewise there is a restriction map for each real Archimedian prime v, i.e., for each embedding $K \to \mathbb{R}$ we have a map

$$\mathrm{res}_v : \mathrm{H}^1(K, A) \to \mathrm{H}^1(\mathbb{R}, A).$$

Exercise 2.5. Let $A = E(\mathbb{C})$ be the group of points on an elliptic curve over $\mathbb{R}$. Prove that $\mathrm{H}^1(\mathbb{R}, E) = \mathrm{H}^1(\mathbb{C}/\mathbb{R}, E(\mathbb{C}))$ is a group of order 1 or 2.

Exercise 2.6. Prove that for any Galois moduloe A and for all primes $\wp$ the kernel of $\mathrm{res}_\wp$ does not depend on the choice of embedding of $\overline{\mathbb{Q}}$ in $\overline{\mathbb{Q}}_p$. (See [**Cp86**, Ch. V]).

2.2.3. The Selmer Group.

Let E be an elliptic curve over a number field K. Let v be either a prime $\wp$ of K or a real Archimedian place (i.e., embedding $K \to \mathbb{R}$). As in Section 2.2.1 we also obtain a local Kummer sequence

$$0 \to E(K_v)/nE(K_v) \to \mathrm{H}^1(K_v, E[n]) \to H^1(K_v, E)[n] \to 0.$$

Putting these together for all v we obtain a commutative diagram:
(2.2.2)

$$\begin{tikzcd}
0 \arrow[r] & E(K)/nE(K) \arrow[r] \arrow[d] & \mathrm{H}^1(K, E[n]) \arrow[r] \arrow[d] & H^1(K, E)[n] \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \prod_v E(K_v)/nE(K_v) \arrow[r] & \prod_v \mathrm{H}^1(K_v, E[n]) \arrow[r] & \prod_v H^1(K_v, E)[n] \arrow[r] & 0.
\end{tikzcd}$$

Definition 2.7. The *n-Selmer group* of an elliptic curve E over a number field K is

$$\mathrm{Sel}^{(n)}(E/K) = \ker\left(\mathrm{H}^1(K, E[n]) \to \prod_v \mathrm{H}^1(K_v, E)[n]\right).$$

2.2.4. The Shafarevich-Tate Group and the Mordell-Weil Theorem.

Definition 2.8 (Shafarevich-Tate Group)**.** The *Shafarevich-Tate group* of an elliptic curve E over a number field K is

$$\text{Ш}(E/K) = \ker\left(\mathrm{H}^1(K,E) \to \prod_v \mathrm{H}^1(K_v,E)\right).$$

For any positive integer n, we may thus add in a row to (2.2.2):

$$\begin{tikzcd}
0 \arrow[r] & E(K)/nE(K) \arrow[r] \arrow[d, equal] & \mathrm{Sel}^{(n)}(E/K) \arrow[r] \arrow[d, hook] & \text{Ш}(E/K)[n] \arrow[r] \arrow[d, hook] & 0 \\
0 \arrow[r] & E(K)/nE(K) \arrow[r] \arrow[d] & \mathrm{H}^1(K,E[n]) \arrow[r] \arrow[d] & H^1(K,E)[n] \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \prod_v E(K_v)/nE(K_v) \arrow[r] & \prod_v \mathrm{H}^1(K_v,E[n]) \arrow[r] & \prod_v H^1(K_v,E)[n] \arrow[r] & 0.
\end{tikzcd}$$

The *n-descent sequence* for E is the short exact sequence

$$0 \to E(K)/nE(K) \to \mathrm{Sel}^{(n)}(E/K) \to \text{Ш}(E/K)[n] \to 0. \tag{2.2.3}$$

Theorem 2.9. *For every integer n the group* $\mathrm{Sel}^{(n)}(E/K)$ *is finite.*

Sketch of Proof. Let $K(E[n])$ denote the finite Galois extension of K obtained by adjoining to K all x and y coordinates of elements of $E(\overline{\mathbb{Q}})$ of order dividing n. The inf-res sequence for $K(E[n])/K$ is

$$0 \to \mathrm{H}^1(K(E[n])/K, E[n]) \to \mathrm{H}^1(K,E[n]) \to \mathrm{H}^1(K(E[n]),E[n]). \tag{2.2.4}$$

Because $\mathrm{Gal}(K(E[n])/K)$ and $E[n]$ are both finite groups, the cohomology group $\mathrm{H}^1(K(E[n])/K, E[n])$ is also finite.

Since $\mathrm{Sel}^{(n)}(E/K) \subset \mathrm{H}^1(K,E[n])$, restriction defines a map

$$\mathrm{Sel}^{(n)}(E/K) \to \mathrm{Sel}^{(n)}(E/K[n]). \tag{2.2.5}$$

The kernel of (2.2.5) is finite since it is contained in the first term of (2.2.4), which is finite. It thus suffices to prove that $\mathrm{Sel}^{(n)}(E/K[n])$ is finite.

But

$$\mathrm{Sel}^{(n)}(E/K[n]) \subset \mathrm{H}^1(K[n],E[n]) \cong \mathrm{Hom}(\mathrm{Gal}(\overline{\mathbb{Q}}/K[n]),E[n])).$$

So each element of $\mathrm{Sel}^{(n)}(E/K[n])$ determines (and is determined by) a homomorphism $\mathrm{Gal}(\overline{\mathbb{Q}}/K[n]) \to (\mathbb{Z}/n\mathbb{Z})^2$. That that the fixed field of such a homomorphism is a Galois extension of $K[n]$ with Galois group contained in $(\mathbb{Z}/n\mathbb{Z})^2$.

To complete the proof, one uses the theory of elliptic curves over local fields to show that there is a finite set S of primes such that any such homomorphism corresponding to an element of the Selmer group corresponds to an extension of $K[n]$ ramified only at primes in S. Then the two main theorems of algebraic number theory — that class groups are finite and unit groups are finitely generated — together imply that there are only finitely many such extensions of $K[n]$.

□

Exercise 2.10. Prove the that $E[n]$ is a finite Galois extension of K.

Theorem 2.11 (Mordell-Weil)**.** *The group $E(\mathbb{Q})$ is finitely generated.*

Proof. The exact sequence (2.2.3) with $n = 2$ and Theorem 2.9 imply that $E(\mathbb{Q})/2E(\mathbb{Q})$ is a finite group. Recall Lemma 1.4 which asserted that if B is a positive real number such that

$$S = \{P \in E(\mathbb{Q}) \,:\, \hat{h}(P) \leq B\}$$

contains a set of generators for $E(\mathbb{Q})/2E(\mathbb{Q})$, then S generates $E(\mathbb{Q})$. Since $E(\mathbb{Q})/2E(\mathbb{Q})$ is finite, it makes sense to define B to be the maximum of the heights of arbitrary lifts of all the elements of $E(\mathbb{Q})/2E(\mathbb{Q})$. Then the corresponding set S generates $E(\mathbb{Q})$. A basic fact about heights is that the set of points of bounded height is finite, i.e., S is finite, so $E(\mathbb{Q})$ is finitely generated. □

2.2.5. Some Conjectures and Theorems about the Shafarevich-Tate Group.

Conjecture 2.12 (Shafarevich-Tate)**.** *Let E be an elliptic curve over a number field K. Then the group $Ш(E/K)$ is finite.*

Theorem 2.13 (Rubin)**.** *If E is a CM elliptic curve over $\mathbb{Q}$ with $L(E, 1) \neq 0$, then $Ш(E/\mathbb{Q})$ is finite. (He proved more than just this.)*

Thus Rubin's theorem proves that the Shafarevich-Tate group of the CM elliptic curve $y^2 + y = x^3 - 7$ of conductor 27 is finite.

Theorem 2.14 (Kolyvagin et al.)**.** *If E is an elliptic curve over $\mathbb{Q}$ with $\mathrm{ord}_{s=1} L(E, s) \leq 1$, then $Ш(E/\mathbb{Q})$ is finite.*

Kolyvagin's theorem is proved in a completely different way than Rubin's theorem. It combines the Gross-Zagier theorem, the modularity theorem that there is a map $X_0(N) \to E$, a nonvanishing result about the special values $L(E^D, 1)$ of quadratic twists of E, and a highly original explicit study of the structure of the images of certain points on $X_0(N)(\overline{\mathbb{Q}})$ in $E(\overline{\mathbb{Q}})$.

Theorem 2.15 (Cassels)**.** *Let E be an elliptic curve over a number field K. There is an alternating pairing on $Ш(E/K)$, which is nondegenerate on the quotient of $Ш(E/K)$ by its maximal divisible subgroup. Moreover, if $Ш(E/K)$ is finite then $\#Ш(E/K)$ is a perfect square.*

For an abelian group A and a prime p, let $A(p)$ denote the subgroup of elements of p power order in A.

The following problem remains open. It helps illustrate our ignorance about Conjecture 2.12 in any cases beyond those mentioned above.

Problem 2.16. Show that there is an elliptic curve E over $\mathbb{Q}$ with rank ≥ 2 such that $Ш(E/\mathbb{Q})(p)$ is finite for infinitely many primes p.

2.3. The Birch and Swinnerton-Dyer Formula

> "The subject of this lecture is rather a special one. I want to describe some computations undertaken by myself and Swinnerton-Dyer on EDSAC, by which we have calculated the zeta-functions of certain elliptic curves. As a result of these computations we have found an analogue for an elliptic curve of the Tamagawa number of an algebraic group; and conjectures have proliferated. [...] I would like to stress that though the associated theory is both abstract and technically complicated, the objects about which I intend to talk are usually simply defined and often machine computable; experimentally we have detected certain relations between different invariants, but we have been unable to approach proofs of these relations, which must lie very deep."
>
> – Bryan Birch

Conjecture 2.17 (Birch and Swinnerton-Dyer)**.** *Let E be an elliptic curve over $\mathbb{Q}$ of rank r. Then $r = \mathrm{ord}_{s=1} L(E,s)$ and*

$$\frac{L^{(r)}(E,1)}{r!} = \frac{\Omega_E \cdot \mathrm{Reg}(E) \cdot \#Ш(E/\mathbb{Q}) \cdot \prod_p c_p}{\#E(\mathbb{Q})_{\mathrm{tor}}^2}. \tag{2.3.1}$$

Let

$$y^2 + \underline{a}_1 xy + \underline{a}_3 y = x^3 + \underline{a}_2 x^2 + \underline{a}_4 x + \underline{a}_6 \tag{2.3.2}$$

be a minimal Weierstrass equation for E.

Recall from Section 1.5.2 that the *real period* Ω_E is the integral

$$\Omega_E = \int_{E(\mathbb{R})} \frac{dx}{2y + \underline{a}_1 x + \underline{a}_3}.$$

See [**Cre97**, §3.7] for an explanation about how to use the Gauss arithmetic-geometry mean to efficiently compute Ω_E.

To define the *regulator* $\mathrm{Reg}(E)$ let $P_1, \ldots, P_n$ be a basis for $E(\mathbb{Q})$ modulo torsion and recall the Néron-Tate canonical height pairing $\langle\, , \rangle$ from

Section 1.2. The real number $\mathrm{Reg}(E)$ is the absolute value of the determinant of the $n \times n$ matrix whose (i, j) entry is $\langle P_i, P_j \rangle$. See [**Cre97**, §3.4] for a discussion of how to compute $\mathrm{Reg}(E)$.

We defined the group $Ш(E/\mathbb{Q})$ in Section 2.2.4. In general it is not known to be finite, which led to Tate's famous assertion that the above conjecture "relates the value of a function at a point at which it is not known to be defined[1] to the order of a group that is not known to be finite." The paper [**GJP$^+$05**] discusses methods for computing $\#Ш(E/\mathbb{Q})$ in practice, though no general algorithm for computing $\#Ш(E/\mathbb{Q})$ is known. In fact, in general even if we assume truth of the BSD rank conjecture (Conjecture 1.1) and assume that $Ш(E/\mathbb{Q})$ is finite, there is still no known way to compute $\#Ш(E/\mathbb{Q})$, i.e., there is no analogue of Proposition 1.3. Given finiteness of $Ш(E/\mathbb{Q})$ we can compute the p-part $Ш(E/\mathbb{Q})(p)$ of $Ш(E/\mathbb{Q})$ for any prime p, but we don't know when to stop considering new primes p. (Note that when $r_{E,\mathrm{an}} \leq 1$, Kolyvagin's work provides an explicit upper bound on $\#Ш(E/\mathbb{Q})$, so in that case $Ш(E/\mathbb{Q})$ is computable.)

The *Tamagawa numbers* c_p are 1 for all primes $p \nmid \Delta_E$, where Δ_E is the discriminant of (2.3.2). When $p \mid \Delta_E$, the number c_p is a more refined measure of the structure of the E locally at p. If p is a prime of *additive reduction* (see Section 1.3), then one can prove that $c_p \leq 4$. The other alternatives are that p is a prime of split or nonsplit multiplicative reduction. If p is a *nonsplit prime*, then

$$c_p = \begin{cases} 1 & \text{if } \mathrm{ord}_p(\Delta) \text{ is odd} \\ 2 & \text{otherwise} \end{cases}$$

If p is a prime of *split multiplicative* reduction then

$$c_p = \mathrm{ord}_p(\Delta)$$

can be arbitrarily large. The above discussion completely determines c_p except when p is an additive prime – see [**Cre97**, §3.2] for a discussion of how to compute c_p in general.

For those that are very familiar with elliptic curves over local fields,

$$c_p = [E(\mathbb{Q}_p) : E^0(\mathbb{Q}_p)],$$

where $E^0(\mathbb{Q}_p)$ is the subgroup of $E(\mathbb{Q}_p)$ of points that have nonsingular reduction modulo p.

For those with more geometric background, we offer the following conceptual definition of c_p. Let $\mathcal{E}$ be the *Néron model* of E. This is the unique, up to unique isomorphism, smooth commutative (but not proper!) group

[1] When E is defined over $\mathbb{Q}$ it is now known that $L(E, s)$ is defined overwhere.

scheme over $\mathbb{Z}$ that has generic fiber E and satisfies the Néron mapping property:

> for any smooth group scheme X over $\mathbb{Z}$ the natural map
> $$\mathrm{Hom}(X, \mathcal{E}) \to \mathrm{Hom}(X_{\mathbb{Q}}, E)$$
> is an isomorphism.

In particular, note that $\mathcal{E}(\mathbb{Z}) \cong E(\mathbb{Q})$. For each prime p, the reduction $\mathcal{E}_{\mathbb{F}_p}$ of the Néron model modulo p is a smooth commutative group scheme over $\mathbb{F}_p$ (smoothness is a property of morphisms that is closed under base extension). Let $\mathcal{E}^0_{\mathbb{F}_p}$ be the identity component of the group scheme $\mathcal{E}_{\mathbb{F}_p}$, i.e., the connected component of $\mathcal{E}^0_{\mathbb{F}_p}$ that contains the 0 section. The *component group* of E at p is the quotient group scheme

$$\Phi_{E,p} = \mathcal{E}_{\mathbb{F}_p}/\mathcal{E}^0_{\mathbb{F}_p},$$

which is a finite étale group scheme over $\mathbb{F}_p$. Finally

$$c_p = \#\Phi_{E,p}(\mathbb{F}_p).$$

2.4. Examples: The Birch and Swinnerton-Dyer Formula

In each example below we use SAGE to compute the conjectural order of $\text{Ш}(E/\mathbb{Q})$ and find that it appears to be the square of an integer as predicted by Theorem 2.15.

2.4.1. Example: A Curve of Rank 0. Consider the elliptic curve E with Cremona label 11a, which is one the 3 curves of smallest conductor. We now compute each of the quantities in Conjecture 2.17. First we define the curve E in SAGE and compute its rank:

```
sage: E = EllipticCurve('11a'); E
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20
over Rational Field
sage: E.rank()
0
```

Next we compute the number $L(E, 1)$ to double precision (as an element of the real double field RDF):

```
sage: L = RDF(E.Lseries(1)); L
0.253841860856
```

We next compute the real period:

```
sage: Om = RDF(E.omega()); Om
1.26920930428
```

To compute $\prod c_p$ we factor the discriminant of E. It turns at that only 11 divides the discriminant, and since the reduction at 11 is split multiplicative the Tamagawa number is $5 = \mathrm{ord}_{11}(\Delta_E)$.

```
sage: factor(discriminant(E))
-1 * 11^5
sage: c11 = E.tamagawa_number(11); c11
5
```

Next we compute the regulator, which is 1 since E rank 0.

```
sage: Reg = RDF(E.regulator()); Reg
1.0
```

The torsion subgroup has order 5.

```
sage: T = E.torsion_order(); T
5
```

Putting everything together in (2.3.1) and solving for the conjectural order of $Ш(E/\mathbb{Q})$, we see that Conjecture 2.17 for E is equivalent to the assertion that $Ш(E/\mathbb{Q})$ has order 1.

```
sage: Sha_conj = L * T^2 / (Om * Reg * c11); Sha_conj
1.0
```

2.4.2. Example: A Rank 0 curve with nontrivial Sha. Consider the curve E with label 681b. This curve has rank 0, and we compute the conjectural order of $\#Ш(E/\mathbb{Q})$ as in the previous section:

```
sage: E = EllipticCurve('681b'); E
Elliptic Curve defined by y^2 + x*y  = x^3 + x^2 - 1154*x - 15345
over Rational Field
sage: E.rank()
0
sage: L = RDF(E.Lseries(1)); L
1.84481520613
sage: Om = RDF(E.omega()); Om
0.81991786939
```

There are two primes of bad reduction this time.

```
sage: factor(681)
3 * 227
sage: factor(discriminant(E))
3^10 * 227^2
sage: c3 = E.tamagawa_number(3); c227 = E.tamagawa_number(227)
sage: c3, c227
(2, 2)
sage: Reg = RDF(E.regulator()); Reg
1.0
sage: T = E.torsion_order(); T
4
```

In this case it turns out that $\#\text{Ш}(E/\mathbb{Q})$ is conjecturally 9.

```
sage: Sha_conj = L * T^2 / (Om * Reg * c3*c227); Sha_conj
9.0
```

2.4.3. Example: A Curve of Rank 1. Let E be the elliptic curve with label 37a, which is the curve of rank 1 with smallest conductor. We define E and compute its rank, which is 1.

```
sage: E = EllipticCurve('37a'); E
Elliptic Curve defined by y^2 + y = x^3 - x over
Rational Field
sage: E.rank()
1
```

We next compute the value $L'(E,1)$. The corresponding function in SAGE takes a bound on the number of terms of the L-series to use, and returns an approximate to $L'(E,1)$ along with a bound on the error (coming from the tail end of the series).

```
sage: L, error = E.Lseries_deriv_at1(200); L, error
(0.305999773834879, 2.10219814818300e-90)
sage: L = RDF(L); L
0.305999773835
```

We compute Ω_E and the Tamagawa number, regulator, and torsion as above.

```
sage: Om = RDF(E.omega()); Om
5.98691729246
sage: factor(discriminant(E))
37
sage: c37 = 1
sage: Reg = RDF(E.regulator()); Reg
0.05111140824
sage: T = E.torsion_order(); T
1
```

Finally, we solve and find that the conjectural order of $Ш(E/\mathbb{Q})$ is 1.

```
sage: Sha_conj = L * T^2 / (Om * Reg * c37); Sha_conj
1.0
```

2.4.4. Example: A curve of rank 2. Let E be the elliptic curve 389a of rank 2, which is the curve of rank 2 with smallest conductor.

```
sage: E = EllipticCurve(’389a’); E
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x
over Rational Field
sage: E.rank()
2
```

Because the curve has rank 2, we use Dokchitser's L-function package to approximate $L^{(2)}(E,1)$ to high precision:

```
sage: Lser = E.Lseries_dokchitser()
sage: L = RDF(abs(Lser.derivative(1,2))); L
1.51863300058
```

We compute the regulator, Tamagawa numbers, and torsion as usual:

```
sage: Om = RDF(E.omega()); Om
4.98042512171
sage: factor(discriminant(E))
389
sage: c389 = 1
sage: Reg = RDF(E.regulator()); Reg
0.152460177943
sage: T = E.torsion_order(); T
1
```

Finally we solve for the conjectural order of $\#\text{Ш}(E/\mathbb{Q})$.

```
sage: Sha_conj = (L/2) * T^2 / (Om * Reg * c389)
sage: Sha_conj
1.0
```

We pause to emphasize that just getting something that looks like an integer by computing

$$\frac{L^{(r)}(E,1)}{r!} \cdot \#E(\mathbb{Q})^2_{\text{tor}}/(\Omega_E \cdot \text{Reg}(E) \cdot \prod c_P) \tag{2.4.1}$$

is already excellent evidence for Conjecture 2.17. There is also a subtle and deep open problem here:

Open Problem 2.18. Let E be the elliptic curve 389a above. Prove that the quantity (2.4.1) is a rational number.

For curves E of analytic rank 0 it is easy to prove using modular symbols that the conjectural order of $\text{Ш}(E/\mathbb{Q})$ is a rational number. For curves with analytic rank 1, this rationality follows from the very deep Gross-Zagier theorem. For curves of analytic rank ≥ 2 there is not a single example in which the conjectural order of $\text{Ш}(E/\mathbb{Q})$ is known to be a rational number.

2.4.5. Example: A Rank 3 curve. The curve E with label 5077a has rank 3. This is the curve with smallest conductor and rank 3.

```
sage: E = EllipticCurve('5077a'); E
Elliptic Curve defined by y^2 + y = x^3 - 7*x + 6
over Rational Field
sage: E.rank()
3
```

We compute $L(E,s)$ using Dokchitser's algorithm. Note that the order of vanishing appears to be 3.

```
sage: E.root_number()
-1
sage: Lser = E.Lseries_dokchitser()
sage: Lser.derivative(1,1)
-5.63436295355925e-22
sage: Lser.derivative(1,2)
2.08600476044634e-21
sage: L = RDF(abs(Lser.derivative(1,3))); L
10.3910994007
```

That the order of vanishing is really 3 follows from the Gross-Zagier theorem, which asserts that $L'(E,1)$ is a nonzero multiple of the Néron-Tate canonical height of a certain point on E called a Heegner point. One can explicitly construct this point[2] on E and find that it is torsion, hence has height 0, so $L'(E,1) = 0$. That $L''(E,1) = 0$ then follows from the functional equation (see Section 1.3). Finally we compute the other BSD invariants:

```
sage: Om = RDF(E.omega()); Om
4.15168798309
sage: factor(discriminant(E))
5077
sage: c5077 = 1
sage: Reg = RDF(E.regulator()); Reg
0.417143558758
sage: T = E.torsion_order(); T
1
```

Putting everything together we see that the conjectural order of $\text{Ш}(E/\mathbb{Q})$ is 1.

[2] This is not yet implemented in SAGE; if it were, there would be an example right here.

```
sage: Sha_conj = (L/6) * T^2 / (Om * Reg * c5077)
sage: Sha_conj
1.0
```

Note that just as was the case with the curve 389a above, we do not know that the above conjectural order of $Ш(E/\mathbb{Q})$ is a rational number, since there are no know theoretical results that relate any of the three real numbers $L^{(3)}(E,1)$, $\mathrm{Reg}(E/\mathbb{Q})$, and $\Omega_{E/\mathbb{Q}}$.

2.4.6. Example: A Rank 4 curve. Let E be the curve of rank 4 with label 234446b. It is likely that this is the curve with smallest conductor and rank 4 (a big calculation of the author et al. shows that there are no rank 4 curves with smaller *prime* conductor).

```
sage: E = EllipticCurve([1, -1, 0, -79, 289]); E
Elliptic Curve defined by y^2 + x*y  = x^3 - x^2 - 79*x + 289
over Rational Field
sage: E.rank()
4
```

We next compute $L(E,1)$, $L'(E,1)$, $L^{(2)}(E,1)$, $L^{(3)}(E,1)$, and $L^{(4)}(E,1)$. All these special values *look* like they are 0, except for $L^{(4)}(E,1)$ which is about 214, hence clearly nonzero. One can prove that $L(E,1) = 0$ (e.g., using denominator bounds coming from modular symbols), hence since the root number is $+1$, we have either $r_{E,\mathrm{an}} = 2$ or $r_{E,\mathrm{an}} = 4$, and of course suspect (but cannot prove yet) that $r_{E,\mathrm{an}} = 4$.

```
sage: E.root_number()
1
sage: Lser = E.Lseries_dokchitser()
sage: Lser(1)
1.43930352980778e-18
sage: Lser.derivative(1,1)
-4.59277879927938e-24
sage: Lser.derivative(1,2)
-8.85707917856308e-22
sage: Lser.derivative(1,3)
1.01437455701212e-20
sage: L = RDF(abs(Lser.derivative(1,4))); L
214.652337502
```

As above, we compute the other BSD invariants of E.

```
sage: Om = RDF(E.omega()); Om
2.97267184726
sage: factor(discriminant(E))
2^2 * 117223
sage: c2 = 2
sage: c117223 = 1
sage: Reg = RDF(E.regulator()); Reg
1.50434488828
sage: T = E.torsion_order(); T
1
```

Finally, putting everything together, we see that the conjectural order of Ш$(E/\mathbb{Q})$ is 1.

```
sage: Sha_conj = (L/24) * T^2 / (Om * Reg * c2 * c117223)
sage: Sha_conj
1.0
```

Again we emphasize that we do not even know that the conjectural order computed above is a rational number.

It seems almost a miracle that $L^{(4)}(E,1) = 214.65\ldots$, $\Omega_E = 2.97\ldots$, and $\mathrm{Reg}(E) = 1.50\ldots$ have anything to do with each other, but indeed they do:

```
sage: L/24, 2*Om*Reg
(8.9438473959, 8.9438473959)
```

That these two numbers are the same to several decimal places is a fact, independent of any conjectures.

2.5. The p-adic BSD Conjectural Formula

Let E be an elliptic curve over $\mathbb{Q}$ and let p be a prime of good ordinary reduction for E.

In Chapter 1 (see Theorem 1.15) we defined a p-adic L-series

$$\mathcal{L}_p(E,T) \in \mathbb{Q}_p[[T]].$$

Conjecture 1.16 asserted that $\operatorname{ord}_T \mathcal{L}_p(E,T) = \operatorname{rank} E(\mathbb{Q})$. Just as is the cases for $L(E,s)$, there is a conjectural formula for the leading coefficient of the power series $\mathcal{L}_p(E,T)$. This formula is due to Mazur, Tate, and Teitelbaum [**MTT86**].

First, suppose $\operatorname{ord}_T \mathcal{L}_p(E,T) = 0$, i.e., $\mathcal{L}_p(E,0) \neq 0$. Recall that the interpolation property (1.5.1) for $\mathcal{L}_p(E,T)$ implies that

$$\mathcal{L}_p(E,0) = \varepsilon_p \cdot L(E,1)/\Omega_E,$$

where

$$\varepsilon_p = (1-\alpha^{-1})^2, \tag{2.5.1}$$

and $\alpha \in \mathbb{Z}_p$ is the unit root of $x^2 - a_p x + p = 0$. Thus the usual BSD conjecture predicts that if the rank is 1, then

$$\mathcal{L}_p(E,0) = \varepsilon_p \cdot \frac{\prod_\ell c_\ell \cdot \#\text{Ш}(E/\mathbb{Q}) \cdot \operatorname{Reg}(E)}{\#E(\mathbb{Q})_{\text{tor}}^2} \tag{2.5.2}$$

Notice in (2.5.2) that since $E(\mathbb{Q})$ has rank 0, we have $\operatorname{Reg}(E) = 1$, so there is no issue with the left hand side being a p-adic number and the right hand side not making sense. It would be natural to try to generalize (2.5.2) to higher order of vanishing as follows. Let $\mathcal{L}_p^*(E,0)$ denote the leading coefficient of the power series $\mathcal{L}_p(E,T)$. Then

$$\mathcal{L}_p^*(E,0)\text{“}=\text{”}\varepsilon_p \cdot \frac{\prod_\ell c_\ell \cdot \#\text{Ш}(E/\mathbb{Q}) \cdot \operatorname{Reg}(E)}{\#E(\mathbb{Q})_{\text{tor}}^2} \qquad \text{(nonsense!!)}. \tag{2.5.3}$$

Unfortunately (2.5.2) is total nonsense when the rank is bigger than 0. The problem is that $\operatorname{Reg}(E) \in \mathbb{R}$ is a real number, whereas ε_p and $\mathcal{L}_p^*(E,0)$ are both p-adic numbers.

The key *new idea* needed to make a conjecture is to replace the real-number regulator $\operatorname{Reg}(E)$ with a p-adic regulator $\operatorname{Reg}_p(E) \in \mathbb{Q}_p$. This new regulator is defined in a way analogous to the classical regulator, but where many classical complex analytic objects are replaced by p-adic analogues. Moreover, the p-adic regulator was, until recently (see [**MST06**]), much more difficult to compute than the classical real regulator. We will define the p-adic number $\operatorname{Reg}_p(E) \in \mathbb{Q}_p$ in the next section.

Conjecture 2.19 (Mazur, Tate, and Teitelbaum)**.** *Let E be an elliptic curve over $\mathbb{Q}$ and let p be a prime of good ordinary reduction for E. Then the rank of E equals $\mathrm{ord}_T(\mathcal{L}_p(E,T))$ and*

$$\mathcal{L}_p^*(E,0) = \varepsilon_p \cdot \frac{\prod_\ell c_\ell \cdot \#\text{Ш}(E/\mathbb{Q}) \cdot \mathrm{Reg}_p(E)}{\#E(\mathbb{Q})_{\mathrm{tor}}^2}, \tag{2.5.4}$$

where ε_p is as in (2.5.1)*, and the p-adic regulator $\mathrm{Reg}_p(E) \in \mathbb{Q}_p$ will be defined below.*

Remark 2.20. There are analogous conjectures in many other cases, e.g., good supersingular, bad multiplicative, etc. See [**SW07**] for more details.

2.5.1. Example: A Curve of Rank 2. We only consider primes p of good ordinary reduction for a given curve E in this section. If E is an elliptic curve with analytic rank 0, then the p-adic and classical BSD conjecture are the same, so there is nothing new to illustrate. We will thus consider only curves of rank ≥ 1 in this section.

We consider the elliptic curve 446d1 of rank 2 at the prime $p = 5$.

```
sage: E = EllipticCurve('446d1'); p = 5; E
Elliptic Curve defined by y^2 + x*y  = x^3 - x^2 - 4*x + 4
over Rational Field
```

Next we verify that the rank is 2, that p is a good ordinary prime, and that there are 10 points on E modulo p (so E is *ananomolous at* p, i.e., $p \mid \#E(\mathbb{F}_p)$).

```
sage: E.rank()
2
sage: E.is_ordinary(p)
True
sage: E.Np(p)
10
```

Next we compute the p-adic L-series of E at p. We add $O(T^7)$ so that the displayed series doesn't take several lines.

```
sage: Lp  = E.padic_lseries(p)
sage: LpT = Lp.series(4)
sage: LpT = LpT.add_bigoh(7); LpT
(5 + 5^2 + O(5^3))*T^2 + (2*5 + 3*5^2 + O(5^3))*T^3
          + (4*5^2 + O(5^3))*T^4 + (4*5 + O(5^2))*T^5
          + (1 + 2*5 + O(5^3))*T^6 + O(T^7)
```

We compute the p-adic modular form E_2 evaluated on our elliptic curve with differential ω to precision $O(p^8)$. This is the key difficult input to the computation of the p-adic regulator $\mathrm{Reg}_p(E)$.

```
sage: E.padic_E2(p, prec=8)
3*5 + 4*5^2 + 5^3 + 5^4 + 5^5 + 2*5^6 + 4*5^7 + O(5^8)
```

We compute the normalized p-adic regulator, normalized to the choice of $1+p$ as a topological generator of $1+p\,\mathbb{Z}_p$.

```
sage: Regp = E.padic_regulator(p, 10)
sage: R = Regp.parent()
sage: kg = log(R(1+p))
sage: reg = Regp * p^2 / log(R(1+p))^2
sage: reg*kg^2
2*5 + 2*5^2 + 5^4 + 4*5^5 + 2*5^7 + O(5^8)
```

We compute the Tamagawa numbers and torsion subgroup.

```
sage: E.tamagawa_numbers()
[2, 1]
sage: E.torsion_order()
1
```

We compute $\mathcal{L}_p^*(E,0)$, which is the leading term of the p-adic L-function. It is not a unit, so we call the prime p an *irregular* prime.

```
sage: Lpstar = LpT[2]; Lpstar
5 + 5^2 + O(5^3)
```

Finally, putting everything together we compute the conjectural p-adic order of $\#\text{Ш}(E/\mathbb{Q})$. In particular, we see that conjecturally $\#\text{Ш}(E/\mathbb{Q})(5)$ is trivial.

```
sage: eps = (1-1/Lp.alpha(20))^2
sage: Lpstar / (eps*reg*(2*1)) * (1)^2
1 + O(5^2)
```

2.5.2. The p-adic Regulator. Fix an elliptic curve E defined over $\mathbb{Q}$ and a prime p of good ordinary reduction for E. In this section we define the p-adic regulator $\mathrm{Reg}_p(E)$. See [**MTT86**], [**MST06**] and [**SW07**] and the references listed there for a more general discussion of p-adic heights, especially for bad or supersingular primes, and for elliptic curves over number fields. See also forthcoming work of David Harvey for highly optimized computation of p-adic regulators.

The p-adic logarithm $\log_p : \mathbb{Q}_p^* \to (\mathbb{Q}_p, +)$ is the unique group homomorphism with $\log_p(p) = 0$ that extends the homomorphism $\log_p : 1+p\mathbb{Z}_p \to \mathbb{Q}_p$ defined by the usual power series of $\log(x)$ about 1. Explicitly, if $x \in \mathbb{Q}_p^*$, then

$$\log_p(x) = \frac{1}{p-1} \cdot \log_p(u^{p-1}),$$

where $u = p^{-\operatorname{ord}_p(x)} \cdot x$ is the unit part of x, and the usual series for log converges at u^{p-1}.

Example 2.21. For example, in SAGE we compute the logs of a couple of non-unit elements of $\mathbb{Q}_5$ as follows:

```
sage: K = Qp(5,8); K
5-adic Field with capped relative precision 8
sage: a = K(-5^2*17); a
3*5^2 + 5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + O(5^10)
sage: u = a.unit_part()
3 + 5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + O(5^8)
sage: b = K(1235/5); b
2 + 4*5 + 4*5^2 + 5^3 + O(5^8)
sage: log(a)
5 + 3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 5^6 + O(5^8)
sage: log(a*b) - log(a) - log(b)
O(5^8)
```

Note that we can recover b:

```
sage: c = a^b; c
2*5^494 + 4*5^496 + 2*5^497 + 5^499 + 3*5^500 + 5^501 + O(5^502)
sage: log(c)/log(a)
2 + 4*5 + 4*5^2 + 5^3 + O(5^7)
```

Let $\mathcal{E}$ denote the Néron model of E over $\mathbb{Z}$. Let $P \in E(\mathbb{Q})$ be a non-torsion point that reduces to $0 \in E(\mathbb{F}_p)$ and to the connected component of $\mathcal{E}_{\mathbb{F}_\ell}$ at all primes ℓ of bad reduction for E. For example, given any point $Q \in E(\mathbb{Q})$ one can construct such a P by multiplying it by the least common multiple of the Tamagawa numbers of E.

Exercise 2.22. Show that any nonzero point $P = (x(P), y(P)) \in E(\mathbb{Q})$ can be written uniquely in the form $(a/d^2, b/d^3)$, where $a, b, d \in \mathbb{Z}$, $\gcd(a, d) = \gcd(b, d) = 1$, and $d > 0$. (Hint: Use that $\mathbb{Z}$ is a unique factorization domain.)

The function $d(P)$ assigns to P this square root d of the denominator of the x-coordinate $x(P)$.

Example 2.23. We compute a point on a curve, and observe that the denominator of the x coordinate is a perfect square.

```
sage: E = EllipticCurve('446d1')
sage: P = 3*E.gen(0); P
(32/49 : -510/343 : 1)
```

Let

$$x(t) = \frac{1}{t^2} + \cdots \in \mathbb{Z}_p((t)) \tag{2.5.5}$$

be the formal power series that expresses x in terms of the local parameter $t = -x/y$ at infinity. Similarly, let $y(t) = -x(t)/t$ be the corresponding series for y. If we do the change of variables $t = -x/y$ and $w = -1/y$, so $x = t/w$ and $y = -1/w$, then the Weierstrass equation for E becomes

$$s = t^3 + a_1 st + a_2 wt^2 + a_3 w^2 + a_4 w^2 t + a_6 w^3 = F(w, t).$$

Repeatedly substituting this equation into itself recursively yields a power series expansion for $w = -1/y$ in terms of t, hence for both x and y.

Remark 2.24. The *formal group* of E is a power series

$$F(t_1, t_2) \in R = \mathbb{Z}[a_1, \dots, a_6][[t_1, t_2]].$$

defined as follows. Since $x(t)$ and $y(t)$ satisfy the equation of E, the points $P_1 = (x(t_1), y(t_1))$ and $P_2 = (x(t_2), y(t_2))$ are in $E(R)$. As explained explicitly in [**Sil92**, §IV.1], their sum is

$$Q = P_1 + P_2 = (x(F), y(F)) \in E(R)$$

for some $F = F(t_1, t_2) \in R$.

Example 2.25. We compute the above change of variables in SAGE:

```
sage: var('a1 a2 a3 a4 a6')
sage: E = EllipticCurve([a1,a2,a3,a4,a6]); E
Elliptic Curve defined by
     y^2 + a1*x*y + a3*y = x^3 + a2*x^2 + a4*x + a6
over Symbolic Ring
sage: eqn = SR(E); eqn
(y^2 + a1*x*y + a3*y) == (x^3 + a2*x^2 + a4*x + a6)
sage: F = eqn.lhs() - eqn.rhs(); F
y^2 + a1*x*y + a3*y - x^3 - a2*x^2 - a4*x - a6
sage: G = w^3*F(x=t/s, y=-1/w); G.expand()
-t^3 - a2*w*t^2 - a4*w^2*t - a1*w*t - a6*w^3 - a3*w^2 + w
```

Example 2.26. We use SAGE to compute the formal power series $x(t)$ and $y(t)$ for the rank 1 elliptic curve 37a.

```
sage: E = EllipticCurve('37a'); E
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: F = E.formal_group(); F
Formal Group associated to the Elliptic Curve defined by
y^2 + y = x^3 - x over Rational Field
sage: x = F.x(prec=8); x
t^-2 - t + t^2 - t^4 + 2*t^5 - t^6 - 2*t^7 + O(t^8)
sage: y = F.y(prec=8); y
-t^-3 + 1 - t + t^3 - 2*t^4 + t^5 + 2*t^6 - 6*t^7 + O(t^8)
```

Notice that the power series satisfy the equation of the curve.

```
sage: y^2 + y == x^3 - x
True
```

Recall that $\omega_E = \frac{dx}{2y+\underline{a}_1x+\underline{a}_3}$ is the differential on a fixed choice of Weierstrass equation for E. Let

$$\omega(t) = \frac{dx}{2y + \underline{a}_1 x + \underline{a}_3} \in \mathbb{Q}((t))dt$$

be the formal invariant holomorphic differential on E.

Example 2.27. Continuing the above example, we compute the formal differential on E:

```
sage: F.differential(prec=8)
1 + 2*t^3 - 2*t^4 + 6*t^6 - 12*t^7 + O(t^8)
```

We can also compute $\omega(t)$ directly from the definition:

```
sage: x.derivative()/(2*y+1)
1 + 2*t^3 - 2*t^4 + 6*t^6 - 12*t^7 + 6*t^8 + 20*t^9 + O(t^10)
```

The following theorem, which is proved in [**MT91**], uniquely determines a power series $\sigma \in t\mathbb{Z}_p[[t]]$ and constant $c \in \mathbb{Z}_p$.

Theorem 2.28 (Mazur-Tate). *There is exactly one odd function $\sigma(t) = t + \cdots \in t\mathbb{Z}_p[[t]]$ and constant $c \in \mathbb{Z}_p$ that together satisfy the differential equation*

$$x(t) + c = -\frac{d}{\omega}\left(\frac{1}{\sigma}\frac{d\sigma}{\omega}\right), \tag{2.5.6}$$

where ω is the invariant differential $dx/(2y + a_1x + a_3)$ associated with our chosen Weierstrass equation for E.

The above theorem produces a (very inefficient) algorithm to compute c and $\sigma(t)$. Just view c as a formal indeterminate and compute $\sigma(t) \in \mathbb{Q}[c][[t]]$, then obtain constraints on c using that the coefficients of σ must be in $\mathbb{Z}_p$. These determine c to some precision, which increases as we compute $\sigma(t)$ to higher precision. Until recently this was the only known way to compute c and $\sigma(t)$ – fortunately the method of [**MST06**] is much faster in general.

Definition 2.29 (Canonical p-adic Height)**.** Let E be an elliptic curve over $\mathbb{Q}$ with good ordinary reduction at the odd prime p. Let $\log_p$, d, and $\sigma(t)$ be as above and suppose $P \in E(\mathbb{Q})$ and that nP is a nonzero multiple of P such that nP reduces to the identity component of the Néron model of E at each prime of bad reduction. Then the *p-adic canonical height* of P is

$$h_p(P) = \frac{1}{n^2} \cdot \frac{1}{p} \cdot \log_p\left(\frac{\sigma(P)}{d(P)}\right).$$

Definition 2.30 (p-adic Regulator)**.** The *p-adic regulator* of E is the discriminant (well defined up to sign) of the bilinear $\mathbb{Q}_p$-valued pairing

$$(P,Q)_p = h_p(P) + h_p(Q) - h_p(P+Q).$$

Conjecture 2.31 (Schneider)**.** *The p-adic regulator $\mathrm{Reg}_p(E)$ is nonzero.*

Theorem 2.32 (Kato, Schneider, et al.)**.** *Let E be an elliptic curve over $\mathbb{Q}$ with good ordinary reduction at the odd prime p and assume that the p-adic Galois representation $\rho_{E,p}$ is surjective. If*

$$\mathrm{ord}_T(\mathcal{L}_p(E,T)) \leq \mathrm{rank}\, E(\mathbb{Q}),$$

then $\#\text{Ш}(E/\mathbb{Q})(p)$ is finite. Moreover, if $\mathrm{Reg}_p(E)$ is nonzero, then

$$\mathrm{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)) \leq \mathrm{ord}_p\left(\frac{\mathcal{L}_p^*(E,0)}{\prod c_\ell \cdot \mathrm{Reg}_p(E)}\right).$$

Chapter 3

Heegner Points and Kolyvagin's Euler System

3.1. CM Elliptic Curves

In this section we state, and in some cases sketch proofs of, some basic facts about CM elliptic curves.

If E is an elliptic curve over a field K we let $\mathrm{End}(E/K)$ be the ring of all endomorphisms of E that are defined over K.

Definition 3.1 (CM Elliptic Curve)**.** An elliptic curve E over a subfield of $\mathbb{C}$ has *complex multiplication* if $\mathrm{End}(E/\mathbb{C}) \neq \mathbb{Z}$.

Remark 3.2. If E is an elliptic curve over $\mathbb{Q}$, then $\mathrm{End}(E/\mathbb{Q}) = \mathbb{Z}$. This is true even if E has complex multiplication, in which case the complex multiplication must be defined over a bigger field than $\mathbb{Q}$. The reason $\mathrm{End}(E/\mathbb{Q}) = \mathbb{Z}$ is because $\mathrm{End}(E/\mathbb{Q})$ acts faithfully on the 1-dimensional $\mathbb{Q}$-vector space of invariant holomorphic differentials on E over $\mathbb{Q}$ and $\mathrm{End}(E/\mathbb{Q})$ is finitely generated as a $\mathbb{Z}$-module.

A *complex lattice* $\Lambda \subset \mathbb{C}$ is a subgroup abstractly isomorphic to $\mathbb{Z} \times \mathbb{Z}$ such that $\mathbb{R}\Lambda = \mathbb{C}$. Using the Weirestrass $\wp$-function associated to the lattice Λ, one proves that there is a group isomorphism

$$\mathbb{C}/\Lambda \cong E_\Lambda(\mathbb{C}),$$

where E_Λ is an elliptic curve over $\mathbb{C}$. Conversely, if E is any elliptic curve over $\mathbb{C}$, then there is a lattice Λ such that $E = E_\Lambda$. Explicitly, if ω_E is an invariant differential we may take Λ to be the lattice of all periods $\int_\gamma \omega_E \in \mathbb{C}$, where γ runs through the integral homology $\mathrm{H}_1(E(\mathbb{C}), \mathbb{Z})$.

Proposition 3.3. *Let Λ_1 and Λ_2 be complex lattices. Then*

$$\mathrm{Hom}(\mathbb{C}/\Lambda_1, \mathbb{C}/\Lambda_2) \cong \{\alpha \in \mathbb{C} : \alpha\Lambda_1 \subset \Lambda_2\},$$

where the homomorphisms on the left side are as elliptic curves over $\mathbb{C}$. Moreover, the complex number $\alpha \in \mathbb{C}$ corresponds to the homomorphism $[\alpha]$ induced by multiplication by α, and the kernel of $[\alpha]$ is isomorphic to $\Lambda_2/(\alpha\Lambda_1)$.

Corollary 3.4. *If α is any nonzero complex number and Λ is a lattice, then $\mathbb{C}/\Lambda \cong \mathbb{C}/(\alpha\Lambda)$.*

Proof. Since multiplication by α sends Λ into $\alpha\Lambda$, Proposition 3.3 implies that α defines a homomorphism with 0 kernel, hence an isomorphism. □

Now suppose $E/\mathbb{C}$ is a CM elliptic curve, and let Λ be a lattice such that $E \cong E_\Lambda$. Then

$$\mathrm{End}(E/\mathbb{C}) \cong \{\alpha \in \mathbb{C} : \alpha\Lambda \subset \Lambda\}.$$

Proposition 3.5. *Let $E = E_\Lambda$ be a CM elliptic curve. Then there is a complex number ω and a quadratic imaginary field such K that*

$$\omega\Lambda \subset \mathcal{O}_K,$$

where $\mathcal{O}_K$ is the ring of integers of K. Moreover, $\mathrm{End}(E/\mathbb{C})$ is an order (=subring of rank 2) of $\mathcal{O}_K$.

Proof. Write $\Lambda = \mathbb{Z}\omega_1 \oplus \mathbb{Z}\omega_2$. By Corollary 3.4, we have $E_\Lambda \cong E_{\omega_1^{-1}\Lambda}$, so we may assume that $\omega_1 = 1$, i.e., that $\Lambda = \mathbb{Z} + \beta\mathbb{Z}$ for some $\beta \in \mathbb{C}$. To complete the proof, we will show that $\omega\Lambda \subset \mathcal{O}_K$ for some quadratic imaginary field K and complex number ω.

By our hypothesis that E is CM there is a complex number $\alpha \notin \mathbb{Z}$ such that $\alpha\Lambda \subset \Lambda$. Fixing a basis for Λ, we see that α acts on Λ via a 2×2 integral matrix, so satisfies a quadratic equation. Thus α is an algebraic integer of degree 2. In particular, there are integers a, b, c, d such that

$$\alpha 1 = a + b\beta, \qquad \text{and} \qquad \alpha\beta = c + d\beta.$$

Since $\alpha \notin \mathbb{Z}$, the first equation above implies that $\beta \in \mathbb{Q}(\alpha)$, so since $\beta \notin \mathbb{Q}$, $\mathbb{Q}(\beta) = \mathbb{Q}(\alpha)$. Note that $\beta \notin \mathbb{R}$ since Λ is a lattice with basis 1 and β, so $K = \mathbb{Q}(\beta)$ is a quadratic imaginary field. Thus the ring $\mathrm{End}(E/\mathbb{C})$ generated by all such α is an order in the ring $\mathcal{O}_K$ of integers of an imaginary quadratic field. Finally, since $\beta \in K$, there is a complex number ω such that $\omega(\mathbb{Z} + \mathbb{Z}\beta) \subset \mathcal{O}_K$, where ω is chosen so that $\omega\beta \in \mathcal{O}_K$. □

3.1.1. The Set of CM Elliptic Curves with Given CM.

Definition 3.6 (Fractional Ideal)**.** A *fractional ideal* $\mathfrak{a}$ of a number field K is an $\mathcal{O}_K$-submodule of K that is isomorphic to $\mathbb{Z}^{[K:\mathbb{Q}]}$ as an abelian group. In particular, $\mathfrak{a}$ is nonzero.

If $\mathfrak{a}$ is a fractional ideal, the *inverse* $\mathfrak{a}^{-1}$ of $\mathfrak{a}$, which is the set of $x \in K$ such that $x\mathfrak{a} \subset \mathcal{O}_K$, is also a fractional ideal. Moreover, $\mathfrak{a}\mathfrak{a}^{-1} = \mathcal{O}_K$.

Fix a quadratic imaginary field K. Let $\mathrm{Ell}(\mathcal{O}_K)$ be the set of $\mathbb{C}$-isomorphism classes of elliptic curves $E/\mathbb{C}$ with $\mathrm{End}(E) \cong \mathcal{O}_K$. By the above results we may also view $\mathrm{Ell}(\mathcal{O}_K)$ as the set of lattices Λ with $\mathrm{End}(E_\Lambda) \cong \mathcal{O}_K$.

If $\mathfrak{a}$ is a fractional $\mathcal{O}_K$ ideal, then $\mathfrak{a} \subset K \subset \mathbb{C}$ is a lattice in $\mathbb{C}$. For the elliptic curve $E_\mathfrak{a}$ we have

$$\mathrm{End}(E_\mathfrak{a}) = \mathcal{O}_K,$$

because $\mathfrak{a}$ is an $\mathcal{O}_K$-module by definition. Since rescaling a lattice produces an isomorphic elliptic curve, for any nonzero $c \in K$ the fractional ideals $\mathfrak{a}$ and $c\mathfrak{a}$ define the same elements of $\mathrm{Ell}(\mathcal{O}_K)$.

The *class group* $\mathrm{Cl}(\mathcal{O}_K)$ is the group of fractional ideals modulo principal fractional ideals. If $\mathfrak{a}$ is a fractional $\mathcal{O}_K$ ideal, denote by $\overline{\mathfrak{a}}$ its ideal class in the class group $\mathrm{Cl}(\mathcal{O}_K)$ of K. We have a natural map

$$\mathrm{Cl}(\mathcal{O}_K) \to \mathrm{Ell}(\mathcal{O}_K),$$

which sends $\overline{\mathfrak{a}}$ to $E_\mathfrak{a}$.

Theorem 3.7. *Fix a quadratic imaginary field K, and let Λ be a lattice in $\mathbb{C}$ such that $E_\Lambda \in \mathrm{Ell}(\mathcal{O}_K)$. Let $\mathfrak{a}$ and $\mathfrak{b}$ be nonzero fractional $\mathcal{O}_K$-ideals. Then*

1. *$\mathfrak{a}\Lambda$ is a lattice in $\mathbb{C}$,*
2. *We have $\mathrm{End}(E_{\mathfrak{a}\Lambda}) \cong \mathcal{O}_K$.*
3. *We have $E_{\mathfrak{a}\Lambda} \cong E_{\mathfrak{b}\Lambda}$ if and only if $\overline{\mathfrak{a}} = \overline{\mathfrak{b}}$.*

Thus there is a well-defined action of $\mathrm{Cl}(\mathcal{O}_K)$ on $\mathrm{Ell}(\mathcal{O}_K)$ given by

$$\overline{\mathfrak{a}}E_\Lambda = E_{\overline{\mathfrak{a}}^{-1}\Lambda}.$$

Theorem 3.8. *The action of $\mathrm{Cl}(\mathcal{O}_K)$ on $\mathrm{Ell}(\mathcal{O}_K)$ is simply transitive.*

Example 3.9. Let $K = \mathbb{Q}(\sqrt{-23})$. Then the class number h_K is 3. An elliptic curve with CM by $\mathcal{O}_K$ is $\mathbb{C}/(\mathbb{Z} + (1 + \sqrt{-23})/2\mathbb{Z})$, and one can obtain the other two elements of $\mathrm{Ell}(\mathcal{O}_K)$ by multiplying the lattice $\mathbb{Z} + (1 + \sqrt{-23})/2\mathbb{Z}$ by two representative ideal classes for $\mathrm{Cl}(\mathcal{O}_K)$.

3.1.2. Class Field Theory.

Class field theory makes sense for arbitrary number fields, but for simplicity in this section and because it is all that is needed for our application to the BSD conjecture, we assume henceforth that K is a totally imaginary number field, i.e., one with no real embeddings.

Let L/K be a finite abelian extension of number fields, and let $\mathfrak{a}$ be any unramified prime ideal in $\mathcal{O}_K$. Let $\mathfrak{b}$ be an prime of $\mathcal{O}_L$ over $\mathfrak{a}$ and consider the extension $k_{\mathfrak{b}} = \mathcal{O}_L/\mathfrak{b}$ of the finite field $k_{\mathfrak{a}} = \mathcal{O}_K/\mathfrak{a}$. There is an element $\overline{\sigma} \in \mathrm{Gal}(k_{\mathfrak{b}}/k_{\mathfrak{a}})$ that acts via qth powering on $k_{\mathfrak{b}}$, where $q = \#k_{\mathfrak{a}}$. A basic fact one proves in algebraic number theory is that there is an element $\sigma \in \mathrm{Gal}(L/K)$ that acts as $\overline{\sigma}$ on $\mathcal{O}_L/\mathfrak{b}$; moreover, replacing $\mathfrak{b}$ by a different ideal over $\mathfrak{a}$ just changes σ by conjugation. Since $\mathrm{Gal}(L/K)$ is abelian it follows that σ is uniquely determined by $\mathfrak{a}$. The association $\mathfrak{a} \mapsto \sigma = [\mathfrak{a}, L/K]$ is called the *Artin reciprocity map.*

Exercise 3.10. Prove that if an unramified prime $\mathfrak{p}$ of K splits completely in an abelian exension L/K, then $[\mathfrak{p}, L/K] = 1$.

Let $\mathfrak{c}$ be an integral ideal divisible by all primes of K that ramify in L, and let $I(\mathfrak{c})$ be the group of fractional ideals that are coprime to $\mathfrak{c}$. Then the reciprocity map extends to a map

$$I(\mathfrak{c}) \to \mathrm{Gal}(L/K) \qquad a \mapsto [\mathfrak{a}, L/K]$$

Let

$$P(\mathfrak{c}) = \{(\alpha) : \alpha \in K^*, \quad \alpha \equiv 1 \pmod{\mathfrak{c}}\}.$$

Here $\alpha \equiv 1 \pmod{\mathfrak{c}}$ means that $\mathrm{ord}_{\mathfrak{p}}(\alpha - 1) \geq \mathrm{ord}_p(\mathfrak{c})$ for each prime divisor $\mathfrak{p} \mid \mathfrak{c}$.

Definition 3.11 (Conductor of Extension)**.** The *conductor* of an abelian extension L/K is the largest (nonzero) integral ideal $\mathfrak{c} = \mathfrak{c}_{L/K}$ of $\mathcal{O}_K$ such that $[(\alpha), L/K] = 1$ for all $\alpha \in K^*$ such that $\alpha \equiv 1 \pmod{\mathfrak{c}}$.

Proposition 3.12. *The conductor of L/K exists.*

If $\mathfrak{c} = \mathfrak{c}_{L/K}$ is the conductor of L/K then Artin reciprocity induces a group homomorphism

$$I(\mathfrak{c})/P(\mathfrak{c}) \to \mathrm{Gal}(L/K).$$

Definition 3.13 (Ray Class Field)**.** Let $\mathfrak{c}$ be a nonzero integral ideal of $\mathcal{O}_K$. A *ray class field* associated to $\mathfrak{c}$ is a finite abelian extension $K_{\mathfrak{c}}$ of K such that whenever L/K is an abelian extension such that $\mathfrak{c}_{L/K} \mid \mathfrak{c}$, then $L \subset K_{\mathfrak{c}}$.

Theorem 3.14 (Existence Theorem of Class Field Theory)**.** *Given any nonzero integral ideal $\mathfrak{c}$ of $\mathcal{O}_K$ there exists a unique ray class field $K_{\mathfrak{c}}$ associated to $\mathfrak{c}$, and the conductor of $K_{\mathfrak{c}}$ divides $\mathfrak{c}$.*

Theorem 3.15 (Reciprocity Law of Class Field Theory)**.** *Let L/K be a finite abelian extension.*

(1) *The Artin map is a surjective homomorphism $I(\mathfrak{c}_{L/K}) \to \mathrm{Gal}(L/K)$.*

(2) *The kernel of the Artin map is $N_{L/K}(I_L)\cdot P(\mathfrak{c}_{L/K})$, where $N_{L/K}(I_L)$ is the group of norms from L to K of the fractional ideals of L.*

Definition 3.16 (Hilbert Class Field)**.** The *Hilbert class field* of a number field K is the maximal unramified abelian extension of K.

In particular, since the Hilbert class field is unramified over K, we have:

Theorem 3.17. *Let K be a number field and let H be the Hilbert class field of K. The Artin reciprocity map induces an isomorphism*

$$\mathrm{Cl}(\mathcal{O}_K) \xrightarrow{\cong} \mathrm{Gal}(H/K).$$

3.1.3. The Field of Definition of CM Elliptic Curves.

Theorem 3.18. *Let F be an elliptic curve over $\mathbb{C}$ with CM by $\mathcal{O}_K$, where K is a quadratic imaginary field. Let H be the Hilbert Class Field of K.*

(1) *There is an elliptic curve E defined over K such that $F \cong E_{\mathbb{C}}$.*

(2) *The $\mathrm{Gal}(H/K)$-conjugates of E are representative elements for $\mathrm{Ell}(\mathcal{O}_K)$.*

(3) *If $\sigma \in \mathrm{Gal}(H/K)$ corresponds via Artin reciprocity to $\overline{\mathfrak{a}} \in \mathrm{Cl}(\mathcal{O}_K)$, then*
$$E^{\sigma} = \overline{\mathfrak{a}}E.$$

Theorem 3.18 generalizes in a natural way to the more general situation in which $\mathcal{O}_K$ is replaced by an order $\mathcal{O}_f = \mathbb{Z}+f\mathcal{O}_K \subset \mathcal{O}_K$. Then the Hilbert class field is replaced by the ray class field K_f, which is a finite abelian extension of H that is unramified outside f (see Definition 3.13 above). There is an elliptic curve E defined over K_f whose endomorphism ring is $\mathcal{O}_f$, and the set of $\mathrm{Gal}(K_f/K)$-conjugates of E forms a set of representatives for $\mathrm{Ell}(\mathcal{O}_f)$. Moreover, the group $I(\mathfrak{c}_{L/K})/(N \cdot P(\mathfrak{c}_{L/K}))$ of Theorem 3.15 acts simply transitively on $\mathrm{Ell}(\mathcal{O}_f)$, and the action of $\mathrm{Gal}(K_f/K)$ on the set of conjugates of E is consistent with the Artin reciprocity map.

3.2. Heegner Points

Let E be an elliptic curve defined over $\mathbb{Q}$ with conductor N, and fix a modular parametrization $\pi_E : X_0(N) \to E$.

Let K be a quadratic imaginary field such that the primes dividing N are all unramified and split in K. For simplicity, we will also assume that $K \neq \mathbb{Q}(i), \mathbb{Q}(\sqrt{-3})$. Let $\mathcal{N}$ be an integral ideal of $\mathcal{O}_K$ such that $\mathcal{O}_K/\mathcal{N} \cong \mathbb{Z}/N\mathbb{Z}$. Then $\mathbb{C}/\mathcal{O}_K$ and $\mathbb{C}/\mathcal{N}^{-1}$ define two elliptic curves over $\mathbb{C}$, and since $\mathcal{O}_K \subset \mathcal{N}^{-1}$, there is a natural map

$$\mathbb{C}/\mathcal{O}_K \to \mathbb{C}/\mathcal{N}^{-1}. \tag{3.2.1}$$

By Proposition 3.3 the kernel of this map is

$$\mathcal{N}^{-1}/\mathcal{O}_K \cong \mathcal{O}_K/\mathcal{N} \cong \mathbb{Z}/N\mathbb{Z}.$$

Exercise 3.19. Prove that there is an isomorphism $\mathcal{N}^{-1}/\mathcal{O}_K \cong \mathcal{O}_K/\mathcal{N}$ of finite abelian group.

The modular curve $X_0(N)$ parametrizes isomorphism classes of pairs (F, ϕ), where ϕ is an isogeny with kernel cyclic of order N. Thus $\mathbb{C}/\mathcal{O}_K$ and the isogeny (3.2.1) define an element $x_1 \in X_0(N)(\mathbb{C})$. The discussion of Section 3.1.3 along with properties of modular curves proves the following proposition.

Proposition 3.20. *We have*

$$x_1 \in X_0(N)(H),$$

where H is the Hilbert class field of K.

Definition 3.21 (Heegner point)**.** The *Heegner point* associated to K is

$$y_K = \mathrm{Tr}_{H/K}(\pi_E(x_1)) \in E(K).$$

More generally, for any integer n, let $\mathcal{O}_n = \mathbb{Z} + n\mathcal{O}_K$ be the order in $\mathcal{O}_K$ of index n. Then $\mathcal{N}_n = \mathcal{N} \cap \mathcal{O}_n$ satisfies $\mathcal{O}_n/\mathcal{N}_n \cong \mathbb{Z}/N\mathbb{Z}$, and the pair

$$(\mathbb{C}/\mathcal{O}_n,\ \mathbb{C}/\mathcal{O}_n \to \mathbb{C}/\mathcal{N}_n^{-1})$$

defines a point $x_n \in X_0(N)(K_n)$, where K_n is the ray class field of conductor n over K.

Definition 3.22 (Heegner point of conductor n)**.** The Heegner point of conductor n is

$$y_n = \pi_E(x_n) \in E(K_n).$$

3.3. Computing Heegner Points

[[This section will be my take on what's in Cohen's book and Watkins paper, hopefully generalized to compute Heegner points over ring class fields (?).]]

3.4. Kolyvagin's Euler System

3.4.1. Kolyvagin's Cohomology Classes. In this section we define Kolyvagin's cohomology classes. Later we will explain the properties that these classes have, and eventually use them to sketch a proof of finiteness of Shafarevich-Tate groups of certain elliptic curves.

We will use, when possible, similar notation to the notation Kolyvagin uses in his papers (e.g., [**Kol91**]). If A is an abelian group let $A/M = A/(MA)$. Kolyvagin writes A_M for the M-torsion subgroup, but we will instead write $A[M]$ for this group.

Let E be an elliptic curve over $\mathbb{Q}$ with no constraint on the rank of E. Fix a modular parametrization $\pi : X_0(N) \to E$, where N is the conductor of E. Let K be a quadratic imaginary field with discriminant D that satisfies the Heegner hypothesis for E, so each prime dividing N splits in K, and assume for simplicity that $D \neq -3, -4$.

Let $\mathcal{O}_K$ be the ring of integer of K. Since K satisfies the Heegner hypothesis, there is an ideal $\mathcal{N}$ in $\mathcal{O}_K$ such that $\mathcal{O}_K/\mathcal{N}$ is cyclic of order N. For any positive integer λ, let K_λ be the ray class field of K associated to the conductor λ (see Definition 3.13). Recall that K_λ is an abelian extension of K that is unramified outside λ, whose existence is guaranteed by class field theory. Let $\mathcal{O}_\lambda = \mathbb{Z} + \lambda\mathcal{O}_K$ be the order in $\mathcal{O}_K$ of conductor λ, and let $\mathcal{N}_\lambda = \mathcal{N} \cap \mathcal{O}_\lambda$. Let

$$z_\lambda = [(\mathbb{C}/\mathcal{O}_\lambda, \mathcal{N}_\lambda^{-1}/\mathcal{O}_\lambda)] = X_0(N)(K_\lambda)$$

be the Heegner point associated to λ. Also, let

$$y_\lambda = \pi(z_\lambda) \in E(K_\lambda)$$

be the image of the Heegner point on the curve E.

Let $R = \mathrm{End}(E/\mathbb{C})$, and let $B(E)$ be the set of primes $\ell \geq 3$ in $\mathbb{Z}$ that do not divide the discriminant of R and are such that the image of the representation

$$\rho_{E,\ell} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(\mathrm{Tate}_\ell(E))$$

contains $\mathrm{Aut}_R(\mathrm{Tate}_\ell(E))$, where $\mathrm{Aut}_R(\mathrm{Tate}_\ell(E))$ is the set of automorphisms that commute with the action of R on $\mathrm{Tate}_\ell(E)$. Note that if $\ell \geq 5$ the condition that $\rho_{E,\ell}$ is surjective is equivalent to the simpler condition that

$$\overline{\rho}_{E,\ell} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}_R(E[\ell])$$

is surjective. The set $B(E)$ contains all but finitely many primes, by theorems of Serre [**Ser72**], Mazur [**Maz78**], and CM theory, and one can compute $B(E)$.

```
sage: E = EllipticCurve('11a')
sage: E.non_surjective()
[(5, '5-torsion')]
sage: E = EllipticCurve('389a')
sage: E.non_surjective()
[]
```

Fix a prime $\ell \in B(E)$. We next introduce some very useful notation. Let Λ^1 denote the set of all primes $p \in \mathbb{Z}$ such that $p \nmid N$, p remains prime in $\mathcal{O}_K$, and for which

$$n(p) = \mathrm{ord}_\ell(\gcd(p+1, a_p)) \geq 1.$$

For any positive integer r, let Λ^r denote the set of all products of r distinct primes in Λ^1; by definition $\Lambda^0 = \{1\}$. Finally, let

$$\Lambda = \bigcup_{r \geq 0} \Lambda^r.$$

For any $r > 0$ and $\lambda \in \Lambda^r$, let

$$n(\lambda) = \min_{p \mid \lambda} n(p)$$

be the "worst" of all the powers of p that divide $\gcd(p+1, a_p)$. If $\lambda = 1$, set $n(\lambda) = +\infty$.

Fix an element $\lambda \in \Lambda$, with $\lambda \neq 1$, and consider the ℓ-power

$$M = M_\lambda = \ell^{n(\lambda)}.$$

Recall from Section 2.2.1 that we associate to the short exact sequence

$$0 \to E[M] \to E \xrightarrow{[M]} E \to 0$$

an exact sequence

$$0 \to E(K)/M \to \mathrm{H}^1(K, E[M]) \to H^1(K, E)[M] \to 0.$$

Our immediate goal is to construct an *interesting* cohomology class

$$c_\lambda \in \mathrm{H}^1(K, E[M]).$$

If L/K is any Galois extension, we have (see Section 2.1.2 for most of this) an exact sequence

(3.4.1)

$$0 \to \mathrm{H}^1(L/K, E[M](L)) \to \mathrm{H}^1(K, E[M]) \to \mathrm{H}^1(L, E[M])^{\mathrm{Gal}(L/K)} \to 0.$$

Lemma 3.23. *We have $E[M](K_\lambda) = 0$.*

Proof. For simplicity we prove the statement only in the non-CM case. The integer M is a power of a prime ℓ, so it suffices to show that $E[\ell](K_\lambda) = 0$. Since $\ell \in B(E)$ the Galois representation

$$\overline{\rho}_{E,\ell} : G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{F}_\ell)$$

is surjective. The group $\mathrm{GL}_2(\mathbb{F}_\ell)$ acts transitively on $(\mathbb{F}_\ell)^2$, so the $G_{\mathbb{Q}}$ orbit of any nonzero point in $E[\ell](\overline{\mathbb{Q}})$ is equal to the set of all nonzero points in $E[\ell](\overline{\mathbb{Q}})$. By class field theory, the extension K_λ of $\mathbb{Q}$ is Galois, so if $E[\ell](K_\lambda)$ is nonzero, then it is equal to $E[\ell](\overline{\mathbb{Q}})$. Using properties of the Weil pairing, we see that the field generated by the coordinates of the elements of $E[\ell](\overline{\mathbb{Q}})$ contains the cyclotomic field $\mathbb{Q}(\zeta_\ell)$, which is a field totally ramified at ℓ. But $K \cap \mathbb{Q}(\zeta_\ell) = \mathbb{Q}$, since $\mathrm{disc}(K) \neq -3, -4$, and K_λ is ramified only at primes in Λ^1 and $\ell \notin \Lambda^1$. We conclude that $K_\lambda \cap \mathbb{Q}(\zeta_\ell) = \mathbb{Q}$, so we must have $E[\ell](K_\lambda) = 0$. (Compare [**Gro91**, Lem. 4.3].) □

Thus (3.4.1) with $L = K_\lambda$ becomes

$$\mathrm{H}^1(K, E[M]) \xrightarrow{\cong} \mathrm{H}^1(K_\lambda, E[M])^{G_\lambda} \tag{3.4.2}$$

where $G_\lambda = \mathrm{Gal}(K_\lambda/K)$. Putting this together, we obtain the following commutative diagram with exact rows and columns:

$$\begin{tikzcd}
0 \arrow[r] & (E(K_\lambda)/M)^{G_\lambda} \arrow[r] & \mathrm{H}^1(K_\lambda, E[M])^{G_\lambda} \arrow[r] & \mathrm{H}^1(K_\lambda, E)[M]^{G_\lambda} & \\
0 \arrow[r] & E(K)/M \arrow[r] \arrow[u, hook] & \mathrm{H}^1(K, E[M]) \arrow[r] \arrow[u, "\cong", "\mathrm{res}"'] & \mathrm{H}^1(K, E)[M] \arrow[r] \arrow[u, "\mathrm{res}"] & 0 \\
 & & & \mathrm{H}^1(K_\lambda/K, E)[M] \arrow[u, hook, "\mathrm{inf}"] &
\end{tikzcd}$$

Thus to construct $c_\lambda \in \mathrm{H}^1(K, E[M])$, it suffices to construct a class $c'_\lambda \in \mathrm{H}^1(K_\lambda, E[M])$ that is invariant under the action of G_λ. We will do this by constructing an element of $E(K_\lambda)$ and using the inclusion

$$E(K_\lambda)/M \hookrightarrow \mathrm{H}^1(K_\lambda, E[M]). \tag{3.4.3}$$

In particular, we will construct an element of the group $E(K_\lambda)/M$ that is invariant under the action of G_λ.

Recall that $y_\lambda \in E(K_\lambda)$. Unfortunately, there is no reason that the class

$$[y_\lambda] \in E(K_\lambda)/M$$

should be invariant under the action of G_λ. To deal with this problem, Kolyvagin introduced a *new and original idea* which we now explain.

Let $H = K_1$ be the Hilbert class field of K. Write $\lambda = p_1 \cdots p_r$, and for each $p = p_i$ let $G_p = \mathrm{Gal}(K_p/K)$ where K_p is the ray class field associated to p. Class field theory implies that the natural map

$$\mathrm{Gal}(K_\lambda/K_1) \cong\!\rightarrow G_{p_1} \times G_{p_2} \times \cdots \times G_{p_r}$$

is an isomorphism. Moreover, each group G_{p_i} is cyclic of order $p_i + 1$. For each $p = p_i$, let σ_p be a fixed choice of generator of G_p, and let

$$\mathrm{Tr}_p = \sum_{\sigma \in G_p} \sigma \in \mathbb{Z}[G_p].$$

Finally, let $D_p \in \mathbb{Z}[G_p]$ be any solution of the equation

$$(\sigma_p - 1) \cdot D_p = p + 1 - \mathrm{Tr}_p\,. \tag{3.4.4}$$

For example, Kolyvagin always takes

$$D_p = \sum_{i=1}^{p} i\sigma_p^i = -\sum_{i=1}^{p+1} (\sigma_p^i - 1)/(\sigma_p - 1).$$

Notice that the choice of D_p is well defined up to addition of elements in $\mathbb{Z}\,\mathrm{Tr}_p$. Let

$$D_\lambda = \prod D_p = D_{p_1} \cdot D_{p_2} \cdot \cdots \cdot D_{p_r} \in \mathbb{Z}[G_\lambda].$$

Finally, let S be a set of coset representatives for $\mathrm{Gal}(K_\lambda/K_1)$ in $G_\lambda = \mathrm{Gal}(K_\lambda/K)$, and let

$$J_\lambda = \sum_{\sigma \in S} \sigma \in \mathbb{Z}[G_\lambda].$$

Let

$$P_\lambda = J_\lambda D_\lambda y_\lambda \in E(K_\lambda).$$

Note that if $\lambda = 1$, then $K_\lambda = K_1$, so

$$P_1 = J_1 y_\lambda = \mathrm{Tr}_{K_1/K}(y_\lambda) = y_K \in E(K).$$

Before proving that we can use P_λ to define a cohomology class in $\mathrm{H}^1(K, E[M])$, we state two crucial facts about the structure of the Heegner points y_λ.

Proposition 3.24. *Write $\lambda = p\lambda'$, and let $a_p = a_p(E) = p + 1 - \#E(\mathbb{F}_p)$.*

(1) *We have*

$$\mathrm{Tr}_p(y_\lambda) = a_p y_{\lambda'}$$

in $E(K_{\lambda'})$.

(2) *Each prime factor $\wp_\lambda$ of p in K_λ divides a unique prime $\wp_{\lambda'}$ of $K_{\lambda'}$, and we have a congruence*

$$y_\lambda \equiv \mathrm{Frob}(\wp_{\lambda'})(y_{\lambda'}) \pmod{\wp_\lambda}.$$

Proof. See [**Gro91**, Prop. 3.7]. The proof uses a description of the action of Hecke operators on modular curves. □

Proposition 3.25. *The class* $[P_\lambda]$ *of* P_λ *in* $E(K_\lambda)/M$ *is fixed by* G_λ.

Proof. We follow the proof of [**Gro91**, Prop. 3.6]. It suffices to show that $[D_\lambda y_\lambda]$ is fixed by σ_p for each prime $p \mid \lambda$, since the σ_p generate $\mathrm{Gal}(K_\lambda/K_1)$, the elements of the set S of coset representatives fix the image of J_λ, and G_λ is generated by the σ_p and S. Thus we will prove that

$$(\sigma_p - 1)D_\lambda y_\lambda \in ME(K_\lambda)$$

for each $p \mid \lambda$.

Write $\lambda = pm$. By (3.4.4), we have in $\mathbb{Z}[G_\lambda]$ that

$$(\sigma_p - 1)D_\lambda = (\sigma_p - 1)D_p D_m = (p + 1 - \mathrm{Tr}_p)D_m,$$

so using Proposition 3.24 we have

$$\begin{aligned}(\sigma_p - 1)D_\lambda y_\lambda &= (p + 1 - \mathrm{Tr}_p)D_m y_\lambda\\ &= (p+1)D_m y_\lambda - D_m \,\mathrm{Tr}_p(y_\lambda)\\ &= (p+1)D_m y_\lambda - a_p D_m y_{\lambda'}\end{aligned}$$

Since $p \in \Lambda^1$ and $M = \ell^{n(p)}$ and $n(p) = \min(\mathrm{ord}_\ell(p+1), \mathrm{ord}_\ell(a_p))$, we have $M \mid p+1$ and $M \mid a_p$. Thus $(p+1)D_m y_\lambda \in ME(K_\lambda)$ and $a_p y_{\lambda'} \in ME(K_\lambda)$, which proves the proposition. □

We have now constructed an element of $E(K_\lambda)/M$ that is fixed by G_λ. Via (3.4.3) this defines an element $c'_\lambda \in \mathrm{H}^1(K_\lambda, E[M])$. But then using (3.4.2) we obtain our sought after class $c_\lambda \in \mathrm{H}^1(K, E[M])$.

We will also be interested in the image d_λ of c_λ in $\mathrm{H}^1(K, E)[M]$.

Proposition 3.26. *If* v *is archimedean or* $v \nmid \lambda$, *then*

$$\mathrm{res}_v(d_\lambda) = 0.$$

Proof. If v is archimedean we are done, since $K_v = \mathbb{C}$ is algebraically closed. Otherwise, the class d_λ splits over K_λ and K_λ is unramified at v, so

$$\mathrm{res}_v(d_\lambda) \in \mathrm{H}^1(K_v^{\mathrm{unr}}/K_v, E).$$

But the latter group is isomorphic to the component group of E at v, and a theorem of Gross-Zagier implies that the Heegner point maps to the identity component. (See [**Gro91**, Prop. 6.2] for more details.) □

Proposition 3.27. *Write $\lambda = pm$ and let $\wp = p\mathcal{O}_K$ be the unique prime ideal of K dividing p. Let v be a place of K_m that divides $\wp$. Then the order of $\mathrm{res}_\wp(d_\lambda)$ is the same as the order of*

$$[P_m] \in E(K_\wp)/ME(K_\wp),$$

where $K_\wp$ denotes the completion of K at $\wp$. (Note that $\wp$ splits completely in K_m/K by class field theory, since $\wp = p\mathcal{O}_K$ is principal and coprime to m, so $P_m \in E(K_\wp)$.)

Proof. See [**Gro91**, Prop. 6.2] for the case $M = \ell$. The argument involves standard properties of Galois cohomology of elliptic curves, some diagram chasing, reduction modulo a prime, and use of formal groups. □

Next we consider a consequence of Proposition 3.27 when y_K is not a torsion point. Note that y_K nontorsion implies that $y_K \notin ME(K)$ for all but finitely many M. Moreover, the Gross-Zagier theorem implies that y_K is nontorsion if and only if $\mathrm{ord}_{s=1} L(E, s) \leq 1$.

Proposition 3.28. *Suppose that $y_K \in E(K)$ is not divisible by M. Then there are infinitely many $p \in \Lambda^1$ such that $d_p \in \mathrm{H}^1(K, E)[M]$ is nonzero.*

Proof. This follows from Proposition 3.27 with $m = 1$ and the Chebotarev density theorem. See e.g., [**Ste02**, §4.1] for a proof. □

Remark 3.29. See, e.g., [**Ste02**] for an application of this idea to a problem raised by Lang and Tate in [**LT58**].

Theorem 3.30 (Kolyvagin)**.** *Suppose E is a modular elliptic curve over $\mathbb{Q}$ and K is a quadratic imaginary field that satisfies the Heegner hypothesis for E and is such that $y_K \in E(K)$ is nontorsion. Then $E(K)$ has rank 1 and*

$$\#\text{Ш}(E/K) \mid b \cdot [E(K) : \mathbb{Z}y_K]^2,$$

where b is a positive integer divisible only by primes $\ell \in B(E)$ (i.e., for which the ℓ-adic representation is not as surjective as possible).

Proof. See the entire paper [**Gro91**]. Kolyvagin proves this theorem by bounding $\mathrm{Sel}^{(M)}(E/K)$ for various M using Proposition 3.28 in conjunction with a careful study of various pairings coming from Galois cohomology, the Weil pairing, Tate local daulity, etc. Since

$$0 \to E(K)/ME(K) \to \mathrm{Sel}^{(M)}(E/K) \to \text{Ш}(E/K),$$

a bound on the Selmer group translates into a bound on $E(K)$ and $\text{Ш}(E/K)$. □

After Kolyvagin proved his theorem, independently Murty-Murty, Bump-Friedberg-Hoffstein, Waldspurger, each proved that infinitely many such quadratic imaginary K always exists so long as E has analytic rank 0 or 1. Also, Taylor and Wiles proved that every E over $\mathbb{Q}$ is modular. Thus we have the following theorem:

Theorem 3.31. *Suppose E is an elliptic curve over $\mathbb{Q}$ with*

$$r_{E,\mathrm{an}} = \mathrm{ord}_{s=1} L(E,s) \le 1.$$

Then $E(\mathbb{Q})$ has rank $r_{E,\mathrm{an}}$, the group $Ш(E/\mathbb{Q})$ is finite, and there is an explicit computable upper bound on $\#Ш(E/\mathbb{Q})$.

The author has computed the upper bound of the theorem for all elliptic curves with conductor up to 1000 and $r_{E,\mathrm{an}} \le 1$.

3.4.2. Kolyvagin's Conjectures. What about curves E with $r_{E,\mathrm{an}} \ge 2$? Suppose that E is an elliptic curve over $\mathbb{Q}$ with $r_{E,\mathrm{an}} \ge 2$. In the short paper [**Kol91**], Kolyvagin states an amazing structure theorems for Selmer groups assuming the following unproved conjecture, which is the appropriate generalization of the condition that P_1 has infinite order.

Conjecture 3.32 (Kolyvagin [**Kol91**])**.** *Let E be any elliptic curve over $\mathbb{Q}$ and fix a prime $\ell \in B(E)$ and a prime power $M = \ell^n$ of ℓ. Then there is at least one cohomology class $c_\lambda \in H^1(K, E[M])$ that is nonzero.*

So far nobody has been able to show that Conjecture 3.32 is satisfied by every elliptic curve E over $\mathbb{Q}$, though several people are currently working hard on this problem (including Vatsal and Cornut). Proposition 3.28 above implies that Conjecture 3.32 is true for elliptic curves with $r_{E,\mathrm{an}} \le 1$.

Kolyvagin also goes on in [**Kol91**] to give a *conjectural construction* of a subgroup

$$V \subset E(K)/E(K)_{\mathrm{tor}}$$

for which $\mathrm{rank}(E(\mathbb{Q})) = \mathrm{rank}(V)$. Let ℓ be an arbitrary prime, i.e., so we do not necessarily assume $\ell \in B(E)$. One can construct cohomology class $c_\lambda \in \mathrm{H}^1(K, E[M])$, so long as $\lambda \in \Lambda^{n+k_0}$, where $\ell^{k_0/2}E(\mathbf{K})[\ell^\infty] = 0$, and $\mathbf{K}$ is the compositum of all class field K_λ for $\lambda \in \Lambda$. For any $n \ge 1$, $k \ge k_0$, and $r \ge 0$, let

$$V^r_{n,k} \subset \varinjlim_m \mathrm{H}^1(K, E[\ell^m])/E(K)_{\mathrm{tor}}$$

be the subgroup generated by the images of the classes $\tau_\lambda = \tau_{\lambda,n} \in \mathrm{H}^1(K, E[\ell^n])$ where λ runs through Λ^r_{n+k}.

Conjecture 3.33 (Kolyvagin)**.** *Let E be any elliptic curve over $\mathbb{Q}$. Then for all prime numbers ℓ, there exists an integer r such that for all $k \ge k_0$ there is an n such that $V^r_{n,k} \ne 0$.*

Recall that

$$n(p) = \mathrm{ord}_\ell(\gcd(p+1, a_p)) \geq 1$$

and

$$n(\lambda) = \min_{p|\lambda} n(p).$$

Let $m'(\lambda)$ be the maximal nonnegative integer such that $P_\lambda \in \ell^{m'(\lambda)} E(K_\lambda)$. Let $m(\lambda) = m'(\lambda)$ if $m'(\lambda) < n(\lambda)$, and $m(\lambda) = \infty$ otherwise. For any $r \geq 0$, let

$$m_r = \min\{m(\lambda) : \lambda \in \Lambda^r\},$$

and let f be the minimal r such that m_r is finite.

Proposition 3.34. *We have $f = 0$ if and only if y_K has infinite order.*

Let $SD = \ell^n S$, where

$$S = \varinjlim_{n} \mathrm{Sel}^{(\ell^n)}(K, E[\ell^n]).$$

If A is a $\mathbb{Z}[1,\sigma]$-module and $\varepsilon = (-1)^{r_{E,\mathrm{an}}-1}$. then

$$A^v = \{b \in A : \sigma(b) = (-1)^{v+1}\varepsilon b\}$$

Assuming his conjectures, Kolyvagin deduces that for every prime number ℓ there exists integers k_1 and k_2 such that for any integer $k \geq k_1$ we have

$$\ell^{k_2} SD^{(f+1)}[M] \subset V^f_{n,k} \subset SD^{(f+1)}[M].$$

Here the exponent of $f+1$ means the $+1$ or -1 eigenspace for the conjugation action.

Conjecture 3.35 (Kolyvagin)**.** *Let E be any elliptic curve over $\mathbb{Q}$ and ℓ any prime. There exists $v \in \{0,1\}$ and a subgroup*

$$V \subset (E(K)/E(K)_{\mathrm{tors}})^{(v)}$$

such that

$$1 \leq \mathrm{rank}(V) \equiv v \pmod{2}.$$

Let $a = \mathrm{rank}(V) - 1$. Then for all sufficiently large k and all n, one has that

$$V^a_{n,k} \equiv V \mod \ell^n(E(K)/E(K)_{\mathrm{tor}}).$$

Assuming the above conjecture for all primes ℓ, the group V is uniquely determined by the congruence condition in the second part of the conjecture. Also, Kolyvagin proves that if the above conjecture is true, then the rank of $E^v(\mathbb{Q})$ equals the rank of V, and that $Ш(E^v/\mathbb{Q})[\ell^\infty]$ is finite. (Here E^v is E or its quadratic twist.)

When P_1 has infinite order, the conjecture is true with $v = 1$ and $V = \mathbb{Z}P_1$. (I think here E has $r_{E,\mathrm{an}} = 0$.)

32 Open Source Mathematical Software, with David Joyner

Open Source Mathematical Software

Mathematical software has greatly contributed to mathematical research, enabling exciting advances in mathematics and providing extensive data for conjectures. Perhaps three of the most well-known applications of computation to mathematical research are the resolution of the *four-color conjecture* by Appel and Haken in 1976 (though it is now reproven with less need for computer verification by N. Robertson, D. P. Sanders, P. D. Seymour and R. Thomas), Thomas Hales's proof of *Kepler's conjecture*, and the formulation of the *Birch and Swinnerton-Dyer conjecture*, which grew out of extensive numerical computation.

Open source software, such as TEX, Mozilla Firefox, and Linux has had a profound effect on computing during the last decade, and we hope that open source mathematical software will have a similar positive impact on mathematics.

> I think we need a symbolic standard to make computer manipulations easier to document and verify. And with all due respect to the free market, perhaps we should not be dependent on commercial software here. An open source project could, perhaps, find better answers to the obvious problems such as availability, bugs, backward compatibility, platform independence, standard libraries, etc. One can learn from the success of TEX and more specialized software like Macaulay2. I do hope that funding agencies are looking into this.
>
> —*Andrei Okounkov, 2006 Fields medalist*
> (see "Interviews with three Fields medalists" *Notices of the AMS*, **54**(3) (2007), 405–410).

The term *open source* is defined at `http://www.opensource.org/`, but basically it means anyone (including commercial companies or the defense department) should be able to inspect open source software, modify it, and share it with others.

One key difference between mathematical theorems and software is that theorems require little maintenance, whereas *mathematical software requires substantial and potentially expensive maintenance* (bug fixes, updates when algorithms or languages change, etc.). Mathematical research usually generates no direct revenue for researchers, and likewise open source mathematical software is free to share and extend, so it rarely generates revenue. Volunteer effort, donations, and financial support from the NSF and other organizations is thus critical to the success of open source mathematical software.

There is a proof in the article by Campbell et al. in *The Atlas of Finite Groups—Ten Years On* (1998) that describes how many separate software packages were "easily used" to deduce various mathematical facts—no code is given, and some of the programs are proprietary software that runs only on hardware many years out of date. Such proofs may become increasingly common in mathematics if something isn't done to reverse this trend.

Suppose Jane is a well-known mathematician who announces she has proved a theorem. We probably will believe her, but she knows that she will be required to produce a proof if requested. However, suppose now Jane says a theorem is true based partly on the results of software. The closest we can reasonably hope to get to a rigorous proof (without new ideas) is the open inspection and ability to use all the computer code on which the result depends. If the program is proprietary, this is not possible. We have every right to be distrustful, not only due to a vague distrust of computers but because even the best programmers regularly make mistakes.

If one reads the proof of Jane's theorem in hopes of extending her ideas or applying them in a new context, it is limiting to not have access to the inner workings of the software on which Jane's result builds. For example, consider the following quote from the Mathematica tutorial[1]:

> Particularly in more advanced applications of Mathematica, it may sometimes seem worthwhile to try to analyze internal algorithms in order to predict which way of doing a given computation will be the most efficient. [...] But most often the analyses will not be worthwhile. For the internals of Mathematica are quite complicated, and even given a basic description of the algorithm used for a particular purpose, it is usually extremely difficult to reach a reliable conclusion about how the detailed implementation of this algorithm will actually behave in particular circumstances.

No journal would make a statement like the above about the proofs of the theorems they publish. Increasingly, proprietary software and the algorithms used are an essential part of mathematical proofs. To quote J. Neubüser, "*with this situation two of the most basic rules of conduct in mathematics are violated: In mathematics information is passed on free of charge and everything is laid open for checking.*"

Full disclosure: The second author started a new mathematics software system in 2005 called SAGE (see `www.sagemath.org`), which combines Python, GAP, Singular, PARI, Maxima, SciPy, etc. with several hundred thousand lines of new code. SAGE receives contributions from many mathematicians worldwide that synthesize the latest algorithms from a broad range of topics into a comprehensive toolkit for mathematical research.

33 On the generation of the coefficient field of a newform by a single Hecke eigenvalue, with K. Koo and G. Wiese

On the generation of the coefficient field of a newform by a single Hecke eigenvalue

Koopa Tak-Lun Koo* and William Stein† and Gabor Wiese‡

November 20, 2007

Abstract

Let f be a non-CM newform of weight $k \geq 2$ without nontrivial inner twists. In this article we study the set of primes p such that the eigenvalue $a_p(f)$ of the Hecke operator T_p acting on f generates the field of coefficients of f. We show that this set has density 1, and prove a natural analogue for newforms having inner twists. We also present some new data on reducibility of Hecke polynomials, which suggest questions for further investigation.

Mathematics Subject Classification (2000): 11F30 (primary); 11F11, 11F25, 11F80, 11R45 (secondary).

1 Introduction

The main aim of this paper is to prove the following theorem.

Theorem 1. *Let f be a newform (i.e., a new normalized cuspidal Hecke eigenform) of weight $k \geq 2$, level N and Dirichlet character χ which does not have complex multiplication (CM, see [R80, p. 48]). Let $E_f = \mathbf{Q}(a_n(f) : (n, N) = 1)$ be the field of coefficients of f and $F_f = \mathbf{Q}\left(\frac{a_n(f)^2}{\chi(n)} : (n, N) = 1\right)$.*

†Department of Mathematics, University of Washington, Seattle, Box 354350 WA 98195, USA; e-mail: wstein@math.washington.edu

‡Institut für Experimentelle Mathematik, Universität Duisburg-Essen, Ellernstraße 29, 45326 Essen, Germany; e-mail: gabor@pratum.net

(a) The set

$$\left\{p \text{ prime} : \mathbf{Q}\left(\frac{a_p(f)^2}{\chi(p)}\right) = F_f\right\}$$

has density 1.

(b) If f does not have any nontrivial inner twists, then the set

$$\{p \text{ prime} : \mathbf{Q}(a_p(f)) = E_f\}$$

has density 1.

A twist of f by a Dirichlet character ϵ is said to be *inner* if there exists a (necessarily unique) field automorphism $\sigma_\epsilon : E_f \to E_f$ such that

$$a_p(f \otimes \epsilon) = a_p(f)\epsilon(p) = \sigma_\epsilon(a_p(f))$$

for almost all primes p. If N is square free, $k = 2$ and the Dirichlet character χ of f is the trivial character, then there are no nontrivial inner twists of f. For a discussion of inner twists we refer the reader to [R80, §3] and [R85, §3].

In the presence of nontrivial inner twists, the conclusion of Part (b) of the theorem never holds. To see this, we let ϵ be a nontrivial inner twist with associated field automorphism σ_ϵ. The set of primes p such that $\epsilon(p) = 1$ has a positive density and for any such p we have $\sigma_\epsilon(a_p(f)) = a_p(f)$. Therefore, $a_p(f) \in E_f^{\langle\sigma\rangle} \subsetneq E_f$ for a set of primes p of positive density.

In the literature there are related but weaker results in the context of Maeda's conjecture, i.e., they concern the case of level 1 and assume that $S_k(1)$ consists of a single Galois orbit of newforms (see, e.g., [JO98] and [BM03]). We now show how Part (b) of Theorem 1 extends the principal results of these two papers.

Let f be a newform of level N, weight $k \geq 2$ and trivial Dirichlet character $\chi = 1$ which neither has CM nor nontrivial inner twists. This is true when $N = 1$. Let $\mathbb{T}$ be the $\mathbf{Q}$-algebra generated by all T_n with $n \geq 1$ inside $\mathrm{End}(S_k(N, 1))$ and let $\mathfrak{P}$ be the kernel of the $\mathbf{Q}$-algebra homomorphism $\mathbb{T} \xrightarrow{T_n \mapsto a_n(f)} E_f$. As $\mathbb{T}$ is reduced, the map $\mathbb{T}_{\mathfrak{P}} \xrightarrow{T_n \mapsto a_n(f)} E_f$ is a ring isomorphism with $\mathbb{T}_{\mathfrak{P}}$ the localization of $\mathbb{T}$ at $\mathfrak{P}$. Non canonically $\mathbb{T}_{\mathfrak{P}}$ is also isomorphic as a $\mathbb{T}_{\mathfrak{P}}$-module (equivalently as an E_f-vector space) to its $\mathbf{Q}$-linear dual, which can be identified with the localization at $\mathfrak{P}$ of the $\mathbf{Q}$-vector space $S_k(N, 1; \mathbf{Q})$ of cusp forms in $S_k(N, 1)$ with q-expansion in $\mathbf{Q}[[q]]$. Hence, $\mathbf{Q}(a_p(f)) = E_f$ precisely means that the characteristic polynomial $P_p \in \mathbf{Q}[X]$ of T_p acting on the localization at $\mathfrak{P}$ of $S_k(N, 1; \mathbf{Q})$

is irreducible. Part (b) of Theorem 1 hence shows that the set of primes p such that P_p is irreducible has density 1.

This extends Theorem 1 of [JO98] and Theorem 1.1 of [BM03]. Both theorems restrict to the case $N = 1$ and assume that there is a unique Galois orbit of newforms, i.e., a unique $\mathfrak{P}$, so that no localization is needed. Theorem 1 of [JO98] says that

$$\#\{p < X \text{ prime } : P_p \text{ is irreducible in } \mathbf{Q}[X]\} \gg \frac{X}{\log X}$$

and Theorem 1.1 of [BM03] states that there is $\delta > 0$ such that

$$\#\{p < X \text{ prime } : P_p \text{ is reducible in } \mathbf{Q}[X]\} \ll \frac{X}{(\log X)^{1+\delta}}.$$

Acknowledgements. The authors would like to thank the MSRI, where part of this research was done, for its hospitality. The first author would like to thank his advisor Ralph Greenberg for suggesting the problem. The second author acknowledges partial support from the National Science Foundation grant No. 0555776, and also used [SAGE] for some calculations related to this paper. All three authors thank Jordi Quer for useful discussions.

2 Group theoretic input

Lemma 1. *Let q be a prime power and ϵ a generator of the cyclic group $\mathbb{F}_q^\times$.*

(a) The conjugacy classes c in $\mathrm{GL}_2(\mathbb{F}_q)$ have the following four kinds of representatives:

$$S_a = \begin{pmatrix} a & 0 \\ 0 & a \end{pmatrix}, \quad T_a = \begin{pmatrix} a & 0 \\ 1 & a \end{pmatrix}, \quad U_{a,b} = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}, \quad V_{x,y} = \begin{pmatrix} x & \epsilon y \\ y & x \end{pmatrix}$$

where $a \neq b$, and $y \neq 0$.

(b) The number of elements in each of these conjugacy classes are: $1, q^2 - 1, q^2 + q$, and $q^2 - q$, respectively.

Proof. See Fulton-Harris [FH91], page 68. □

We use the notation $[g]_G$ for the conjugacy class of g in G.

Proposition 1. *Let q be a prime power and r a positive integer. Let further $R \subseteq \widetilde{R} \subseteq \mathbb{F}_{q^r}^\times$ be subgroups. Put $\sqrt{\widetilde{R}} = \{s \in \mathbb{F}_{q^r}^\times \,:\, s^2 \in \widetilde{R}\}$. Set*

$$H = \{g \in \mathrm{GL}_2(\mathbb{F}_q) \,:\, \det(g) \in R\}$$

and let

$$G \subseteq \{g \in \mathrm{GL}_2(\mathbb{F}_{q^r}) \,:\, \det(g) \in \widetilde{R}\}$$

be any subgroup such that H is a normal subgroup of G. Then the following statements hold.

(a) The group $G/(G \cap \mathbb{F}_{q^r}^\times)$ (with $\mathbb{F}_{q^r}^\times$ identified with scalar matrices) is either equal to $\mathrm{PSL}_2(\mathbb{F}_q)$ or to $\mathrm{PGL}_2(\mathbb{F}_q)$. More precisely, if we let $\{s_1, \dots, s_n\}$ be a system of representatives for $\sqrt{\widetilde{R}}/R$, then for all $g \in G$ there is i such that $g \begin{pmatrix} s_i^{-1} & 0 \\ 0 & s_i^{-1} \end{pmatrix} \in G \cap \mathrm{GL}_2(\mathbb{F}_q)$ and $\left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right) \in G$.

(b) Let $g \in G$ such that $g \begin{pmatrix} s_i^{-1} & 0 \\ 0 & s_i^{-1} \end{pmatrix} \in G \cap \mathrm{GL}_2(\mathbb{F}_q)$ and $\left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right) \in G$. Then

$$[g]_G = [g \begin{pmatrix} s_i^{-1} & 0 \\ 0 & s_i^{-1} \end{pmatrix}]_{G \cap \mathrm{GL}_2(\mathbb{F}_q)} \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right).$$

(c) Let $P(X) = X^2 - aX + b \in \mathbb{F}_{q^r}[X]$ be a polynomial. Then the inequality

$$\sum_C |C| \;\leq\; 2|\widetilde{R}/R|(q^2 + q)$$

holds, where the sum runs over the conjugacy classes C of G with characteristic polynomial equal to $P(X)$.

Proof. (a) The classification of the finite subgroups of $\mathrm{PGL}_2(\overline{\mathbb{F}}_q)$ yields that the group $G/(G \cap \mathbb{F}_{q^r}^\times)$ is either $\mathrm{PGL}_2(\mathbb{F}_{q^u})$ or $\mathrm{PSL}_2(\mathbb{F}_{q^u})$ for some $u \mid r$. This, however, can only occur with $u = 1$, as $\mathrm{PSL}_2(\mathbb{F}_{q^u})$ is simple. The rest is only a reformulation.

(b) This follows from (a), since scalar matrices are central.

(c) From (b) we get the inclusion

$$\bigsqcup_C C \subseteq \bigsqcup_{i=1}^n \bigsqcup_D D \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right),$$

where C runs over the conjugacy classes of G with characteristic polynomial equal to $P(X)$ and D runs over the conjugacy classes of $G \cap \mathrm{GL}_2(\mathbb{F}_q)$ with characteristic polynomial equal to $X^2 - as_i^{-1}X + bs_i^{-2}$ (such a conjugacy class is empty if the polynomial is not in $\mathbb{F}_q[X]$). The group $G \cap \mathrm{GL}_2(\mathbb{F}_q)$ is normal in $\mathrm{GL}_2(\mathbb{F}_q)$, as it contains $\mathrm{SL}_2(\mathbb{F}_q)$. Hence, any conjugacy class of $\mathrm{GL}_2(\mathbb{F}_q)$ either has an empty intersection with $G \cap \mathrm{GL}_2(\mathbb{F}_q)$ or is a disjoint union of conjugacy classes of $G \cap \mathrm{GL}_2(\mathbb{F}_q)$. Consequently, by Lemma 1, the disjoint union $\bigsqcup_D D \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right)$ is equal to one of

(i) $[U_{a,b}]_{\mathrm{GL}_2(\mathbb{F}_q)} \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right)$,

(ii) $[V_{x,y}]_{\mathrm{GL}_2(\mathbb{F}_q)} \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right)$ or

(iii) $[S_a]_{\mathrm{GL}_2(\mathbb{F}_q)} \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right) \sqcup [T_a]_{\mathrm{GL}_2(\mathbb{F}_q)} \left(\begin{smallmatrix} s_i & 0 \\ 0 & s_i \end{smallmatrix}\right)$.

Still by Lemma 1, the first set contains q^2+q, the second set q^2-q and the third one q^2 elements. Hence, the set $\bigsqcup_C C$ contains at most $2|\widetilde{R}/R|(q^2+q)$ elements. □

3 Proof

The proof of Theorem 1 relies on the following important theorem by Ribet, which, roughly speaking, says that the image of the mod ℓ Galois representation attached to a fixed newform is as big as it can be for almost all primes ℓ.

Theorem 2 (Ribet). *Let f be a Hecke eigenform of weight $k \geq 2$, level N and Dirichlet character $\chi : (\mathbf{Z}/N\mathbf{Z})^\times \to \mathbf{C}^\times$. Suppose that f does not have CM. Let E_f and F_f be as in Theorem 1 and denote by $\mathcal{O}_{E_f}$ and $\mathcal{O}_{F_f}$ the corresponding rings of integers.*

There exists an abelian extension $K/\mathbf{Q}$ such that for almost all prime numbers ℓ the following statement holds:

> *Let $\widetilde{\mathcal{L}}$ be a prime ideal of $\mathcal{O}_{E_f}$ dividing ℓ. Put $\mathcal{L} = \widetilde{\mathcal{L}} \cap \mathcal{O}_{F_f}$ and $\mathcal{O}_{F_f}/\mathcal{L} \cong \mathbb{F}$. Consider the residual Galois representation*
>
> $$\overline{\rho}_{f,\widetilde{\mathcal{L}}} : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_2(\mathcal{O}_{E_f}/\widetilde{\mathcal{L}})$$
>
> *attached to f. Then the image $\overline{\rho}_{f,\widetilde{\mathcal{L}}}(\mathrm{Gal}(\overline{\mathbf{Q}}/K))$ is equal to*
>
> $$\{g \in \mathrm{GL}_2(\mathbb{F}) \,:\, \det(g) \in \mathbb{F}_\ell^{\times(k-1)}\}.$$

Proof. It suffices to take Ribet [R85, Thm. 3.1] mod $\widetilde{\mathcal{L}}$. Note that F_f is the field E_f^Γ. To see this, one checks immediately that $F_f \subseteq E_f^\Gamma$ with Γ the group of the field automorphisms associated with the inner twists as in [R80, §3]. On the other hand, let σ be a field embedding $E_f \to \mathbf{C}$ which is the identity on F_f, i.e., on $\frac{a_n(f)^2}{\chi(n)}$ for all n with $(n, N) = 1$. Then $\frac{\sigma(a_n(f))^2}{a_n(f)^2} = \frac{\sigma(\chi(n))}{\chi(n)}$ is a root of unity, and, thus, so is $\epsilon(n) = \frac{\sigma(a_n(f))}{a_n(f)}$. This defines a Dirichlet character ϵ by which f has an inner twist. Hence, $\sigma \in \Gamma$ and $F_f = E_f^\Gamma$.

Ribet does not say explicitly that $K/\mathbf{Q}$ is abelian, but this follows since it is a composite of abelian extensions of K, which are each cut out by a character. □

Remark 1. *The field F_f defined in Theorem 1 is invariant under twisting. More precisely, let ϵ be any Dirichlet character and consider the twisted modular form $f \otimes \epsilon$, the Dirichlet character of which is $\chi\epsilon^2$. Then the Fourier coefficients satisfy $a_n(f \otimes \epsilon) = a_n(f)\epsilon(n)$ and, thus, $\frac{a_n(f\otimes\epsilon)^2}{\chi(n)\epsilon(n)^2} = \frac{a_n(f)^2}{\chi(n)}$.*

Remark 2. *If f in Theorem 1 does not have any nontrivial inner twists, then $K = \mathbf{Q}$ and $F_f = E_f$, since $F_f = E_f^\Gamma$ with Γ the group of field automorphisms associated with the inner twists (see the proof of Theorem 2).*

Theorem 3. *Let f be a non-CM newform of weight $k \geq 2$, level N and Dirichlet character χ. Let F_f be as in Theorem 1 and let $L \subset F_f$ be any proper subfield. Then the set*

$$\left\{ p \text{ prime} : \frac{a_p(f)^2}{\chi(p)} \in L \right\}$$

has density zero.

Proof. Let $L \subsetneq F_f$ be a proper subfield and $\mathcal{O}_L$ its integer ring. We define the set

$$S := \{\mathcal{L} \subset \mathcal{O}_{F_f} \text{ prime ideal} : [\mathcal{O}_{F_f}/\mathcal{L} : \mathcal{O}_L/(L \cap \mathcal{L})] \geq 2\}.$$

Notice that this set is infinite. For, if it were finite, then all but finitely many primes would split completely in the extension F_f/L, which is not the case by Chebotarev's density theorem.

Let $\mathcal{L} \in S$ be any prime, ℓ its residue characteristic and $\widetilde{\mathcal{L}}$ a prime of $\mathcal{O}_{E_f}$ lying over $\mathcal{L}$. Put $\mathbb{F}_q = \mathcal{O}_L/(L \cap \mathcal{L})$, $\mathbb{F}_{q^r} = \mathcal{O}_{F_f}/\mathcal{L}$ and $\mathbb{F}_{q^{rs}} = \mathcal{O}_{E_f}/\widetilde{\mathcal{L}}$. We have $r \geq 2$. Let W be the subgroup of $\mathbb{F}_{q^{rs}}^\times$ consisting of the values of χ modulo $\widetilde{\mathcal{L}}$; its size $|W|$ is less than or equal to $|(\mathbf{Z}/N\mathbf{Z})^\times|$. Let $R = \mathbb{F}_\ell^{\times(k-1)}$ be the subgroup of $(k-1)$st powers of elements in the multiplicative group $\mathbb{F}_\ell^\times$ and let $\widetilde{R} = \langle R, W\rangle \subset \mathbb{F}_{q^{rs}}^{\times}$. The size of $\widetilde{R}$ is less than or equal to $|R| \cdot |W|$. Let $H = \{g \in \mathrm{GL}_2(\mathbb{F}_{q^r}) \ : \ \det(g) \in R\}$ and $G = \mathrm{Gal}(\overline{\mathbf{Q}}^{\ker \overline{\rho}_{f,\widetilde{\mathcal{L}}}}/\mathbf{Q})$. By Galois theory, G can be identified with the image of the residual representation $\overline{\rho}_{f,\widetilde{\mathcal{L}}}$, and we shall make this identification from now on. By Theorem 2 we have the inclusion of groups

$$H \subseteq G \subseteq \{g \in \mathrm{GL}_2(\mathbb{F}_{q^{rs}}) : \det(g) \in \widetilde{R}\}$$

with H being normal in G.

If C is a conjugacy class of G, by Chebotarev's density theorem the density of

$$\{p\,\text{prime} : \ [\overline{\rho}_{f,\widetilde{\mathcal{L}}}(\mathrm{Frob}_p)]_G = C\}$$

equals $|C|/|G|$. We consider the set

$$M_{\mathcal{L}} := \bigsqcup_C \{p\,\text{prime} : \ [\overline{\rho}_{f,\widetilde{\mathcal{L}}}(\mathrm{Frob}_p)]_G = C\} \supseteq \left\{ p\,\text{prime} : \ \overline{\left(\frac{a_p(f)^2}{\chi(p)}\right)} \in \mathbb{F}_q \right\},$$

where the reduction modulo $\mathcal{L}$ of an element $x \in \mathcal{O}_{F_f}$ is denoted by $\overline{x}$ and C runs over the conjugacy classes of G with characteristic polynomials equal to some $X^2 - aX + b \in \mathbb{F}_{q^{rs}}[X]$ such that

$$a^2 \in \{t \in \mathbb{F}_{q^{rs}} \ : \ \exists u \in \mathbb{F}_q \ \exists w \in W : t = uw\}$$

and automatically $b \in \widetilde{R}$. The set $M_{\mathcal{L}}$ has the density $\delta(M_{\mathcal{L}}) = \sum_C \frac{|C|}{|G|}$ with C as before. There are at most $2q|W|^2 \cdot |R|$ such polynomials. We are now precisely in the situation to apply Prop. 1, Part (c), which yields the inequality

$$\delta(M_{\mathcal{L}}) \leq \frac{4|W|^3 q(q^{2r} + q^r)}{(q^{3r} - q^r)} = O\left(\frac{1}{q^{r-1}}\right) \leq O\left(\frac{1}{q}\right),$$

where for the denominator we used $|G| \geq |H| = |R| \cdot |\mathrm{SL}_2(\mathbb{F}_{q^r})|$.

Since q is unbounded for $\mathcal{L} \in S$, the intersection $M := \bigcap_{\mathcal{L} \in S} M_{\mathcal{L}}$ is a set having a density and this density is 0. The inclusion

$$\left\{ p\,\text{prime} : \ \frac{a_p(f)^2}{\chi(p)} \in L \right\} \subseteq M$$

finishes the proof. □

Proof of Theorem 1. To obtain (a), it suffices to apply Theorem 3 to each of the finitely many sub-extension of F_f. (b) follows from (a) by Remark 2 and the fact that χ must take values in $\{\pm 1\}$, as otherwise E_f would be a CM-field and complex conjugation would give a nontrivial inner twist. □

4 Reducibility of Hecke polynomials: questions

Motivated by a conjecture of Maeda, there has been some speculation that for every integer k and prime number p, the characteristic polynomial of T_p acting on $S_k(1)$ is irreducible. See, for example, [FJ02], which verifies this for all $k < 2000$ and $p < 2000$. The most general such speculation might be the following question: *if f is a non-CM newform of level $N \geq 1$ and weight $k \geq 2$ such that some $a_p(f)$ generates the field $E_f = \mathbf{Q}(a_n(f) : n \geq 1)$, do all but finitely many prime-indexed Fourier coefficients $a_p(f)$ have irreducible characteristic polynomial?* The answer in general is no. An example is given by the newform in level 63 and weight 2 that has an inner twist by $\left(\frac{\cdot}{4}\right)$. Also for non-CM newforms of weight 2 without nontrivial inner twists such that $[E_f : \mathbf{Q}] = 2$, we think that the answer is likely no.

Let $f \in S_k(\Gamma_0(N))$ be a newform of weight k and level N. The *degree* of f is the degree of the field E_f, and we say that f is a *reducible newform* if the characteristic polynomial of $a_p(f)$ is reducible for infinitely many primes p.

For each even weight $k \leq 12$ and degree $d = 2, 3, 4$, we used [SAGE] to find newforms f of weight k and degree d. For each of these forms, we computed the *reducible primes* $p < 1000$, i.e., the primes such that the characteristic polynomial of $a_p(f)$ is reducible. The result of this computation is given in Table 1. Table 2 contains the number of reducible primes $p < 10000$ for the first 20 newforms of degree 2 and weight 2. This data inspires the following question.

Question 1. *If $f \in S_2(\Gamma_0(N))$ is a newform of degree 2, is f necessarily reducible? That is, are there infinitely many primes p such that $a_p(f) \in \mathbf{Z}$, or equivalently, such that the characteristic polynomial of $a_p(f)$ is reducible?*

Tables 4–6 contain additional data about the first few newforms of given degree and weight, which may suggest other similar questions. In particular, Table 4 contains data for all primes up to 10^6 for the first degree 2 form f with $L(f, 1) \neq 0$, and for the first degree 2 form g with $L(g, 1) = 0$. We find that there are 386 primes $< 10^6$ with $a_p(f) \in \mathbf{Z}$ (i.e., has reducible characteristic polynomial), and 309 with $a_p(g) \in \mathbf{Z}$.

Question 2. *If $f \in S_2(\Gamma_0(N))$ is a newform of degree 2, can the asymptotic behaviour of the function*

$$N(x) := \#\{p\,\text{prime} : \, p < x, a_p(f) \in \mathbf{Z}\}$$

be described as a function of x?

The authors intend to investigate these questions in a subsequent paper.

34 Three Lectures about Explicit Methods in Number Theory Using Sage

Three Lectures about Explicit Methods in Number Theory Using Sage

William Stein

October 2008

Abstract

This article is about using the mathematical software Sage to do computations with number fields and modular forms. It was written for the October 2008 Bordeaux meeting on explicit methods in number theory (`http://www.math.u-bordeaux.fr/gtem2008/`). It assumes no prior knowledge about Sage, but assumes a graduate level background in algebraic number theory.

Contents

Introduction

Sage (see http://sagemath.org) is a comprehensive mathematical software system for computations in many areas of pure and applied mathematics. We program Sage using the mainstream programming language Python (see http://python.org), or its compiled variant Cython. It is also very easy to efficiently use code written in C/C++ from Sage.

The author of this article started the Sage project in 2005. Sage is free and open source, meaning you can change any part of Sage and redistribute the result without having to pay any license fees, and Sage can also leverage the power of commercial mathematical software such as Magma and Mathematica, if you happen to have access to those closed source commercial systems.

This paper assumes no prior knowledge of either Python or Sage. Our goal is to help number theorists do computations involving number fields and modular forms using Sage.

As you read this article, please try every example in Sage, and make sure things works as I claim, and do all of the exercises. Moreover, you should experiment by typing in similar examples and checking that the output you get agrees with what you expect.

To use Sage, install it on your computer, and use either the command line or start the Sage notebook by typing `notebook()` at the command line.

We show Sage sessions as follows:

```
sage: factor(123456)
2^6 * 3 * 643
```

This means that if you type `factor(123456)` as input to Sage, then you'll get `2^6 * 3 * 643` as output. If you're using the Sage command line, you type `factor(123456)` and press enter; if you're using the Sage notebook via your web browser, you type `factor(123456)` into an input cell and press shift-enter; in the output cell you'll see `2^6 * 3 * 643`.

After trying the `factor` command in the previous paragraph (do this now!), you should try factoring some other numbers.

Exercise 0.1. What happens if you factor a negative number? a rational number?

You can also draw both 2d and 3d pictures using Sage. For example, the following input plots the number of prime divisors of each positive integer up to 500.

```
sage: line([(n, len(factor(n))) for n in [1..500]])
```

And, this example draws a similar 3d plot:

```
sage: v = [[len(factor(n*m)) for n in [1..15]] for m in [1..15]]
sage: list_plot3d(v, interpolation_type='nn')
```

The main difference between Sage and Pari is that Sage is vastly larger than Pari with a much wider range of functionality, and has many more datatypes and much more structured objects. Sage in fact includes Pari, and a typical Sage install takes nearly a gigabyte of disk space, whereas a typical Pari install is much more nimble, using only a few megabytes. There are many number-theoretic algorithms that are included in Sage, which have never been implemented in Pari, and Sage has 2d and 3d graphics which can be helpful for visualizing number theoretic ideas, and a graphical user interface. Both Pari and Sage are free and open source, which means anybody can read or change anything in either program, and the software is free.

The biggest difference between Sage and Magma is that Magma is closed source, not free, and difficult for users to extend. This means that most of Magma cannot be changed except by the core Magma developers, since Magma itself is well over two million lines of compiled C code, combined with about a half million lines of interpreted Magma code (that anybody can read and modify). In designing Sage, we carried over some of the excellent design ideas from Magma, such as the parent, element, category hierarchy.

Any mathematician who is serious about doing extensive computational work in algebraic number theory and arithmetic geometry is strongly urged to become familiar with all three systems, since they all have their pros and cons. Pari is sleek and small, Magma has much unique functionality for computations in arithmetic geometry, and Sage has a wide range of functionality in most areas of mathematics, a large developer community, and much unique new code.

1 Number Fields

In Sage, we can create the number field $\mathbb{Q}(\sqrt[3]{2})$ as follows.

```
sage: K.<alpha> = NumberField(x^3 - 2)
```

The above creates *two* Sage objects, K and α. Here K "is" (isomorphic to) the number field $\mathbb{Q}(\sqrt[3]{2})$, as we confirm below:

```
sage: K
Number Field in alpha with defining polynomial x^3 - 2
```

and α is a root of $x^3 - 2$, so α is an abstract choice of $\sqrt[3]{2}$ (no specific embedding of the number field K into $\mathbb{C}$ is chosen by default in Sage-3.1.2):

```
sage: alpha^3
2
sage: (alpha+1)^3
3*alpha^2 + 3*alpha + 3
```

Note that we did *not* define x above before using it. You could "break" the above example by redefining x to be something funny:

```
sage: x = 1
sage: K.<alpha> = NumberField(x^3 - 2)
Traceback (most recent call last):
...
TypeError: polynomial (=-1) must be a polynomial.
```

The *Traceback* above indicates that there was an error. Potentially lots of detailed information about the error (a "traceback") may be given after the word `Traceback` and before the last line, which contains the actual error messages.

Important: *whenever you use Sage and get a big error, look at the last line for the actual error, and only look at the rest if you are feeling adventurous.* In the notebook, the part indicated by ... above is not displayed; to see it, click just to the left of the word *Traceback* and the traceback will appear.

If you redefine x as above, but need to define a number field using the indeterminate x, you have several options. You can reset x to its default value at the start of Sage, you can redefine x to be a symbolic variable, or you can define x to be a polynomial indeterminant (a polygen):

```
sage: reset('x')
sage: x
x
sage: x = 1
sage: x = var('x')
sage: x
x
sage: x = 1
sage: x = polygen(QQ, 'x')
sage: x
x
sage: x = 1
sage: R.<x> = PolynomialRing(QQ)
sage: x
x
```

One you have created a number field K, type `K.[tab key]` to see a list of functions. Type, e.g., `K.Minkowski_embedding?[tab key]` to see help on the `Minkowski_embedding` command. To see source code, type `K.Minkowski_embedding??[tab key]`.

```
sage: K.<alpha> = NumberField(x^3 - 2)
sage: K.[tab key]
```

1.1 Symbolic Expressions

Another natural way for us to create certain number fields is to create a symbolic expression and adjoin it to the rational numbers. Unlike Pari and Magma (and like Mathematica and Maple), Sage also supports manipulation of symbolic expressions and solving equations, without defining abstract structures such as a number fields. For example, we can define a variable $a = \sqrt{2}$ as an abstract symbolic object by simply typing `a = sqrt(2)`. When we type `parent(a)` below, Sage tells us the mathematical object that it views a as being an element of; in this case, it's the ring of all symbolic expressions.

```
sage: a = sqrt(2)
sage: parent(a)
Symbolic Ring
```

In particular, typing `sqrt(2)` does *not* numerically extract an approximation to $\sqrt{2}$, like it would in Pari or Magma. We illustrate this below by calling Pari (via the gp interpreter) and Magma directly from within Sage. After we evaluate the following two input lines, copies of GP/Pari and Magma are running, and there is a persistent connection between Sage and those sessions.

```
sage: gp('sqrt(2)')
1.414213562373095048801688724
sage: magma('Sqrt(2)')                    # optional
1.41421356237309504880168872421
```

You probably noticed a pause when evaluated the second line as Magma started up. Also, note the `# optional` comment, which indicates that the line won't work if you don't have Magma installed.

Incidentally, if you want to numerically evaluate $\sqrt{2}$ in Sage, just give the optional `prec` argument to the `sqrt` function, which takes the required number of *bits* (binary digits) of precision.

```
sage: sqrt(2, prec=100)
1.4142135623730950488016887242
```

It's important to note in computations like this that there is not an *a priori* guarantee that `prec` bits of the *answer* are all correct. Instead, what happens is that Sage creates the number 2 as a floating point number with 100 bits of accuracy, then asks Paul Zimmerman's MPFR C library to compute the square root of that approximate number.

We return now to our symbolic expression $a = \sqrt{2}$. If you ask to square $a + 1$ you simply get the formal square. To expand out this formal square, we use the expand command.

```
sage: a = sqrt(2)
sage: (a+1)^2
(sqrt(2) + 1)^2
sage: expand((a+1)^2)
2*sqrt(2) + 3
```

Given any symbolic expression for which Sage can computes its minimal polynomial, you can construct the number field obtained by adjoining that expression to $\mathbb{Q}$. The notation is quite simple – just type `QQ[a]` where `a` is the symbolic expression.

```
sage: a = sqrt(2)
sage: K.<b> = QQ[a]
sage: K
Number Field in sqrt2 with defining polynomial x^2 - 2
sage: b
sqrt2
sage: (b+1)^2
2*sqrt2 + 3
sage: QQ[a/3 + 5]
Number Field in a with defining polynomial x^2 - 10*x + 223/9
```

You can't create the number field $\mathbb{Q}(a)$ in Sage by typing `QQ(a)`, which has a *very different* meaning in Sage. It means "try to create a rational number from a." Thus `QQ(a)` in Sage is the analogue of `QQ!a` in Magma (Pari has no notion of rings such as `QQ`).

```
sage: a = sqrt(2)
sage: QQ(a)
Traceback (most recent call last):
...
TypeError: unable to convert sqrt(2) to a rational
```

In general, if X is a ring, or vector space or other "parent structure" in Sage, and a is an element, type `X(a)` to make an element of X from a. For example, if X is the finite field of order 7, and $a = 2/5$ is a rational number, then `X(a)` is the finite field element 6 (as a quick exercise, check that this is mathematically the correct interpretation).

```
sage: X = GF(7); a = 2/5
sage: X(a)
6
```

As a slightly less trivial illustration of symbolic manipulation, consider the cubic equation

$$x^3 + \sqrt{2}x + 5 = 0. \tag{1.1}$$

In Sage, we can create this equation, and find an exact symbolic solution.

```
sage: x = var('x')
sage: eqn =  x^3 + sqrt(2)*x + 5 == 0
sage: a = solve(eqn, x)[0].rhs()
```

The first line above makes sure that the symbolic variable x is defined, the second creates the equation `eqn`, and the third line solves `eqn` for x, extracts the first solution (there are three), and takes the right hand side of that solution and assigns it to the variable `a`.

To see the solution nicely typeset, use the `show` command:

```
sage: show(a)
{{\left(...
```

$$\left(\frac{\sqrt{8\sqrt{2}+675}}{6\sqrt{3}}-\frac{5}{2}\right)^{\frac{1}{3}}\left(\frac{-\sqrt{3}i}{2}-\frac{1}{2}\right)-\frac{\sqrt{2}\left(\frac{\sqrt{3}i}{2}-\frac{1}{2}\right)}{3\left(\frac{\sqrt{8\sqrt{2}+675}}{6\sqrt{3}}-\frac{5}{2}\right)^{\frac{1}{3}}}$$

You can also see the latex needed to paste a into a paper by typing `latex(a)`. The `latex` command works on most Sage objects.

```
sage: latex(a)
{{\left( \frac{\sqrt{ {8 \sqrt{ 2 }} ...
```

Next, we construct the number field obtained by adjoining the solution `a` to $\mathbb{Q}$. Notice that the minimal polynomial of the root is $x^6 + 10x^3 - 2x^2 + 25$.

```
sage: K.<b> = QQ[a]
sage: K
Number Field in a with defining
polynomial x^6 + 10*x^3 - 2*x^2 + 25
sage: a.minpoly()
x^6 + 10*x^3 - 2*x^2 + 25
sage: b.minpoly()
x^6 + 10*x^3 - 2*x^2 + 25
```

We can now compute interesting invariants of the number field K:

```
sage: K.class_number()
5
sage: K.galois_group().order()
72
```

1.2 Galois Groups

We can compute the Galois group of the Galois closure as an abstract "Pari group" using the `galois_group` function, which by default calls Pari (`http://pari.math.u-bordeaux.fr/`). You do not have to worry about installing Pari, since *Pari is part of Sage.* In fact, despite appearances much of the difficult algebraic number theory in Sage is actually done by the Pari C library (be sure to also cite Pari in papers that use Sage).

```
sage: K.<alpha> = NumberField(x^3 - 2)
sage: G = K.galois_group()
sage: G
Galois group PARI group [6, -1, 2, "S3"] of degree 3 of the
Number Field in alpha with defining polynomial x^3 - 2
```

We can find out more about G, too:

```
sage: G.order()
6
```

We compute two more Galois groups of degree 5 extensions, and see that one has Galois group S_5, so is not solvable by radicals:

```
sage: NumberField(x^5 - 2, 'a').galois_group()
Galois group PARI group [20, -1, 3, "F(5) = 5:4"] of
degree 5 of the Number Field in a with defining
polynomial x^5 - 2
sage: NumberField(x^5 - x + 2, 'a').galois_group()
Galois group PARI group [120, -1, 5, "S5"] of degree 5 of
the Number Field in a with defining polynomial x^5 - x + 2
```

Recent versions of Magma have an algorithm for computing Galois groups that in theory applies when the input polynomial has any degree. There are no open source implementation of this algorithm (as far as I know). If you have Magma, you can use this algorithm from Sage by calling the `galois_group` function and giving the `algorithm='magma'` option.

```
sage: K.<a> = NumberField(x^3 - 2)
sage: K.galois_group(algorithm='magma')    # optional
verbose...
Galois group Transitive group number 2 of degree 3 of
the Number Field in a with defining polynomial x^3 - 2
```

We emphasize that the above example should not work if you don't have Magma.

It is also possible to work explicitly with the group of automorphisms of a field (though the link in Sage between abstract groups and automorphisms of fields is currently poor[1]). For example, here we first define $\mathbb{Q}(\sqrt[3]{2})$, then compute its Galois closure, which we represent as $\mathbb{Q}(b)$, where $b^6 + 40b^3 + 1372 = 0$. Then we compute the automorphism group of the field L, and explicitly list its elements.

```
sage: K.<a> = NumberField(x^3 - 2)
sage: L.<b> = K.galois_closure()
sage: L
Number Field in b with defining polynomial x^6 + 40*x^3 + 1372
sage: G = Hom(L, L)
sage: G
Automorphism group of Number Field in b ...
sage: G.list()
[
Ring endomorphism of Number Field in b ...
  Defn: b |--> b,
Ring endomorphism of Number Field in b ...
```

```
  Defn: b |--> 1/36*b^4 + 1/18*b,
...
Ring endomorphism of Number Field in b ...
  Defn: b |--> -2/63*b^4 - 31/63*b
]
```

You can explicitly apply any of the automorphisms above to any elements of L.

```
sage: phi = G.list()[1]
sage: phi
Ring endomorphism of Number Field in b ...
  Defn: b |--> 1/36*b^4 + 1/18*b
sage: phi(b^2 + 2/3*b)
-1/36*b^5 + 1/54*b^4 - 19/18*b^2 + 1/27*b
```

You can also enumerate all complex embeddings of a number field:

```
sage: K.complex_embeddings()
[
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Double Field
  Defn: a |--> -0.629960524947 - 1.09112363597*I,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Double Field
  Defn: a |--> -0.629960524947 + 1.09112363597*I,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Double Field
  Defn: a |--> 1.25992104989
]
```

1.3 Class Numbers and Class Groups

The class group C_K of a number field K is the group of fractional ideals of the maximal order R of K modulo the subgroup of principal fractional ideals. One of the main theorems of algebraic number theory asserts that C_K is a finite group. For example, the quadratic number field $\mathbb{Q}(\sqrt{-23})$ has class number 3, as we see using the Sage class_number command.

```
sage: L.<a> = NumberField(x^2 + 23)
sage: L.class_number()
3
```

There are only 9 quadratic imaginary field $\mathbb{Q}(\sqrt{D})$ that have class number 1:

$$D = -3, -4, -7, -8, -11, -19, -43, -67, -163.$$

To find this list using Sage, we first experiment with making lists in Sage. For example, typing [1..10] makes the list of integers between 1 and 10.

```
sage: [1..10]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

We can also make the list of odd integers between 1 and 11, by typing [1,3,..,11], i.e., by giving the second term in the arithmetic progression.

```
sage: [1,3,..,11]
[1, 3, 5, 7, 9, 11]
```

Applying this idea, we make the list of negative numbers from -1 down to -10.

```
sage: [-1,-2,..,-10]
[-1, -2, -3, -4, -5, -6, -7, -8, -9, -10]
```

The first two lines below makes a list v of every D from -1 down to -200 such that D is a fundamental discriminant (the discriminant of a quadratic imaginary field). Note that you will not see the ... in the output below; this ... notation just means that part of the output is omitted below.

```
sage: w = [-1,-2,..,-200]
sage: v = [D for D in w if is_fundamental_discriminant(D)]
sage: v
[-3, -4, -7, -8, -11, -15, -19, -20, ..., -195, -199]
```

Finally, we make the list of D in our list v such that the quadratic number field $\mathbb{Q}(\sqrt{D})$ has class number 1. Notice that QuadraticField(D) is a shorthand for NumberField(x^2 - D).

```
sage: [D for D in v if QuadraticField(D,'a').class_number()==1]
[-3, -4, -7, -8, -11, -19, -43, -67, -163]
```

Of course, we have *not* proved that this is the list of all negative D so that $\mathbb{Q}(\sqrt{D})$ has class number 1.

A frustrating open problem is to prove that there are infinitely many number fields with class number 1. It is quite easy to be convinced that this is probably true by computing a bunch of class numbers of real quadratic fields. For example, over 58 percent of the real quadratic number fields with discriminant $D < 1000$ have class number 1!

```
sage: w = [1..1000]
sage: v = [D for D in w if is_fundamental_discriminant(D)]
sage: len(v)
302
sage: len([D for D in v if QuadraticField(D,'a').class_number() == 1])
176
sage: 176.0/302
0.582781456953642
```

For more intuition about what is going on, read about the Cohen-Lenstra heuristics.

Sage can also compute class numbers of extensions of higher degree, within reason. Here we use the shorthand `CyclotomicField(n)` to create the number field $\mathbb{Q}(\zeta_n)$.

```
sage: CyclotomicField(7)
Cyclotomic Field of order 7 and degree 6
sage: for n in [2..15]: print n, CyclotomicField(n).class_number()
2 1
3 1
...
15 1
```

In the code above, the notation `for n in [2..15]: ...` means "do ... for n equal to each of the integers $2, 3, 4, \ldots, 15$."

Exercise 1.1. Compute what is omitted (replaced by ...) in the output of the previous example.

Computations of class numbers and class groups in Sage is done by the Pari C library, and *unlike in Pari*, by default Sage tells Pari *not to assume* any conjectures. This can make some commands vastly slower than they might be directly in Pari, which *does assume unproved conjectures* by default. Fortunately, it is easy to tell Sage to be more permissive and allow Pari to assume conjectures, either just for this one call or henceforth for all number field functions. For example, with `proof=False` it takes only a few seconds to verify, modulo the conjectures assumed by Pari, that the class number of $\mathbb{Q}(\zeta_{23})$ is 3.

```
sage: CyclotomicField(23).class_number(proof=False)
3
```

Exercise 1.2. What is the smallest n such that $\mathbb{Q}(\zeta_n)$ has class number bigger than 1?

In addition to computing class numbers, Sage can also compute the group structure and generators for class groups. For example, the quadratic field $\mathbb{Q}(\sqrt{-30})$ has class group $C = (\mathbb{Z}/2\mathbb{Z})^{\oplus 2}$, with generators the ideal classes containing $(5, \sqrt{-30})$ and $(3, \sqrt{-30})$.

```
sage: K.<a> = QuadraticField(-30)
sage: C = K.class_group()
sage: C
Class group of order 4 with structure C2 x C2 of Number Field
in a with defining polynomial x^2 + 30
sage: category(C)
Category of groups
sage: C.gens()
[Fractional ideal class (5, a), Fractional ideal class (3, a)]
```

In Sage, the notation C.i means "the ith generator of the object C," where the generators are indexed by numbers $0, 1, 2, \ldots$. Below, when we write C.0 * C.1, this means "the product of the 0th and 1st generators of the class group C."

```
sage: K.<a> = QuadraticField(-30)
sage: C = K.class_group()
sage: C.0
Fractional ideal class (5, a)
sage: C.0.ideal()
Fractional ideal (5, a)
sage: I = C.0 * C.1
sage: I
Fractional ideal class (2, a)
```

Next we find that the class of the fractional ideal $(2, \sqrt{-30} + 4/3)$ is equal to the ideal class I.

```
sage: A = K.ideal([2, a+4/3])
sage: J = C(A)
sage: J
Fractional ideal class (2/3, 1/3*a)
sage: J == I
True
```

Unfortunately, there is currently no Sage function that writes a fractional ideal class in terms of the generators for the class group.

1.4 Orders in Number Fields

An *order* in a number field K is a subring of K whose rank over $\mathbb{Z}$ equals the degree of K. For example, if $K = \mathbb{Q}(\sqrt{-1})$, then $\mathbb{Z}[7i]$ is an order in K. A good first exercise is to prove that every element of an order is an algebraic integer.

```
sage: K.<I> = NumberField(x^2 + 1)
sage: R = K.order(7*I)
sage: R
Order in Number Field in I with defining polynomial x^2 + 1
sage: R.basis()
[1, 7*I]
```

Using the discriminant command, we compute the discriminant of this order:

```
sage: factor(R.discriminant())
-1 * 2^2 * 7^2
```

You can give any list of elements of the number field, and it will generate the smallest ring R that contains them.

```
sage: K.<a> = NumberField(x^4 + 2)
sage: K.order([12*a^2, 4*a + 12]).basis()
[1, 4*a, 4*a^2, 16*a^3]
```

If R isn't of rank equal to the degree of the number field (i.e., R isn't an order), then you'll get an error message.

```
sage: K.order([a^2])
Traceback (most recent call last):
...
ValueError: the rank of the span of gens is wrong
```

We can also compute the maximal order, using the `maxima_order` command, which behind the scenes finds an integral basis using Pari's `nfbasis` command. For example, $\mathbb{Q}(\sqrt[4]{2})$ has maximal order $\mathbb{Z}[\sqrt[4]{2}]$, and if α is a root of $x^3 + x^2 - 2x + 8$, then $\mathbb{Q}(\alpha)$ has maximal order with $\mathbb{Z}$-basis

$$1, \frac{1}{2}a^2 + \frac{1}{2}a, a^2.$$

```
sage: K.<a> = NumberField(x^4 + 2)
sage: K.maximal_order().basis()
[1, a, a^2, a^3]
sage: L.<a> = NumberField(x^3 + x^2 - 2*x+8)
sage: L.maximal_order().basis()
[1, 1/2*a^2 + 1/2*a, a^2]
sage: L.maximal_order().basis()[1].minpoly()
x^3 - 2*x^2 + 3*x - 10
```

There is still much important functionality for computing with non-maximal orders that is missing in Sage. For example, there is no support at all in Sage for computing with modules over orders or with ideals in non-maximal orders.

```
sage: K.<a> = NumberField(x^3 + 2)
sage: R = K.order(3*a)
sage: R.ideal(5)
Traceback (most recent call last):
...
NotImplementedError: ideals of non-maximal orders not
yet supported.
```

1.5 Relative Extensions

A *relative number field* L is a number field of the form $K(\alpha)$, where K is a number field, and an *absolute number field* is a number field presented in the form $\mathbb{Q}(\alpha)$. By the primitive element theorem, any relative number field $K(\alpha)$ can be written as $\mathbb{Q}(\beta)$ for some $\beta \in L$. However, in practice it is often convenient to view L as $K(\alpha)$. In Section 1.1 we constructed the number field $\mathbb{Q}(\sqrt{2})(\alpha)$, where α is a root of $x^3 + \sqrt{2}x + 5$, but *not* as a relative field—we obtained just the number field defined by a root of $x^6 + 10x^3 - 2x^2 + 25$.

To construct this number field as a relative number field, first we let K be $\mathbb{Q}(\sqrt{2})$.

```
sage: K.<sqrt2> = QuadraticField(2)
```

Next we create the univariate polynomial ring $R = K[X]$. In Sage, we do this by typing `R.<X> = K[]`. Here `R.<X>` means "create the object R with generator X" and `K[]` means a "polynomial ring over K", where the generator is named based on the afformentioned X (to create a polynomial ring in two variables X, Y simply replace `R.<X>` by `R.<X,Y>`).

```
sage: R.<X> = K[]
sage: R
Univariate Polynomial Ring in X over Number Field in sqrt2
with defining polynomial x^2 - 2
```

Now we can make a polynomial over the number field $K = \mathbb{Q}(\sqrt{2})$, and construct the extension of K obtained by adjoining a root of that polynomial to K.

```
sage: L.<a> = K.extension(X^3 + sqrt2*X + 5)
sage: L
Number Field in a with defining polynomial X^3 + sqrt2*X + 5...
```

Finally, L is the number field $\mathbb{Q}(\sqrt{2})(\alpha)$, where α is a root of $X^3 + \sqrt{2}\alpha + 5$. We can do now do arithmetic in this number field, and of course include $\sqrt{2}$ in expressions.

```
sage: a^3
(-sqrt2)*a - 5
sage: a^3 + sqrt2*a
-5
```

The relative number field L also has numerous functions, many of which are by default relative. For example the `degree` function on L returns the relative degree of L over K; for the degree of L over $\mathbb{Q}$ use the `absolute_degree` function.

```
sage: L.degree()
3
sage: L.absolute_degree()
6
```

Given any relative number field you can also an absolute number field that is isomorphic to it. Below we create $M = \mathbb{Q}(b)$, which is isomorphic to L, but is an absolute field over $\mathbb{Q}$.

```
sage: M.<b> = L.absolute_field()
sage: M
Number Field in b with defining
polynomial x^6 + 10*x^3 - 2*x^2 + 25
```

The `structure` function returns isomorphisms in both directions between M and L.

```
sage: M.structure()
(Isomorphism from Number Field in b ...,
 Isomorphism from Number Field in a ...)
```

In Sage one can create arbitrary towers of relative number fields (unlike in Pari, where a relative extension must be a single extension of an absolute field).

```
sage: R.<X> = L[]
sage: Z.<b> = L.extension(X^3 - a)
sage: Z
Number Field in b with defining polynomial
X^3 + (-1)*a over its base field
sage: Z.absolute_degree()
18
```

Exercise 1.3. Construct the relative number field $L = K(\sqrt[3]{\sqrt{2}+\sqrt{3}})$, where $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$.

One shortcoming with relative extensions in Sage is that behind the scenes all arithmetic is done in terms of a single absolute defining polynomial, and in some cases this can be very slow (much slower than Magma). Perhaps this could be fixed by using Singular's multivariate polynomials modulo an appropriate ideal, since Singular polynomial arithmetic is extremely flast. Also, Sage has very little direct support for constructive class field theory, which is a major motivation for explicit computation with relative orders; it would be good to expose more of Pari's functionality in this regard.

2 A Birds Eye View

We now take a whirlwind tour of some of the number theoretical functionality of Sage. There is much that we won't cover here, but this should help give you a flavor for some of the number theoretic capabilities of Sage, much of which is unique to Sage.

2.1 Integer Factorization

Bill Hart's quadratic sieve is included with Sage. The quadratic sieve is the best algorithm for factoring numbers of the form pq up to around 100 digits. It involves searching for relations, solving a linear algebra problem modulo 2, then factoring n using a relation $x^2 \equiv y^2 \mod n$.

```
sage: qsieve(next_prime(2^90)*next_prime(2^91), time=True)   # not tested
([1237940039285380274899124357, 2475880078570760549798248507],
 '14.94user 0.53system 0:15.72elapsed 98%CPU (0avgtext+0avgdata 0maxresident)k')
```

Using *qsieve* is twice as fast as Sage's *general* factor command in this example. Note that Sage's general factor command does nothing but call Pari's factor C library function.

```
sage: time factor(next_prime(2^90)*next_prime(2^91))     # not tested
CPU times: user 28.71 s, sys: 0.28 s, total: 28.98 s
Wall time: 29.38 s
1237940039285380274899124357 * 2475880078570760549798248507
```

Obviously, Sage's `factor` command should not just call Pari, but nobody has gotten around to rewriting it yet.

Paul Zimmerman's GMP-ECM is included in Sage. The elliptic curve factorization (ECM) algorithm is the best algorithm for factoring numbers of the form $n = pm$, where p is not "too big". ECM is an algorithm due to Hendrik Lenstra, which works by "pretending" that n is prime, chosing a random elliptic curve over $\mathbb{Z}/n\mathbb{Z}$, and doing arithmetic on that curve—if something goes wrong when doing arithmetic, we factor n.

In the following example, GMP-ECM is over 10 times faster than Sage's generic factor function. Again, this emphasizes that Sage's generic `factor` command would benefit from a rewrite that uses GMP-ECM and qsieve.

```
sage: time ecm.factor(next_prime(2^40) * next_prime(2^300))    # not tested
CPU times: user 0.85 s, sys: 0.01 s, total: 0.86 s
Wall time: 1.73 s
[1099511627791,
 2037035976334486086268445688409378161051468393665936250636140449354381299763336706183397533
sage: time factor(next_prime(2^40) * next_prime(2^300))        # not tested
CPU times: user 23.82 s, sys: 0.04 s, total: 23.86 s
Wall time: 24.35 s
1099511627791 * 2037035976334486086268445688409378161051468393665936250636140449354381299763
```

2.2 Elliptic Curves

Cremona's databases of elliptic curves is part of Sage. The curves up to conductor 10,000 come standard with Sage, and an optional 75MB download gives all his tables up to conductor 130,000. Type `sage -i database_cremona_ellcurve-20071019` to automatically download and install this extended table.

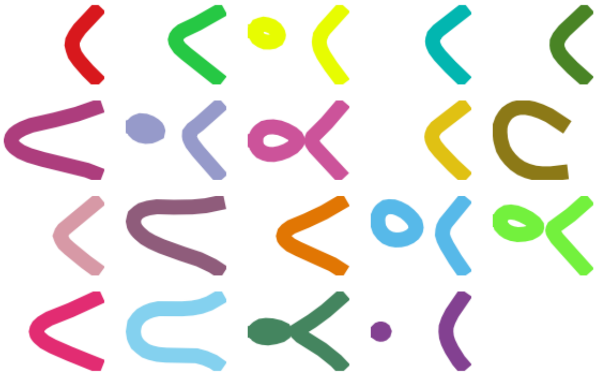
To use the database, just create a curve by giving

```
sage: EllipticCurve('5077a1')
Elliptic Curve defined by y^2 + y = x^3 - 7*x + 6 over Rational Field
sage: C = CremonaDatabase()
sage: C.number_of_curves()
847550
sage: C[37]
{'a': {'a1': [[0, 0, 1, -1, 0], 1, 1],
       'b1': [[0, 1, 1, -23, -50], 0, 3], ...
sage: C.isogeny_class('37b')
[Elliptic Curve defined by y^2 + y = x^3 + x^2 - 23*x - 50
over Rational Field, ...]
```

There is also a Stein-Watkins database that contains hundreds of millions of elliptic curves. It's over a 2GB download though!

Bryan Birch's recently had a birthday conference, and I used Sage to draw the cover of his birthday card by enumerating all optimal elliptic curves of conductor up to 37, then plotting them with thick randomly colored lines. As you can see below, plotting an elliptic curve is as simple as calling the plot method on it. Also, the `graphics_array` command allows us to easily combine numerous plots into a single graphics object.

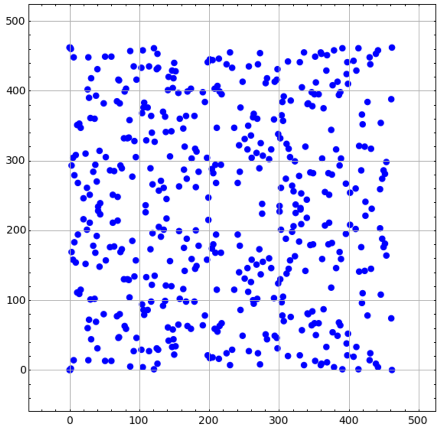
```
sage: v = cremona_optimal_curves([11..37])
sage: w = [E.plot(thickness=10,
   rgbcolor=(random(),random(),random())) for E in v]
sage: graphics_array(w, 4, 5).show(axes=False)
```



We can use Sage's interact feature to draw a plot of an elliptic curve modulo p, with a slider that one drags to change the prime p. The interact feature of Sage is very helpful for interactively changing parameters and viewing the results. Type `interact?` for more help and examples and visit the webpage `http://wiki.sagemath.org/interact`.

In the code below we first define the elliptic curve E using the Cremona label `37a`. Then we define an interactive function f, which is made interactive using the `@interact` Python *decorator*. Because the default for p is `primes(2,500)`, the Sage notebook constructs a slider that varies over the primes up to 500. When you drag the slider and let go, a plot is drawn of the affine $\mathbb{F}_p$ points on the curve $E_{\mathbb{F}_p}$. Of course, one *should* never plot curves over finite fields, which makes this even more fun.

```
E = EllipticCurve('37a')
@interact
def f(p=primes(2,500)):
    show(plot(E.change_ring(GF(p)),pointsize=30),
    axes=False, frame=True, gridlines="automatic",
    aspect_ratio=1, gridlinesstyle={'rgbcolor':(0.7,0.7,0.7)})
```



Sage includes `sea.gp`, which is a fast implementation of the SEA (Schoff-Elkies-Atkin) algorithm for counting the number of points on an elliptic curve over $\mathbb{F}_p$.

We create the finite field $k = \mathbb{F}_p$, where p is the next prime after 10^{20}. The `next_prime` command uses Pari's `nextprime` function, but proves primality of the result (unlike Pari which gives only the next probable prime after a number). Sage also has a `next_probable_prime` function.

```
sage: k = GF(next_prime(10^20))
```

compute its cardinality, which behind the scenes uses SEA.

```
sage: E = EllipticCurve(k.random_element())
sage: E.cardinality()                   # less than a second
100000000005466254167
```

To see how Sage chooses when to use SEA versus other methods, type `E.cardinality??` and read the source code. As of this writing, it simply uses SEA whenever $p > 10^{18}$.

Sage has the world's best code for computing p-adic regulators of elliptic curves, thanks to work of David Harvey and Robert Bradshaw. The p-adic regulator of an elliptic curve E at a good ordinary prime p is the determinant of the global p-adic height pairing matrix on the Mordell-Weil group $E(\mathbb{Q})$. (This has nothing to do with local or archimedean heights.) This is the analogue of the regulator in the Mazur-Tate-Teitelbaum p-adic analogue of the Birch and Swinnerton-Dyer conjecture.

In particular, Sage implements Harvey's improvement on an algorithm of Mazur-Stein-Tate, which builds on Kiran Kedlaya's Monsky-Washnitzer approach to computing p-adic cohomology groups.

We create the elliptic curve with Cremona label 389a, which is the curve of smallest conductor and rank 2. We then compute both the 5-adic and 997-adic regulators of this curve.

```
sage: E = EllipticCurve('389a')
sage: E.padic_regulator(5, 10)
5^2 + 2*5^3 + 2*5^4 + 4*5^5 + 3*5^6 + 4*5^7 + 3*5^8 + 5^9 + O(5^11)
sage: E.padic_regulator(997, 10)
740*997^2 + 916*997^3 + 472*997^4 + 325*997^5 + 697*997^6
          + 642*997^7 + 68*997^8 + 860*997^9 + 884*997^10 + O(997^11)
```

Before the new algorithm mentioned above, even computing a 7-adic regulator to 3 digits of precision was a nontrivial computational challenge. Now in Sage computing the 100003-adic regulator is routine:

```
sage: E.padic_regulator(100003,5)  # a couple of seconds
42582*100003^2 + 35250*100003^3 + 12790*100003^4 + 64078*100003^5 + O(100003^6)
```

p-adic L-functions play a central role in the arithmetic study of elliptic curves. They are p-adic analogues of complex analytic L-function, and their leading coefficient (at 0) is the analogue of $L^{(r)}(E,1)/\Omega_E$ in the p-adic analogue of the Birch and Swinnerton-Dyer conjecture. They also appear in theorems of Kato, Schneider, and others that prove partial results toward p-adic BSD using Iwasawa theory.

The implementation in Sage is mainly due to work of myself, Christian Wuthrich, and Robert Pollack. We use Sage to compute the 5-adic L-series of the elliptic curve 389a of rank 2.

```
sage: E = EllipticCurve('389a')
sage: L = E.padic_lseries(5)
sage: L
```

```
5-adic L-series of Elliptic Curve defined
by y^2 + y = x^3 + x^2 - 2*x over Rational Field
sage: L.series(3)
O(5^5) + O(5^2)*T + (4 + 4*5 + O(5^2))*T^2 +
(2 + 4*5 + O(5^2))*T^3 + (3 + O(5^2))*T^4 + O(T^5)
```

Sage implements code to compute numerous explicit bounds on Shafarevich-Tate Groups of elliptic curves. This functionality is *only* available in Sage, and uses results Kolyvagin, Kato, Perrin-Riou, etc., and unpublished papers of Wuthrich and me.

```
sage: E = EllipticCurve('11a1')
sage: E.sha().bound()           # so only 2,3,5 could divide sha
[2, 3, 5]
sage: E = EllipticCurve('37a1')  # so only 2 could divide sha
sage: E.sha().bound()
([2], 1)
sage: E = EllipticCurve('389a1')
sage: E.sha().bound()
(0, 0)
```

The $(0, 0)$ in the last output above indicates that the Euler systems results of Kolyvagin and Kato give no information about finiteness of the Shafarevich-Tate group of the curve E. In fact, it is an open problem to prove this finiteness, since E has rank 2, and finiteness is only known for elliptic curves for which $L(E, 1) \neq 0$ or $L'(E, 1) \neq 0$.

Partial results of Kato, Schneider and others on the p-adic analogue of the BSD conjecture yield algorithms for bounding the p-part of the Shafarevich-Tate group. These algorithms require as input explicit computation of p-adic L-functions, p-adic regulators, etc., as explained in Stein-Wuthrich. For example, below we use Sage to prove that 5 and 7 do not divide the Shafarevich-Tate group of our rank 2 curve 389a.

```
sage: E = EllipticCurve('389a1')
sage: sha = E.sha()
sage: sha.p_primary_bound(5)  # iwasawa theory ==> 5 doesn't divide sha
0
sage: sha.p_primary_bound(7)  # iwasawa theory ==> 7 doesn't divide sha
0
```

This is consistent with the Birch and Swinnerton-Dyer conjecture, which predicts that the Shafarevich-Tate group is trivial. Below we compute this predicted order, which is the floating point number 1.000000 to some precision. That the result is a floating point number helps emphasize that it is an open problem to show that the *conjectural order* of the Shafarevich-Tate group is even a rational number in general!

```
sage: E.sha().an()
1.00000000000000
```

2.3 Mordell-Weil Groups and Integral Points

Sage includes both Cremona's mwrank library and Simon's 2-descent GP scripts for computing Mordell-Weil groups of elliptic curves.

```
sage: E = EllipticCurve([1,2,5,7,17])
sage: E.conductor()       # not in the Tables
154907
sage: E.gens()            # a few seconds
[(1 : 3 : 1), (67/4 : 507/8 : 1)]
```

Sage can also compute the torsion subgroup, isogeny class, determine images of Galois representations, determine reduction types, and includes a full implementation of Tate's algorithm over number fields.

Sage has the world's fastest implementation of computation of all integral points on an elliptic curve over $\mathbb{Q}$, due to work of Cremona, Michael Mardaus, and Tobias Nagel. This is also the only free open source implementation available.

```
sage: E = EllipticCurve([1,2,5,7,17])
sage: E.integral_points(both_signs=True)
[(1 : -9 : 1), (1 : 3 : 1)]
```

A very impressive example is the lowest conductor elliptic curve of rank 3, which has 36 integral points.

```
sage: E = elliptic_curves.rank(3)[0]
sage: E.integral_points(both_signs=True)   # less than 3 seconds
[(-3 : -1 : 1), (-3 : 0 : 1), (-2 : -4 : 1), (-2 : 3 : 1),
 ...(816 : -23310 : 1), (816 : 23309 : 1)]
```

The algorithm to compute all integral points involves first computing the Mordell-Weil group, then bounding the integral points, and listing all integral points satisfying those bounds. See Cohen's new GTM 239 for complete details.

The complexity grows exponentially in the rank of the curve. We can do the above calculation, but with the first known curve of rank 4, and it finishes in about a minute (and outputs 64 points).

```
sage: E = elliptic_curves.rank(4)[0]
sage: E.integral_points(both_signs=True)   # about a minute
[(-10 : 3 : 1), (-10 : 7 : 1), ...
 (19405 : -2712802 : 1), (19405 : 2693397 : 1)]
```

2.4 Elliptic Curve L-functions

We next compute with the complex L-function

$$L(E,s) = \prod_{p\nmid\Delta=389} \frac{1}{1-a_p p^{-s}+pp^{-2s}} \cdot \prod_{p\mid\Delta=389} \frac{1}{1-a_p p^{-s}}$$

of E. Though the above Euler product only defines an analytic function on the right half plane where $\mathrm{Re}(s) > 3/2$, a deep theorem of Wiles et al. (the **Modularity Theorem**) implies that it has an analytic continuation to the whole complex plane and functional equation. We can evaluate the function L anywhere on the complex plane using Sage (via code of Tim Dokchitser).

```
sage: E = EllipticCurve('389a1')
sage: L = E.lseries()
sage: L
Complex L-series of the Elliptic Curve defined by
       y^2 + y = x^3 + x^2 - 2*x over Rational Field
sage: L(1)
-1.04124792770327e-19
sage: L(1+I)
-0.638409938588039 + 0.715495239204667*I
sage: L(100)
1.00000000000000
```

We can also compute the Taylor series of L about *any* point, thanks to Tim Dokchitser's code.

```
sage: E = EllipticCurve('389a1')
sage: L = E.lseries()
sage: Ld = L.dokchitser()
sage: Ld.taylor_series(1,4)
-1.28158145691931e-23 + (7.26268290635587e-24)*z + 0.759316500288427*z^2
                      - 0.430302337583362*z^3 + O(z^4)
```

The Generalized Riemann Hypothesis asserts that all nontrivial zeros of $L(E, s)$ are of the form $1 + iy$. Mike Rubinstein has written a C++ program that is part of Sage that can for any n compute the first n values of y such that $1 + iy$ is a zero of $L(E, s)$. It also verifies the Riemann Hypothesis for these zeros (I think). Rubinstein's program can also do similar computations for a wide class of L-functions, though not all of this functionality is as easy to use from Sage as for elliptic curves. Below we compute the first 10 zeros of $L(E, s)$, where E is still the rank 2 curve 389a.

```
sage: L.zeros(10)
[0.000000000, 0.000000000, 2.87609907, 4.41689608, 5.79340263,
 6.98596665, 7.47490750, 8.63320525, 9.63307880, 10.3514333]
```

2.5 The Matrix of Frobenius on Hyperelliptic Curves

Sage has a highly optimized implementation of the Harvey-Kedlaya algorithm for computing the matrix of Frobenius associated to a curve over a finite field. This is an implementation by David Harvey, which is GPL'd and depends only on NTL and `zn_poly` (a C library in Sage for fast arithmetic $(\mathbb{Z}/n\mathbb{Z})[x]$).

We import the `hypellfrob` function and call it on a polynomial over $\mathbb{Z}$.

```
sage: from sage.schemes.hyperelliptic_curves.hypellfrob import hypellfrob
sage: R.<x> = PolynomialRing(ZZ)
sage: f = x^5 + 2*x^2 + x + 1; p = 101
sage: M = hypellfrob(p, 1, f); M
[ 0 + O(101)  0 + O(101) 93 + O(101) 62 + O(101)]
[ 0 + O(101)  0 + O(101) 55 + O(101) 19 + O(101)]
[ 0 + O(101)  0 + O(101) 65 + O(101) 42 + O(101)]
[ 0 + O(101)  0 + O(101) 89 + O(101) 29 + O(101)]
```

We do the same calculation but in $\mathbb{Z}/101^4\mathbb{Z}$, which gives enough precision to recognize the exact characteristic polynomial in $\mathbb{Z}[x]$ of Frobenius as an element of the endomorphism ring. This computation is still very fast, taking only a fraction of a second.

```
sage: M = hypellfrob(p, 4, f)   # about 0.25 seconds
sage: M[0,0]
91844754 + O(101^4)
```

The characteristic polynomial of Frobenius is $x^4 + 7x^3 + 167x^2 + 707x + 10201$, which determines the ζ function of the curve $y^2 = f(x)$.

```
sage: M.charpoly()
(1 + O(101^4))*x^4 + (7 + O(101^3))*x^3 + (167 + O(101^3))*x^2
   + (707 + O(101^3))*x + (10201 + O(101^4))
```

2.6 Modular Symbols

Modular symbols play a key role in algorithms for computing with modular forms, special values of L-functions, elliptic curves, and modular abelian varieties. Sage has the most general implementation of modular symbols available, thanks to work of myself, Jordi Quer (of Barcelona) and Craig Citro (a student of Hida). Moreover, computation with modular symbols is by far my *most favorite* part of computational mathematics. There is still a lot of tuning and optimization work to be done for modular symbols in Sage, in order for it to be across the board the fastest implementation in the world, since my Magma implementation is still better in some important cases.

We create the space M of weight 4 modular symbols for a certain congruence subgroup $\Gamma_H(13)$ of level 13. Then we compute a basis for this space, expressed in terms of *Manin symbols*. Finally, we compute the Hecke operator T_2 acting on M, find its characteristic polynomial and factor it. We also compute the dimension of the cuspidal subspace.

```
sage: M = ModularSymbols(GammaH(13,[3]), weight=4)
sage: M
Modular Symbols space of dimension 14 for Congruence Subgroup
Gamma_H(13) with H generated by [3] of weight 4 with sign 0
and over Rational Field
sage: M.basis()
```

```
([X^2,(0,1)], [X^2,(0,7)], [X^2,(2,5)], [X^2,(2,8)], [X^2,(2,9)],
 [X^2,(2,10)], [X^2,(2,11)], [X^2,(2,12)], [X^2,(4,0)], [X^2,(4,3)],
 [X^2,(4,6)], [X^2,(4,8)], [X^2,(4,12)], [X^2,(7,1)])
sage: factor(charpoly(M.T(2)))
(x - 7) * (x + 7) * (x - 9)^2 * (x + 5)^2
        * (x^2 - x - 4)^2 * (x^2 + 9)^2
sage: dimension(M.cuspidal_subspace())
10
```

Sage includes John Cremona's specialized and *insanely fast* implementation of modular symbols for weight 2 and trivial character. We illustrate below computing the space of modular symbols of level 20014, which has dimension 5005, along with a Hecke operator on this space. The whole computation below takes only a few seconds; a similar computation takes a few minutes using Sage's generic modular symbols code. Moreover, Cremona has done computations at levels over 200,000 using his library, so the code is known to scale well to large problems. The new code in Sage for modular symbols is much more general, but doesn't scale nearly so well (yet).

```
sage: M = CremonaModularSymbols(20014)       # few seconds
sage: M
Cremona Modular Symbols space of dimension 5005 for
Gamma_0(20014) of weight 2 with sign 0
sage: t = M.hecke_matrix(3)              # few seconds
```

2.7 Enumerating Totally Real Number Fields

As part of his project to enumerate Shimura curves, John Voight has contributed code to Sage for enumerating totally real number fields. The algorithm isn't extremely complicated, but it involves some "inner loops" that have to be coded to run very quickly. Using *Cython*, Voight was able to implement exactly the variant of Newton iteration that he needed for his problem.

The function `enumerate_totallyreal_fields_prim(n, B, ...)` enumerates without using a database (!) primitive (no proper subfield) totally real fields of degree $n > 1$ with discriminant $d \leq B$.

We compute the totally real quadratic fields of discriminant ≤ 50. The calculation below, which is almost instant, is done in real time and is not a table lookup.

```
sage: enumerate_totallyreal_fields_prim(2,50)
[[5, x^2 - x - 1], [8, x^2 - 2], [12, x^2 - 3], [13, x^2 - x - 3],
 [17, x^2 - x - 4], [21, x^2 - x - 5], [24, x^2 - 6], [28, x^2 - 7],
 [29, x^2 - x - 7], [33, x^2 - x - 8], [37, x^2 - x - 9],
 [40, x^2 - 10], [41, x^2 - x - 10], [44, x^2 - 11]]
```

We compute all totally real quintic fields of discriminant $\leq 10^5$. Again, this is done in real time – it's not a table lookup!

```
sage: enumerate_totallyreal_fields_prim(5,10^5)
[[14641, x^5 - x^4 - 4*x^3 + 3*x^2 + 3*x - 1],
 [24217, x^5 - 5*x^3 - x^2 + 3*x + 1],
 [36497, x^5 - 2*x^4 - 3*x^3 + 5*x^2 + x - 1],
 [38569, x^5 - 5*x^3 + 4*x - 1],
 [65657, x^5 - x^4 - 5*x^3 + 2*x^2 + 5*x + 1],
 [70601, x^5 - x^4 - 5*x^3 + 2*x^2 + 3*x - 1],
 [81509, x^5 - x^4 - 5*x^3 + 3*x^2 + 5*x - 2],
 [81589, x^5 - 6*x^3 + 8*x - 1],
 [89417, x^5 - 6*x^3 - x^2 + 8*x + 3]]
```

2.8 Bernoulli Numbers

From the mathematica website:

> "**Today We Broke the Bernoulli Record: From the Analytical Engine to Mathematica**
> April 29, 2008
> Oleksandr Pavlyk, Kernel Technology
> A week ago, I took our latest development version of Mathematica, and I typed `BernoulliB[10^7]`.
> And then I waited.
> Yesterday—5 days, 23 hours, 51 minutes, and 37 seconds later—I got the result!"

Tom Boothby did that same computation in Sage, which uses Pari's `bernfrac` command that uses evaluation of ζ and factorial to high precision, and it took 2 days, 12 hours.

Then David Harvey came up with an entirely new algorithm that parallelizes well. He gives these timings for computing B_{10^7} on his machine (it takes 59 minutes, 57 seconds on my 16-core 1.8ghz Opteron box):

```
PARI: 75 h, Mathematica: 142 h
bernmm (1 core) = 11.1 h, bernmm (10 cores) = 1.3 h
```

> "Running on 10 cores for 5.5 days, I [David Harvey] computed [the Bernoulli number] B_k for $k = 10^8$, which I believe is a new record. Essentially it's the multimodular algorithm I suggested earlier on this thread, but I figured out some tricks to optimise the crap out of the computation of $B_k \text{mod} p$."

So now Sage is the fastest in the world for large Bernoulli numbers. The timings below are on a 16-core 1.8Ghz Opteron box.

```
sage: w = bernoulli(100000, num_threads=16)     # 1.87 seconds
sage: w = bernoulli(100000, algorithm='pari')   # 28 seconds
```

2.9 Polynomial Arithmetic

Sage uses Bill Hart and David Harvey's GPL'd Flint C library for arithmetic in $\mathbb{Z}[x]$. Its main claim to fame is that it is the world's fastest for polynomial multiplication, e.g., in the benchmark below it is 3 times faster than NTL and twice as fast as Magma. Behind the scenes it contains some carefully tuned discrete Fourier transform code (which I know nearly nothing about).

```
sage: Rflint = PolynomialRing(ZZ, 'x')
sage: f = Rflint([ZZ.random_element(2^64) for _ in [1..32]])
sage: g = Rflint([ZZ.random_element(2^64) for _ in [1..32]])
sage: timeit('f*g')                # random output
625 loops, best of 3: 105 microseconds per loop
sage: Rntl = PolynomialRing(ZZ, 'x', implementation='NTL')
sage: f = Rntl([ZZ.random_element(2^64) for _ in [1..32]])
sage: g = Rntl([ZZ.random_element(2^64) for _ in [1..32]])
sage: timeit('f*g')                # random output
625 loops, best of 3: 310 microseconds per loop
sage: ff = magma(f); gg = magma(g)
sage: s = 'time v := [%s * %s for _ in [1..10^5]];'%(ff.name(), gg.name())
sage: magma.eval(s)      # random output
'Time: 17.120'
sage: (17.120/10^5)*10^(6)    # convert to microseconds
171.200000000000
```

Multivariate polynomial arithmetic in many cases uses Singular in library mode (Martin Albrecht), which is quite fast. For example, below we do the Fateman benchmark over the finite field of order 32003.

```
sage: P.<x,y,z> = GF(32003)[]
sage: p = (x+y+z+1)^20
sage: q = p+1
sage: timeit('p*q')   # random output
5 loops, best of 3: 384 ms per loop
sage: pp = magma(p); qq = magma(q)
sage: s = 'time w := %s*%s;'%(pp.name(),qq.name())
sage: magma.eval(s)
'Time: 1.480'
```

Notice that the multiplication takes about four times as long in Magma.

3 Modular Forms

This section is about computing with modular forms, modular symbols, and modular abelian varieties. Most of the Sage functionality we describe below is new code written for Sage by myself, Craig Citro, Robert Bradshaw, and Jordi Quer in consultation with John Cremona. It has much overlap in functionality with the modular forms code in Magma, which I developed during 1998–2004.

3.1 Modular Forms and Hecke Operators

A *congruence subgroup* is a subgroup of the group $\mathrm{SL}_2(\mathbb{Z})$ of determinant ±1 integer matrices that contains

$$\Gamma(N) = \mathrm{Ker}(\mathrm{SL}_2(\mathbb{Z}) \to \mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z}))$$

for some positive integer N. Since $\Gamma(N)$ has finite index in $\mathrm{SL}_2(\mathbb{Z})$, all congruence subgroups have finite index. The converse is *not* true, though in many other settings it is true (see [paper of Serre]).

The inverse image $\Gamma_0(N)$ of the subgroup of upper triangular matrices in $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ is a congruence subgroup, as is the inverse image $\Gamma_1(N)$ of the subgroup of matrices of the form $\left(\begin{smallmatrix} 1 & * \\ 0 & 1 \end{smallmatrix}\right)$. Also, for any subgroup $H \subset (\mathbb{Z}/N\mathbb{Z})^*$, the inverse image $\Gamma_H(N)$ of the subgroup of $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ of all elements of the form $\left(\begin{smallmatrix} a & * \\ 0 & d \end{smallmatrix}\right)$ with $d \in H$ is a congruence subgroup.

We can create each of the above congruence subgroups in Sage, using the `Gamma0`, `Gamma1`, and `GammaH` commands.

```
sage: Gamma0(8)
Congruence Subgroup Gamma0(8)
sage: Gamma1(13)
Congruence Subgroup Gamma1(13)
sage: GammaH(11,[2])
Congruence Subgroup Gamma_H(11) with H generated by [2]
```

The second argument to the `GammaH` command is a list of generators of the subgroup H of $(\mathbb{Z}/N\mathbb{Z})^*$.
Sage can compute a list of generators for these subgroups. The algorithm Sage uses is a straightforward generic procedure that uses coset representatives for the congruence subgroup (which are easy to enumerate) to obtain a list of generators [[ref my modular forms book]].

```
sage: Gamma0(2).gens()
([1 1]
 [0 1],
 [-1  0]
 [ 0 -1],
 [ 1 -1]
 [ 0  1],
 [ 1 -1]
 [ 2 -1],
 [-1  1]
 [-2  1])
sage: len(Gamma1(13).gens())
284
```

As you can see above, the list of generators Sage computes is unfortunately large. Improving this would be an excellent Sage development project, which would involve much beautiful mathematics.

A *modular form* on a congruence subgroup Γ of integer weight k is a holomorphic function $f(z)$ on the upper half plane

$$\mathfrak{h}^* = \{z \in \mathbb{C} : \mathrm{Im}(z) > 0\} \cup \mathbb{Q} \cup \{i\infty\}$$

such that for every matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma$, we have

$$f\left(\frac{az+b}{cz+d}\right) = (cz+d)^k f(z). \qquad (3.1)$$

A *cusp form* is a modular form that vanishes at all of the *cusps* $\mathbb{Q} \cup \{i\infty\}$.

If Γ contains $\Gamma_1(N)$ for some N, then $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) \in \Gamma$, so (3.1) implies that $f(z) = f(z+1)$. This, coupled with the holomorphicity condition, implies that $f(z)$ has a Fourier expansion

$$f(z) = \sum_{n=0}^{\infty} a_n e^{2\pi i n z},$$

with $a_n \in \mathbb{C}$. We let $q = e^{2\pi i z}$, and call $f = \sum_{n=0}^{\infty} a_n q^n$ the *q-expansion* of f.

Henceforth we assume that Γ is either $\Gamma_1(N)$, $\Gamma_0(N)$, or $\Gamma_H(N)$ for some H and N. The complex vector space $M_k(\Gamma)$ of all modular forms of weight k on Γ is a finite dimensional vector space.

We create the space $M_k(\Gamma)$ in Sage by typing `ModularForms(G, k)` where G is the congruence subgroup and k is the weight.

```
sage: ModularForms(Gamma0(25), 4)
Modular Forms space of dimension 11 for ...
sage: S = CuspForms(Gamma0(25),4, prec=15); S
Cuspidal subspace of dimension 5 of Modular Forms space ...
sage: S.basis()
[
q + q^9 - 8*q^11 - 8*q^14 + O(q^15),
q^2 - q^7 - q^8 - 7*q^12 + 7*q^13 + O(q^15),
q^3 + q^7 - 2*q^8 - 6*q^12 - 5*q^13 + O(q^15),
q^4 - q^6 - 3*q^9 + 5*q^11 - 2*q^14 + O(q^15),
q^5 - 4*q^10 + O(q^15)
]
```

Sage computes the dimensions of all these spaces using simple arithmetic formulas instead of actually computing bases for the spaces in question. In fact, Sage has the most general collection of modular forms dimension formulas of any software; type `help(sage.modular.dims)` to see a list of arithmetic functions that are used to implement these dimension formulas.

```
sage: ModularForms(Gamma1(949284), 456).dimension()
11156973844800
sage: a = [dimension_cusp_forms(Gamma0(N),2) for N in [1..25]]; a
[0, 0, ..., 1, 0, 0, 1, 1, 0, 1, 0, 1, 1, 1, 2, 2, 1, 0]
```

```
sage: sloane_find(a)
Searching Sloane’s online database...
[[1617,
  ’Genus of modular group GAMMA_0 (n). Or, genus of
   modular curve X_0(n).’,...
```

Sage doesn’t have simple formulas for dimensions of spaces of modular forms of weight 1, since such formulas perhaps do not exist.

The space $M_k(\Gamma_1(N))$ is equipped with an action of $(\mathbb{Z}/N\mathbb{Z})^*$ by *diamond bracket operators* $\langle d\rangle$, and this induces a decomposition

$$M_k(\Gamma_1(N)) = \bigoplus_{\varepsilon:(\mathbb{Z}/N\mathbb{Z})^*\to\mathbb{C}^*} M_k(N,\varepsilon),$$

where the sum is over all complex characters of the finite abelian group $(\mathbb{Z}/N\mathbb{Z})^*$. These characters are called *Dirichlet characters*, which are central in number theory.

Theorem 3.1. *The space $M_k(\Gamma_1(N))$ has a basis of elements whose q-expansions $f(q)$ are all elements of $\mathbb{Z}[[q]]$.*

The factors $M_k(N,\varepsilon)$ then have bases whose q-expansions are elements of $R[[q]]$, where $R = \mathbb{Z}[\varepsilon]$ is the ring generated over $\mathbb{Z}$ by the image of ε. We illustrate this with $N = k = 5$ below, where `DirichletGroup` will be described later.

```
sage: CuspForms(DirichletGroup(5).0, 5).basis()
[q + (-zeta4 - 1)*q^2 + (6*zeta4 - 6)*q^3 - ... + O(q^6)]
```

Use the command `DirichletGroup(N,R)` to create the group of all Dirichlet characters of modulus N taking values in the ring R. If R is omited, it defaults to a cyclotomic field.

```
sage: G = DirichletGroup(8); G
Group of Dirichlet characters of modulus 8 over Cyclotomic
Field of order 2 and degree 1
sage: v = G.list(); v
[[1, 1], [-1, 1], [1, -1], [-1, -1]]
sage: eps = G.0; eps
[-1, 1]
sage: [eps(3), eps(5)]
[-1, 1]
```

Sage both represents Dirichlet characters by giving a “matrix”, i.e., the list of images of canonical generators of $(\mathbb{Z}/N\mathbb{Z})^*$, and as vectors modulo and integer n. For years, I was torn between these two representations, until J. Quer and I realized that the best approach is to use both and make it easy to convert between them.

```
sage: parent(eps.element())
Vector space of dimension 2 over Ring of integers modulo 2
```

Given a Dirichlet character, Sage also lets you compute the associated Jacobi and Gauss sums, generalized Bernoulli numbers, the conductor, Galois orbit, etc.

Recall that Dirichlet characters give a decomposition

$$M_k(\Gamma_1(N)) = \bigoplus_{\varepsilon:(\mathbb{Z}/N\mathbb{Z})^* \to \mathbb{C}^*} M_k(N, \varepsilon).$$

Given a Dirichlet character ε we type `ModularForms(eps, weight)` to create the space of modular forms with that character and a given integer weight. For example, we create the space of forms of weight 5 with the character modulo 8 above that is -1 on 3 and 1 on 5 as follows.

```
sage: ModularForms(eps,5)
Modular Forms space of dimension 6, character [-1, 1] and
weight 5 over Rational Field
sage: sum([ModularForms(eps,5).dimension() for eps in v])
11
sage: ModularForms(Gamma1(8),5)
Modular Forms space of dimension 11 ...
```

Exercise 3.2. Compute the dimensions of all spaces $M_2(37, \varepsilon)$ for all Dirichlet characters ε.

The space $M_k(\Gamma)$ is equipped with an action of a commuting ring $\mathbb{T}$ of Hecke operators T_n for $n \geq 1$. A standard computational problem in the theory of modular forms is to compute an explicit basis of q-expansion for $M_k(\Gamma)$ along with matrices for the action of any Hecke operator T_n, and to compute the subspace $S_k(\Gamma)$ of cusp forms.

```
sage: M = ModularForms(Gamma0(11),4)
sage: M.basis()
[
q + 3*q^3 - 6*q^4 - 7*q^5 + O(q^6),
q^2 - 4*q^3 + 2*q^4 + 8*q^5 + O(q^6),
1 + O(q^6),
q + 9*q^2 + 28*q^3 + 73*q^4 + 126*q^5 + O(q^6)
]
sage: M.hecke_matrix(2)
[0 2 0 0]
[1 2 0 0]
[0 0 9 0]
[0 0 0 9]
```

We can also compute Hecke operators on the cuspidal subspace.

```
sage: S = M.cuspidal_subspace()
sage: S.hecke_matrix(2)
[0 2]
[1 2]
sage: S.hecke_matrix(3)
[ 3 -8]
[-4 -5]
```

Unfortunately, Sage doesn't yet implement computation of the Hecke operators on $M_k(\Gamma_1(N))$.

```
sage: M = ModularForms(Gamma1(5),2)
sage: M
Modular Forms space of dimension 3 for Congruence Subgroup
Gamma1(5) of weight 2 over Rational Field
sage: M.hecke_matrix(2)
Traceback (most recent call last):
...
NotImplementedError
```

However, we can compute Hecke operators on *modular symbols* for $\Gamma_1(N)$, which is a $\mathbb{T}$-module that is isomorphic to $M_k(\Gamma_1(N))$ (see Section 3.2).

```
sage: ModularSymbols(Gamma1(5),2,sign=1).hecke_matrix(2)
[ 2  1  1]
[ 1  2 -1]
[ 0  0 -1]
```

3.2 Modular Symbols

Modular symbols are a beautiful piece of mathematics that was developed since the 1960s by Birch, Manin, Shokorov, Mazur, Merel, Cremona, and others. Not only are modular symbols a powerful computational tool as we will see, they have also been used to prove rationality results for special values of L-series, to construct p-adic L-series, and they play a key role in Merel's proof of the uniform boundedness theorem for torsion points on elliptic curves over number fields.

We view modular symbols as a remarkably flexible computational tool that provides a single uniform algorithm for computing $M_k(N,\varepsilon)$ for any N,ε and $k \geq 2$. There are ways to use computation of those spaces to obtain explicit basis for spaces of weight 1 and half-integral weight, so in a sense modular symbols yield everything. There are also generalizations of modular symbols to higher rank groups, though Sage currently has no code for modular symbols on higher rank groups.

A *modular symbol* of weight k, and level N, with character ε is a sum of terms $X^iY^{k-2-i}\{\alpha,\beta\}$, where $0 \leq i \leq k-2$ and $\alpha,\beta \in \mathbb{P}^1(\mathbb{Q}) = \mathbb{Q}\cup\{\infty\}$. Modular symbols satisfy the relations

$$X^iY^{k-2-i}\{\alpha,\beta\} + X^iY^{k-2-i}\{\beta,\gamma\} + X^iY^{k-2-i}\{\gamma,\alpha\} = 0,$$

$$X^iY^{k-2-i}\{\alpha,\beta\} = -X^iY^{k-2-i}\{\beta,\alpha\},$$

and for every $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$, we have

$$(dX - bY)^i(-cX + aY)^{k-2-i}\{\gamma(\alpha),\gamma(\beta)\} = \varepsilon(d)X^iY^{k-2-i}\{\alpha,\beta\}.$$

The modular symbols space $\mathcal{M}_k(N,\varepsilon)$ is the torsion free $\mathbb{Q}[\varepsilon]$-module generated by all sums of modular symbols, modulo the relations listed above. Here $\mathbb{Q}[\varepsilon]$ is the ring generated by the values of the character ε, so it is of the form $\mathbb{Q}[\zeta_m]$ for some integer m.

The amazing theorem that makes modular symbols useful is that there is an explicit description of an action of a Hecke algebra $\mathbb{T}$ on $\mathcal{M}_k(N,\varepsilon)$, and there is an isomorphism

$$\mathcal{M}_k(N,\varepsilon;\mathbb{C}) \xrightarrow{\approx} M_k(N,\varepsilon) \oplus S_k(N,\varepsilon).$$

This means that if modular symbols are computable (they are!), then they can be used to compute a lot about the $\mathbb{T}$-module $M_k(N,\varepsilon)$.

Though $\mathcal{M}_k(N,\varepsilon)$ as described above is not explicitly generated by finitely many elements, it is finitely generated. Manin, Shokoruv, and Merel give an explicit description of finitely many generators (Manin symbols) for this space, along with all explicit relations that these generators satisfy (see my book). In particular, if we let

$$(i,c,d) = [X^iY^{2-k-i},(c,d)] = (dX - bY)^i(-cX + aY)^{k-2-i}\{\gamma(0),\gamma(\infty)\},$$

where $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then the Manin symbols (i,c,d) with $0 \leq i \leq k-2$ and $(c,d) \in \mathbb{P}^1(N)$ generate $\mathcal{M}_k(N,\varepsilon)$.

We compute a basis for the space of weight 4 modular symbols for $\Gamma_0(11)$, then coerce in $(2,0,1)$ and $(1,1,3)$.

```
sage: M = ModularSymbols(11,4)
sage: M.basis()
([X^2,(0,1)], [X^2,(1,6)], [X^2,(1,7)], [X^2,(1,8)],
 [X^2,(1,9)], [X^2,(1,10)])
sage: M( (2,0,1) )
[X^2,(0,1)]
sage: M( (1,1,3) )
2/7*[X^2,(1,6)] + 1/14*[X^2,(1,7)] - 4/7*[X^2,(1,8)]
                  + 3/14*[X^2,(1,10)]
```

We compute a modular symbols representation for the Manin symbol $(2,1,6)$, and verify this by converting back.

```
sage: a = M.1; a
[X^2,(1,6)]
sage: a.modular_symbol_rep()
36*X^2*{5/6,1} - 60*X*Y*{5/6,1} + 25*Y^2*{5/6,1}
sage: 36*M([2,5/6,1]) - 60*M([1,5/6,1]) + 25*M([0,5/6,1])
[X^2,(1,6)]
```

3.3 Method of Graphs

The Mestre Method of Graphs is an intriguing algorithm for computing the action of Hecke operators on yet another module X that is isomorphic to $M_2(\Gamma_0(N))$. The implementation in Sage unfortunately only works when N is prime; in contrast, my implementation in Magma works when $N = pM$ and $S_2(\Gamma_0(M)) = 0$.

The matrices of Hecke operators on X are *vastly* sparser than on any basis of $M_2(\Gamma_0(N))$ that you are likely to use.

```
sage: X = SupersingularModule(389); X
Module of supersingular points on X_0(1)/F_389 over Integer Ring
sage: t2 = X.T(2).matrix(); t2[0]
(1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0)
sage: factor(charpoly(t2))
(x - 3) * (x + 2) * (x^2 - 2) * (x^3 - 4*x - 2) * ...
sage: t2 = ModularSymbols(389,sign=1).hecke_matrix(2); t2[0]
(3, 0, -1, 0, 0, -1, 1, 0, 0, 0, -1, 1, 0, 1, -1, 0, 1, 1,
 0, 1, -1, 1, -1, 1, 0, 0, 0, 0, 0, 0, 1, -1, -1)
sage: factor(charpoly(t2))
(x - 3) * (x + 2) * (x^2 - 2) * (x^3 - 4*x - 2) * ...
```

The method of graphs is also used in computer science to construct *expander graphs* with good properties. And it is important in my algorithm for computing Tamagawa numbers of purely toric modular abelian varieties. This algorithm is not implemented in Sage yet, since it is only interesting in the case of non-prime level, as it turns out.

3.4 Level One Modular Forms

The modular form

$$\Delta = q \prod (1 - q^n)^{24} = \sum \tau(n) q^n$$

is perhaps the world's most famous modular form. We compute some terms from the definition.

```
sage: R.<q> = QQ[[]]
sage: q * prod( 1-q^n+O(q^6) for n in (1..5) )^24
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 + O(q^7)
```

There are much better ways to compute Δ, which amount to just a few polynomial multiplactions over $\mathbb{Z}$.

```
sage: D = delta_qexp(10^5)      # less than 10 seconds
sage: D[:10]
q - 24*q^2 + 252*q^3 - 1472*q^4 + ...
sage: [p for p in primes(10^5) if D[p] % p == 0]
```

```
[2, 3, 5, 7, 2411]
sage: D[2411]
4542041100095889012
sage: f = eisenstein_series_qexp(12,6) - D[:6]; f
691/65520 + 2073*q^2 + 176896*q^3 + 4197825*q^4 + 48823296*q^5 + O(q^6)
sage: f % 691
O(q^6)
```

The Victor Miller basis for $M_k(\mathrm{SL}_2(\mathbb{Z}))$ is the reduced row echelon basis. It's a lemma that it has all integer coefficients, and a rather nice diagonal shape.

```
sage: victor_miller_basis(24, 6)
[
1 + 52416000*q^3 + 39007332000*q^4 + 6609020221440*q^5 + O(q^6),
q + 195660*q^3 + 12080128*q^4 + 44656110*q^5 + O(q^6),
q^2 - 48*q^3 + 1080*q^4 - 15040*q^5 + O(q^6)
]
sage: dimension_modular_forms(1,200)
17
sage: time B = victor_miller_basis(200, 18)
CPU time: 4.43 s,  Wall time: 5.07 s
sage: B
[
1 + 79288314420681734048660707200000*q^17 + O(q^18),
q + 2687602718106772837928968846869*q^17 + O(q^18),
...
q^16 + 96*q^17 + O(q^18)
]
```

Note: Craig Citro has made the above computation an order of magnitude faster in code he hasn't quite got into Sage yet. "I'll clean those up and submit them soon, since I need them for something I'm working on ... I'm currently in the process of making spaces of modular forms of level one subclass the existing code, and actually take advantage of all our fast E_k and Δ computation code, as well as cleaning things up a bit."

3.5 Half Integral Weight Forms

ALGORITHM: Basmaji (page 55 of his Essen thesis, "Ein Algorithmus zur Berechnung von Hecke-Operatoren und Anwendungen auf modulare Kurven", `http://wstein.org/scans/papers/basmaji/`).

Let $S = S_{k+1}(\varepsilon)$ be the space of cusp forms of even integer weight $k+1$ and character $\varepsilon = \chi\psi^{(k+1)/2}$, where ψ is the nontrivial mod-4 Dirichlet character. Let U be the subspace of $S \times S$ of elements (a, b) such that $\Theta_2 a = \Theta_3 b$. Then U is isomorphic to $S_{k/2}(\chi)$ via the map $(a, b) \mapsto a/\Theta_3$.

This algorithm is implemented in Sage. I'm sure it could be implemented in a way that is much faster than the current implementation...

```
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 3, 10)
[]
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 5, 10)
[q - 2*q^3 - 2*q^5 + 4*q^7 - q^9 + O(q^10)]
sage: half_integral_weight_modform_basis(DirichletGroup(16*7).0^2,3,30)
[q - 2*q^2 - q^9 + 2*q^14 + 6*q^18 - 2*q^21 - 4*q^22 - q^25 + O(q^30),
 q^2 - q^14 - 3*q^18 + 2*q^22 + O(q^30),
 q^4 - q^8 - q^16 + q^28 + O(q^30), q^7 - 2*q^15 + O(q^30)]
```

3.6 Generators for Rings of Modular Forms

For any congruence subgroup Γ, the direct sum

$$M(\Gamma) = \bigoplus_{k\geq 0} M_k(\Gamma)$$

is a ring, since the product of modular forms $f \in M_k(\Gamma)$ and $g \in M_{k'}(\Gamma)$ is an element $fg \in M_{k+k'}(\Gamma)$. Sage can compute likely generators for rings of modular forms, but currently doesn't prove any of these results.

We verify the statement proved in Serre's "A Course in Arithmetic" that E_4 and E_6 generate the space of level one modular forms.

```
sage: from sage.modular.modform.find_generators import modform_generators
sage: modform_generators(1)
[(4, 1 + 240*q + 2160*q^2 + 6720*q^3 + O(q^4)),
 (6, 1 - 504*q - 16632*q^2 - 122976*q^3 + O(q^4))]
```

Have you ever wondered which forms generate the ring $M(\Gamma_0(2))$? it turns out a form of weight 2 and two forms of weight 4 together generate.

```
sage: modform_generators(2)
[(2, 1 + 24*q + 24*q^2 + ... + 288*q^11 + O(q^12)),
 (4, 1 + 240*q^2 + .. + 30240*q^10 + O(q^12)),
 (4, q + 8*q^2 + .. + 1332*q^11 + O(q^12))]
```

Here's generators for $M(\Gamma_0(3))$. Notice that elements of weight 6 are now required, in addition to weights 2 and 4.

```
sage: modform_generators(3)
[(2, 1 + 12*q + 36*q^2 + .. + 168*q^13 + O(q^14)),
 (4, 1 + 240*q^3 + 2160*q^6 + 6720*q^9 + 17520*q^12 + O(q^14)),
 (4, q + 9*q^2 + 27*q^3 + 73*q^4 + .. + O(q^14)),
 (6, q - 6*q^2 + 9*q^3 + 4*q^4 + .. + O(q^14)),
 (6, 1 - 504*q^3 - 16632*q^6 .. + O(q^14)),
 (6, q + 33*q^2 + 243*q^3 + .. + O(q^14))]
```

3.7 L-series

Thanks to wrapping work of Jennifer Balakrishnan of M.I.T., we can compute explicitly with the L-series of the modular form Δ. Like for elliptic curves, behind these scenes this uses Dokchitsers L-functions calculation Pari program.

```
sage: L = delta_lseries(); L
L-series associated to the modular form Delta
sage: L(1)
0.0374412812685155
```

In some cases we can also compute with L-series attached to a cusp form.

```
 sage: f = CuspForms(2,8).0
 sage: L = f.cuspform_lseries()
 sage: L(1)
 0.0884317737041015
 sage: L(0.5)
 0.0296568512531983
```

Unfortunately, computing with the L-series of a general newform is not yet implemented.

```
sage: S = CuspForms(23,2); S
Cuspidal subspace of dimension 2 of Modular Forms space of
dimension 3 for Congruence Subgroup Gamma0(23) of weight
2 over Rational Field
sage: f = S.newforms('a')[0]; f
q + a0*q^2 + (-2*a0 - 1)*q^3 + (-a0 - 1)*q^4 + 2*a0*q^5 + O(q^6)
```

Computing with $L(f, s)$ totally not implemented yet, though should be easy via Dokchitser.

3.8 Modular Abelian Varieties

The quotient of the extended upper half plane $\mathfrak{h}^*$ by the congruence subgroup $\Gamma_1(N)$ is the modular curve $X_1(N)$. Its Jacobian $J_1(N)$ is an abelian variety that is canonically defined over $\mathbb{Q}$. Likewise, one defines a modular abelian variety $J_0(N)$ associated to $\Gamma_0(N)$.

Definition 3.3. A *modular abelian variety* is an abelian variety over $\mathbb{Q}$ that is a quotient of $J_1(N)$ for some N.

The biggest recent theorem in number theory is the proof of Serre's conjecture by Khare and Wintenberger. According to an argument of Ribet and Serre, this implies the following modularity theorem, which generalizes the modularity theorem that Taylor-Wiles proved in the course of proving Fermat's Last Theorem.

Theorem 3.4 (Modularity Theorem)**.** *Let A be a simple abelian variety defined over $\mathbb{Q}$. Then* $\mathrm{End}(A) \otimes \mathbb{Q}$ *is a number field of degree* $\dim(A)$ *if and only if A is modular.*

One of my longterm research goals is to develop a systematic theory for computing with modular abelian varieties. A good start is the observation using the Abel-Jacobi theorem that every modular abelian variety (up to isomorphism) can be specified by giving a lattice in a space of modular symbols.

We define some modular abelian varieties of level 39, and compute some basic invariants.

```
sage: D = J0(39).decomposition(); D
[
Simple abelian subvariety 39a(1,39) of dimension 1 of J0(39),
Simple abelian subvariety 39b(1,39) of dimension 2 of J0(39)
]
sage: D[1].lattice()
Free module of degree 6 and rank 4 over Integer Ring
Echelon basis matrix:
[ 1  0  0  1 -1  0]
[ 0  1  1  0 -1  0]
[ 0  0  2  0 -1  0]
[ 0  0  0  0  0  1]
sage: G = D[1].rational_torsion_subgroup(); G
Torsion subgroup of Simple abelian subvariety 39b(1,39)
of dimension 2 of J0(39)
sage: G.order()
28
sage: G.gens()
[[(1/14, 2/7, 0, 1/14, -3/14, 1/7)], [(0, 1, 0, 0, -1/2, 0)],
 [(0, 0, 1, 0, -1/2, 0)]]
sage: B, phi = D[1]/G
sage: B
Abelian variety factor of dimension 2 of J0(39)
sage: phi.kernel()
(Finite subgroup with invariants [2, 14] ...
```

There is an algorithm in Sage for computing the exact endomorphism ring of any modular abelian variety.

```
sage: A = J0(91)[2]; A
Simple abelian subvariety 91c(1,91) of dimension 2 of J0(91)
sage: R = End(A); R
Endomorphism ring of Simple abelian subvariety 91c(1,91)
of dimension 2 of J0(91)
sage: for x in R.gens(): print x.matrix(),'\n'
[1 0 0 0]
```

```
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

[ 0  4 -2  0]
[-1  5 -2  1]
[-1  2  0  2]
[-1  1  0  3]
```

It is also possible to test isomorphism of two modular abelian varieties. But much exciting theoretical and computational work remains to be done.

35 Book – Elementary Number Theory: Primes, Congruences, and Secrets

Elementary Number Theory: Primes, Congruences, and Secrets

William Stein

July 22, 2009

To my wife Clarita Lefthand

Contents

Preface

This is a book about prime numbers, congruences, secret messages, and elliptic curves that you can read cover to cover. It grew out of undergraduate courses that the author taught at Harvard, UC San Diego, and the University of Washington.

The systematic study of number theory was initiated around 300B.C. when Euclid proved that there are infinitely many prime numbers, and also cleverly deduced the fundamental theorem of arithmetic, which asserts that every positive integer factors uniquely as a product of primes. Over a thousand years later (around 972A.D.) Arab mathematicians formulated the *congruent number problem* that asks for a way to decide whether or not a given positive integer n is the area of a right triangle, all three of whose sides are rational numbers. Then another thousand years later (in 1976), Diffie and Hellman introduced the first ever public-key cryptosystem, which enabled two people to communicate secretely over a public communications channel with no predetermined secret; this invention and the ones that followed it revolutionized the world of digital communication. In the 1980s and 1990s, elliptic curves revolutionized number theory, providing striking new insights into the congruent number problem, primality testing, public-key cryptography, attacks on public-key systems, and playing a central role in Andrew Wiles' resolution of Fermat's Last Theorem.

Today, pure and applied number theory is an exciting mix of simultaneously broad and deep theory, which is constantly informed and motivated by algorithms and explicit computation. Active research is underway that promises to resolve the congruent number problem, deepen our understanding into the structure of prime numbers, and both challenge and improve our ability to communicate securely. The goal of this book is to bring the reader closer to this world.

The reader is strongly encouraged to do every exercise in this book, checking their answers in the back (where many, but not all, solutions are given). Also, throughout the text there, are examples of calculations done using the powerful free open source mathematical software system Sage (`http://www.sagemath.org`), and the reader should try every such example and experiment with similar examples.

Background. The reader should know how to read and write mathematical proofs and must have know the basics of groups, rings, and fields. Thus, the prerequisites for this book are more than the prerequisites for most elementary number theory books, while still being aimed at undergraduates.

Notation and Conventions. We let $\mathbf{N} = \{1, 2, 3, \ldots\}$ denote the natural numbers, and use the standard notation $\mathbf{Z}$, $\mathbf{Q}$, $\mathbf{R}$, and $\mathbf{C}$ for the rings of integer, rational, real, and complex numbers, respectively. In this book, we will use the words proposition, theorem, lemma, and corollary as follows. Usually a proposition is a less important or less fundamental assertion, a theorem is a deeper culmination of ideas, a lemma is something that we will use later in this book to prove a proposition or theorem, and a corollary is an easy consequence of a proposition, theorem, or lemma. More difficult exercises are marked with a (*).

Acknowledgements. I would like to thank Brian Conrad, Carl Pomerance, and Ken Ribet for many clarifying comments and suggestions. Baurzhan Bektemirov, Lawrence Cabusora, and Keith Conrad read drafts of this book and made many comments, and Carl Witty commented extensively on the first two chapters. Frank Calegari used the course when teaching Math 124 at Harvard, and he and his students provided much feedback. Noam Elkies made comments and suggested Exercise 4.6. Seth Kleinerman wrote a version of Section 5.4 as a class project. Hendrik Lenstra made helpful remarks about how to present his factorization algorithm. Michael Abshoff, Sabmit Dasgupta, David Joyner, Arthur Patterson, George Stephanides, Kevin Stern, Eve Thompson, Ting-You Wang, and Heidi Williams all suggested corrections. I also benefited from conversations with Henry Cohn and David Savitt. I used Sage ([Sag08]), emacs, and LaTeX in the preparation of this book.

1
Prime Numbers

Every positive integer can be written uniquely as a product of prime numbers, e.g., $100 = 2^2 \cdot 5^2$. This is surprisingly difficult to prove, as we will see below. Even more astounding is that actually *finding* a way to write certain 1,000-digit numbers as a product of primes seems out of the reach of present technology, an observation that is used by millions of people every day when they buy things online.

Since prime numbers are the building blocks of integers, it is natural to wonder how the primes are distributed among the integers.

> "There are two facts about the distribution of prime numbers. The first is that, [they are] the most arbitrary and ornery objects studied by mathematicians: they grow like weeds among the natural numbers, seeming to obey no other law than that of chance, and nobody can predict where the next one will sprout. The second fact is even more astonishing, for it states just the opposite: that the prime numbers exhibit stunning regularity, that there are laws governing their behavior, and that they obey these laws with almost military precision."
>
> — Don Zagier [Zag75]

The Riemann Hypothesis, which is the most famous unsolved problem in number theory, postulates a very precise answer to the question of how the prime numbers are distributed.

This chapter lays the foundations for our study of the theory of numbers by weaving together the themes of prime numbers, integer factorization, and the distribution of primes. In Section 1.1, we rigorously prove that the every positive integer is a product of primes, and give examples of specific integers for which finding such a decomposition would win one a large cash bounty. In Section 1.2, we discuss theorems about the set of prime numbers, starting with Euclid's proof that this set is infinite, and discuss the largest known prime. Finally we discuss the distribution of primes via the prime number theorem and the Riemann Hypothesis.

1.1 Prime Factorization

1.1.1 Primes

The set of *natural numbers* is

$$\mathbf{N} = \{1, 2, 3, 4, \dots\},$$

and the set of *integers* is

$$\mathbf{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}.$$

Definition 1.1.1 (Divides)**.** If $a, b \in \mathbf{Z}$ we say that *a divides b*, written $a \mid b$, if $ac = b$ for some $c \in \mathbf{Z}$. In this case, we say a is a *divisor* of b. We say that *a does not divide b*, written $a \nmid b$, if there is no $c \in \mathbf{Z}$ such that $ac = b$.

For example, we have $2 \mid 6$ and $-3 \mid 15$. Also, all integers divide 0, and 0 divides only 0. However, 3 does not divide 7 in $\mathbf{Z}$.

Remark 1.1.2. The notation $b \,\vdots\, a$ for "b is divisible by a" is common in Russian literature on number theory.

Definition 1.1.3 (Prime and Composite)**.** An integer $n > 1$ is *prime* if the only positive divisors of n are 1 and n. We call n *composite* if n is not prime.

The number 1 is neither prime nor composite. The first few primes of $\mathbf{N}$ are

$$2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, \dots,$$

and the first few composites are

$$4, 6, 8, 9, 10, 12, 14, 15, 16, 18, 20, 21, 22, 24, 25, 26, 27, 28, 30, 32, 33, 34, \dots.$$

Remark 1.1.4. J. H. Conway argues in [Con97, viii] that -1 should be considered a prime, and in the 1914 table [Leh14], Lehmer considers 1 to be a prime. In this book, we consider neither -1 nor 1 to be prime.

SAGE Example 1.1.5. We use Sage to compute all prime numbers between a and $b - 1$.

```
sage: prime_range(10,50)
[11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47]
```

We can also compute the composites in an interval.

```
sage: [n for n in range(10,30) if not is_prime(n)]
[10, 12, 14, 15, 16, 18, 20, 21, 22, 24, 25, 26, 27, 28]
```

Every natural number is built, in a unique way, out of prime numbers:

Theorem 1.1.6 (Fundamental Theorem of Arithmetic)**.** *Every natural number can be written as a product of primes uniquely up to order.*

Note that primes are the products with only one factor and 1 is the empty product.

Remark 1.1.7. Theorem 1.1.6, which we will prove in Section 1.1.4, is trickier to prove than you might first think. For example, unique factorization fails in the *ring*

$$\mathbf{Z}[\sqrt{-5}] = \{a + b\sqrt{-5} : a, b \in \mathbf{Z}\} \subset \mathbf{C},$$

where 6 factors in two different ways:

$$6 = 2 \cdot 3 = (1 + \sqrt{-5}) \cdot (1 - \sqrt{-5}).$$

1.1.2 The Greatest Common Divisor

We will use the notion of the greatest common divisor of two integers to prove that if p is a prime and $p \mid ab$, then $p \mid a$ or $p \mid b$. Proving this is the key step in our proof of Theorem 1.1.6.

Definition 1.1.8 (Greatest Common Divisor)**.** Let

$$\gcd(a, b) = \max\left\{d \in \mathbf{Z} : d \mid a \text{ and } d \mid b\right\},$$

unless both a and b are 0 in which case $\gcd(0, 0) = 0$.

For example, $\gcd(1, 2) = 1$, $\gcd(6, 27) = 3$, and for any a, $\gcd(0, a) = \gcd(a, 0) = a$.

If $a \neq 0$, the greatest common divisor exists because if $d \mid a$ then $d \leq |a|$, and there are only $|a|$ positive integers $\leq |a|$. Similarly, the gcd exists when $b \neq 0$.

Lemma 1.1.9. *For any integers a and b, we have*

$$\gcd(a, b) = \gcd(b, a) = \gcd(\pm a, \pm b) = \gcd(a, b - a) = \gcd(a, b + a).$$

Proof. We only prove that $\gcd(a, b) = \gcd(a, b - a)$, since the other cases are proved in a similar way. Suppose $d \mid a$ and $d \mid b$, so there exist integers c_1 and c_2 such that $dc_1 = a$ and $dc_2 = b$. Then $b - a = dc_2 - dc_1 = d(c_2 - c_1)$, so $d \mid b-a$. Thus $\gcd(a,b) \leq \gcd(a, b-a)$, since the set over which we are taking the max for $\gcd(a,b)$ is a subset of the set for $\gcd(a,b-a)$. The same argument with a replaced by $-a$ and b replaced by $b-a$, shows that $\gcd(a,b-a) = \gcd(-a,b-a) \leq \gcd(-a,b) = \gcd(a,b)$, which proves that $\gcd(a,b) = \gcd(a,b-a)$. □

Lemma 1.1.10. *Suppose* $a, b, n \in \mathbf{Z}$. *Then* $\gcd(a,b) = \gcd(a, b-an)$.

Proof. By repeated application of Lemma 1.1.9, we have

$$\gcd(a,b) = \gcd(a,b-a) = \gcd(a,b-2a) = \cdots = \gcd(a,b-an).$$

□

Assume for the moment that we have already proved Theorem 1.1.6. A naive way to compute $\gcd(a,b)$ is to factor a and b as a product of primes using Theorem 1.1.6; then the prime factorization of $\gcd(a,b)$ can be read off from that of a and b. For example, if $a = 2261$ and $b = 1275$, then $a = 7 \cdot \mathbf{17} \cdot 19$ and $b = 3 \cdot 5^2 \cdot \mathbf{17}$, so $\gcd(a,b) = 17$. It turns out that the greatest common divisor of two integers, even huge numbers (millions of digits), is surprisingly easy to compute using Algorithm 1.1.13 below, which computes $\gcd(a,b)$ without factoring a or b.

To motivate Algorithm 1.1.13, we compute $\gcd(2261, 1275)$ in a different way. First, we recall a helpful fact.

Proposition 1.1.11. *Suppose that* a *and* b *are integers with* $b \neq 0$. *Then there exists unique integers* q *and* r *such that* $0 \leq r < |b|$ *and* $a = bq + r$.

Proof. For simplicity, assume that both a and b are positive (we leave the general case to the reader). Let Q be the set of all nonnegative integers n such that $a - bn$ is nonnegative. Then Q is nonempty because $0 \in Q$ and Q is bounded because $a - bn < 0$ for all $n > a/b$. Let q be the largest element of Q. Then $r = a - bq < b$, otherwise $q+1$ would also be in Q. Thus q and r satisfy the existence conclusion.

To prove uniqueness, suppose that q' and r' also satisfy the conclusion. Then $q' \in Q$ since $r' = a - bq' \geq 0$, so $q' \leq q$, and we can write $q' = q - m$ for some $m \geq 0$. If $q' \neq q$, then $m \geq 1$ so

$$r' = a - bq' = a - b(q-m) = a - bq + bm = r + bm \geq b$$

since $r \geq 0$, a contradiction. Thus $q = q'$ and $r' = a - bq' = a - bq = r$, as claimed. □

For us, an *algorithm* is a finite sequence of instructions that can be followed to perform a specific task, such as a sequence of instructions in a computer program, which must terminate on any valid input. The word "algorithm" is sometimes used more loosely (and sometimes more precisely) than defined here, but this definition will suffice for us.

Algorithm 1.1.12 (Division Algorithm)**.** Suppose a and b are integers with $b \neq 0$. This algorithm computes integers q and r such that $0 \leq r < |b|$ and $a = bq + r$.

We will not describe the actual steps of Algorithm 1.1.12, since it is just the familiar long division algorithm. Note that it might not be exactly the same as the standard long division algorithm you learned in school, because we make the remainder positive even when dividing a negative number by a positive number.

We use the division algorithm repeatedly to compute $\gcd(2261, 1275)$. Dividing 2261 by 1275 we find that

$$2261 = 1 \cdot 1275 + 986,$$

so $q = 1$ and $r = 986$. Notice that if a natural number d divides both 2261 and 1275, then d divides their difference 986 and d still divides 1275. On the other hand, if d divides both 1275 and 986, then it has to divide their sum 2261 as well! We have made progress:

$$\gcd(2261, 1275) = \gcd(1275, 986).$$

This equality also follows by applying Lemma 1.1.9. Repeating, we have

$$1275 = 1 \cdot 986 + 289,$$

so $\gcd(1275, 986) = \gcd(986, 289)$. Keep going:

$$\begin{aligned} 986 &= 3 \cdot 289 + 119 \\ 289 &= 2 \cdot 119 + 51 \\ 119 &= 2 \cdot 51 + 17. \end{aligned}$$

Thus $\gcd(2261, 1275) = \cdots = \gcd(51, 17)$, which is 17 because $17 \mid 51$. Thus

$$\gcd(2261, 1275) = 17.$$

Aside from some tedious arithmetic, that computation was systematic, and it was not necessary to factor any integers (which is something we do not know how to do quickly if the numbers involved have hundreds of digits).

Algorithm 1.1.13 (Greatest Common Division)**.** Given integers a, b, this algorithm computes $\gcd(a, b)$.

1. [Assume $a > b > 0$] We have $\gcd(a, b) = \gcd(|a|, |b|) = \gcd(|b|, |a|)$, so we may replace a and b by their absolute values and hence assume $a, b \geq 0$. If $a = b$, output a and terminate. Swapping if necessary, we assume $a > b$. If $b = 0$, we output a.
2. [Quotient and Remainder] Using Algorithm 1.1.12, write $a = bq + r$, with $0 \leq r < b$ and $q \in \mathbf{Z}$.

3. [Finished?] If $r = 0$, then $b \mid a$, so we output b and terminate.
4. [Shift and Repeat] Set $a \leftarrow b$ and $b \leftarrow r$, then go to Step 2.

Proof. Lemmas 1.1.9–1.1.10 imply that $\gcd(a, b) = \gcd(b, r)$ so the gcd does not change in Step 4. Since the remainders form a decreasing sequence of nonnegative integers, the algorithm terminates. □

Example 1.1.14. Set $a = 15$ and $b = 6$.

$$\begin{aligned} 15 &= 6 \cdot 2 + 3 \qquad \gcd(15, 6) = \gcd(6, 3) \\ 6 &= 3 \cdot 2 + 0 \qquad \gcd(6, 3) = \gcd(3, 0) = 3 \end{aligned}$$

Note that we can just as easily do an example that is ten times as big, an observation that will be important in the proof of Theorem 1.1.19 below.

Example 1.1.15. Set $a = 150$ and $b = 60$.

$$\begin{aligned} 150 &= 60 \cdot 2 + 30 \qquad \gcd(150, 60) = \gcd(60, 30) \\ 60 &= 30 \cdot 2 + 0 \qquad \gcd(60, 30) = \gcd(30, 0) = 30 \end{aligned}$$

SAGE Example 1.1.16. Sage uses the `gcd` command to compute the greatest common divisor of two integers. For example,

```
sage: gcd(97,100)
1
sage: gcd(97 * 10^15, 19^20 * 97^2)
97
```

Lemma 1.1.17. *For any integers a, b, n, we have*

$$\gcd(an, bn) = \gcd(a, b) \cdot |n|.$$

Proof. The idea is to follow Example 1.1.15; we step through Euclid's algorithm for $\gcd(an, bn)$ and note that at every step the equation is the equation from Euclid's algorithm for $\gcd(a, b)$ but multiplied through by n. For simplicity, assume that both a and b are positive. We will prove the lemma by induction on $a + b$. The statement is true in the base case when $a + b = 2$, since then $a = b = 1$. Now assume a, b are arbitrary with $a \geq b$. Let q and r be such that $a = bq + r$ and $0 \leq r < b$. Then by Lemmas 1.1.9–1.1.10, we have $\gcd(a, b) = \gcd(b, r)$. Multiplying $a = bq + r$ by n we see that $an = bnq + rn$, so $\gcd(an, bn) = \gcd(bn, rn)$. Then

$$b + r = b + (a - bq) = a - b(q - 1) \leq a < a + b,$$

so by induction $\gcd(bn, rn) = \gcd(b, r) \cdot |n|$. Since $\gcd(a, b) = \gcd(b, r)$, this proves the lemma. □

Lemma 1.1.18. *Suppose $a, b, n \in \mathbf{Z}$ are such that $n \mid a$ and $n \mid b$. Then $n \mid \gcd(a, b)$.*

Proof. Since $n \mid a$ and $n \mid b$, there are integers c_1 and c_2, such that $a = nc_1$ and $b = nc_2$. By Lemma 1.1.17, $\gcd(a, b) = \gcd(nc_1, nc_2) = n \gcd(c_1, c_2)$, so n divides $\gcd(a, b)$. □

With Algorithm 1.1.13, we can prove that if a prime divides the product of two numbers, then it has got to divide one of them. This result is the key to proving that prime factorization is unique.

Theorem 1.1.19 (Euclid)**.** *Let p be a prime and $a, b \in \mathbf{N}$. If $p \mid ab$ then $p \mid a$ or $p \mid b$.*

You might think this theorem is "intuitively obvious," but that might be because the fundamental theorem of arithmetic (Theorem 1.1.6) is deeply ingrained in your intuition. Yet Theorem 1.1.19 will be needed in our proof of the fundamental theorem of arithmetic.

Proof of Theorem 1.1.19. If $p \mid a$ we are done. If $p \nmid a$ then $\gcd(p, a) = 1$, since only 1 and p divide p. By Lemma 1.1.17, $\gcd(pb, ab) = b$. Since $p \mid pb$ and, by hypothesis, $p \mid ab$, it follows (using Lemma 1.1.17) that

$$p \mid \gcd(pb, ab) = b \gcd(p, a) = b \cdot 1 = b.$$

□

1.1.3 Numbers Factor as Products of Primes

In this section, we prove that every natural number factors as a product of primes. Then we discuss the difficulty of finding such a decomposition in practice. We will wait until Section 1.1.4 to prove that factorization is unique.

As a first example, let $n = 1275$. The sum of the digits of n is divisible by 3, so n is divisible by 3 (see Proposition 2.1.9), and we have $n = 3 \cdot 425$. The number 425 is divisible by 5, since its last digit is 5, and we have $1275 = 3 \cdot 5 \cdot 85$. Again, dividing 85 by 5, we have $1275 = 3 \cdot 5^2 \cdot 17$, which is the prime factorization of 1275. Generalizing this process proves the following proposition.

Proposition 1.1.20. *Every natural number is a product of primes.*

Proof. Let n be a natural number. If $n = 1$, then n is the empty product of primes. If n is prime, we are done. If n is composite, then $n = ab$ with $a, b < n$. By induction, a and b are products of primes, so n is also a product of primes. □

Two questions immediately arise: (1) is this factorization unique, and (2) how quickly can we find such a factorization? Addressing (1), what if we had done something differently when breaking apart 1275 as a product of primes? Could the primes that show up be different? Let's try: we have

$1275 = 5 \cdot 255$. Now $255 = 5 \cdot 51$ and $51 = 17 \cdot 3$, and again the factorization is the same, as asserted by Theorem 1.1.6. We will prove the uniqueness of the prime factorization of any integer in Section 1.1.4.

SAGE Example 1.1.21. The `factor` command in Sage factors an integer as a product of primes with multiplicities. For example,

```
sage: factor(1275)
3 * 5^2 * 17
sage: factor(2007)
3^2 * 223
sage: factor(31415926535898)
2 * 3 * 53 * 73 * 2531 * 534697
```

Regarding (2), there are algorithms for integer factorization. It is a major open problem to decide how fast integer factorization algorithms can be. We say that an algorithm to factor n is *polynomial time* if there is a polynomial $f(x)$ such that for any n the number of steps needed by the algorithm to factor n is less than $f(\log_{10}(n))$. Note that $\log_{10}(n)$ is an approximation for the number of digits of the input n to the algorithm.

Open Problem 1.1.22. *Is there an algorithm that can factor any integer n in polynomial time?*

Peter Shor [Sho97] devised a polynomial time algorithm for factoring integers on quantum computers. We will not discuss his algorithm further, except to note that in 2001 IBM researchers built a quantum computer that used Shor's algorithm to factor 15 (see [LMG$^+$01, IBM01]). Building much larger quantum computers appears to be extremely difficult.

You can earn money by factoring certain large integers. Many cryptosystems would be easily broken if factoring certain large integers was easy. Since nobody has proven that factoring integers is difficult, one way to increase confidence that factoring is difficult is to offer cash prizes for factoring certain integers. For example, until recently there was a \$10,000 bounty on factoring the following 174-digit integer (see [RSA]):

$$\begin{array}{l}
188198812920607963838697239461650439807163563379417382700 7\\
633564229888597152346654853190606065047430453173880113033 9\\
671619969232120573403187955065699622130516875930765025705 9
\end{array}$$

This number is known as RSA-576 since it has 576 digits when written in binary (see Section 2.3.2 for more on binary numbers). It was factored at the German Federal Agency for Information Technology Security in December 2003 (see [Wei03]):

$$\begin{array}{l}
398075086424064937397125500550386491199064362342526708406\\
\quad 385189575946388957261768583317\\
\times\\
472772146107435302536223071973048224632914695302097116459\\
\quad 852171130520711256363590397527
\end{array}$$

The previous RSA challenge was the 155-digit number

10941738641570527421809707322040357612003732945449205990913
84213147634998428893478471799725789126733249762575289978183
3797076537244027146743531593354333897.

It was factored on 22 August 1999 by a group of sixteen researchers in four months on a cluster of 292 computers (see [ACD+99]). They found that RSA-155 is the product of the following two 78-digit primes:

$$\begin{aligned} p &= 102639592829741105772054196573991675900716567808038066\\ &\quad 803341933521790711307779\\ q &= 106603488380168454820927220360012878679207958575989291\\ &\quad 522270608237193062808643. \end{aligned}$$

The next RSA challenge is RSA-640:

3107418240490043721350750035888567930037346022842727545720161948
8232064405180815045563468296717232867824379162728380334154710731
0850191954852900733772482278352574238645401469173660247765
2346609,

and its factorization was worth $20,000 until November 2005 when it was factored by F. Bahr, M. Boehm, J. Franke, and T. Kleinjun. This factorization took five months. Here is one of the prime factors (you can find the other):

16347336458092538484431338838650908598417836700330923121811108
52389333100104508151212118167511579.

(This team also factored a 663-bit RSA challenge integer.)

The smallest currently open challenge is RSA-704, worth $30,000:

74037563479561712828046796097429573142593188889231289084936232
63897276503402826627689199641962511784399589433050212758537011
89680982867331732731089309005525051168770632990723963807867100
86096962537934650563796359

SAGE Example 1.1.23. Using Sage, we see that the above number has 212 decimal digits and is definitely composite:

```
sage: n = 740375634795617128280467960974295731425931888\
...923128908493623263897276503402826627689199641962511 7\
...843995894330502127585370118968098286733173273108930 9\
...005525051168770632990723963807867100860969625379346 5\
...0563796359
sage: len(n.str(2))
```

```
704
sage: len(n.str(10))
212
sage: n.is_prime()              # this is instant
False
```

These RSA numbers were factored using an algorithm called the number field sieve (see [LL93]), which is the best-known general purpose factorization algorithm. A description of how the number field sieve works is beyond the scope of this book. However, the number field sieve makes extensive use of the elliptic curve factorization method, which we will describe in Section 6.3.

1.1.4 The Fundamental Theorem of Arithmetic

We are ready to prove Theorem 1.1.6 using the following idea. Suppose we have two factorizations of n. Using Theorem 1.1.19, we cancel common primes from each factorization, one prime at a time. At the end, we discover that the factorizations must consist of exactly the same primes. The technical details are given below.

Proof. If $n = 1$, then the only factorization is the empty product of primes, so suppose $n > 1$.

By Proposition 1.1.20, there exist primes $p_1, \ldots, p_d$ such that

$$n = p_1 p_2 \cdots p_d.$$

Suppose that

$$n = q_1 q_2 \cdots q_m$$

is another expression of n as a product of primes. Since

$$p_1 \mid n = q_1(q_2 \cdots q_m),$$

Euclid's theorem implies that $p_1 = q_1$ or $p_1 \mid q_2 \cdots q_m$. By induction, we see that $p_1 = q_i$ for some i.

Now cancel p_1 and q_i, and repeat the above argument. Eventually, we find that, up to order, the two factorizations are the same. □

1.2 The Sequence of Prime Numbers

This section is concerned with three questions:

1. Are there infinitely many primes?

2. Given $a, b \in \mathbf{Z}$, are there infinitely many primes of the form $ax + b$?

3. How are the primes spaced along the number line?

We first show that there are infinitely many primes, then state Dirichlet's theorem that if $\gcd(a, b) = 1$, then $ax + b$ is a prime for infinitely many values of x. Finally, we discuss the Prime Number Theorem which asserts that there are asymptotically $x/\log(x)$ primes less than x, and we make a connection between this asymptotic formula and the Riemann Hypothesis.

1.2.1 There Are Infinitely Many Primes

Each number on the left in the following table is prime. We will see soon that this pattern does not continue indefinitely, but something similar works.

$$\begin{aligned} 3 &= 2 + 1 \\ 7 &= 2 \cdot 3 + 1 \\ 31 &= 2 \cdot 3 \cdot 5 + 1 \\ 211 &= 2 \cdot 3 \cdot 5 \cdot 7 + 1 \\ 2311 &= 2 \cdot 3 \cdot 5 \cdot 7 \cdot 11 + 1 \end{aligned}$$

Theorem 1.2.1 (Euclid)**.** *There are infinitely many primes.*

Proof. Suppose that $p_1, p_2, \ldots, p_n$ are n distinct primes. We construct a prime p_{n+1} not equal to any of $p_1, \ldots, p_n$, as follows. If

$$N = p_1 p_2 p_3 \cdots p_n + 1, \tag{1.2.1}$$

then by Proposition 1.1.20 there is a factorization

$$N = q_1 q_2 \cdots q_m$$

with each q_i prime and $m \geq 1$. If $q_1 = p_i$ for some i, then $p_i \mid N$. Because of (1.2.1), we also have $p_i \mid N - 1$, so $p_i \mid 1 = N - (N - 1)$, which is a contradiction. Thus the prime $p_{n+1} = q_1$ is not in the list $p_1, \ldots, p_n$, and we have constructed our new prime. □

For example,

$$2 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 13 + 1 = 30031 = 59 \cdot 509.$$

Multiplying together the first six primes and adding 1 doesn't produce a prime, but it produces an integer that is merely divisible by a new prime.

Joke 1.2.2 (Hendrik Lenstra)**.** *There are infinitely many composite numbers. Proof.* To obtain a new composite number, multiply together the first n composite numbers and don't add 1.

1.2.2 Enumerating Primes

In this section we describe a sieving process that allows us to enumerate all primes up to n. The sieve works by first writing down all numbers up to n, noting that 2 is prime, and crossing off all multiples of 2. Next, note that the first number not crossed off is 3, which is prime, and cross off all multiples of 3, etc. Repeating this process, we obtain a list of the primes up to n. Formally, the algorithm is as follows:

Algorithm 1.2.3 (Prime Sieve)**.** Given a positive integer n, this algorithm computes a list of the primes up to n.

1. [Initialize] Let $X = [3, 5, \ldots]$ be the list of all odd integers between 3 and n. Let $P = [2]$ be the list of primes found so far.
2. [Finished?] Let p be the first element of X. If $p \geq \sqrt{n}$, append each element of X to P and terminate. Otherwise append p to P.
3. [Cross Off] Set X equal to the sublist of elements in X that are not divisible by p. Go to Step 2.

For example, to list the primes ≤ 40 using the sieve, we proceed as follows. First $P = [2]$ and

$$X = [3, 5, 7, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39].$$

We append 3 to P and cross off all multiples of 3 to obtain the new list

$$X = [5, 7, 11, 13, 17, 19, 23, 25, 29, 31, 35, 37].$$

Next we append 5 to P, obtaining $P = [2, 3, 5]$, and cross off the multiples of 5, to obtain $X = [7, 11, 13, 17, 19, 23, 29, 31, 37]$. Because $7^2 \geq 40$, we append X to P and find that the primes less than 40 are

$$2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37.$$

Proof of Algorithm 1.2.3. The part of the algorithm that is not clear is that when the first element a of X satisfies $a \geq \sqrt{n}$, then each element of X is prime. To see this, suppose m is in X, so $\sqrt{n} \leq m \leq n$ and that m is divisible by no prime that is $\leq \sqrt{n}$. Write $m = \prod p_i^{e_i}$ with the p_i distinct primes ordered so that $p_1 < p_2 < \ldots$. If $p_i > \sqrt{n}$ for each i and there is more than one p_i, then $m > n$, a contradiction. Thus some p_i is less than $\sqrt{n}$, which also contradicts our assumptions on m. □

1.2.3 The Largest Known Prime

Though Theorem 1.2.1 implies that there are infinitely many primes, it still makes sense to ask the question "What is the largest *known* prime?"

A *Mersenne prime* is a prime of the form $2^q - 1$. According to [Cal] the largest known prime as of March 2007 is the 44th known Mersenne prime

$$p = 2^{32582657} - 1,$$

which has 9,808,358 decimal digits[1]. This would take over 2000 pages to print, assuming a page contains 60 lines with 80 characters per line. The Electronic Frontier Foundation has offered a $100,000 prize to the first person who finds a 10,000,000 digit prime.

Euclid's theorem implies that there definitely are infinitely many primes bigger than p. Deciding whether or not a number is prime is interesting, as a theoretical problem, and as a problem with applications to cryptography, as we will see in Section 2.4 and Chapter 3.

SAGE Example 1.2.4. We can compute the decimal expansion of p in Sage, although watch out as this is a serious computation that may take around a minute on your computer. Also, do not print out p or s below, because both would take a very long time to scroll by.

```
sage: p = 2^32582657 - 1
sage: p.ndigits()
9808358
```

Next we convert p to a decimal string and look at some of the digits.

```
sage: s = p.str(10) # this takes a long time
sage: len(s)        # s is a very long string  (long time)
9808358
sage: s[:20]        # the first 20 digits of p (long time)
'12457502601536945540'
sage: s[-20:]       # the last 20 digits       (long time)
'11752880154053967871'
```

1.2.4 Primes of the Form $ax + b$

Next we turn to primes of the form $ax+b$, where a and b are fixed integers with $a > 1$ and x varies over the natural numbers $\mathbf{N}$. We assume that $\gcd(a, b) = 1$, because otherwise there is no hope that $ax + b$ is prime infinitely often. For example, $2x + 2 = 2(x + 1)$ is only prime if $x = 0$, and is not prime for any $x \in \mathbf{N}$.

Proposition 1.2.5. *There are infinitely many primes of the form* $4x - 1$.

Why might this be true? We list numbers of the form $4x-1$ and underline those that are prime.

$$\underline{3},\ \underline{7},\ \underline{11},\ 15,\ \underline{19},\ \underline{23},\ 27,\ \underline{31},\ 35,\ 39,\ \underline{43},\ \underline{47},\ \ldots$$

[1] The 45th known Mersenne prime may have been found on August 23, 2008 as this book goes to press.

Not only is it plausible that underlined numbers will continue to appear indefinitely, it is something we can easily prove.

Proof. Suppose $p_1, p_2, \ldots, p_n$ are distinct primes of the form $4x-1$. Consider the number

$$N = 4p_1p_2\cdots p_n - 1.$$

Then $p_i \nmid N$ for any i. Moreover, not every prime $p \mid N$ is of the form $4x+1$; if they all were, then N would be of the form $4x+1$. Since N is odd, each prime divisor p_i is odd so there is a $p \mid N$ that is of the form $4x-1$. Since $p \neq p_i$ for any i, we have found a new prime of the form $4x-1$. We can repeat this process indefinitely, so the set of primes of the form $4x-1$ cannot be finite. □

Note that this proof does not work if $4x-1$ is replaced by $4x+1$, since a product of primes of the form $4x-1$ can be of the form $4x+1$.

Example 1.2.6. Set $p_1 = 3$, $p_2 = 7$. Then

$$N = 4 \cdot 3 \cdot 7 - 1 = \underline{83}$$

is a prime of the form $4x-1$. Next

$$N = 4 \cdot 3 \cdot 7 \cdot 83 - 1 = \underline{6971},$$

which is again a prime of the form $4x-1$. Again,

$$N = 4 \cdot 3 \cdot 7 \cdot 83 \cdot 6971 - 1 = 48601811 = 61 \cdot \underline{796751}.$$

This time 61 is a prime, but it is of the form $4x+1 = 4 \cdot 15 + 1$. However, 796751 is prime and $796751 = 4 \cdot 199188 - 1$. We are unstoppable.

$$N = 4 \cdot 3 \cdot 7 \cdot 83 \cdot 6971 \cdot 796751 - 1 = \underline{5591} \cdot 6926049421.$$

This time the small prime, 5591, is of the form $4x-1$ and the large one is of the form $4x+1$.

Theorem 1.2.7 (Dirichlet)**.** *Let a and b be integers with* $\gcd(a,b) = 1$. *Then there are infinitely many primes of the form $ax+b$.*

Proofs of this theorem typically use tools from advanced number theory, and are beyond the scope of this book (see e.g., [FT93, §VIII.4]).

1.2.5 How Many Primes are There?

We saw in Section 1.2.1 that there are infinitely many primes. In order to get a sense of just how many primes there are, we consider a few warm-up questions. Then we consider some numerical evidence and state the prime number theorem, which gives an asymptotic answer to our question, and connect this theorem with a form of the famous Riemann Hypothesis. Our discussion of counting primes in this section is very cursory; for more details, read Crandall and Pomerance's excellent book [CP01, §1.1.5].

The following vague discussion is meant to motivate a precise way to measure the number (or percentage) of primes. What percentage of natural numbers are even? Answer: Half of them. What percentage of natural numbers are of the form $4x-1$? Answer: One fourth of them. What percentage of natural numbers are perfect squares? Answer: Zero percent of all natural numbers, in the sense that the limit of the proportion of perfect squares to all natural numbers converges to 0. More precisely,

$$\lim_{x\to\infty} \frac{\#\{n \in \mathbf{N} : n \leq x \text{ and } n \text{ is a perfect square}\}}{x} = 0,$$

since the numerator is roughly $\sqrt{x}$ and $\lim_{x\to\infty} \frac{\sqrt{x}}{x} = 0$. Likewise, it is an easy consequence of Theorem 1.2.10 that zero percent of all natural numbers are prime (see Exercise 1.4).

We are thus led to ask another question: How many positive integers $\leq x$ are perfect squares? Answer: Roughly $\sqrt{x}$. In the context of primes, we ask,

Question 1.2.8. How many natural numbers $\leq x$ are prime?

Let

$$\pi(x) = \#\{p \in \mathbf{N} : p \leq x \text{ is a prime}\}.$$

For example,

$$\pi(6) = \#\{2, 3, 5\} = 3.$$

Some values of $\pi(x)$ are given in Table 1.1, and Figures 1.1 and 1.2 contain graphs of $\pi(x)$. These graphs look like straight lines, which maybe bend down slightly.

SAGE Example 1.2.9. To compute $\pi(x)$ in Sage use the `prime_pi(x)` command:

```
sage: prime_pi(6)
3
sage: prime_pi(100)
25
sage: prime_pi(3000000)
216816
```

We can also draw a plot of $\pi(x)$ using the `plot` command:

```
sage: plot(prime_pi, 1,1000, rgbcolor=(0,0,1))
```

Gauss was an inveterate computer: he wrote in an 1849 letter that there are $216,745$ primes less than $3,000,000$ (this is wrong but close; the correct count is $216,816$).

TABLE 1.1. Values of $\pi(x)$

x	100	200	300	400	500	600	700	800	900	1000
$\pi(x)$	25	46	62	78	95	109	125	139	154	168

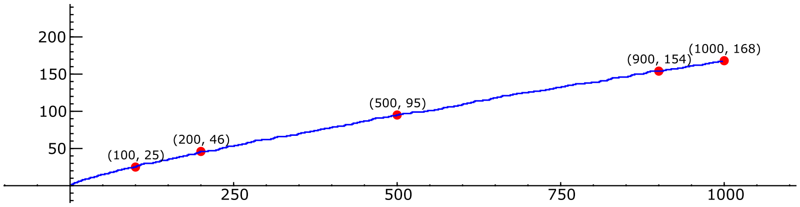

FIGURE 1.1. Graph of $\pi(x)$ for $x < 1000$

Gauss conjectured the following asymptotic formula for $\pi(x)$, which was later proved independently by Hadamard and Vallée Poussin in 1896 (but will not be proved in this book).

Theorem 1.2.10 (Prime Number Theorem)**.** *The function $\pi(x)$ is asymptotic to $x/\log(x)$, in the sense that*

$$\lim_{x\to\infty} \frac{\pi(x)}{x/\log(x)} = 1.$$

We do nothing more here than motivate this deep theorem with a few further observations. The theorem implies that

$$\lim_{x\to\infty} \frac{\pi(x)}{x} = \lim_{x\to\infty} \frac{1}{\log(x)} = 0,$$

so for any a,

$$\lim_{x\to\infty} \frac{\pi(x)}{x/(\log(x)-a)} = \lim_{x\to\infty} \frac{\pi(x)}{x/\log(x)} - \frac{a\pi(x)}{x} = 1.$$

Thus $x/(\log(x)-a)$ is also asymptotic to $\pi(x)$ for any a. See [CP01, §1.1.5] for a discussion of why $a = 1$ is the best choice. Table 1.2 compares $\pi(x)$ and $x/(\log(x)-1)$ for several $x < 10000$.

The record for counting primes is

$$\pi(10^{23}) = 1925320391606803968923.$$

Note that such computations are very difficult to get exactly right, so the above might be slightly wrong.

For the reader familiar with complex analysis, we mention a connection between $\pi(x)$ and the Riemann Hypothesis. The Riemann zeta function $\zeta(s)$ is a complex analytic function on $\mathbf{C} \setminus \{1\}$ that extends the function

TABLE 1.2. Comparison of $\pi(x)$ and $x/(\log(x) - 1)$

x	$\pi(x)$	$x/(\log(x) - 1)$ (approx)
1000	168	169.2690290604408165186256278
2000	303	302.9888734545463878029800994

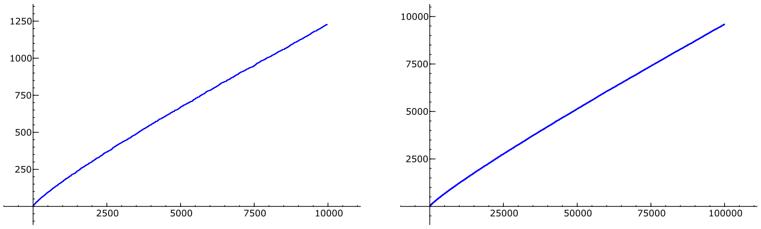

FIGURE 1.2. Graphs of $\pi(x)$ for $x < 10000$ and $x < 100000$

defined on a right half plane by $\sum_{n=1}^{\infty} n^{-s}$. The Riemann Hypothesis is the conjecture that the zeros in $\mathbf{C}$ of $\zeta(s)$ with positive real part lie on the line $\mathrm{Re}(s) = 1/2$. This conjecture is one of the Clay Math Institute million dollar millennium prize problems [Cla].

According to [CP01, §1.4.1], the Riemann Hypothesis is equivalent to the conjecture that

$$\mathrm{Li}(x) = \int_2^x \frac{1}{\log(t)} dt$$

is a "good" approximation to $\pi(x)$, in the following precise sense.

Conjecture 1.2.11 (Equivalent to the Riemann Hypothesis)**.**
For all $x \geq 2.01$,

$$|\pi(x) - \mathrm{Li}(x)| \leq \sqrt{x}\log(x).$$

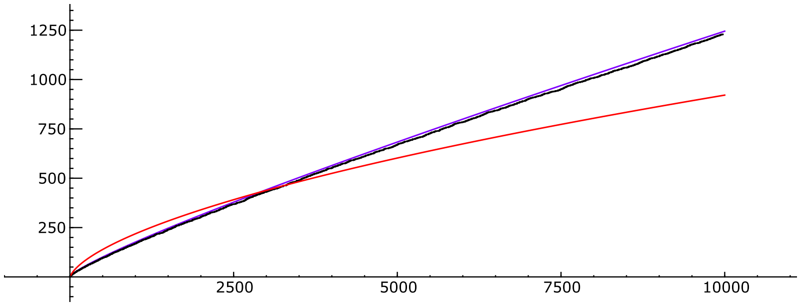
If $x = 2$, then $\pi(2) = 1$ and $\mathrm{Li}(2) = 0$, but $\sqrt{2}\log(2) = 0.9802\ldots$, so the inequality is not true for $x \geq 2$, but 2.01 is big enough. We will do nothing more to explain this conjecture, and settle for one numerical example.

Example 1.2.12. Let $x = 4 \cdot 10^{22}$. Then

$$\begin{aligned}
\pi(x) &= 783964159847056303858, \\
\mathrm{Li}(x) &= 783964159852157952242.7155276025801473\ldots, \\
|\pi(x) - \mathrm{Li}(x)| &= 5101648384.71552760258014\ldots, \\
\sqrt{x}\log(x) &= 10408633281397.77913344605\ldots, \\
x/(\log(x) - 1) &= 783650443647303761503.5237113087392967\ldots.
\end{aligned}$$

SAGE Example 1.2.13. We use Sage to graph $\pi(x)$, $\mathrm{Li}(x)$, and $\sqrt{x}\log(x)$.

```
sage: P = plot(Li, 2,10000, rgbcolor='purple')
sage: Q = plot(prime_pi, 2,10000, rgbcolor='black')
sage: R = plot(sqrt(x)*log(x),2,10000,rgbcolor='red')
sage: show(P+Q+R,xmin=0, figsize=[8,3])
```



The topmost line is $\mathrm{Li}(x)$, the next line is $\pi(x)$, and the bottom line is $\sqrt{x}\log(x)$.

For more on the prime number theorem and the Riemann hypothesis see [Zag75] and [MS08].

1.3 Exercises

1.1 Compute the greatest common divisor $\gcd(455, 1235)$ by hand.

1.2 Use the prime enumeration sieve to make a list of all primes up to 100.

1.3 Prove that there are infinitely many primes of the form $6x - 1$.

1.4 Use Theorem 1.2.10 to deduce that $\displaystyle\lim_{x\to\infty} \frac{\pi(x)}{x} = 0$.

1.5 Let $\psi(x)$ be the number of primes of the form $4k-1$ that are $\leq x$. Use a computer to make a conjectural guess about $\lim_{x\to\infty} \psi(x)/\pi(x)$.

1.6 So far 44 Mersenne primes $2^p - 1$ have been discovered. Give a guess, backed up by an argument, about when the next Mersenne prime might be discovered (you will have to do some online research).

1.7 (a) Let $y = 10000$. Compute $\pi(y) = \#\{\text{primes } p \leq y\}$.

(b) The prime number theorem implies $\pi(x)$ is asymptotic to $\frac{x}{\log(x)}$. How close is $\pi(y)$ to $y/\log(y)$, where y is as in (a)?

1.8 Let a, b, c, n be integers. Prove that

(a) if $a \mid n$ and $b \mid n$ with $\gcd(a, b) = 1$, then $ab \mid n$.

(b) if $a \mid bc$ and $\gcd(a, b) = 1$, then $a \mid c$.

1.9 Let a, b, c, d, and m be integers. Prove that

(a) if $a \mid b$ and $b \mid c$ then $a \mid c$.

(b) if $a \mid b$ and $c \mid d$ then $ac \mid bd$.

(c) if $m \neq 0$, then $a \mid b$ if and only if $ma \mid mb$.

(d) if $d \mid a$ and $a \neq 0$, then $|d| \leq |a|$.

1.10 In each of the following, apply the division algorithm to find q and r such that $a = bq + r$ and $0 \leq r < |b|$:

$$a = 300, b = 17,\ \ a = 729, b = 31,\ \ a = 300, b = -17,\ \ a = 389, b = 4.$$

1.11 (a) (Do this part by hand.) Compute the greatest common divisor of 323 and 437 using the algorithm described in class that involves quotients and remainders (i.e., do not just factor a and b).

(b) Compute by any means the greatest common divisor of

$$31415926535897932384626433 8$$

and

$$2718281828459045235360287 47.$$

1.12 (a) Suppose a, b and n are positive integers. Prove that if $a^n \mid b^n$, then $a \mid b$.

(b) Suppose p is a prime and a and k are positive integers. Prove that if $p \mid a^k$, then $p^k \mid a^k$.

1.13 (a) Prove that if a positive integer n is a perfect square, then n cannot be written in the form $4k + 3$ for k an integer. (Hint: Compute the remainder upon division by 4 of each of $(4m)^2$, $(4m + 1)^2$, $(4m + 2)^2$, and $(4m + 3)^2$.)

(b) Prove that no integer in the sequence

$$11, 111, 1111, 11111, 111111, \ldots$$

is a perfect square. (Hint: $111 \cdots 111 = 111 \cdots 108 + 3 = 4k + 3$.)

1.14 Prove that a positive integer n is prime if and only if n is not divisible by any prime p with $1 < p \leq \sqrt{n}$.

2
The Ring of Integers Modulo n

A startling fact about numbers is that it takes less than a second to decide with near certainty whether or not any given 1,000 digit number n is a prime, *without actually factoring* n. The algorithm for this involves doing some arithmetic with n that works differently depending on whether n is prime or composite. In particular, we do arithmetic with the set (in fact, "ring") of integers $\{0, 1, \ldots, n-1\}$ using an innovative rule for addition and multiplication, where the sum and product of two elements of that set is again in that set.

Another surprising fact is that one can almost instantly compute the last 1,000 digits of a massive multi-billion digit number like $n = 1234^{1234567890}$ without explicitly writing down all the digits of n. Again, this calculation involves arithmetic with the ring $\{0, 1, \ldots, n-1\}$.

This chapter is about the ring $\mathbf{Z}/n\mathbf{Z}$ of integers modulo n, the beautiful structure this ring has, and how to apply it to the above mentioned problems, among others. It is foundational for the rest of this book. In Section 2.1, we discuss when linear equations modulo n have a solution, then introduce the Euler φ function and prove Euler's Theorem and Wilson's theorem. In Section 2.2, we prove the Chinese Remainer Theorem, which addresses simultaneous solubility of several linear equations modulo coprime moduli. With these theoretical foundations in place, in Section 2.3, we introduce algorithms for doing powerful computations modulo n, including computing large powers quickly, and solving linear equations. We finish in Section 2.4 with a discussion of recognizing prime numbers using arithmetic modulo n.

2.1 Congruences Modulo n

Definition 2.1.1 (Group)**.** A *group* is a set G equipped with a binary operation $G \times G \to G$ (denoted by multiplication below) and an identity element $1 \in G$ such that:

1. For all $a, b, c \in G$, we have $(ab)c = a(bc)$.
2. For each $a \in G$, we have $1a = a1 = a$, and there exists $b \in G$ such that $ab = 1$.

Definition 2.1.2 (Abelian Group)**.** An *abelian group* is a group G such that $ab = ba$ for every $a, b \in G$.

Definition 2.1.3 (Ring)**.** A *ring* R is a set equipped with binary operations $+$ and $\times$ and elements $0, 1 \in R$ such that R is an abelian group under $+$, and for all $a, b, c \in R$ we have

- $1a = a1 = a$
- $(ab)c = a(bc)$
- $a(b + c) = ab + ac$.

If, in addition, $ab = ba$ for all $a, b \in R$, then we call R a *commutative ring.*

In this section, we define the ring $\mathbf{Z}/n\mathbf{Z}$ of integers modulo n, introduce the Euler φ-function, and relate it to the multiplicative order of certain elements of $\mathbf{Z}/n\mathbf{Z}$.

If $a, b \in \mathbf{Z}$ and $n \in \mathbf{N}$, we say that a is *congruent to b modulo n* if $n \mid a - b$, and write $a \equiv b \pmod{n}$. Let $n\mathbf{Z} = (n)$ be the subset of $\mathbf{Z}$ consisting of all multiples of n (this is called the "ideal of $\mathbf{Z}$ generated by n").

Definition 2.1.4 (Integers Modulo n)**.** The ring $\mathbf{Z}/n\mathbf{Z}$ of *integers modulo n* is the set of equivalence classes of integers modulo n. It is equipped with its natural ring structure:

$$(a + n\mathbf{Z}) + (b + n\mathbf{Z}) = (a + b) + n\mathbf{Z}$$

$$(a + n\mathbf{Z}) \cdot (b + n\mathbf{Z}) = (a \cdot b) + n\mathbf{Z}.$$

Example 2.1.5. For example,

$$\mathbf{Z}/3\mathbf{Z} = \{\{\ldots, -3, 0, 3, \ldots\}, \{\ldots, -2, 1, 4, \ldots\}, \{\ldots, -1, 2, 5, \ldots\}\}$$

SAGE Example 2.1.6. In Sage, we list the elements of $\mathbf{Z}/n\mathbf{Z}$ as follows:

```
sage: R = Integers(3)
sage: list(R)
[0, 1, 2]
```

We use the notation $\mathbf{Z}/n\mathbf{Z}$ because $\mathbf{Z}/n\mathbf{Z}$ is the quotient of the ring $\mathbf{Z}$ by the "ideal" $n\mathbf{Z}$ of multiples of n. Because $\mathbf{Z}/n\mathbf{Z}$ is the quotient of a ring by an ideal, the ring structure on $\mathbf{Z}$ induces a ring structure on $\mathbf{Z}/n\mathbf{Z}$. We often let a or $a \pmod{n}$ denote the equivalence class $a + n\mathbf{Z}$ of a.

Definition 2.1.7 (Field)**.** A *field* K is a ring such that for every nonzero element $a \in K$ there is an element $b \in K$ such that $ab = 1$.

For example, if p is a prime, then $\mathbf{Z}/p\mathbf{Z}$ is a field (see Exercise 2.12).

Definition 2.1.8 (Reduction Map and Lift)**.** We call the natural reduction map $\mathbf{Z} \to \mathbf{Z}/n\mathbf{Z}$, which sends a to $a + n\mathbf{Z}$, *reduction modulo n*. We also say that a is a *lift* of $a + n\mathbf{Z}$. Thus, e.g., 7 is a lift of 1 mod 3, since $7 + 3\mathbf{Z} = 1 + 3\mathbf{Z}$.

We can use that arithmetic in $\mathbf{Z}/n\mathbf{Z}$ is well defined is to derive tests for divisibility by n (see Exercise 2.8).

Proposition 2.1.9. *A number $n \in \mathbf{Z}$ is divisible by* 3 *if and only if the sum of the digits of n is divisible by* 3*.*

Proof. Write

$$n = a + 10b + 100c + \cdots ,$$

where the digits of n are a, b, c, etc. Since $10 \equiv 1 \pmod{3}$,

$$n = a + 10b + 100c + \cdots \equiv a + b + c + \cdots \pmod{3},$$

from which the proposition follows. □

2.1.1 Linear Equations Modulo n

In this section, we are concerned with how to decide whether or not a linear equation of the form $ax \equiv b \pmod{n}$ has a solution modulo n. Algorithms for *computing* solutions to $ax \equiv b \pmod{n}$ are the topic of Section 2.3.

First, we prove a proposition that gives a criterion under which one can cancel a quantity from both sides of a congruence.

Proposition 2.1.10 (Cancellation)**.** *If* $\gcd(c, n) = 1$ *and*

$$ac \equiv bc \pmod{n},$$

then $a \equiv b \pmod{n}$*.*

Proof. By definition

$$n \mid ac - bc = (a - b)c.$$

Since $\gcd(n, c) = 1$, it follows from Theorem 1.1.6 that $n \mid a - b$, so

$$a \equiv b \pmod{n},$$

as claimed. □

When a has a multiplicative inverse a' in $\mathbf{Z}/n\mathbf{Z}$ (i.e., $aa' \equiv 1 \pmod{n}$) then the equation $ax \equiv b \pmod{n}$ has a unique solution $x \equiv a'b \pmod{n}$. Thus, it is of interest to determine the units in $\mathbf{Z}/n\mathbf{Z}$, i.e., the elements which have a multiplicative inverse.

We will use complete sets of residues to prove that the units in $\mathbf{Z}/n\mathbf{Z}$ are exactly the $a \in \mathbf{Z}/n\mathbf{Z}$ such that $\gcd(\tilde{a}, n) = 1$ for any lift $\tilde{a}$ of a to $\mathbf{Z}$ (it doesn't matter which lift).

Definition 2.1.11 (Complete Set of Residues)**.** We call a subset $R \subset \mathbf{Z}$ of size n whose reductions modulo n are pairwise distinct a *complete set of residues* modulo n. In other words, a complete set of residues is a choice of representative for each equivalence class in $\mathbf{Z}/n\mathbf{Z}$.

For example,

$$R = \{0, 1, 2, \ldots, n-1\}$$

is a complete set of residues modulo n. When $n = 5$, $R = \{0, 1, -1, 2, -2\}$ is a complete set of residues.

Lemma 2.1.12. *If R is a complete set of residues modulo n and $a \in \mathbf{Z}$ with $\gcd(a, n) = 1$, then $aR = \{ax : x \in R\}$ is also a complete set of residues modulo n.*

Proof. If $ax \equiv ax' \pmod{n}$ with $x, x' \in R$, then Proposition 2.1.10 implies that $x \equiv x' \pmod{n}$. Because R is a complete set of residues, this implies that $x = x'$. Thus the elements of aR have distinct reductions modulo n. It follows, since $\#aR = n$, that aR is a complete set of residues modulo n. □

Proposition 2.1.13 (Units)**.** *If $\gcd(a, n) = 1$, then the equation $ax \equiv b \pmod{n}$ has a solution, and that solution is unique modulo n.*

Proof. Let R be a complete set of residues modulo n, so there is a unique element of R that is congruent to b modulo n. By Lemma 2.1.12, aR is also a complete set of residues modulo n, so there is a unique element $ax \in aR$ that is congruent to b modulo n, and we have $ax \equiv b \pmod{n}$. □

Algebraically, this proposition asserts that if $\gcd(a, n) = 1$, then the map $\mathbf{Z}/n\mathbf{Z} \to \mathbf{Z}/n\mathbf{Z}$ given by left multiplication by a is a bijection.

Example 2.1.14. Consider the equation $2x \equiv 3 \pmod{7}$, and the complete set $R = \{0, 1, 2, 3, 4, 5, 6\}$ of coset representatives. We have

$$2R = \{0, 2, 4, 6, 8 \equiv 1, 10 \equiv 3, 12 \equiv 5\},$$

so $2 \cdot 5 \equiv 3 \pmod{7}$.

When $\gcd(a, n) \neq 1$, then the equation $ax \equiv b \pmod{n}$ may or may not have a solution. For example, $2x \equiv 1 \pmod{4}$ has no solution, but $2x \equiv 2 \pmod{4}$ does, and in fact it has more than one mod 4 ($x = 1$ and $x = 3$). Generalizing Proposition 2.1.13, we obtain the following more general criterion for solvability.

Proposition 2.1.15 (Solvability)**.** *The equation* $ax \equiv b \pmod{n}$ *has a solution if and only if* $\gcd(a, n)$ *divides* b*.*

Proof. Let $g = \gcd(a, n)$. If there is a solution x to the equation $ax \equiv b \pmod{n}$, then $n \mid (ax - b)$. Since $g \mid n$ and $g \mid a$, it follows that $g \mid b$.

Conversely, suppose that $g \mid b$. Then $n \mid (ax - b)$ if and only if

$$\frac{n}{g} \mid \left(\frac{a}{g}x - \frac{b}{g}\right).$$

Thus $ax \equiv b \pmod{n}$ has a solution if and only if $\frac{a}{g}x \equiv \frac{b}{g} \pmod{\frac{n}{g}}$ has a solution. Since $\gcd(a/g, n/g) = 1$, Proposition 2.1.13 implies this latter equation does have a solution. □

In Chapter 4, we will study quadratic reciprocity, which gives a nice criterion for whether or not a quadratic equation modulo n has a solution.

2.1.2 Euler's Theorem

Let $(\mathbf{Z}/n\mathbf{Z})^*$ denote the set of elements $[x] \in \mathbf{Z}/n\mathbf{Z}$ such that $\gcd(x, n) = 1$.

The set $(\mathbf{Z}/n\mathbf{Z})^*$ is a group, called the *group of units of the ring* $\mathbf{Z}/n\mathbf{Z}$; it will be of great interest to us. Each element of this group has an order, and Lagrange's theorem from group theory implies that each element of $(\mathbf{Z}/n\mathbf{Z})^*$ has an order that divides the order of $(\mathbf{Z}/n\mathbf{Z})^*$. In elementary number theory, this fact goes by the monicker "Fermat's Little Theorem" when n is prime and "Euler's Theorem" in general, and we reprove it from basic principles in this section.

Definition 2.1.16 (Order of an Element)**.** Let $n \in \mathbf{N}$ and $x \in \mathbf{Z}$ and suppose that $\gcd(x, n) = 1$. The *order* of x modulo n is the smallest $m \in \mathbf{N}$ such that

$$x^m \equiv 1 \pmod{n}.$$

To show that the definition makes sense, we verify that such an m exists. Consider $x, x^2, x^3, \ldots$ modulo n. There are only finitely many residue classes modulo n, so we must eventually find two integers i, j with $i < j$ such that

$$x^j \equiv x^i \pmod{n}.$$

Since $\gcd(x, n) = 1$, Proposition 2.1.10 implies that we can cancel x's and conclude that

$$x^{j-i} \equiv 1 \pmod{n}.$$

SAGE Example 2.1.17. Use `x.multiplicative_order()` to compute the order of an element of $\mathbf{Z}/n\mathbf{Z}$ in Sage.

```
sage: R = Integers(10)
sage: a = R(3)                 # create an element of Z/10Z
sage: a.multiplicative_order()
4
```

Notice that the powers of a are periodic with period 4, i.e., there are four powers and they repeat:

```
sage: [a^i for i in range(15)]
[1, 3, 9, 7, 1, 3, 9, 7, 1, 3, 9, 7, 1, 3, 9]
```

The command `range(n)` we use above returns the list of integers between 0 and $n-1$, inclusive.

Definition 2.1.18 (Euler's φ-function)**.** For $n \in \mathbf{N}$, let

$$\varphi(n) = \#\{a \in \mathbf{N} : a \leq n \text{ and } \gcd(a,n) = 1\}.$$

For example,

$$\begin{aligned}\varphi(1) &= \#\{1\} = 1,\\ \varphi(2) &= \#\{1\} = 1,\\ \varphi(5) &= \#\{1,2,3,4\} = 4,\\ \varphi(12) &= \#\{1,5,7,11\} = 4.\end{aligned}$$

Also, if p is any prime number then

$$\varphi(p) = \#\{1,2,\ldots,p-1\} = p-1.$$

In Section 2.2.1, we prove that if $\gcd(m,r) = 1$, then $\varphi(mr) = \varphi(m)\varphi(r)$. This will yield an easy way to compute $\varphi(n)$ in terms of the prime factorization of n.

SAGE Example 2.1.19. Use the `euler_phi(n)` command to compute $\varphi(n)$ in Sage:

```
sage: euler_phi(2007)
1332
```

Theorem 2.1.20 (Euler's Theorem)**.** *If* $\gcd(x,n) = 1$*, then*

$$x^{\varphi(n)} \equiv 1 \pmod{n}.$$

Proof. As mentioned above, Euler's Theorem has the following group-theoretic interpretation. The set of units in $\mathbf{Z}/n\mathbf{Z}$ is a group

$$(\mathbf{Z}/n\mathbf{Z})^* = \{a \in \mathbf{Z}/n\mathbf{Z} : \gcd(a,n) = 1\}$$

that has order $\varphi(n)$. The theorem then asserts that the order of an element of $(\mathbf{Z}/n\mathbf{Z})^*$ divides the order $\varphi(n)$ of $(\mathbf{Z}/n\mathbf{Z})^*$. This is a special case of the more general fact (Lagrange's Theorem) that if G is a finite group and $g \in G$, then the order of g divides the cardinality of G.

We now give an elementary proof of the theorem. Let

$$P = \{a : 1 \leq a \leq n \text{ and } \gcd(a,n) = 1\}.$$

In the same way that we proved Lemma 2.1.12, we see that the reductions modulo n of the elements of xP are the same as the reductions of the elements of P. Thus

$$\prod_{a \in P} (xa) \equiv \prod_{a \in P} a \pmod{n},$$

since the products are over the same numbers modulo n. Now cancel the a's on both sides to get

$$x^{\#P} \equiv 1 \pmod{n},$$

as claimed. □

SAGE Example 2.1.21. We illustrate Euler's Theorem using Sage. The `Mod(x,n)` command returns the equivalence class of x in $\mathbf{Z}/n\mathbf{Z}$.

```
sage: n = 20
sage: k = euler_phi(n); k
8
sage: [Mod(x,n)^k for x in range(n) if gcd(x,n) == 1]
[1, 1, 1, 1, 1, 1, 1, 1]
```

2.1.3 Wilson's Theorem

The following characterization of prime numbers, from the 1770s, is called "Wilson's Theorem," though it was first proved by Lagrange.

Proposition 2.1.22 (Wilson's Theorem). *An integer $p > 1$ is prime if and only if $(p-1)! \equiv -1 \pmod{p}$.*

For example, if $p = 3$, then $(p-1)! = 2 \equiv -1 \pmod{3}$. If $p = 17$, then

$$(p-1)! = 20922789888000 \equiv -1 \pmod{17}.$$

But if $p = 15$, then

$$(p-1)! = 87178291200 \equiv 0 \pmod{15},$$

so 15 is composite. Thus Wilson's theorem could be viewed as a primality test, though, from a computational point of view, it is probably one of the world's *least efficient* primality tests since computing $(n-1)!$ takes so many steps.

Proof. The statement is clear when $p = 2$, so henceforth we assume that $p > 2$. We first assume that p is prime and prove that $(p-1)! \equiv -1 \pmod{p}$. If $a \in \{1, 2, \ldots, p-1\}$, then the equation

$$ax \equiv 1 \pmod{p}$$

has a unique solution $a' \in \{1, 2, \ldots, p-1\}$. If $a = a'$, then $a^2 \equiv 1 \pmod{p}$, so $p \mid a^2 - 1 = (a-1)(a+1)$, so $p \mid (a-1)$ or $p \mid (a+1)$, so $a \in \{1, p-1\}$. We can thus pair off the elements of $\{2, 3, \ldots, p-2\}$, each with their inverse. Thus

$$2 \cdot 3 \cdot \cdots \cdot (p-2) \equiv 1 \pmod{p}.$$

Multiplying both sides by $p-1$ proves that $(p-1)! \equiv -1 \pmod{p}$.

Next, we assume that $(p-1)! \equiv -1 \pmod{p}$ and prove that p must be prime. Suppose not, so that $p \geq 4$ is a composite number. Let ℓ be a prime divisor of p. Then $\ell < p$, so $\ell \mid (p-1)!$. Also, by assumption,

$$\ell \mid p \mid ((p-1)! + 1).$$

This is a contradiction, because a prime can not divide a number a and also divide $a+1$, since it would then have to divide $(a+1) - a = 1$. □

Example 2.1.23. We illustrate the key step in the above proof in the case $p = 17$. We have

$$2 \cdot 3 \cdots 15 = (2 \cdot 9) \cdot (3 \cdot 6) \cdot (4 \cdot 13) \cdot (5 \cdot 7) \cdot (8 \cdot 15) \cdot (10 \cdot 12) \cdot (14 \cdot 11) \equiv 1 \pmod{17},$$

where we have paired up the numbers a, b for which $ab \equiv 1 \pmod{17}$.

SAGE Example 2.1.24. We use Sage to create a table of triples; the first column contains n, the second column contains $(n-1)!$ modulo n, and the third contains -1 modulo n. Notice that the first columns contains a prime precisely when the second and third columns are equal. (The ... notation indicates a multi-line command in Sage; you should not type the dots in explicitly.)

```
sage: for n in range(1,10):
...     print n, factorial(n-1) % n, -1 % n
1 0 0
2 1 1
3 2 2
4 2 3
5 4 4
6 0 5
7 6 6
8 0 7
9 0 8
```

2.2 The Chinese Remainder Theorem

In this section, we prove the Chinese Remainder Theorem, which gives conditions under which a system of linear equations is guaranteed to have a solution. In the 4th century a Chinese mathematician asked the following:

Question 2.2.1. There is a quantity whose number is unknown. Repeatedly divided by 3, the remainder is 2; by 5 the remainder is 3; and by 7 the remainder is 2. What is the quantity?

In modern notation, Question 2.2.1 asks us to find a positive integer solution to the following system of three equations:

$$\begin{aligned} x &\equiv 2 \pmod{3}\\ x &\equiv 3 \pmod{5}\\ x &\equiv 2 \pmod{7} \end{aligned}$$

The Chinese Remainder Theorem asserts that a solution exists, and the proof gives a method to find one. (See Section 2.3 for the necessary algorithms.)

Theorem 2.2.2 (Chinese Remainder Theorem)**.** *Let* $a, b \in \mathbf{Z}$ *and* $n, m \in \mathbf{N}$ *such that* $\gcd(n, m) = 1$*. Then there exists* $x \in \mathbf{Z}$ *such that*

$$\begin{aligned} x &\equiv a \pmod{m},\\ x &\equiv b \pmod{n}. \end{aligned}$$

Moreover x *is unique modulo* mn*.*

Proof. If we can solve for t in the equation

$$a + tm \equiv b \pmod{n},$$

then $x = a + tm$ will satisfy both congruences. To see that we can solve, subtract a from both sides and use Proposition 2.1.13 together with our assumption that $\gcd(n, m) = 1$ to see that there is a solution.

For uniqueness, suppose that x and y solve both congruences. Then $z = x - y$ satisfies $z \equiv 0 \pmod{m}$ and $z \equiv 0 \pmod{n}$, so $m \mid z$ and $n \mid z$. Since $\gcd(n, m) = 1$, it follows that $nm \mid z$, so $x \equiv y \pmod{nm}$. □

Algorithm 2.2.3 (Chinese Remainder Theorem)**.** Given coprime integers m and n and integers a and b, this algorithm find an integer x such that $x \equiv a \pmod{m}$ and $x \equiv b \pmod{n}$.

1. [Extended GCD] Use Algorithm 2.3.7 below to find integers c, d such that $cm + dn = 1$.
2. [Answer] Output $x = a + (b - a)cm$ and terminate.

Proof. Since $c \in \mathbf{Z}$, we have $x \equiv a \pmod{m}$, and using that $cm + dn = 1$, we have $a + (b - a)cm \equiv a + (b - a) \equiv b \pmod{n}$. □

Now we can answer Question 2.2.1. First, we use Theorem 2.2.2 to find a solution to the pair of equations

$$\begin{aligned} x &\equiv 2 \pmod{3},\\ x &\equiv 3 \pmod{5}. \end{aligned}$$

Set $a = 2$, $b = 3$, $m = 3$, $n = 5$. Step 1 is to find a solution to $t \cdot 3 \equiv 3 - 2 \pmod{5}$. A solution is $t = 2$. Then $x = a + tm = 2 + 2 \cdot 3 = 8$. Since any x' with $x' \equiv x \pmod{15}$ is also a solution to those two equations, we can solve all three equations by finding a solution to the pair of equations

$$\begin{aligned} x &\equiv 8 \pmod{15}\\ x &\equiv 2 \pmod{7}. \end{aligned}$$

Again, we find a solution to $t \cdot 15 \equiv 2 - 8 \pmod{7}$. A solution is $t = 1$, so

$$x = a + tm = 8 + 15 = 23.$$

Note that there are other solutions. Any $x' \equiv x \pmod{3 \cdot 5 \cdot 7}$ is also a solution; e.g., $23 + 3 \cdot 5 \cdot 7 = 128$.

SAGE Example 2.2.4. The `CRT(a,b,m,n)` command in Sage computes an integer x such that $x \equiv a \pmod{m}$ and $x \equiv b \pmod{n}$. For example,

```
sage: CRT(2,3, 3, 5)
-7
```

The `CRT_list` command computes a number that reduces to several numbers modulo coprime moduli. We use it to answer Question 2.2.1:

```
sage: CRT_list([2,3,2], [3,5,7])
23
```

2.2.1 Multiplicative Functions

Recall from Definition 2.1.18 that the *Euler φ-function* is

$$\varphi(n) = \#\{a : 1 \leq a \leq n \text{ and } \gcd(a, n) = 1\}.$$

Lemma 2.2.5. *Suppose that $m, n \in \mathbf{N}$ and* $\gcd(m, n) = 1$. *Then the map*

$$\psi : (\mathbf{Z}/mn\mathbf{Z})^* \to (\mathbf{Z}/m\mathbf{Z})^* \times (\mathbf{Z}/n\mathbf{Z})^*. \tag{2.2.1}$$

defined by

$$\psi(c) = (c \textit{ mod } m,\ c \textit{ mod } n)$$

is a bijection.

Proof. We first show that ψ is injective. If $\psi(c) = \psi(c')$, then $m \mid c-c'$ and $n \mid c-c'$, so $nm \mid c-c'$ because $\gcd(n,m) = 1$. Thus $c = c'$ as elements of $(\mathbf{Z}/mn\mathbf{Z})^*$.

Next we show that ψ is surjective, i.e., that every element of $(\mathbf{Z}/m\mathbf{Z})^* \times (\mathbf{Z}/n\mathbf{Z})^*$ is of the form $\psi(c)$ for some c. Given a and b with $\gcd(a,m) = 1$ and $\gcd(b,n) = 1$, Theorem 2.2.2 implies that there exists c with $c \equiv a \pmod{m}$ and $c \equiv b \pmod{n}$. We may assume that $1 \leq c \leq nm$, and since $\gcd(a,m) = 1$ and $\gcd(b,n) = 1$, we must have $\gcd(c,nm) = 1$. Thus $\psi(c) = (a,b)$. □

Definition 2.2.6 (Multiplicative Function)**.** A function $f : \mathbf{N} \to \mathbf{C}$ is *multiplicative* if, whenever $m, n \in \mathbf{N}$ and $\gcd(m,n) = 1$, we have

$$f(mn) = f(m) \cdot f(n).$$

Proposition 2.2.7 (Multiplicativity of φ)**.** *The function φ is multiplicative.*

Proof. The map ψ of Lemma 2.2.5 is a bijection, so the set on the left in (2.2.1) has the same size as the product set on the right in (2.2.1). Thus

$$\varphi(mn) = \varphi(m) \cdot \varphi(n).$$

□

The proposition is helpful in computing $\varphi(n)$, at least if we assume we can compute the factorization of n (see Section 3.4.1 for a connection between factoring n and computing $\varphi(n)$). For example,

$$\varphi(12) = \varphi(2^2) \cdot \varphi(3) = 2 \cdot 2 = 4.$$

Also, for $n \geq 1$, we have

$$\varphi(p^n) = p^n - \frac{p^n}{p} = p^n - p^{n-1} = p^{n-1}(p-1), \tag{2.2.2}$$

since $\varphi(p^n)$ is the number of numbers less than p^n minus the number of those that are divisible by p. Thus, e.g.,

$$\varphi(389 \cdot 11^2) = 388 \cdot (11^2 - 11) = 388 \cdot 110 = 42680.$$

2.3 Quickly Computing Inverses and Huge Powers

This section is about how to solve the equation $ax \equiv 1 \pmod{n}$ when we know it has a solution, and how to efficiently compute $a^m \pmod{n}$. We also discuss a simple probabilistic primality test that relies on our ability to compute $a^m \pmod{n}$ quickly. All three of these algorithms are of fundamental importance to the cryptography algorithms of Chapter 3.

2.3.1 How to Solve $ax \equiv 1 \pmod{n}$

Suppose $a, n \in \mathbf{N}$ with $\gcd(a, n) = 1$. Then by Proposition 2.1.13 the equation $ax \equiv 1 \pmod{n}$ has a unique solution. How can we find it?

Proposition 2.3.1 (Extended Euclidean Representation)**.** *Suppose* $a, b \in \mathbf{Z}$ *and let* $g = \gcd(a, b)$*. Then there exists* $x, y \in \mathbf{Z}$ *such that*

$$ax + by = g.$$

Remark 2.3.2. If $e = cg$ is a multiple of g, then $cax + cby = cg = e$, so $e = (cx)a + (cy)b$ can also be written in terms of a and b.

Proof of Proposition 2.3.1. Let $g = \gcd(a, b)$. Then $\gcd(a/g, b/g) = 1$, so by Proposition 2.1.15, the equation

$$\frac{a}{g} \cdot x \equiv 1 \left(\mathrm{mod}\ \frac{b}{g}\right) \tag{2.3.1}$$

has a solution $x \in \mathbf{Z}$. Multiplying (2.3.1) through by g yields $ax \equiv g \pmod{b}$, so there exists y such that $b \cdot (-y) = ax - g$. Then $ax + by = g$, as required. □

Given a, b and $g = \gcd(a, b)$, our proof of Proposition 2.3.1 gives a way to explicitly find x, y such that $ax + by = g$, assuming one knows an algorithm to solve linear equations modulo n. Since we do not know such an algorithm, we now discuss a way to explicitly find x and y. This algorithm will in fact enable us to solve linear equations modulo n. To solve $ax \equiv 1 \pmod{n}$ when $\gcd(a, n) = 1$, use the Algorithm 2.3.7 to find x and y such that $ax + ny = 1$. Then $ax \equiv 1 \pmod{n}$.

Example 2.3.3. Suppose $a = 5$ and $b = 7$. The steps of Algorithm 1.1.13 to compute $\gcd(5, 7)$ are as follows. Here we underline certain numbers, because it clarifies the subsequent back substitution we will use to find x and y.

$$\begin{aligned}
&\underline{7} = 1 \cdot \underline{5} + \underline{2} && \text{so } \underline{2} = \underline{7} - \underline{5}\\
&\underline{5} = 2 \cdot \underline{2} + \underline{1} && \text{so } \underline{1} = \underline{5} - 2 \cdot \underline{2} = \underline{5} - 2(\underline{7} - \underline{5}) = 3 \cdot \underline{5} - 2 \cdot \underline{7}
\end{aligned}$$

On the right, we have back-substituted in order to write each partial remainder as a linear combination of a and b. In the last step, we obtain $\gcd(a, b)$ as a linear combination of a and b, as desired.

Example 2.3.4. That example was not too complicated, so we try another one. Let $a = 130$ and $b = 61$. We have

$$\begin{aligned}
\underline{130} &= 2 \cdot \underline{61} + \underline{8} & \underline{8} &= \underline{130} - 2 \cdot \underline{61}\\
\underline{61} &= 7 \cdot \underline{8} + \underline{5} & \underline{5} &= -7 \cdot \underline{130} + 15 \cdot \underline{61}\\
\underline{8} &= 1 \cdot \underline{5} + \underline{3} & \underline{3} &= 8 \cdot \underline{130} - 17 \cdot \underline{61}\\
\underline{5} &= 1 \cdot \underline{3} + \underline{2} & \underline{2} &= -15 \cdot \underline{130} + 32 \cdot \underline{61}\\
\underline{3} &= 1 \cdot \underline{2} + \underline{1} & \underline{1} &= 23 \cdot \underline{130} - 49 \cdot \underline{61}
\end{aligned}$$

Thus $x = 23$ and $y = -49$ is a solution to $130x + 61y = 1$.

Example 2.3.5. This example is just like Example 2.3.4 above, except we make the notation on the right more compact.

$$\begin{aligned}
\underline{130} &= 2 \cdot \underline{61} + \underline{8} & \qquad \underline{8} &= (1, -2)\\
\underline{61} &= 7 \cdot \underline{8} + \underline{5} & \underline{5} &= (-7, 15) = (0, 1) - 7(1, -2)\\
\underline{8} &= 1 \cdot \underline{5} + \underline{3} & \underline{3} &= (8, -17) = (1, -2) - (-7, 15)\\
\underline{5} &= 1 \cdot \underline{3} + \underline{2} & \underline{2} &= (-15, 32) = (-7, 15) - (8, -17)\\
\underline{3} &= 1 \cdot \underline{2} + \underline{1} & \underline{1} &= (23, -49) = (8, -17) - (-15, 32)
\end{aligned}$$

Notice at each step that the vector on the right is just the vector from two steps ago minus a multiple of the vector from one step ago, where the multiple is the cofficient of what we divide by.

SAGE Example 2.3.6. The `xgcd(a,b)` command computes the greatest common divisor g of a and b along with x, y such that $ax + by = g$.

```
sage: xgcd(5,7)
(1, -4, 3)
sage: xgcd(130,61)
(1, 23, -49)
```

Algorithm 2.3.7 (Extended Euclidean Algorithm)**.** Suppose a and b are integers and let $g = \gcd(a, b)$. This algorithm finds g, x and y such that $ax + by = g$. We describe only the steps when $a > b \geq 0$, since one can easily reduce to this case.

1. [Initialize] Set $x = 1$, $y = 0$, $r = 0$, $s = 1$.
2. [Finished?] If $b = 0$, set $g = a$ and terminate.
3. [Quotient and Remainder] Use Algorithm 1.1.12 to write $a = qb + c$ with $0 \leq c < b$.
4. [Shift] Set $(a, b, r, s, x, y) = (b, c, x - qr, y - qs, r, s)$ and go to Step 2. (This shift step is nicely illustrated in Example 2.3.5.)

Proof. This algorithm is the same as Algorithm 1.1.13, except that we keep track of extra variables x, y, r, s, so it terminates and when it terminates $d = \gcd(a, b)$. We omit the rest of the inductive proof that the algorithm is correct, and instead refer the reader to [Knu97, §1.2.1]. □

Algorithm 2.3.8 (Inverse Modulo n)**.** Suppose a and n are integers and $\gcd(a, n) = 1$. This algorithm finds an x such that $ax \equiv 1 \pmod{n}$.

1. [Compute Extended GCD] Use Algorithm 2.3.7 to compute integers x, y such that $ax + ny = \gcd(a, n) = 1$.
2. [Finished] Output x.

Proof. Reduce $ax+ny = 1$ modulo n to see that x satisfies $ax \equiv 1 \pmod{n}$. □

Example 2.3.9. Solve $17x \equiv 1 \pmod{61}$. First, we use Algorithm 2.3.7 to find x, y such that $17x + 61y = 1$:

$$\begin{array}{rlcrl}
\underline{61} &= 3 \cdot \underline{17} + \underline{10} & \qquad & \underline{10} &= \underline{61} - 3 \cdot \underline{17} \\
\underline{17} &= 1 \cdot \underline{10} + \underline{7} & & \underline{7} &= -\underline{61} + 4 \cdot \underline{17} \\
\underline{10} &= 1 \cdot \underline{7} + \underline{3} & & \underline{3} &= 2 \cdot \underline{61} - 7 \cdot \underline{17} \\
\underline{3} &= 2 \cdot \underline{3} + \underline{1} & & \underline{1} &= -5 \cdot \underline{61} + 18 \cdot \underline{17}
\end{array}$$

Thus $17 \cdot 18 + 61 \cdot (-5) = 1$ so $x = 18$ is a solution to $17x \equiv 1 \pmod{61}$.

SAGE Example 2.3.10. Sage implements the above algorithm for quickly computing inverses modulo n. For example,

```
sage: a = Mod(17, 61)
sage: a^(-1)
18
```

2.3.2 How to Compute $a^m \pmod{n}$

Let a and n be integers, and m a nonnegative integer. In this section, we describe an efficient algorithm to compute $a^m \pmod{n}$. For the cryptography applications in Chapter 3, m will have hundreds of digits.

The naive approach to computing $a^m \pmod{n}$ is to simply compute $a^m = a \cdot a \cdots a \pmod{n}$ by repeatedly multiplying by a and reducing modulo m. Note that after each arithmetic operation is completed, we reduce the result modulo n so that the sizes of the numbers involved do not get too large. Nonetheless, this algorithm is horribly inefficient because it takes $m - 1$ multiplications, which is huge if m has hundreds of digits.

A much more efficient algorithm for computing $a^m \pmod{n}$ involves writing m in binary, then expressing a^m as a product of expressions a^{2^i}, for various i. These latter expressions can be computed by repeatedly squaring a^{2^i}. This more clever algorithm is not “simpler,” but it is vastly more efficient since the number of operations needed grows with the number of binary digits of m, whereas with the naive algorithm in the previous paragraph, the number of operations is $m - 1$.

Algorithm 2.3.11 (Write a number in binary)**.** Let m be a nonnegative integer. This algorithm writes m in binary, so it finds $\varepsilon_i \in \{0, 1\}$ such that $m = \sum_{i=0}^{r} \varepsilon_i 2^i$ with each $\varepsilon_i \in \{0, 1\}$.

1. [Initialize] Set $i = 0$.
2. [Finished?] If $m = 0$, terminate.
3. [Digit] If m is odd, set $\varepsilon_i = 1$, otherwise $\varepsilon_i = 0$. Increment i.

4. [Divide by 2] Set $m = \left\lfloor \frac{m}{2} \right\rfloor$, the greatest integer $\leq m/2$. Goto Step 2.

SAGE Example 2.3.12. To write a number in binary using Sage, use the `str` command:

```
sage: 100.str(2)
'1100100'
```

Notice the above is the correct binary expansion:

```
sage: 0*2^0 + 0*2^1 + 1*2^2 + 0*2^3 + 0*2^4 + 1*2^5 + 1*2^6
100
```

Algorithm 2.3.13 (Compute Power)**.** Let a and n be integers and m a nonnegative integer. This algorithm computes a^m modulo n.

1. [Write in Binary] Write m in binary using Algorithm 2.3.11, so $a^m = \prod_{\varepsilon_i=1} a^{2^i} \pmod{n}$.
2. [Compute Powers] Compute a, a^2, $a^{2^2} = (a^2)^2$, $a^{2^3} = (a^{2^2})^2$, etc., up to a^{2^r}, where $r+1$ is the number of binary digits of m.
3. [Multiply Powers] Multiply together the a^{2^i} such that $\varepsilon_i = 1$, always working modulo n.

Example 2.3.14. We can compute the last 2 digits of 7^{91}, by finding 7^{91} (mod 100). First, because $\gcd(7, 100) = 1$, we have by Theorem 2.1.20 that $7^{\varphi(100)} \equiv 1 \pmod{100}$. Because φ is multiplicative,

$$\varphi(100) = \varphi(2^2 \cdot 5^2) = (2^2 - 2) \cdot (5^2 - 5) = 40.$$

Thus $7^{40} \equiv 1 \pmod{100}$, hence

$$7^{91} \equiv 7^{40+40+11} \equiv 7^{11} \pmod{100}.$$

We now compute $7^{11} \pmod{100}$ using the above algorithm. First, write 11 in binary by repeatedly dividing by 2.

$$\begin{aligned} 11 &= 5 \cdot 2 + 1 \\ 5 &= 2 \cdot 2 + 1 \\ 2 &= 1 \cdot 2 + 0 \\ 1 &= 0 \cdot 2 + 1 \end{aligned}$$

So in binary, $(11)_2 = 1011$, which we check:

$$11 = 1 \cdot 8 + 1 \cdot 2 + 1.$$

Next, compute a, a^2, a^4, a^8 and output $a^8 \cdot a^2 \cdot a$. We have

$$\begin{aligned} a &= 7\\ a^2 &\equiv 49\\ a^4 &\equiv 49^2 \equiv 1\\ a^8 &\equiv 1^2 \equiv 1 \end{aligned}$$

Note: it is easiest to square 49 by working modulo 4 and 25 and using the Chinese Remainder Theorem. Finally,

$$7^{91} \equiv 7^{11} \equiv a^8 \cdot a^2 \cdot a \equiv 1 \cdot 49 \cdot 7 \equiv 43 \pmod{100}.$$

SAGE Example 2.3.15. Sage implements the above algorithm for computing powers efficiently. For example,

```
sage: Mod(7,100)^91
43
```

We can also, of course, directly compute 7^{91} in Sage, though we would not want to do this by hand:

```
sage: 7^91
80153343160247310515380886994816022539378033762994852
007501964604841680190743
```

2.4 Primality Testing

Theorem 2.4.1 (Pseudoprimality)**.** *An integer $p > 1$ is prime if and only if for* every $a \not\equiv 0 \pmod{p}$,

$$a^{p-1} \equiv 1 \pmod{p}.$$

Proof. If p is prime, then the statement follows from Proposition 2.1.22. If p is composite, then there is a divisor a of p with $2 \leq a < p$. If $a^{p-1} \equiv 1 \pmod{p}$, then $p \mid a^{p-1} - 1$. Since $a \mid p$, we have $a \mid a^{p-1} - 1$, hence there exists an integer k such that $ak = a^{p-1} - 1$. Subtracting, we see that $a^{p-1} - ak = 1$, so $a(a^{p-2} - k) = 1$. This implies that $a \mid 1$, which is a contradiction since $a \geq 2$. □

Suppose $n \in \mathbf{N}$. Using Theorem 2.4.1 and Algorithm 2.3.13, we can either quickly prove that n is not prime, or convince ourselves that n is likely prime (but not quickly prove that n is prime). For example, if $2^{n-1} \not\equiv 1 \pmod{n}$, then we have proved that n is not prime. On the other hand, if $a^{n-1} \equiv 1 \pmod{n}$ for a few a, it "seems likely" that n is prime, and we loosely refer to such a number that seems prime for several bases as a *pseudoprime.*

There are composite numbers n (called *Carmichael numbers*) with the amazing property that $a^{n-1} \equiv 1 \pmod{n}$ for *all* a with $\gcd(a, n) = 1$. The first Carmichael number is 561, and it is a theorem that there are infinitely many such numbers ([AGP94]).

Example 2.4.2. Is $p = 323$ prime? We compute $2^{322} \pmod{323}$. Making a table as above, we have

i	m	ε_i	$2^{2^i} \bmod 323$
0	322	0	2
1	161	1	4
2	80	0	16
3	40	0	256
4	20	0	290
5	10	0	120
6	5	1	188
7	2	0	137
8	1	1	35

Thus

$$2^{322} \equiv 4 \cdot 188 \cdot 35 \equiv 157 \pmod{323},$$

so 323 is not prime, though this computation gives no information about how 323 factors as a product of primes. In fact, one finds that $323 = 17 \cdot 19$.

SAGE Example 2.4.3. It's possible to easily prove that a large number is composite, but the proof does not easily yield a factorization. For example if

$$n = 95468093486093450983409583409850934850938459083,$$

then $2^{n-1} \not\equiv 1 \pmod{n}$, so n is composite.

```
sage: n = 95468093486093450983409583409850934850938459083
sage: Mod(2,n)^(n-1)
34173444139265553870830266378598407069248687241
```

Note that factoring n actually takes much longer than the above computation (which was essentially instant).

```
sage: factor(n)                # takes up to a few seconds.
1610302526747 * 59285812386415488446397191791023889
```

Another practical primality test is the Miller-Rabin test, which has the property that each time it is run on a number n it either correctly asserts that the number is definitely not prime, or that it is probably prime, and the probability of correctness goes up with each successive call. If Miller-Rabin is called m times on n and in each case claims that n is probably prime, then one can in a precise sense bound the probability that n is composite in terms of m.

We state the Miller-Rabin algorithm precisely, but do not prove anything about the probability that it will succeed.

Algorithm 2.4.4 (Miller-Rabin Primality Test)**.** Given an integer $n \geq 5$ this algorithm outputs either true or false. If it outputs true, then n is "probably prime," and if it outputs false, then n is definitely composite.

1. [Split Off Power of 2] Compute the unique integers m and k such that m is odd and $n - 1 = 2^k \cdot m$.
2. [Random Base] Choose a random integer a with $1 < a < n$.
3. [Odd Power] Set $b = a^m \pmod{n}$. If $b \equiv \pm 1 \pmod{n}$ output true and terminate.
4. [Even Powers] If $b^{2^r} \equiv -1 \pmod{n}$ for any r with $1 \leq r \leq k-1$, output true and terminate. Otherwise output false.

If Miller-Rabin outputs true for n, we can call it again with n and if it again outputs true then the probability that we have incorrectly determined that n is prime (when n is actually composite) decreases.

Proof. We will prove that the algorithm is correct, but will prove nothing about how likely the algorithm is to assert that a composite is prime. We must prove that if the algorithm pronounces an integer n composite, then n really is composite. Thus suppose n is prime, yet the algorithm pronounces n composite. Then $a^m \not\equiv \pm 1 \pmod{n}$, and for all r with $1 \leq r \leq k-1$ we have $a^{2^r m} \not\equiv -1 \pmod{n}$. Since n is prime and $2^{k-1}m = (n-1)/2$, Proposition 4.2.1 implies that $a^{2^{k-1}m} \equiv \pm 1 \pmod{n}$, so by our hypothesis $a^{2^{k-1}m} \equiv 1 \pmod{n}$. But then $(a^{2^{k-2}m})^2 \equiv 1 \pmod{n}$, so by Proposition 2.5.3 (which is proved right after it is stated, and whose proof does not depend on this argument), we have $a^{2^{k-2}m} \equiv \pm 1 \pmod{n}$. Again, by our hypothesis, this implies $a^{2^{k-2}} \equiv 1 \pmod{n}$. Repeating this argument inductively, we see that $a^m \equiv \pm 1 \pmod{n}$, which contradicts our hypothesis on a. □

Until recently it was an open problem to give an algorithm (with proof) that decides whether or not any integer is prime in time bounded by a polynomial in the number of digits of the integer. Agrawal, Kayal, and Saxena recently found the first polynomial-time primality test (see [AKS02]). We will not discuss their algorithm further, because for our applications to cryptography Miller-Rabin or pseudoprimality tests will be sufficient. See [Sho05, Ch. 21] for a book that gives a detailed exposition of this algorithm.

SAGE Example 2.4.5. The `is_prime` command uses a combination of techniques to determines (provably correctly!) whether or not an integer is prime.

```
sage: n = 95468093486093450983409583409850934850938459083
```

```
sage: is_prime(n)
False
```

We use the is_prime function to make a table of the first few Mersenne primes (see Section 1.2.3).

```
sage: for p in primes(100):
...   if is_prime(2^p - 1):
...       print p, 2^p - 1
2 3
3 7
5 31
7 127
13 8191
17 131071
19 524287
31 2147483647
61 2305843009213693951
89 618970019642690137449562111
```

There is a specialized test for primality of Mersenne numbers called the Lucas-Lehmer test. This remarkably simple algorithm determines provably correctly whether or not a number $2^p - 1$ is prime. We implement it in a few lines of code and use the Lucas-Lehmer test to check for primality of two Mersenne numbers:

```
sage: def is_prime_lucas_lehmer(p):
...    s = Mod(4, 2^p - 1)
...    for i in range(3, p+1):
...        s = s^2 - 2
...    return s == 0
sage: # Check primality of 2^9941 - 1
sage: is_prime_lucas_lehmer(9941)
True
sage: # Check primality of 2^next_prime(1000)-1
sage: is_prime_lucas_lehmer(next_prime(1000))
False
```

For more on Mersenne primes, see the Great Internet Mersenne Prime Search (GIMPS) project at http://www.mersenne.org/.

2.5 The Structure of $(\mathbf{Z}/p\mathbf{Z})^*$

This section is about the structure of the group $(\mathbf{Z}/p\mathbf{Z})^*$ of units modulo a prime number p. The main result is that this group is always cyclic. We will use this result later in Chapter 4 in our proof of quadratic reciprocity.

Definition 2.5.1 (Primitive root)**.** A *primitive root* modulo an integer n is an element of $(\mathbf{Z}/n\mathbf{Z})^*$ of order $\varphi(n)$.

We will prove that there is a primitive root modulo every prime p. Since the unit group $(\mathbf{Z}/p\mathbf{Z})^*$ has order $p-1$, this implies that $(\mathbf{Z}/p\mathbf{Z})^*$ is a cyclic group, a fact that will be extremely useful, since it completely determines the structure of $(\mathbf{Z}/p\mathbf{Z})^*$ as a group.

If n is an odd prime power, then there is a primitive root modulo n (see Exercise 2.28), but there is no primitive root modulo the prime power 2^3, and hence none mod 2^n for $n \geq 3$ (see Exercise 2.27).

Section 2.5.1 is the key input to our proof that $(\mathbf{Z}/p\mathbf{Z})^*$ is cyclic; here we show that for every divisor d of $p-1$ there are exactly d elements of $(\mathbf{Z}/p\mathbf{Z})^*$ whose order divides d. We then use this result in Section 2.5.2 to produce an element of $(\mathbf{Z}/p\mathbf{Z})^*$ of order q^r when q^r is a prime power that exactly divides $p-1$ (i.e., q^r divides $p-1$, but q^{r+1} does not divide $p-1$), and multiply together these elements to obtain an element of $(\mathbf{Z}/p\mathbf{Z})^*$ of order $p-1$.

SAGE Example 2.5.2. Use the `primitive_root` command to compute the smallest positive integer that is a primitive root modulo n. For example, below we compute primitive roots modulo p for each prime $p < 20$.

```
sage: for p in primes(20):
...     print p, primitive_root(p)
2 1
3 2
5 2
7 3
11 2
13 2
17 3
19 2
```

2.5.1 Polynomials over $\mathbf{Z}/p\mathbf{Z}$

The polynomials $x^2 - 1$ has four roots in $\mathbf{Z}/8\mathbf{Z}$, namely 1, 3, 5, and 7. In contrast, the following proposition shows that a polynomial of degree d over a field, such as $\mathbf{Z}/p\mathbf{Z}$, can have at most d roots.

Proposition 2.5.3 (Root Bound)**.** *Let $f \in k[x]$ be a nonzero polynomial over a field k. Then there are at most* $\deg(f)$ *elements $\alpha \in k$ such that $f(\alpha) = 0$.*

Proof. We prove the proposition by induction on $\deg(f)$. The cases in which $\deg(f) \leq 1$ are clear. Write $f = a_n x^n + \cdots a_1 x + a_0$. If $f(\alpha) = 0$, then

$$\begin{aligned} f(x) &= f(x) - f(\alpha) \\ &= a_n(x^n - \alpha^n) + \cdots + a_1(x - \alpha) + a_0(1 - 1) \\ &= (x - \alpha)(a_n(x^{n-1} + \cdots + \alpha^{n-1}) + \cdots + a_2(x + \alpha) + a_1) \\ &= (x - \alpha)g(x), \end{aligned}$$

for some polynomial $g(x) \in k[x]$. Next, suppose that $f(\beta) = 0$ with $\beta \neq \alpha$. Then $(\beta - \alpha)g(\beta) = 0$, so, since $\beta - \alpha \neq 0$ and k is a field, we have $g(\beta) = 0$. By our inductive hypothesis, g has at most $n - 1$ roots, so there are at most $n - 1$ possibilities for β. It follows that f has at most n roots. □

SAGE Example 2.5.4. We use Sage to find the roots of a polynomials over $\mathbf{Z}/13\mathbf{Z}$.

```
sage: R.<x> = PolynomialRing(Integers(13))
sage: f = x^15 + 1
sage: f.roots()
[(12, 1), (10, 1), (4, 1)]
sage: f(12)
0
```

The output of the roots command above lists each root along with its multiplicity (which is 1 in each case above).

Proposition 2.5.5. *Let p be a prime number and let d be a divisor of $p - 1$. Then $f = x^d - 1 \in (\mathbf{Z}/p\mathbf{Z})[x]$ has exactly d roots in $\mathbf{Z}/p\mathbf{Z}$.*

Proof. Let $e = (p - 1)/d$. We have

$$\begin{aligned} x^{p-1} - 1 &= (x^d)^e - 1 \\ &= (x^d - 1)((x^d)^{e-1} + (x^d)^{e-2} + \cdots + 1) \\ &= (x^d - 1)g(x), \end{aligned}$$

where $g \in (\mathbf{Z}/p\mathbf{Z})[x]$ and $\deg(g) = de - d = p - 1 - d$. Theorem 2.1.20 implies that $x^{p-1} - 1$ has exactly $p - 1$ roots in $\mathbf{Z}/p\mathbf{Z}$, since every nonzero element of $\mathbf{Z}/p\mathbf{Z}$ is a root! By Proposition 2.5.3, g has *at most* $p - 1 - d$ roots and $x^d - 1$ has at most d roots. Since a root of $(x^d - 1)g(x)$ is a root of either $x^d - 1$ or $g(x)$ and $x^{p-1} - 1$ has $p - 1$ roots, g must have exactly $p - 1 - d$ roots and $x^d - 1$ must have exactly d roots, as claimed. □

SAGE Example 2.5.6. We use Sage to illustrate the proposition.

```
sage: R.<x> = PolynomialRing(Integers(13))
sage: f = x^6 + 1
sage: f.roots()
[(11, 1), (8, 1), (7, 1), (6, 1), (5, 1), (2, 1)]
```

We pause to reemphasize that the analog of Proposition 2.5.5 is false when p is replaced by a composite integer n, since a root mod n of a product of two polynomials need not be a root of either factor. For example, $f = x^2 - 1 = (x-1)(x+1) \in \mathbf{Z}/15\mathbf{Z}[x]$ has the four roots 1, 4, 11, and 14.

2.5.2 Existence of Primitive Roots

Recall from Section 2.1.2 that the *order* of an element x in a finite group is the smallest $m \geq 1$ such that $x^m = 1$. In this section, we prove that $(\mathbf{Z}/p\mathbf{Z})^*$ is cyclic by using the results of Section 2.5.1 to produce an element of $(\mathbf{Z}/p\mathbf{Z})^*$ of order d for each prime power divisor d of $p-1$, and then we multiply these together to obtain an element of order $p-1$.

We will use the following lemma to assemble elements of each order dividing $p-1$ to produce an element of order $p-1$.

Lemma 2.5.7. *Suppose $a, b \in (\mathbf{Z}/n\mathbf{Z})^*$ have orders r and s, respectively, and that* $\gcd(r,s) = 1$. *Then ab has order rs.*

Proof. This is a general fact about commuting elements of any group; our proof only uses that $ab = ba$ and nothing special about $(\mathbf{Z}/n\mathbf{Z})^*$. Since

$$(ab)^{rs} = a^{rs}b^{rs} = 1,$$

the order of ab is a divisor of rs. Write this divisor as $r_1 s_1$ where $r_1 \mid r$ and $s_1 \mid s$. Raise both sides of the equation

$$a^{r_1 s_1} b^{r_1 s_1} = (ab)^{r_1 s_1} = 1$$

to the power $r_2 = r/r_1$ to obtain

$$a^{r_1 r_2 s_1} b^{r_1 r_2 s_1} = 1.$$

Since $a^{r_1 r_2 s_1} = (a^{r_1 r_2})^{s_1} = 1$, we have

$$b^{r_1 r_2 s_1} = 1,$$

so $s \mid r_1 r_2 s_1$. Since $\gcd(s, r_1 r_2) = \gcd(s, r) = 1$, it follows that $s = s_1$. Similarly $r = r_1$, so the order of ab is rs. □

Theorem 2.5.8 (Primitive Roots)**.** *There is a primitive root modulo any prime p. In particular, the group $(\mathbf{Z}/p\mathbf{Z})^*$ is cyclic.*

Proof. The theorem is true if $p = 2$, since 1 is a primitive root, so we may assume $p > 2$. Write $p - 1$ as a product of distinct prime powers $q_i^{n_i}$:

$$p - 1 = q_1^{n_1} q_2^{n_2} \cdots q_r^{n_r}.$$

By Proposition 2.5.5, the polynomial $x^{q_i^{n_i}} - 1$ has exactly $q_i^{n_i}$ roots, and the polynomial $x^{q_i^{n_i - 1}} - 1$ has exactly $q_i^{n_i - 1}$ roots. There are $q_i^{n_i} - q_i^{n_i - 1} =$

$q_i^{n_i-1}(q_i-1)$ elements $a \in \mathbf{Z}/p\mathbf{Z}$ such that $a^{q_i^{n_i}} = 1$ but $a^{q_i^{n_i-1}} \neq 1$; each of these elements has order $q_i^{n_i}$. Thus for each $i = 1, \ldots, r$, we can choose an a_i of order $q_i^{n_i}$. Then, using Lemma 2.5.7 repeatedly, we see that

$$a = a_1 a_2 \cdots a_r$$

has order $q_1^{n_1} \cdots q_r^{n_r} = p - 1$, so a is a primitive root modulo p. □

Example 2.5.9. We illustrate the proof of Theorem 2.5.8 when $p = 13$. We have

$$p - 1 = 12 = 2^2 \cdot 3.$$

The polynomial $x^4 - 1$ has roots $\{1, 5, 8, 12\}$ and $x^2 - 1$ has roots $\{1, 12\}$, so we may take $a_1 = 5$. The polynomial $x^3 - 1$ has roots $\{1, 3, 9\}$, and we set $a_2 = 3$. Then $a = 5 \cdot 3 = 15 \equiv 2$ is a primitive root. To verify this, note that the successive powers of $2 \pmod{13}$ are

$$2,\ 4,\ 8,\ 3,\ 6,\ 12,\ 11,\ 9,\ 5,\ 10,\ 7,\ 1.$$

Example 2.5.10. Theorem 2.5.8 is false if, for example, p is replaced by a power of 2 bigger than 4. For example, the four elements of $(\mathbf{Z}/8\mathbf{Z})^*$ each have order dividing 2, but $\varphi(8) = 4$.

Theorem 2.5.11 (Primitive Roots mod p^n)**.** *Let p^n be a power of an odd prime. Then there is a primitive root modulo p^n.*

The proof is left as Exercise 2.28.

Proposition 2.5.12 (Number of primitive roots)**.** *If there is a primitive root modulo n, then there are exactly $\varphi(\varphi(n))$ primitive roots modulo n.*

Proof. The primitive roots modulo n are the generators of $(\mathbf{Z}/n\mathbf{Z})^*$, which by assumption is cyclic of order $\varphi(n)$. Thus they are in bijection with the generators of any cyclic group of order $\varphi(n)$. In particular, the number of primitive roots modulo n is the same as the number of elements of $\mathbf{Z}/\varphi(n)\mathbf{Z}$ with additive order $\varphi(n)$. An element of $\mathbf{Z}/\varphi(n)\mathbf{Z}$ has additive order $\varphi(n)$ if and only if it is coprime to $\varphi(n)$. There are $\varphi(\varphi(n))$ such elements, as claimed. □

Example 2.5.13. For example, there are $\varphi(\varphi(17)) = \varphi(16) = 2^4 - 2^3 = 8$ primitive roots mod 17, namely $3, 5, 6, 7, 10, 11, 12, 14$. The $\varphi(\varphi(9)) = \varphi(6) = 2$ primitive roots modulo 9 are 2 and 5. There are no primitive roots modulo 8, even though $\varphi(\varphi(8)) = \varphi(4) = 2 > 0$.

2.5.3 Artin's Conjecture

Conjecture 2.5.14 (Emil Artin)**.** *Suppose $a \in \mathbf{Z}$ is not -1 or a perfect square. Then there are infinitely many primes p such that a is a primitive root modulo p.*

There is no single integer a such that Artin's conjecture is known to be true. For any given a, Pieter [Mor93] proved that there are infinitely many p such that the order of a is divisible by the largest prime factor of $p-1$. Hooley [Hoo67] proved that something called the Generalized Riemann Hypothesis implies Conjecture 2.5.14.

Remark 2.5.15. Artin conjectured more precisely that if $N(x,a)$ is the number of primes $p \leq x$ such that a is a primitive root modulo p, then $N(x,a)$ is asymptotic to $C(a)\pi(x)$, where $C(a)$ is a positive constant that depends only on a and $\pi(x)$ is the number of primes up to x.

2.5.4 Computing Primitive Roots

Theorem 2.5.8 does not suggest an efficient algorithm for finding primitive roots. To actually find a primitive root mod p in practice, we try $a = 2$, then $a = 3$, etc., until we find an a that has order $p-1$. Computing the order of an element of $(\mathbf{Z}/p\mathbf{Z})^*$ requires factoring $p-1$, which we do not know how to do quickly in general, so finding a primitive root modulo p for large p seems to be a difficult problem.

Algorithm 2.5.16 (Primitive Root)**.** Given a prime p, this algorithm computes the smallest positive integer a that generates $(\mathbf{Z}/p\mathbf{Z})^*$.

1. [$p = 2$?] If $p = 2$ output 1 and terminate. Otherwise set $a = 2$.
2. [Prime Divisors] Compute the prime divisors $p_1, \ldots, p_r$ of $p-1$.
3. [Generator?] If for every p_i, we have $a^{(p-1)/p_i} \not\equiv 1 \pmod{p}$, then a is a generator of $(\mathbf{Z}/p\mathbf{Z})^*$, so output a and terminate.
4. [Try next] Set $a = a + 1$ and go to Step 3.

Proof. Let $a \in (\mathbf{Z}/p\mathbf{Z})^*$. The order of a is a divisor d of the order $p-1$ of the group $(\mathbf{Z}/p\mathbf{Z})^*$. Write $d = (p-1)/n$, for some divisor n of $p-1$. If a is not a generator of $(\mathbf{Z}/p\mathbf{Z})^*$, then since $n \mid (p-1)$, there is a prime divisor p_i of $p-1$ such that $p_i \mid n$. Then

$$a^{(p-1)/p_i} = (a^{(p-1)/n})^{n/p_i} \equiv 1 \pmod{p}.$$

Conversely, if a is a generator, then $a^{(p-1)/p_i} \not\equiv 1 \pmod{p}$ for any p_i. Thus the algorithm terminates with Step 3 if and only if the a under consideration is a primitive root. By Theorem 2.5.8, there is at least one primitive root, so the algorithm terminates. □

2.6 Exercises

2.1 Prove that for any positive integer n, the set $(\mathbf{Z}/n\mathbf{Z})^*$ under multiplication modulo n is a group.

2.2 Compute the following gcd's using Algorithm 1.1.13:

$$\gcd(15,35) \quad \gcd(247,299) \quad \gcd(51,897) \quad \gcd(136,304)$$

2.3 Use Algorithm 2.3.7 to find x, $y \in \mathbf{Z}$ such that $2261x + 1275y = 17$.

2.4 Prove that if a and b are integers and p is a prime, then $(a+b)^p \equiv a^p + b^p \pmod{p}$. You may assume that the binomial coefficient

$$\frac{p!}{r!(p-r)!}$$

is an integer.

2.5 (a) Prove that if x, y is a solution to $ax + by = d$, then for all $c \in \mathbf{Z}$,

$$x' = x + c \cdot \frac{b}{d}, \qquad y' = y - c \cdot \frac{a}{d} \tag{2.6.1}$$

is also a solution to $ax + by = d$.

(b) Find two distinct solutions to $2261x + 1275y = 17$.

(c) Prove that all solutions are of the form (2.6.1) for some c.

2.6 Let $f(x) = x^2 + ax + b \in \mathbf{Z}[x]$ be a quadratic polynomial with integer coefficients, for example, $f(x) = x^2 + x + 6$. Formulate a conjecture about when the set

$$\{f(n) : n \in \mathbf{Z} \text{ and } f(n) \text{ is prime}\}$$

is infinite. Give numerical evidence that supports your conjecture.

2.7 Find four complete sets of residues modulo 7, where the ith set satisfies the ith condition: (1) nonnegative, (2) odd, (3) even, (4) prime.

2.8 Find rules in the spirit of Proposition 2.1.9 for divisibility of an integer by 5, 9, and 11, and prove each of these rules using arithmetic modulo a suitable n.

2.9 (*) *(The following problem is from the 1998 Putnam Competition.)* Define a sequence of decimal integers a_n as follows: $a_1 = 0$, $a_2 = 1$, and a_{n+2} is obtained by writing the digits of a_{n+1} immediately followed by those of a_n. For example, $a_3 = 10$, $a_4 = 101$, and $a_5 = 10110$. Determine the n such that a_n is a multiple of 11, as follows:

(a) Find the smallest integer $n > 1$ such that a_n is divisible by 11.

(b) Prove that a_n is divisible by 11 if and only if $n \equiv 1 \pmod{6}$.

2.10 Find an integer x such that $37x \equiv 1 \pmod{101}$.

2.11 What is the order of 2 modulo 17?

2.12 Let p be a prime. Prove that $\mathbf{Z}/p\mathbf{Z}$ is a field.

2.13 Find an $x \in \mathbf{Z}$ such that $x \equiv -4 \pmod{17}$ and $x \equiv 3 \pmod{23}$.

2.14 Prove that if $n > 4$ is composite then

$$(n-1)! \equiv 0 \pmod{n}.$$

2.15 For what values of n is $\varphi(n)$ odd?

2.16 (a) Prove that φ is multiplicative as follows. Suppose m, n are positive integers and $\gcd(m, n) = 1$. Show that the natural map $\psi : \mathbf{Z}/mn\mathbf{Z} \to \mathbf{Z}/m\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$ is an injective homomorphism of rings, hence bijective by counting, then look at unit groups.

(b) Prove conversely that if $\gcd(m, n) > 1$, then the natural map $\psi : \mathbf{Z}/mn\mathbf{Z} \to \mathbf{Z}/m\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$ is not an isomorphism.

2.17 Seven competitive math students try to share a huge hoard of stolen math books equally between themselves. Unfortunately, six books are left over, and in the fight over them, one math student is expelled. The remaining six math students, still unable to share the math books equally since two are left over, again fight, and another is expelled. When the remaining five share the books, one book is left over, and it is only after yet another math student is expelled that an equal sharing is possible. What is the minimum number of books that allows this to happen?

2.18 Show that if p is a positive integer such that both p and $p^2 + 2$ are prime, then $p = 3$.

2.19 Let $\varphi : \mathbf{N} \to \mathbf{N}$ be the Euler φ function.

(a) Find all natural numbers n such that $\varphi(n) = 1$.

(b) Do there exist natural numbers m and n such that $\varphi(mn) \neq \varphi(m) \cdot \varphi(n)$?

2.20 Find a formula for $\varphi(n)$ directly in terms of the prime factorization of n.

2.21 (a) Prove that if $\varphi : G \to H$ is a group homomorphism, then $\ker(\varphi)$ is a subgroup of G.

(b) Prove that $\ker(\varphi)$ is *normal*, i.e., if $a \in G$ and $b \in \ker(\varphi)$, then $a^{-1}ba \in \ker(\varphi)$.

2.22 Is the set $\mathbf{Z}/5\mathbf{Z} = \{0, 1, 2, 3, 4\}$ with binary operation multiplication modulo 5 a group?

2.23 Find all *four* solutions to the equation

$$x^2 - 1 \equiv 0 \pmod{35}.$$

2.24 Prove that for any positive integer n the fraction $(12n+1)/(30n+2)$ is in reduced form.

2.25 Suppose a and b are positive integers.

(a) Prove that $\gcd(2^a - 1,\ 2^b - 1) = 2^{\gcd(a,b)} - 1$.

(b) Does it matter if 2 is replaced by an arbitrary prime p?

(c) What if 2 is replaced by an arbitrary positive integer n?

2.26 For every positive integer b, show that there exists a positive integer n such that the polynomial $x^2 - 1 \in (\mathbf{Z}/n\mathbf{Z})[x]$ has at least b roots.

2.27 (a) Prove that there is no primitive root modulo 2^n for any $n \geq 3$.

(b) (*) Prove that $(\mathbf{Z}/2^n\mathbf{Z})^*$ is generated by -1 and 5.

2.28 Let p be an odd prime.

(a) (*) Prove that there is a primitive root modulo p^2. (Hint: Use that if a, b have orders n, m, with $\gcd(n, m) = 1$, then ab has order nm.)

(b) Prove that for any n, there is a primitive root modulo p^n.

(c) Explicitly find a primitive root modulo 125.

2.29 (*) In terms of the prime factorization of n, characterize the integers n such that there is a primitive root modulo n.

2.30 Compute the last two digits of 3^{45}.

2.31 Find the integer a such that $0 \leq a < 113$ and

$$102^{70} + 1 \equiv a^{37} \pmod{113}.$$

2.32 Find the proportion of primes $p < 1000$ such that 2 is a primitive root modulo p.

2.33 Find a prime p such that the smallest primitive root modulo p is 37.

3
Public-key Cryptography

In the 1970s, techniques from number theory changed the world forever by providing, for the first time ever, a way for two people to communicate secret messages under the assumption that *all* of their communication is intercepted and read by an adversary. This idea has stood the test of time. In fact, whenever you buy something online, you use such a system, which typically involves working in the ring of integers modulo n. This chapter tells the story of several such systems.

3.1 Playing with Fire

I recently watched a TV show called La Femme Nikita about a woman named Nikita who is forced to be an agent for a shady anti-terrorist organization called Section One. Nikita has strong feelings for fellow agent Michael, and she most trusts Walter, Section One's ex-biker gadgets and explosives expert. Often Nikita's worst enemies are her superiors and coworkers at Section One. A synopsis for a Season Three episode is as follows:

> PLAYING WITH FIRE
>
> On a mission to secure detonation chips from a terrorist organization's heavily armed base camp, Nikita is captured as a hostage by the enemy. Or so it is made to look. Michael and Nikita have actually created the scenario in order to secretly rendezvous with each other. The ruse works, but when Birkoff

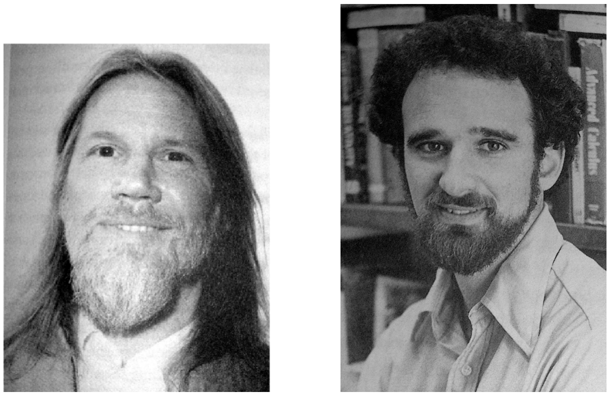


FIGURE 3.1. Diffie and Hellman (photos from [Sin99])

> [Section One's master hacker] accidentally discovers encrypted messages between Michael and Nikita sent with Walter's help, Birkoff is forced to tell Madeline. Suspecting that Michael and Nikita may be planning a coup d'état, Operations and Madeline use a second team of operatives to track Michael and Nikita's next secret rendezvous... killing them if necessary.

What sort of encryption might Walter have helped them to use? I let my imagination run free, and this is what I came up with. After being captured at the base camp, Nikita is given a phone by her captors in hopes that she'll use it and they'll be able to figure out what she is really up to. Everyone is eagerly listening in on her calls.

Remark 3.1.1. In this book, we will assume a method is available for producing random integers. Methods for generating random integers are involved and interesting, but we will not discuss them in this book. For an in-depth treatment of random numbers, see [Knu98, Ch. 3].

Nikita remembers a conversation with Walter about a public-key cryptosystem called the "Diffie-Hellman key exchange." She remembers that it allows two people to agree on a secret key in the presence of eavesdroppers. Moreover, Walter mentioned that though Diffie-Hellman was the first ever public-key exchange system, it is still in common use today (for example, in OpenSSH protocol version 2, see `http://www.openssh.com/`).

Nikita pulls out her handheld computer and phone, calls up Michael, and they do the following, which is *wrong* (try to figure out what is wrong as you read it).

1. Together they choose a big prime number p and a number g with $1 < g < p$.

2. Nikita *secretly* chooses an integer n.

3. Michael *secretly* chooses an integer m.
4. Nikita tells Michael $ng \pmod{p}$.
5. Michael tells $mg \pmod{p}$ to Nikita.
6. The “secret key” is $s = nmg \pmod{p}$, which both Nikita and Michael can easily compute.

Here’s a very simple example with small numbers that illustrates what Michael and Nikita do. (They really used much larger numbers.)

1. $p = 97$, $g = 5$
2. $n = 31$
3. $m = 95$
4. $ng \equiv 58 \pmod{97}$
5. $mg \equiv 87 \pmod{97}$
6. $s = nmg = 78 \pmod{97}$

Nikita and Michael are foiled because everyone easily figures out s:

1. Everyone knows p, g, $ng \pmod{p}$, and $mg \pmod{p}$.
2. Using Algorithm 2.3.7, anyone can easily find $a, b \in \mathbf{Z}$ such that $ag + bp = 1$, which exists because $\gcd(g, p) = 1$.
3. Then, $ang \equiv n \pmod{p}$, so everyone knows Nikita’s secret key n, and hence can easily compute the shared secret s.

To taunt her, Nikita’s captors give her a paragraph from a review of Diffie and Hellman’s 1976 paper “New Directions in Cryptography” [DH76]:

> “The authors discuss some recent results in communications theory [...] The first [method] has the feature that an unauthorized ‘eavesdropper’ will find it computationally infeasible to decipher the message [...] They propose a couple of techniques for implementing the system, but the reviewer was unconvinced.”

3.2 The Diffie-Hellman Key Exchange

As night darkens Nikita’s cell, she reflects on what has happened. Upon realizing that she mis-remembered how the system works, she phones Michael and they do the following:

1. Together Michael and Nikita choose a 200-digit integer p that is likely to be prime (see Section 2.4), and choose a number g with $1 < g < p$.
2. Nikita *secretly* chooses an integer n.
3. Michael *secretly* chooses an integer m.
4. Nikita computes $g^n \pmod{p}$ on her handheld computer and tells Michael the resulting number over the phone.
5. Michael tells Nikita $g^m \pmod{p}$.
6. The shared secret key is then
$$s \equiv (g^n)^m \equiv (g^m)^n \equiv g^{nm} \pmod{p},$$
which both Nikita and Michael can compute.

Here is a simplified example that illustrates what they did, that involves only relatively simple arithmetic.

1. $p = 97$, $g = 5$
2. $n = 31$
3. $m = 95$
4. $g^n \equiv 7 \pmod{p}$
5. $g^m \equiv 39 \pmod{p}$
6. $s \equiv (g^n)^m \equiv 14 \pmod{p}$

3.2.1 The Discrete Log Problem

Nikita communicates with Michael by encrypting everything using their agreed upon secret key (for example, using a standard symmetric cipher such as AES, Arcfour, Cast128, 3DES, or Blowfish). In order to understand the conversation, the eavesdropper needs s, but it takes a long time to compute s given only p, g, g^n, and g^m. One way would be to compute n from knowledge of g and g^n; this is possible, but appears to be "computationally infeasible," in the sense that it would take too long to be practical.

Let a, b, and n be real numbers with $a, b > 0$ and $n \geq 0$. Recall that the "log to the base b" function is characterized by
$$\log_b(a) = n \text{ if and only if } a = b^n.$$
We use the $\log_b$ function in algebra to solve the following problem: Given a base b and a power a of b, find an exponent n such that
$$a = b^n.$$

That is, given $a = b^n$ and b, find n.

SAGE Example 3.2.1. The number $a = 19683$ is the nth power of $b = 3$ for some n. We quickly find that

$$n = \log_3(19683) = \log(19683)/\log(3) = 9.$$

```
sage: log(19683.0)
9.88751059801299
sage: log(3.0)
1.09861228866811
sage: log(19683.0) / log(3.0)
9.00000000000000
```

Sage can quickly compute a numerical approximation for $\log(x)$, for any x, by computing a partial sum of an appropriate rapidly-converging infinite series (at least for x in a certain range).

The discrete log problem is the analog of computing $\log_b(a)$ but where both b and a are elements of a finite group.

Problem 3.2.2 (Discrete Log Problem)**.** Let G be a finite group, for example, $G = (\mathbf{Z}/p\mathbf{Z})^*$. Given $b \in G$ and a power a of b, find a positive integer n such that $b^n = a$.

As far as we know, finding discrete logarithms in $(\mathbf{Z}/p\mathbf{Z})^*$ when p is large is "very difficult" in practice. Over the years, many people have been very motivated to try. For example, if Nikita's captors could efficiently solve Problem 3.2.2, then they could read the messages she exchanges with Michael. Unfortunately, we have no formal proof that computing discrete logarithms on a classical computer is difficult. Also, Peter Shor [Sho97] showed that if one could build a sufficiently complicated quantum computer, it could solve the discrete logarithm problem in time bounded by a polynomial function of the number of digits of $\#G$.

It is easy to give an inefficient algorithm that solves the discrete log problem. Simply try b^1, b^2, b^3, etc., until we find an exponent n such that $b^n = a$. For example, suppose $a = 18$, $b = 5$, and $p = 23$. Working modulo 23, we have

$$b^1 = 5,\ b^2 = 2,\ b^3 = 10,\ \ldots,\ b^{12} = 18,$$

so $n = 12$. When p is large, computing the discrete log this way soon becomes impractical, because increasing the number of digits of the modulus makes the computation take vastly longer.

SAGE Example 3.2.3. Perhaps part of the reason that computing discrete logarithms is difficult, is that the logarithm in the real numbers is continuous, but the (minimum) logarithm of a number mod n bounces around at random. We illustrate this exotic behavior in Figure 3.2.

This draws the continuous plot.

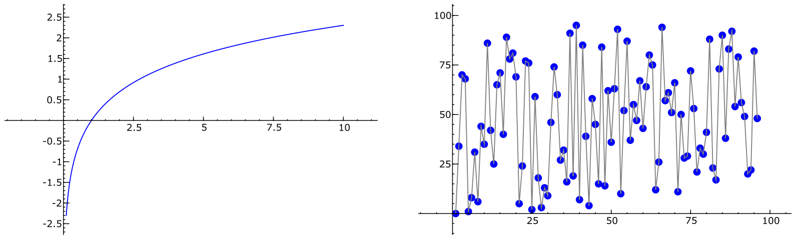

FIGURE 3.2. Graphs of the continuous log and of the discrete log modulo 53. Which picture looks easier to predict?

```
sage: plot(log, 0.1,10, rgbcolor=(0,0,1))
```

This draws the discrete plot.

```
sage: p = 53
sage: R = Integers(p)
sage: a = R.multiplicative_generator()
sage: v = sorted([(a^n, n) for n in range(p-1)])
sage: G = plot(point(v,pointsize=50,rgbcolor=(0,0,1)))
sage: H = plot(line(v,rgbcolor=(0.5,0.5,0.5)))
sage: G + H
```

3.2.2 Realistic Diffie-Hellman Example

In this section, we present an example that uses bigger numbers. First, we prove a proposition that we can use to choose a prime p in such a way that it is easy to find a $g \in (\mathbf{Z}/p\mathbf{Z})^*$ with order $p-1$. We have already seen in Section 2.5 that for every prime p there exists an element g of order $p-1$, and we gave Algorithm 2.5.16 for finding a primitive root for any prime. The significance of Proposition 3.2.4 below is that it suggests an algorithm for finding a primitive root that is easier to use in practice when p is large, because it does not require factoring $p-1$. Of course, one could also just use a random g for Diffie-Hellman; it is not essential that g generates $(\mathbf{Z}/p\mathbf{Z})^*$.

Proposition 3.2.4. *Suppose p is a prime such that $(p-1)/2$ is also prime. Then each element of $(\mathbf{Z}/p\mathbf{Z})^*$ has order one of 1, 2, $(p-1)/2$, or $p-1$.*

Proof. Since p is prime, the group $(\mathbf{Z}/p\mathbf{Z})^*$ is of order $p-1$. By assumption, the prime factorization of $p-1$ is $2 \cdot ((p-1)/2)$. Let $a \in (\mathbf{Z}/p\mathbf{Z})^*$. Then by Theorem 2.1.20, $a^{p-1} = 1$, so the order of a is a divisor of $p-1$, which proves the proposition. □

Given a prime p with $(p-1)/2$ prime, find an element of order $p-1$ as follows. If 2 has order $p-1$, we are done. If not, 2 has order $(p-1)/2$ since 2 does not have order either 1 or 2. Then -2 has order $p-1$.

Let $p = 93450983094850938450983409611$. Then p is prime, but $(p-1)/2$ is not. So we keep adding 2 to p and testing pseudoprimality using algorithms from Section 2.4 until we find that the next pseudoprime after p is

$$q = 93450983094850938450983409623.$$

It turns out that q pseudoprime and $(q-1)/2$ is also pseudoprime. We find that 2 has order $(q-1)/2$, so $g = -2$ has order $q-1$ modulo q, and is hence a generator of $(\mathbf{Z}/q\mathbf{Z})^*$, at least assuming that q is really prime.

The secret random numbers generated by Nikita and Michael are

$$n = 18319922375531859171613379181$$

and

$$m = 82335836243866695680141440300.$$

Nikita sends

$$g^n = 45416776270485369791375944998 \in (\mathbf{Z}/p\mathbf{Z})^*$$

to Michael, and Michael sends

$$g^m = 15048074151770884271824225393 \in (\mathbf{Z}/p\mathbf{Z})^*$$

to Nikita. They agree on the secret key

$$g^{nm} = 85771409470770521212346739540 \in (\mathbf{Z}/p\mathbf{Z})^*.$$

SAGE Example 3.2.5. We illustrate the above computations using Sage.

```
sage: q = 93450983094850938450983409623
sage: q.is_prime()
True
sage: is_prime((q-1)//2)
True
sage: g = Mod(-2, q)
sage: g.multiplicative_order()
93450983094850938450983409622
sage: n = 18319922375531859171613379181
sage: m = 82335836243866695680141440300
sage: g^n

85771409470770521212346739540
sage: (g^m)^n
85771409470770521212346739540
```

3.2.3 The Man in the Middle Attack

Since their first system was broken, instead of talking on the phone, Michael and Nikita can now only communicate via text messages. One of her captors, The Man, is watching each of the transmissions; moreover, he can intercept messages and send false messages. When Nikita sends a message to Michael announcing $g^n \pmod{p}$, The Man intercepts this message, and sends his own number $g^t \pmod{p}$ to Michael. Eventually, Michael and The Man agree on the secret key $g^{tm} \pmod{p}$, and Nikita and The Man agree on the key $g^{tn} \pmod{p}$. When Nikita sends a message to Michael she unwittingly uses the secret key $g^{tn} \pmod{p}$; The Man then intercepts it, decrypts it, changes it, and re-encrypts it using the key $g^{tm} \pmod{p}$, and sends it on to Michael. This is bad because now The Man can read every message sent between Michael and Nikita, and moreover, he can change them in transmission in subtle ways.

One way to get around this attack is to use a digital signature scheme based on the RSA cryptosystem. We will not discuss digital signatures further in this book, but will discuss RSA in the next section.

3.3 The RSA Cryptosystem

The Diffie-Hellman key exchange has drawbacks. As discussed in Section 3.2.3, it is susceptible to the man in the middle attack. This section is about the RSA public-key cryptosystem of Rivest, Shamir, and Adleman [RSA78], which is an alternative to Diffie-Hellman that is more flexible in some ways.

We first describe the RSA cryptosystem, then discuss several ways to attack it. It is important to be aware of such weaknesses, in order to avoid foolish mistakes when implementing RSA. We barely scratched the surface here of the many possible attacks on specific implementations of RSA or other cryptosystems.

3.3.1 How RSA works

The fundamental idea behind RSA is to try to construct a trap-door or one-way function on a set X. This is an invertible function

$$E : X \to X$$

such that it is easy for Nikita to compute E^{-1}, but extremely difficult for anybody else to do so.

Here is how Nikita makes a one-way function E on the set of integers modulo n.

1. Using a method hinted at in Section 2.4, Nikita picks two large primes p and q, and lets $n = pq$.

2. It is then easy for Nikita to compute
$$\varphi(n) = \varphi(p) \cdot \varphi(q) = (p-1) \cdot (q-1).$$
3. Nikita next chooses a random integer e with
$$1 < e < \varphi(n) \text{ and } \gcd(e, \varphi(n)) = 1.$$
4. Nikita uses the algorithm from Section 2.3.2 to find a solution $x = d$ to the equation
$$ex \equiv 1 \pmod{\varphi(n)}.$$
5. Finally, Nikita defines a function $E : \mathbf{Z}/n\mathbf{Z} \to \mathbf{Z}/n\mathbf{Z}$ by
$$E(x) = x^e \in \mathbf{Z}/n\mathbf{Z}.$$

Note that anybody can compute E fairly quickly using the repeated-squaring algorithm from Section 2.3.2. Nikita's *public key* is the pair of integers (n, e), which is just enough information for people to easily compute E. Nikita knows a number d such that $ed \equiv 1 \pmod{\varphi(n)}$, so, as we will see, she can quickly compute E^{-1}.

To send Nikita a message, proceed as follows. Encode your message, in some way, as a sequence of numbers modulo n (see Section 3.3.2)
$$m_1, \ldots, m_r \in \mathbf{Z}/n\mathbf{Z},$$
then send
$$E(m_1), \ldots, E(m_r)$$
to Nikita. (Recall that $E(m) = m^e$ for $m \in \mathbf{Z}/n\mathbf{Z}$.)

When Nikita receives $E(m_i)$, she finds each m_i by using that $E^{-1}(m) = m^d$, a fact that follows from Proposition 3.3.1

Proposition 3.3.1 (Decryption Key)**.** *Let n be an integer that is a product of distinct primes and let $d, e \in \mathbf{N}$ be such that $p-1 \mid de-1$ for each prime $p \mid n$. Then $a^{de} \equiv a \pmod{n}$ for all $a \in \mathbf{Z}$.*

Proof. Since $n \mid a^{de} - a$, if and only if $p \mid a^{de} - a$ for each prime divisor p of n, it suffices to prove that $a^{de} \equiv a \pmod{p}$ for each prime divisor p of n. If $\gcd(a, p) \neq 1$, then $a \equiv 0 \pmod{p}$, so $a^{de} \equiv a \pmod{p}$. If $\gcd(a, p) = 1$, then Theorem 2.1.20 asserts that $a^{p-1} \equiv 1 \pmod{p}$. Since $p - 1 \mid de - 1$, we have $a^{de-1} \equiv 1 \pmod{p}$ as well. Multiplying both sides by a shows that $a^{de} \equiv a \pmod{p}$. □

Thus to decrypt $E(m_i)$ Nikita computes
$$E(m_i)^d = (m_i^e)^d = m_i.$$

SAGE Example 3.3.2. We implement the RSA cryptosystem using Sage. The rsa function creates a key with (at most) the given number of bits, i.e., if bits equals 20, it creates a key $n = pq$ such that n is approximately 2^{20}. Typical real-life cryptosystems would choose keys that are 512, 1024, or 2048 bits long. Try generating large keys yourself using Sage; how long does it take?

```
sage: def rsa(bits):
...     # only prove correctness up to 1024 bits
...     proof = (bits <= 1024)
...     p = next_prime(ZZ.random_element(2**(bits//2 +1)),
...                 proof=proof)
...     q = next_prime(ZZ.random_element(2**(bits//2 +1)),
...                 proof=proof)
...     n = p * q
...     phi_n = (p-1) * (q-1)
...     while True:
...         e = ZZ.random_element(1,phi_n)
...         if gcd(e,phi_n) == 1: break
...     d = lift(Mod(e,phi_n)^(-1))
...     return e, d, n
...
sage: def encrypt(m,e,n):
...     return lift(Mod(m,n)^e)
...
sage: def decrypt(c,d,n):
...     return lift(Mod(c,n)^d)
...
sage: e,d,n = rsa(20)
sage: c = encrypt(123, e, n)
sage: decrypt(c, d, n)
123
```

3.3.2 Encoding a Phrase in a Number

In order to use the RSA cryptosystem to encrypt messages, it is necessary to encode them as a sequence of numbers of size less than $n = pq$. We now describe a simple way to do this. Note that in any actual deployed implementation, it is crucial that you add extra random characters ("salt") at the beginning of each block of the message, so that the same plain text encodes differently each time. This helps thwart chosen plain text attacks.

Suppose s is a sequence of capital letters and spaces, and that s does not begin with a space. We encode s as a number in base 27 as follows: a single space corresponds to 0, the letter A to 1, B to 2, …, Z to 26. Thus "RUN

NIKITA” is a number written in base 27.

$$\begin{aligned}\text{RUN NIKITA} \quad \leftrightarrow \quad & 27^9 \cdot 18 + 27^8 \cdot 21 + 27^7 \cdot 14 + 27^6 \cdot 0 + 27^5 \cdot 14 \\ & + 27^4 \cdot 9 + 27^3 \cdot 11 + 27^2 \cdot 9 + 27 \cdot 20 + 1 \\ & = 143338425831991 \text{ (in decimal).}\end{aligned}$$

To recover the letters from the decimal number, repeatedly divide by 27 and read off the letter corresponding to each remainder.

$$\begin{array}{rcrcrc}
143338425831991 & = & 5308830586370 \cdot 27 & + & 1 & \text{“A”} \\
5308830586370 & = & 196623355050 \cdot 27 & + & 20 & \text{“T”} \\
196623355050 & = & 7282346483 \cdot 27 & + & 9 & \text{“I”} \\
7282346483 & = & 269716536 \cdot 27 & + & 11 & \text{“K”} \\
269716536 & = & 9989501 \cdot 27 & + & 9 & \text{“I”} \\
9989501 & = & 369981 \cdot 27 & + & 14 & \text{“N”} \\
369981 & = & 13703 \cdot 27 & + & 0 & \text{“ ”} \\
13703 & = & 507 \cdot 27 & + & 14 & \text{“N”} \\
507 & = & 18 \cdot 27 & + & 21 & \text{“U”} \\
18 & = & 0 \cdot 27 & + & 18 & \text{“R”}
\end{array}$$

If $27^k \leq n$, then any sequence of k letters can be encoded as above using a positive integer $\leq n$. Thus if we can encrypt integers of size at most n, then we must break our message up into blocks of size at most $\log_{27}(n)$.

SAGE Example 3.3.3. We use Sage to implement conversion between a string and a number, though in a bit more generally than in the toy illustration above (which used only base 27). The input string s on a computer is stored in a format called ASCII, so each “letter” corresponds to an integer between 0 and 255, inclusive. This number is obtained from the letter using the `ord` command.

```
sage: def encode(s):
...     s = str(s)      # make input a string
...     return sum(ord(s[i])*256^i for i in range(len(s)))
sage: def decode(n):
...     n = Integer(n)  # make input an integer
...     v = []
...     while n != 0:
...         v.append(chr(n % 256))
...         n //= 256    # this replaces n by floor(n/256).
...     return ''.join(v)
sage: m = encode('Run Nikita!'); m
40354769014714649421968722
sage: decode(m)
'Run Nikita!'
```

3.3.3 Some Complete Examples

To make the arithmetic easier to follow, we use small prime numbers p and q and encrypt the single letter "X" using the RSA cryptosystem. First, we compute the parameters of an RSA cryptosystem.

1. Choose p and q: Let $p = 17$, $q = 19$, so $n = pq = 323$.
2. Compute $\varphi(n)$:
$$\begin{aligned}\varphi(n) &= \varphi(p \cdot q) = \varphi(p) \cdot \varphi(q) = (p-1)(q-1) \\ &= pq - p - q + 1 = 323 - 17 - 19 + 1 = 288.\end{aligned}$$
3. Randomly choose an $e < 288$: We choose $e = 95$.
4. Solve
$$95x \equiv 1 \pmod{288}.$$
Using the GCD algorithm, we find that $d = 191$ solves the equation.

We have thus computed the parameters of an RSA public key cryptosystem. The public key is $(323, 95)$, so the encryption function is

$$E(x) = x^{95},$$

and the decryption function is $D(x) = x^{191}$.

Next, we encrypt the letter "X". It is encoded as the number 24, since X is the 24th letter of the alphabet. We have

$$E(24) = 24^{95} = 294 \in \mathbf{Z}/323\mathbf{Z}.$$

To decrypt, we compute E^{-1}:

$$E^{-1}(294) = 294^{191} = 24 \in \mathbf{Z}/323\mathbf{Z}.$$

This next example illustrates RSA but with bigger numbers. Let

$$p = 738873402423833494183027176953, \; q = 3787776806865662882378273.$$

Then,

$$n = p \cdot q = 2798687536910915970127263606347911460948554197853542169$$

and

$$\begin{aligned}\varphi(n) &= (p-1)(q-1) \\ &= 2798687536910915970127262867470721260308194351943986944.\end{aligned}$$

Using a pseudo-random number generator on a computer, the author randomly chose the integer

$$e = 148395919486620417934853601028471665544213902491572069 9.$$

Then,

$$d = 2113367928496305469541348387088632973457802358781610803$$

Since $\log_{27}(n) \approx 38.04$, we can encode then encrypt single blocks of up to 38 letters. Let's encrypt the string `RUN NIKITA`, which encodes as $m = 143338425831991$. We have

$$\begin{aligned} E(m) &= m^e \\ &= 1504554432996568133393088878600948101773726800878873990. \end{aligned}$$

Remark 3.3.4. In practice, one usually choses e to be small, since that does not seem to reduce the security of RSA, and makes the key size smaller. For example, in the OpenSSL documentation (see `http://www.openssl.org/`) about their implementation of RSA, it states that "The exponent is an odd number, typically 3, 17 or 65537."

3.4 Attacking RSA

Suppose Nikita's public key is (n, e) and her decryption key is d, so $ed \equiv 1 \pmod{\varphi(n)}$. If somehow we compute the factorization $n = pq$, then we can compute $\varphi(n) = (p-1)(q-1)$ and hence compute d. Thus, if we can factor n then we can break the corresponding RSA public-key cryptosystem.

3.4.1 Factoring n Given $\varphi(n)$

Suppose $n = pq$. Given $\varphi(n)$, it is very easy to compute p and q. We have

$$\varphi(n) = (p-1)(q-1) = pq - (p+q) + 1,$$

so we know both $pq = n$ and $p + q = n + 1 - \varphi(n)$. Thus, we know the polynomial

$$x^2 - (p+q)x + pq = (x-p)(x-q)$$

whose roots are p and q. These roots can be found using the quadratic formula.

Example 3.4.1. The number $n = pq = 31615577110997599711$ is a product of two primes, and $\varphi(n) = 31615577098574867424$. We have

$$\begin{aligned} f &= x^2 - (n + 1 - \varphi(n))x + n \\ &= x^2 - 12422732288x + 31615577110997599711 \\ &= (x - 3572144239)(x - 8850588049), \end{aligned}$$

where the factorization step is easily accomplished using the quadratic formula:

$$\begin{aligned}\frac{-b+\sqrt{b^2-4ac}}{2a}\\ &= \frac{12422732288+\sqrt{12422732288^2-4\cdot 31615577110997599711}}{2}\\ &= 8850588049.\end{aligned}$$

We conclude that $n = 3572144239 \cdot 8850588049$.

SAGE Example 3.4.2. The following Sage function factors $n = pq$ given n and $\varphi(n)$.

```
sage: def crack_rsa(n, phi_n):
...     R.<x> = PolynomialRing(QQ)
...     f = x^2 - (n+1 -phi_n)*x + n
...     return [b for b, _ in f.roots()]
sage: crack_rsa(31615577110997599711, 31615577098574867424)
[8850588049, 3572144239]
```

3.4.2 When p and q are Close

Suppose that p and q are "close" to each other. Then it is easy to factor n using a factorization method of Fermat called the *Fermat Factorization Method*.

Suppose $n = pq$ with $p > q$. Then,

$$n = \left(\frac{p+q}{2}\right)^2 - \left(\frac{p-q}{2}\right)^2.$$

Since p and q are "close,"

$$s = \frac{p-q}{2}$$

is small,

$$t = \frac{p+q}{2}$$

is only slightly larger than $\sqrt{n}$, and $t^2 - n = s^2$ is a perfect square. So, we just try

$$t = \lceil\sqrt{n}\rceil, \quad t = \lceil\sqrt{n}\rceil + 1, \quad t = \lceil\sqrt{n}\rceil + 2, \ldots$$

until $t^2 - n$ is a perfect square s^2. (Here $\lceil x\rceil$ denotes the least integer $n \geq x$.) Then

$$p = t + s, \qquad q = t - s.$$

Example 3.4.3. Suppose $n = 23360947609$. Then

$$\sqrt{n} = 152842.88\ldots.$$

If $t = 152843$, then $\sqrt{t^2 - n} = 187.18\ldots$.
If $t = 152844$, then $\sqrt{t^2 - n} = 583.71\ldots$.
If $t = 152845$, then $\sqrt{t^2 - n} = 804 \in \mathbf{Z}$.
Thus $s = 804$. We find that $p = t + s = 153649$ and $q = t - s = 152041$.

SAGE Example 3.4.4. We implement the above algorithm for factoring an RSA modulus $n = pq$, when one of p and q is close to $\sqrt{n}$.

```
sage: def crack_when_pq_close(n):
...     t = Integer(ceil(sqrt(n)))
...     while True:
...        k = t^2 - n
...        if k > 0:
...           s = Integer(int(round(sqrt(t^2 - n))))
...           if s^2 + n == t^2:
...              return t+s, t-s
...
...        t += 1
...
sage: crack_when_pq_close(23360947609)
(153649, 152041)
```

For example, you might think that choosing a random prime, and the next prime after would be a good idea, but instead it creates an easy-to-crack cryptosystem.

```
sage: p = next_prime(2^128); p
340282366920938463463374607431768211507
sage: q = next_prime(p)
sage: crack_when_pq_close(p*q)
(340282366920938463463374607431768211537,
      340282366920938463463374607431768211507)
```

3.4.3 Factoring n Given d

In this section, we show that finding the decryption key d for an RSA cryptosystem is, in practice, at least as difficult as factoring n. We give a probabilistic algorithm that given a decryption key determines the factorization of n.

Consider an RSA cryptosystem with modulus n and encryption key e. Suppose we somehow finding an integer d such that

$$a^{ed} \equiv a \pmod{n}$$

for all a. Then $m = ed - 1$ satisfies $a^m \equiv 1 \pmod{n}$ for all a that are coprime to n. As we saw in Section 3.4.1, knowing $\varphi(n)$ leads directly to a factorization of n. Unfortunately, knowing d does not seem to lead easily to a factorization of n. However, there is a probabilistic procedure that, given an m such that $a^m \equiv 1 \pmod{n}$, will find a factorization of n with "high probability" (we will not analyze the probability here).

Algorithm 3.4.5 (Probabilistic Algorithm to Factor n)**.** Let $n = pq$ be the product of two distinct odd primes, and suppose m is an integer such that $a^m \equiv 1 \pmod{n}$ for all a coprime to n. This probabilistic algorithm factors n with "high probability." In the steps below, a always denotes an integer coprime to $n = pq$.

1. [Divide out powers of 2] If m is even and $a^{m/2} \equiv 1 \pmod{n}$ for several randomly chosen a, set $m = m/2$, and go to Step 1, otherwise let a be such that $a^{m/2} \not\equiv 1 \pmod{n}$.
2. [Compute GCD] Choose a random a and compute $g = \gcd(a^{m/2} - 1, n)$.
3. [Terminate?] If g is a proper divisor of n, output g and terminate. Otherwise go to Step 2.

Before giving the proof, we introduce some more terminology from algebra.

Definition 3.4.6 (Group Homomorphism)**.** Let G and H be groups. A map $\varphi : G \to H$ is a *group homomorphism* if for all $a, b \in G$ we have $\varphi(ab) = \varphi(a)\varphi(b)$. A group homomorphism is called *surjective* if for every $c \in H$ there is $a \in G$ such that $\varphi(a) = c$. The *kernel* of a group homomorphism $\varphi : G \to H$ is the set $\ker(\varphi)$ of elements $a \in G$ such that $\varphi(a) = 1$. A group homomorphism is *injective* if $\ker(\varphi) = \{1\}$.

Definition 3.4.7 (Subgroup)**.** If G is a group and H is a subset of G, then H is a *subgroup* if H is a group under the group operation on G.

For example, if $\varphi : G \to H$ is a group homomorphism, then $\ker(\varphi)$ is a subgroup of G (see Exercise 2.21).

We now return to discussing Algorithm 3.4.5. In Step 1, note that m is even since $(-1)^m \equiv 1 \pmod{n}$, so it makes sense to consider $m/2$. It is not practical to determine whether or not $a^{m/2} \equiv 1 \pmod{n}$ for all a, because it would require doing a computation for too many a. Instead, we try a few random a; if $a^{m/2} \equiv 1 \pmod{n}$ for the a we check, we divide m by 2. Also note that if there exists even a single a such that $a^{m/2} \not\equiv 1 \pmod{n}$, then half the a have this property, since then $a \mapsto a^{m/2}$ is a surjective homomorphism $(\mathbf{Z}/n\mathbf{Z})^* \to \{\pm 1\}$ and the kernel has index 2.

Proposition 2.5.3 implies that if $x^2 \equiv 1 \pmod{p}$ then $x = \pm 1 \pmod{p}$. In Step 2, since $(a^{m/2})^2 \equiv 1 \pmod{n}$, we also have $(a^{m/2})^2 \equiv 1 \pmod{p}$ and $(a^{m/2})^2 \equiv 1 \pmod{q}$, so $a^{m/2} \equiv \pm 1 \pmod{p}$ and $a^{m/2} \equiv \pm 1 \pmod{q}$. Since $a^{m/2} \not\equiv 1 \pmod{n}$, there are three possibilities for these signs, so with positive probability one of the following two possibilities occurs:

1. $a^{m/2} \equiv +1 \pmod{p}$ and $a^{m/2} \equiv -1 \pmod{q}$

2. $a^{m/2} \equiv -1 \pmod{p} \qquad \text{and} \qquad a^{m/2} \equiv +1 \pmod{q}.$

The only other possibility is that both signs are -1. In the first case,

$$p \mid a^{m/2} - 1 \qquad \text{but} \qquad q \nmid a^{m/2} - 1,$$

so $\gcd(a^{m/2} - 1, pq) = p$, and we have factored n. Similarly, in the second case, $\gcd(a^{m/2} - 1, pq) = q$, and we again factor n.

Example 3.4.8. Somehow we discover that the RSA cryptosystem with

$$n = 32295194023343 \qquad \text{and} \qquad e = 29468811804857$$

has decryption key $d = 11127763319273$. We use this information and Algorithm 3.4.5 to factor n. If

$$m = ed - 1 = 327921963064646896263108960,$$

then $\varphi(pq) \mid m$, so $a^m \equiv 1 \pmod{n}$ for all a coprime to n. For each $a \leq 20$ we find that $a^{m/2} \equiv 1 \pmod{n}$, so we replace m with

$$\frac{m}{2} = 163960981532323448131554480.$$

Again, we find with this new m that for each $a \leq 20$, $a^{m/2} \equiv 1 \pmod{n}$, so we replace m by 81980490766161724065777240. Yet again, for each $a \leq 20$, $a^{m/2} \equiv 1 \pmod{n}$, so we replace m by 40990245383080862032888620. This is enough, since $2^{m/2} \equiv 4015382800099 \pmod{n}$. Then,

$$\gcd(2^{m/2} - 1, n) = \gcd(4015382800098, 32295194023343) = 737531,$$

and we have found a factor of n. Dividing, we find that

$$n = 737531 \cdot 43788253.$$

SAGE Example 3.4.9. We implement Algorithm 3.4.5 in Sage.

```
sage: def crack_given_decrypt(n, m):
...     n = Integer(n); m = Integer(m);  # some type checking
...     # Step 1: divide out powers of 2
...     while True:
...         if is_odd(m): break
...         divide_out = True
...         for i in range(5):
...            a = randrange(1,n)
...            if gcd(a,n) == 1:
...               if Mod(a,n)^(m//2) != 1:
...                   divide_out = False
...                   break
...         if divide_out:
...             m = m//2
...         else:
...             break
...     # Step 2: Compute GCD
...     while True:
...         a = randrange(1,n)
...         g = gcd(lift(Mod(a, n)^(m//2)) - 1, n)
...         if g != 1 and g != n:
...             return g
...
```

We show how to verify Example 3.4.8 using Sage.

```
sage: n=32295194023343; e=29468811804857; d=11127763319273
sage: crack_given_decrypt(n, e*d - 1)
737531
sage: factor(n)
737531 * 43788253
```

We try a much larger example.

```
sage: e = 22601762315966221465875845336488389513
sage: d = 31940292321834506197902778067109010093
sage: n = 268494924039590992469444675130990465673
sage: p = crack_given_decrypt(n, e*d - 1)
sage: p   # random output (could be other prime divisor)
13432418150982799907
sage: n % p
0
```

3.4.4 Further Remarks

If one were to implement an actual RSA cryptosystem, there are many additional tricks and ideas to keep in mind. For example, one can add some extra random letters to each block of text, so that a given string will encrypt differently each time it is encrypted. This makes it more difficult for an attacker who knows the encrypted and plaintext versions of one message to gain information about subsequent encrypted messages. In any particular implementation, there might be attacks that would be devastating in practice, but which would not require factorization of the RSA modulus.

RSA is in common use, for example, it is used in OpenSSH protocol version 1 (see `http://www.openssh.com/`).

We will consider the ElGamal cryptosystem in Sections 6.4.2. It has a similar flavor to RSA, but is more flexible in some ways.

Probably the best general purpose attack on RSA is the number field sieve, which is a general algorithm for factoring integers of the form pq. A description of the sieve is beyond the scope of this book. The elliptic curve method is another related general algorithm that we will discuss in detail in Section 6.3.

SAGE Example 3.4.10. Here is a simple example of using a variant of the number field sieve (called the quadratic sieve) in Sage to factor an RSA key with about 192 bits:

```
sage: set_random_seed(0)
sage: p = next_prime(randrange(2^96))
sage: q = next_prime(randrange(2^97))
sage: n = p * q
sage: qsieve(n)
([6340271405786663791648052309,
  46102313108592180286398757159], '')
```

3.5 Exercises

3.1 This problem concerns encoding phrases using numbers using the encoding of Section 3.3.2. What is the longest that an arbitrary sequence of letters (no spaces) can be if it must fit in a number that is less than 10^{20}?

3.2 Suppose Michael creates an RSA cryptosystem with a very large modulus n for which the factorization of n cannot be found in a reasonable amount of time. Suppose that Nikita sends messages to Michael by representing each alphabetic character as an integer between 0 and 26 (`A` corresponds to 1, `B` to 2, etc., and a space ␣ to 0), then encrypts each number *separately* using Michael's RSA cryptosystem. Is this method secure? Explain your answer.

3.3 For any $n \in \mathbf{N}$, let $\sigma(n)$ be the sum of the divisors of n; for example, $\sigma(6) = 1 + 2 + 3 + 6 = 12$ and $\sigma(10) = 1 + 2 + 5 + 10 = 18$. Suppose that $n = pqr$ with p, q, and r distinct primes. Devise an "efficient" algorithm that given n, $\varphi(n)$ and $\sigma(n)$, computes the factorization of n. For example, if $n = 105$, then $p = 3$, $q = 5$, and $r = 7$, so the input to the algorithm would be

$$n = 105, \qquad \varphi(n) = 48, \qquad \text{and} \quad \sigma(n) = 192,$$

and the output would be 3, 5, and 7.

3.4 You and Nikita wish to agree on a secret key using the Diffie-Hellman key exchange. Nikita announces that $p = 3793$ and $g = 7$. Nikita secretly chooses a number $n < p$ and tells you that $g^n \equiv 454 \pmod{p}$. You choose the random number $m = 1208$. What is the secret key?

3.5 You see Michael and Nikita agree on a secret key using the Diffie-Hellman key exchange. Michael and Nikita choose $p = 97$ and $g = 5$. Nikita chooses a random number n and tells Michael that $g^n \equiv 3 \pmod{97}$, and Michael chooses a random number m and tells Nikita that $g^m \equiv 7 \pmod{97}$. Brute force crack their code: What is the secret key that Nikita and Michael agree upon? What is n? What is m?

3.6 In this problem, you will "crack" an RSA cryptosystem. What is the secret decoding number d for the RSA cryptosystem with public key $(n, e) = (5352381469067, 4240501142039)$?

3.7 Nikita creates an RSA cryptosystem with public key

$$(n, e) = (1433811615146881, 329222149569169).$$

In the following two problems, show the steps you take to factor n. (Don't simply factor n directly using a computer.)

(a) Somehow you discover that $d = 116439879930113$. Show how to use the probabilistic algorithm of Section 3.4.3 to factor n.

(b) In part (a) you found that the factors p and q of n are very close. Show how to use the Fermat Factorization Method of Section 3.4.2 to factor n.

4
Quadratic Reciprocity

A linear equation

$$ax \equiv b \pmod{n}$$

has a solution if and only if $\gcd(a, n)$ divides b (see Proposition 2.1.15). This chapter is about some amazing mathematics motivated by the search for a criterion for whether or not a given quadratic equation

$$ax^2 + bx + c \equiv 0 \pmod{n}$$

has a solution. In many cases, the Chinese Remainder Theorem and the quadratic formula reduce this to the key question of whether a given integer a is a perfect square modulo a prime p.

The Quadratic Reciprocity Law of Gauss provides a precise answer to the following question: For which primes p is the image of a in $(\mathbf{Z}/p\mathbf{Z})^*$ a perfect square? A deep fact, which we will completely prove in this chapter, is that the answer depends only on the reduction of p modulo $4a$. Thus *to decide if a is a square modulo p, one only needs to consider the residue of p modulo $4a$*, which is extremely surprising. It turns out that this "reciprocity law" goes to the heart of modern number theory and touches on advanced topics such as class field theory and the Langlands program.

There are over a hundred proofs of the Quadratic Reciprocity Law (see [Lem] for a long list). In this chapter, we give two proofs. The first, which we give in Section 4.3, is completely elementary and involves keeping track of integer points in intervals. It is satisfying because one can understand every detail without much abstraction, but it might be unsatisfying if you find it difficult to conceptualize what is going on. In contrast, our second proof, which we give in Section 4.4, is more abstract and uses a conceptual development of properties of Gauss sums. You should read Sections 4.1 and 4.2, then at least one of Section 4.3 or Section 4.4, depending on your taste and how much abstract algebra you know.

In Section 4.5, we return to the computational question of actually finding square roots and solving quadratic equations in practice.

4.1 Statement of the Quadratic Reciprocity Law

In this section, we state the Quadratic Reciprocity Law.

Definition 4.1.1 (Quadratic Residue)**.** Fix a prime p. An integer a not divisible by p is a *quadratic residue* modulo p if a is a square modulo p; otherwise, a is a *quadratic nonresidue.*

For example, the squares modulo 5 are

$$1^2 = 1, \quad 2^2 = 4, \quad 3^2 = 4, \quad 4^2 = 1, \qquad \pmod 5$$

so 1 and 4 are both quadratic residues and 2 and 3 are quadratic nonresidues.

The quadratic reciprocity theorem is the deepest theorem that we will prove in this book. It connects the question of whether or not a is a quadratic residue modulo p to the question of whether p is a quadratic residue modulo each of the prime divisors of a. To express it precisely, we introduce some new notation.

Definition 4.1.2 (Legendre Symbol)**.** Let p be an odd prime and let a be an integer. Set

$$\left(\frac{a}{p}\right) = \begin{cases} 0 & \text{if } \gcd(a,p) \neq 1, \\ +1 & \text{if } a \text{ is a quadratic residue, and} \\ -1 & \text{if } a \text{ is a quadratic nonresidue.} \end{cases}$$

We call this symbol the *Legendre Symbol.*

For example, we have

$$\left(\frac{1}{5}\right) = 1, \quad \left(\frac{2}{5}\right) = -1, \quad \left(\frac{3}{5}\right) = -1, \quad \left(\frac{4}{5}\right) = 1, \quad \left(\frac{5}{5}\right) = 1.$$

This notation is well entrenched in the literature even though it is also the notation for “a divided by p;” be careful not to confuse the two.

SAGE Example 4.1.3. Use the `legendre_symbol` command to compute the Legendre symbol in Sage.

```
sage: legendre_symbol(2,3)
-1
sage: legendre_symbol(1,3)
1
sage: legendre_symbol(3,5)
-1
sage: legendre_symbol(Mod(3,5), 5)
-1
```

Since $\left(\frac{a}{p}\right)$ only depends on $a \pmod{p}$, it makes sense to define $\left(\frac{a}{p}\right)$ for $a \in \mathbf{Z}/p\mathbf{Z}$ to be $\left(\frac{\tilde{a}}{p}\right)$ for any lift $\tilde{a}$ of a to $\mathbf{Z}$.

Recall (see Definition 3.4.6) that a group homomorphism $\varphi : G \to H$ is a map such that for every $a, b \in G$ we have $\varphi(ab) = \varphi(a)\varphi(b)$. Moreover, we say that φ is surjective if for every $c \in H$ there is an $a \in G$ with $\varphi(a) = c$. The next lemma explains how the quadratic residue symbol defines a surjective group homomorphism.

Lemma 4.1.4. *The map $\psi : (\mathbf{Z}/p\mathbf{Z})^* \to \{\pm 1\}$ given by $\psi(a) = \left(\frac{a}{p}\right)$ is a surjective group homomorphism.*

Proof. By Theorem 2.5.8, primitive roots exist, so there is $g \in (\mathbf{Z}/p\mathbf{Z})^*$ such that the elements of $(\mathbf{Z}/p\mathbf{Z})^*$ are

$$g, g^2, \ldots, g^{(p-1)/2}, g^{(p+1)/2}, \ldots, g^{p-1} = 1.$$

Since $p - 1$ is even, the squares of elements of $(\mathbf{Z}/p\mathbf{Z})^*$ are

$$g^2, g^4, \ldots, g^{(p-1)/2 \cdot 2} = 1, g^{p+1} = g^2, \ldots, g^{2(p-1)}.$$

Note that the powers of g starting with $g^{p+1} = g^2$ all appeared earlier on the list. Thus, the perfect squares in $(\mathbf{Z}/p\mathbf{Z})^*$ are exactly the powers g^n with $n = 2, 4, \ldots, p - 1$, even, and the nonsquares the powers g^n with $n = 1, 3, \ldots, p - 2$, odd. It follows that ψ is a homomorphism since an odd plus an odd is even, the sum of two evens is even, and odd plus an even is odd. Moreover, since g is not a square, $\psi(g) = -1$, so ψ is surjective.

□

Remark 4.1.5. We rephrase the above proof in the language of group theory. The group $G = (\mathbf{Z}/p\mathbf{Z})^*$ of order $p - 1$ is a cyclic group. Since p is odd, $p - 1$ is even, so the subgroup H of squares of elements of G has index 2 in G. (See Exercise 4.2 for why H is a subgroup.) Since $\left(\frac{a}{p}\right) = 1$ if and only if $a \in H$, we see that ψ is the composition $G \to G/H \cong \{\pm 1\}$, where we identify the nontrivial element of G/H with -1.

Remark 4.1.6. We can alternatively prove that ψ is surjective without using that $(\mathbf{Z}/p\mathbf{Z})^*$ is cyclic, as follows. If $a \in (\mathbf{Z}/p\mathbf{Z})^*$ is a square, say $a \equiv b^2$

TABLE 4.1. When is 5 a square modulo p?

p	$\left(\frac{5}{p}\right)$	p mod 5
7	-1	2
11	1	1
13	-1	3
17	-1	2
19	1	4
23	-1	3
29	1	4
31	1	1
37	-1	2
41	1	1
43	-1	3
47	-1	2

(mod p), then $a^{(p-1)/2} = b^{p-1} \equiv 1 \pmod{p}$, so a is a root of $f = x^{(p-1)/2} - 1$. By Proposition 2.5.3, the polynomial f has at most $(p-1)/2$ roots. Thus, there must be an $a \in (\mathbf{Z}/p\mathbf{Z})^*$ that is not a root of f, and for that a, we have $\psi(a) = \left(\frac{a}{p}\right) = -1$, and trivially $\psi(1) = 1$, so the map ψ is surjective. Note that this argument does not prove that ψ is a homomorphism.

The symbol $\left(\frac{a}{p}\right)$ only depends on the residue class of a modulo p, so making a table of values $\left(\frac{a}{5}\right)$ for many values of a would be easy. Would it be easy to make a table of $\left(\frac{5}{p}\right)$ for many p? Perhaps, since there *appears* to be a simple pattern in Table 4.1. It seems that $\left(\frac{5}{p}\right)$ depends only on the congruence class of p modulo 5. More precisely, $\left(\frac{5}{p}\right) = 1$ if and only if $p \equiv 1, 4 \pmod{5}$, i.e., $\left(\frac{5}{p}\right) = 1$ if and only if p is a square modulo 5.

Based on similar observations, in the 18th century various mathematicians found a conjectural explanation for the mystery suggested by Table 4.1. Finally, on April 8, 1796, at the age of 19, Gauss proved the following theorem.

Theorem 4.1.7 (Gauss's Quadratic Reciprocity Law)**.** *Suppose p and q are distinct odd primes. Then*

$$\left(\frac{p}{q}\right) = (-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}}\left(\frac{q}{p}\right).$$

Also

$$\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2} \qquad \text{and} \qquad \left(\frac{2}{p}\right) = \begin{cases} 1 & \text{if } p \equiv \pm 1 \pmod{8} \\ -1 & \text{if } p \equiv \pm 3 \pmod{8}. \end{cases}$$

We will give two proofs of Gauss's formula relating $\left(\frac{p}{q}\right)$ to $\left(\frac{q}{p}\right)$. The first elementary proof is in Section 4.3, and the second more algebraic proof is in Section 4.4.

In our example, Gauss's theorem implies that

$$\left(\frac{5}{p}\right) = (-1)^{2\cdot\frac{p-1}{2}}\left(\frac{p}{5}\right) = \left(\frac{p}{5}\right) = \begin{cases} +1 & \text{if } p \equiv 1,4 \pmod 5\\ -1 & \text{if } p \equiv 2,3 \pmod 5.\end{cases}$$

As an application, the following example illustrates how to answer questions like "is a a square modulo b" using Theorem 4.1.7.

Example 4.1.8. Is 69 a square modulo the prime 389? We have

$$\left(\frac{69}{389}\right) = \left(\frac{3\cdot 23}{389}\right) = \left(\frac{3}{389}\right)\cdot\left(\frac{23}{389}\right) = (-1)\cdot(-1) = 1.$$

Here

$$\left(\frac{3}{389}\right) = \left(\frac{389}{3}\right) = \left(\frac{2}{3}\right) = -1,$$

and

$$\begin{aligned}\left(\frac{23}{389}\right) &= \left(\frac{389}{23}\right) = \left(\frac{21}{23}\right) = \left(\frac{-2}{23}\right)\\ &= \left(\frac{-1}{23}\right)\left(\frac{2}{23}\right) = (-1)^{\frac{23-1}{2}}\cdot 1 = -1.\end{aligned}$$

Thus 69 is a square modulo 389.

SAGE Example 4.1.9. We could also do this computation in Sage as follows:

```
sage: legendre_symbol(69,389)
1
```

Though we know that 69 is a square modulo 389, we don't know an explicit x such that $x^2 \equiv 69 \pmod{389}$! This is reminiscent of how we proved using Theorem 2.1.20 that certain numbers are composite without knowing a factorization.

Remark 4.1.10. The Jacobi symbol is an extension of the Legendre symbol to composite moduli. For more details, see Exercise 4.9.

4.2 Euler's Criterion

Let p be an odd prime and a an integer not divisible by p. Euler used the existence of primitive roots to show that $\left(\frac{a}{p}\right)$ is congruent to $a^{(p-1)/2}$ modulo p. We will use this fact repeatedly below in both proofs of Theorem 4.1.7.

Proposition 4.2.1 (Euler's Criterion)**.** *We have* $\left(\frac{a}{p}\right) = 1$ *if and only if*

$$a^{(p-1)/2} \equiv 1 \pmod p.$$

Proof. The map $\varphi : (\mathbf{Z}/p\mathbf{Z})^* \to (\mathbf{Z}/p\mathbf{Z})^*$ given by $\varphi(a) = a^{(p-1)/2}$ is a group homomorphism, since powering is a group homomorphism of any abelian group (see Exercise 4.2). Let $\psi : (\mathbf{Z}/p\mathbf{Z})^* \to \{\pm 1\}$ be the homomorphism $\psi(a) = \left(\frac{a}{p}\right)$ of Lemma 4.1.4. If $a \in \ker(\psi)$, then $a = b^2$ for some $b \in (\mathbf{Z}/p\mathbf{Z})^*$, so

$$\varphi(a) = a^{(p-1)/2} = (b^2)^{(p-1)/2} = b^{p-1} = 1.$$

Thus $\ker(\psi) \subset \ker(\varphi)$. By Lemma 4.1.4, $\ker(\psi)$ has index 2 in $(\mathbf{Z}/p\mathbf{Z})^*$, i.e., $\#(\mathbf{Z}/p\mathbf{Z})^* = 2 \cdot \#\ker(\psi)$. Since the kernel of a homomorphism is a group, and the order of a subgroup divides the order of the group, we have either $\ker(\varphi) = \ker(\psi)$ or $\varphi = 1$. If $\varphi = 1$, the polynomial $x^{(p-1)/2} - 1$ has $p - 1$ roots in the field $\mathbf{Z}/p\mathbf{Z}$, which contradicts Proposition 2.5.3. Thus $\ker(\varphi) = \ker(\psi)$, which proves the proposition. □

SAGE Example 4.2.2. From a computational point of view, Corollary 4.2.3 provides a convenient way to compute $\left(\frac{a}{p}\right)$, which we illustrate in Sage:

```
sage: def kr(a, p):
...    if Mod(a,p)^((p-1)//2) == 1:
...       return 1
...    else:
...       return -1
sage: for a in range(1,5):
...    print a, kr(a,5)
1 1
2 -1
3 -1
4 1
```

Corollary 4.2.3. *The equation* $x^2 \equiv a \pmod{p}$ *has no solution if and only if* $a^{(p-1)/2} \equiv -1 \pmod{p}$. *Thus* $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod{p}$.

Proof. This follows from Proposition 4.2.1 and the fact that the polynomial $x^2 - 1$ has no roots besides $+1$ and -1 (which follows from Proposition 2.5.5). □

As additional computational motivation for the value of Corollary 4.2.3, note that to evaluate $\left(\frac{a}{p}\right)$ using Theorem 4.1.7 would not be practical if a and p are both very large, because it would require factoring a. However, Corollary 4.2.3 provides a method for evaluating $\left(\frac{a}{p}\right)$ without factoring a.

Example 4.2.4. Suppose $p = 11$. By squaring each element of $(\mathbf{Z}/11\mathbf{Z})^*$, we see that the squares modulo 11 are $\{1, 3, 4, 5, 9\}$. We compute $a^{(p-1)/2} = a^5$

for each $a \in (\mathbf{Z}/11\mathbf{Z})^*$ and get

$$\begin{aligned}&1^5 = 1,\ 2^5 = -1,\ 3^5 = 1,\ 4^5 = 1,\ 5^5 = 1,\\ &6^5 = -1,\ 7^5 = -1,\ 8^5 = -1,\ 9^5 = 1,\ 10^5 = -1.\end{aligned}$$

Thus the a with $a^5 = 1$ are $\{1, 3, 4, 5, 9\}$, just as Proposition 4.2.1 predicts.

Example 4.2.5. We determine whether or not 3 is a square modulo the prime $p = 726377359$.

```
sage: p = 726377359
sage: Mod(3, p)^((p-1)//2)
726377358
```

so

$$3^{(p-1)/2} \equiv -1 \pmod{726377359}.$$

Thus 3 is not a square modulo p. This computation wasn't difficult, but it would have been tedious by hand. Since 3 is small, the Quadratic Reciprocity Law provides a way to answer this question, which could easily be carried out by hand:

$$\begin{aligned}\left(\frac{3}{726377359}\right) &= (-1)^{(3-1)/2\cdot(726377359-1)/2}\left(\frac{726377359}{3}\right)\\ &= (-1)\cdot\left(\frac{1}{3}\right) = -1.\end{aligned}$$

4.3 First Proof of Quadratic Reciprocity

Our first proof of quadratic reciprocity is elementary. The proof involves keeping track of integer points in intervals. Proving Gauss's lemma is the first step; this lemma computes $\left(\frac{a}{p}\right)$ in terms of the number of integers of a certain type that lie in a certain interval. We next prove Lemma 4.3.3, which controls how the parity of the number of integer points in an interval changes when an endpoint of the interval is changed. We then prove that $\left(\frac{a}{p}\right)$ depends only on p modulo $4a$ by applying Gauss's Lemma and keeping careful track of intervals as they are rescaled and their endpoints are changed. Finally, in Section 4.3.2, we use some basic algebra to deduce the Quadratic Reciprocity Law using the tools we've just developed. Our proof follows the one given in [Dav99] closely.

Lemma 4.3.1 (Gauss's Lemma)**.** *Let p be an odd prime and let a be an integer $\not\equiv 0 \pmod{p}$. Form the numbers*

$$a,\ 2a,\ 3a,\ \ldots,\ \frac{p-1}{2}a$$

and reduce them modulo p to lie in the interval $(-\frac{p}{2},\ \frac{p}{2})$, i.e., for each of the above products $k \cdot a$ find a number in the interval $(-\frac{p}{2},\ \frac{p}{2})$ that is congruent to $k \cdot a$ modulo p. Let ν be the number of negative numbers in the resulting set. Then

$$\left(\frac{a}{p}\right) = (-1)^{\nu}.$$

Proof. In defining ν, we expressed each number in

$$S = \left\{a, 2a, \ldots, \frac{p-1}{2}a\right\}$$

as congruent to a number in the set

$$\left\{1, -1, 2, -2, \ldots, \frac{p-1}{2}, -\frac{p-1}{2}\right\}.$$

No number $1, 2, \ldots, \frac{p-1}{2}$ appears more than once, with either choice of sign, because if it did then either two elements of S are congruent modulo p or 0 is the sum of two elements of S, and both events are impossible (the former case cannot occur because of cancellation modulo p, and in the latter case we would have $ka + ja \equiv 0 \pmod{p}$ for $1 \leq k, j \leq (p-1)/2$, so $k + j \equiv 0 \pmod{p}$, a contradiction). The resulting set must be of the form

$$T = \left\{\varepsilon_1 \cdot 1, \varepsilon_2 \cdot 2, \ldots, \varepsilon_{(p-1)/2} \cdot \frac{p-1}{2}\right\},$$

where each ε_i is either $+1$ or -1. Multiplying together the elements of S and of T, we see that

$$(1a) \cdot (2a) \cdot (3a) \cdots \left(\frac{p-1}{2}a\right) \equiv \\ (\varepsilon_1 \cdot 1) \cdot (\varepsilon_2 \cdot 2) \cdots \left(\varepsilon_{(p-1)/2} \cdot \frac{p-1}{2}\right) \pmod{p},$$

so

$$a^{(p-1)/2} \equiv \varepsilon_1 \cdot \varepsilon_2 \cdots \varepsilon_{(p-1)/2} \pmod{p}.$$

The lemma then follows from Proposition 4.2.1, since $\left(\frac{a}{p}\right) = a^{(p-1)/2}$. □

SAGE Example 4.3.2. We illustrate Gauss's Lemma using Sage. The `gauss` function below prints out a list of the normalized numbers appearing in the statement of Gauss's Lemma, and returns $(-1)^{\nu}$. In each case below, $(-1)^{\nu} = \left(\frac{a}{p}\right)$.

```
sage: def gauss(a, p):
...    # make the list of numbers reduced modulo p
...     v = [(n*a)%p for n in range(1, (p-1)//2 + 1)]
...     # normalize them to be in the range -p/2 to p/2
...     v = [(x if (x < p/2) else x - p) for x in v]
...     # sort and print the resulting numbers
...     v.sort()
...     print v
...     # count the number that are negative
...     num_neg = len([x for x in v if x < 0])
...     return (-1)^num_neg

4.3.1 Euler's Proposition

For rational numbers $a, b \in \mathbf{Q}$, let

$$(a, b) \cap \mathbf{Z} = \{x \in \mathbf{Z} : a \leq x \leq b\}$$

be the set of integers between a and b. The following lemma will help us to keep track of how many integers lie in certain intervals.

Lemma 4.3.3. *Let $a, b \in \mathbf{Q}$. Then for any integer n,*

$$\#\left((a, b) \cap \mathbf{Z}\right) \equiv \#\left((a, b + 2n) \cap \mathbf{Z}\right) \pmod{2}$$

and

$$\#\left((a, b) \cap \mathbf{Z}\right) \equiv \#\left((a - 2n, b) \cap \mathbf{Z}\right) \pmod{2},$$

provided that each interval involved in the congruence is nonempty.

Note that if one of the intervals is empty, then the statement may be false; for example, if $(a, b) = (-1/2, 1/2)$ and $n = -1$, then $\#((a, b) \cap \mathbf{Z}) = 1$ but $\#(a, b - 2) \cap \mathbf{Z} = 0$.

Proof. Let $\lceil x \rceil$ denotes the least integer $\geq x$. Since $n > 0$,

$$(a, b + 2n) = (a, b) \cup [b, b + 2n),$$

where the union is disjoint. There are $2n$ integers

$$\lceil b \rceil, \lceil b \rceil + 1, \ldots, \lceil b \rceil + 2n - 1$$

in the interval $[b, b + 2n)$, so the first congruence of the lemma is true in this case. We also have

$$(a, b - 2n) = (a, b) \text{ minus } [b - 2n, b)$$

and $[b-2n, b)$ contains exactly $2n$ integers, so the lemma is also true when n is negative. The statement about $\#\left((a - 2n, b) \cap \mathbf{Z}\right)$ is proved in a similar manner. □

Once we have proved the following proposition, it will be easy to deduce the Quadratic Reciprocity Law.

Proposition 4.3.4 (Euler). *Let p be an odd prime and let a be a positive integer with $p \nmid a$. If q is a prime with $q \equiv \pm p \pmod{4a}$, then $\left(\frac{a}{p}\right) = \left(\frac{a}{q}\right)$.*

Proof. We will apply Lemma 4.3.1 to compute $\left(\frac{a}{p}\right)$. Let

$$S = \left\{ a, 2a, 3a, \ldots, \frac{p-1}{2} a \right\}$$

and

$$I = \left(\frac{1}{2}p, p\right) \cup \left(\frac{3}{2}p, 2p\right) \cup \cdots \cup \left(\left(b - \frac{1}{2}\right)p, bp\right),$$

where $b = \frac{1}{2}a$ or $\frac{1}{2}(a - 1)$, whichever is an integer.

We check that every element of S that is equivalent modulo p to something in the interval $(-\frac{p}{2}, 0)$ lies in I. First suppose that $b = \frac{1}{2}a$. Then

$$bp = \frac{1}{2}ap = \frac{p}{2}a > \frac{p-1}{2}a,$$

so each element of S that is equivalent modulo p to an element of $(-\frac{p}{2}, 0)$ lies in I. Next suppose that $b = \frac{1}{2}(a - 1)$. Then

$$bp + \frac{p}{2} = \frac{a-1}{2}p + \frac{p}{2} = \frac{p - 1 + a}{2} > \frac{p-1}{2}a,$$

so $((b - \frac{1}{2})p, bp)$ is the last interval that could contain an element of S that reduces to $(-\frac{p}{2}, 0)$. Note that the integer endpoints of I are not in S, since those endpoints are divisible by p, but no element of S is divisible by p. Thus, by Lemma 4.3.1,

$$\left(\frac{a}{p}\right) = (-1)^{\#(S\cap I)}.$$

To compute $\#(S \cap I)$, first rescale by a to see that

$$\#(S\cap I) = \#\left(\frac{1}{a}S \cap \frac{1}{a}I\right) = \#\left(\mathbf{Z} \cap \frac{1}{a}I\right),$$

where

$$\frac{1}{a}I = \left(\left(\frac{p}{2a}, \frac{p}{a}\right) \cup \left(\frac{3p}{2a}, \frac{2p}{a}\right) \cup \cdots \cup \left(\frac{(2b-1)p}{2a}, \frac{bp}{a}\right)\right),$$

$\frac{1}{a}S = \{1, 2, 3, 4, \ldots, (p-1)/2\}$, and the second equality is because $\frac{1}{a}I \subset (0, (p-1)/2 + 1/2]$, since

$$\frac{pb}{a} \leq \frac{p\frac{a}{2}}{a} = \frac{p}{2} = \frac{p-1}{2} + \frac{1}{2}.$$

Write $p = 4ac + r$, and let

$$J = \left(\left(\frac{r}{2a}, \frac{r}{a}\right) \cup \left(\frac{3r}{2a}, \frac{2r}{a}\right) \cup \cdots \cup \left(\frac{(2b-1)r}{2a}, \frac{br}{a}\right)\right).$$

The only difference between $\frac{1}{a}I$ and J is that the endpoints of intervals are changed by addition of an even integer, since

$$\frac{r}{2a} - \frac{p}{2a} = \frac{p}{2a} - 2c - \frac{p}{2a} = -2c.$$

By Lemma 4.3.3,

$$\nu = \#\left(\mathbf{Z} \cap \frac{1}{a}I\right) \equiv \#(\mathbf{Z} \cap J) \pmod{2}.$$

Thus $\left(\frac{a}{p}\right) = (-1)^\nu$ depends only on r and a, i.e., only on p modulo $4a$. Thus if $q \equiv p \pmod{4a}$, then $\left(\frac{a}{p}\right) = \left(\frac{a}{q}\right)$.

If $q \equiv -p \pmod{4a}$, then the only change in the above computation is that r is replaced by $4a - r$. This changes J into

$$K = \left(2 - \frac{r}{2a}, 4 - \frac{r}{a}\right) \cup \left(6 - \frac{3r}{2a}, 8 - \frac{2r}{a}\right) \cup \cdots \\ \cup \left(4b - 2 - \frac{(2b-1)r}{2a}, 4b - \frac{br}{a}\right).$$

Thus K is the same as $-J$, except even integers have been added to the endpoints. By Lemma 4.3.3,

$$\#(K \cap \mathbf{Z}) \equiv \# \left(\frac{1}{a} I \cap \mathbf{Z} \right) \pmod{2},$$

so $\left(\frac{a}{p}\right) = \left(\frac{a}{q}\right)$ again, which completes the proof. □

The following more careful analysis in the special case when $a = 2$ helps illustrate the proof of the above lemma, and the result is frequently useful in computations. For an alternative proof of the proposition, see Exercise 4.6.

Proposition 4.3.5 (Legendre Lymbol of 2)**.** *Let p be an odd prime. Then*

$$\left(\frac{2}{p}\right) = \begin{cases} 1 & \text{if } p \equiv \pm 1 \pmod{8} \\ -1 & \text{if } p \equiv \pm 3 \pmod{8}. \end{cases}$$

Proof. When $a = 2$, the set $S = \{a, 2a, \ldots, 2 \cdot \frac{p-1}{2}\}$ is

$$\{2, 4, 6, \ldots, p - 1\}.$$

We must count the parity of the number of elements of S that lie in the interval $I = (\frac{p}{2}, p)$. Writing $p = 8c + r$, we have

$$\begin{aligned} \#\,(I \cap S) &= \# \left(\frac{1}{2} I \cap \mathbf{Z} \right) = \# \left(\left(\frac{p}{4}, \frac{p}{2} \right) \cap \mathbf{Z} \right) \\ &= \# \left(\left(2c + \frac{r}{4}, 4c + \frac{r}{2} \right) \cap \mathbf{Z} \right) \equiv \# \left(\left(\frac{r}{4}, \frac{r}{2} \right) \cap \mathbf{Z} \right) \pmod{2}, \end{aligned}$$

where the last equality comes from Lemma 4.3.3. The possibilities for r are $1, 3, 5, 7$. When $r = 1$, the cardinality is 0; when $r = 3, 5$ it is 1; and when $r = 7$ it is 2. □

4.3.2 Proof of Quadratic Reciprocity

It is now straightforward to deduce the Quadratic Reciprocity Law.

First Proof of Theorem 4.1.7. First suppose that $p \equiv q \pmod{4}$. By swapping p and q if necessary, we may assume that $p > q$, and write $p - q = 4a$. Since $p = 4a + q$,

$$\left(\frac{p}{q}\right) = \left(\frac{4a + q}{q}\right) = \left(\frac{4a}{q}\right) = \left(\frac{4}{q}\right) \left(\frac{a}{q}\right) = \left(\frac{a}{q}\right),$$

and

$$\left(\frac{q}{p}\right) = \left(\frac{p - 4a}{p}\right) = \left(\frac{-4a}{p}\right) = \left(\frac{-1}{p}\right) \cdot \left(\frac{a}{p}\right).$$

Proposition 4.3.4 implies that $\left(\frac{a}{q}\right) = \left(\frac{a}{p}\right)$, since $p \equiv q \pmod{4a}$. Thus

$$\left(\frac{p}{q}\right) \cdot \left(\frac{q}{p}\right) = \left(\frac{-1}{p}\right) = (-1)^{\frac{p-1}{2}} = (-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}},$$

where the last equality is because $\frac{p-1}{2}$ is even if and only if $\frac{q-1}{2}$ is even.

Next suppose that $p \not\equiv q \pmod 4$, so $p \equiv -q \pmod 4$. Write $p + q = 4a$. We have

$$\left(\frac{p}{q}\right) = \left(\frac{4a-q}{q}\right) = \left(\frac{a}{q}\right), \quad \text{and} \quad \left(\frac{q}{p}\right) = \left(\frac{4a-p}{p}\right) = \left(\frac{a}{p}\right).$$

Since $p \equiv -q \pmod{4a}$, Proposition 4.3.4 implies that $\left(\frac{a}{q}\right) = \left(\frac{a}{p}\right)$. Since $(-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}} = 1$, the proof is complete. □

4.4 A Proof of Quadratic Reciprocity Using Gauss Sums

In this section, we present a beautiful proof of Theorem 4.1.7 using algebraic identities satisfied by sums of "roots of unity." The objects we introduce in the proof are of independent interest, and provide a powerful tool to prove higher-degree analogs of quadratic reciprocity. (For more on higher reciprocity, see [IR90]. See also Section 6 of [IR90], on which the proof below is modeled.)

Definition 4.4.1 (Root of Unity)**.** An nth *root of unity* is a complex number ζ such that $\zeta^n = 1$. A root of unity ζ is a *primitive* nth root of unity if n is the smallest positive integer such that $\zeta^n = 1$.

For example, -1 is a primitive second root of unity, and $\zeta = \frac{\sqrt{-3}-1}{2}$ is a primitive cube root of unity. More generally, for any $n \in \mathbf{N}$ the complex number

$$\zeta_n = \cos(2\pi/n) + i\sin(2\pi/n)$$

is a primitive nth root of unity (this follows from the identity $e^{i\theta} = \cos(\theta) + i\sin(\theta)$). For the rest of this section, we fix an odd prime p and the primitive pth root $\zeta = \zeta_p$ of unity.

SAGE Example 4.4.2. In Sage, use the `CyclotomicField` command to create an exact pth root of ζ unity. Expressions in ζ are always re-expressed as polynomials in ζ of degree at most $p - 1$.

```
sage: K.<zeta> = CyclotomicField(5)
sage: zeta^5
1
```

```
sage: 1/zeta
-zeta^3 - zeta^2 - zeta - 1
```

Definition 4.4.3 (Gauss Sum)**.** Fix an odd prime p. The *Gauss sum* associated to an integer a is

$$g_a = \sum_{n=1}^{p-1} \left(\frac{n}{p}\right) \zeta^{an},$$

where $\zeta = \zeta_p = \cos(2\pi/p) + i\sin(2\pi/p) = e^{2\pi i/p}$.

Note that p is implicit in the definition of g_a. If we were to change p, then the Gauss sum g_a associated to a would be different. The definition of g_a also depends on our choice of ζ; we've chosen $\zeta = \zeta_p$, but could have chosen a different ζ and then g_a could be different.

SAGE Example 4.4.4*.* We define a gauss_sum function and compute the Gauss sum g_2 for $p = 5$:

```
sage: def gauss_sum(a,p):
...    K.<zeta> = CyclotomicField(p)
...    return sum(legendre_symbol(n,p) * zeta^(a*n)
...               for n in range(1,p))
sage: g2 = gauss_sum(2,5); g2
2*zeta^3 + 2*zeta^2 + 1
sage: g2.complex_embedding()
-2.2360679775 + 3.33066907388e-16*I
sage: g2^2
5
```

Here, g_2 is initially output as a polynomial in ζ_5, so there is no loss of precision. The complex_embedding command shows some embedding of g_2 into the complex numbers, which is only correct to about the first 15 digits. Note that $g_2^2 = 5$, so $g_2 = -\sqrt{5}$.

We compute a graphical representation of the Gauss sum g_2 as follows (see Figure 4.1):

```
zeta = CDF(exp(2*pi*I/5))
v = [legendre_symbol(n,5) * zeta^(2*n) for n in range(1,5)]
S = sum([point(tuple(z), pointsize=100) for z in v])
show(S + point(tuple(sum(v)), pointsize=100, rgbcolor='red'))
```

Figure 4.1 illustrates the Gauss sum g_2 for $p = 5$. The Gauss sum is obtained by adding the points on the unit circle, with signs as indicated, to obtain the real number $-\sqrt{5}$. This suggests the following proposition, whose proof will require some work.

Proposition 4.4.5 (Gauss Sum)**.** *For any a not divisible by p,*

$$g_a^2 = (-1)^{(p-1)/2} p.$$

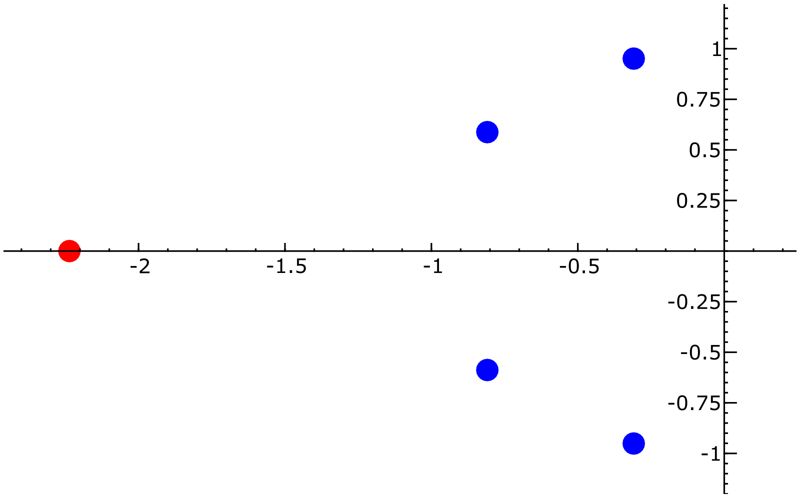

FIGURE 4.1. The red dot is the Gauss sum g_2 for $p = 5$

SAGE Example 4.4.6. We illustrate using Sage that the proposition is correct for $p = 7$ and $p = 13$:

```
sage: [gauss_sum(a, 7)^2 for a in range(1,7)]
[-7, -7, -7, -7, -7, -7]
sage: [gauss_sum(a, 13)^2 for a in range(1,13)]
[13, 13, 13, 13, 13, 13, 13, 13, 13, 13, 13, 13]
```

In order to prove the proposition, we introduce a few lemmas.

Lemma 4.4.7. *For any integer a,*

$$\sum_{n=0}^{p-1} \zeta^{an} = \begin{cases} p & \text{if } a \equiv 0 \pmod{p}, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. If $a \equiv 0 \pmod{p}$, then $\zeta^a = 1$, so the sum equals the number of summands, which is p. If $a \not\equiv 0 \pmod{p}$, then we use the identity

$$x^p - 1 = (x-1)(x^{p-1} + \cdots + x + 1)$$

with $x = \zeta^a$. We have $\zeta^a \neq 1$, so $\zeta^a - 1 \neq 0$ and

$$\sum_{n=0}^{p-1} \zeta^{an} = \frac{\zeta^{ap} - 1}{\zeta^a - 1} = \frac{1-1}{\zeta^a - 1} = 0.$$

□

Lemma 4.4.8. *If x and y are arbitrary integers, then*

$$\sum_{n=0}^{p-1} \zeta^{(x-y)n} = \begin{cases} p & \text{if } x \equiv y \pmod{p}, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. This follows from Lemma 4.4.7 by setting $a = x - y$. □

Lemma 4.4.9. *We have $g_0 = 0$.*

Proof. By definition

$$g_0 = \sum_{n=0}^{p-1} \left(\frac{n}{p}\right). \tag{4.4.1}$$

By Lemma 4.1.4, the map

$$\left(\frac{\cdot}{p}\right) : (\mathbf{Z}/p\mathbf{Z})^* \to \{\pm 1\}$$

is a surjective homomorphism of groups. Thus, half the elements of $(\mathbf{Z}/p\mathbf{Z})^*$ map to $+1$ and half map to -1 (the subgroup that maps to $+1$ has index 2). Since $\left(\frac{0}{p}\right) = 0$, the sum (4.4.1) is 0. □

Lemma 4.4.10. *For any integer a,*

$$g_a = \left(\frac{a}{p}\right) g_1.$$

Proof. When $a \equiv 0 \pmod{p}$, the lemma follows from Lemma 4.4.9, so suppose that $a \not\equiv 0 \pmod{p}$. Then,

$$\left(\frac{a}{p}\right) g_a = \left(\frac{a}{p}\right) \sum_{n=0}^{p-1} \left(\frac{n}{p}\right) \zeta^{an} = \sum_{n=0}^{p-1} \left(\frac{an}{p}\right) \zeta^{an} = \sum_{m=0}^{p-1} \left(\frac{m}{p}\right) \zeta^{m} = g_1.$$

Here, we use that multiplication by a is an automorphism of $\mathbf{Z}/p\mathbf{Z}$. Finally, multiply both sides by $\left(\frac{a}{p}\right)$ and use that $\left(\frac{a}{p}\right)^2 = 1$. □

We have enough lemmas to prove Proposition 4.4.5.

Proof of Proposition 4.4.5. We evaluate the sum $\sum_{a=0}^{p-1} g_a g_{-a}$ in two different ways. By Lemma 4.4.10, since $a \not\equiv 0 \pmod{p}$ we have

$$g_a g_{-a} = \left(\frac{a}{p}\right) g_1 \left(\frac{-a}{p}\right) g_1 = \left(\frac{-1}{p}\right) \left(\frac{a}{p}\right)^2 g_1^2 = (-1)^{(p-1)/2} g_1^2,$$

where the last step follows from Proposition 4.2.1 and that $\left(\frac{a}{p}\right) \in \{\pm 1\}$. Thus

$$\sum_{a=0}^{p-1} g_a g_{-a} = (p-1)(-1)^{(p-1)/2} g_1^2. \tag{4.4.2}$$

On the other hand, by definition

$$\begin{aligned}
g_a g_{-a} &= \sum_{n=0}^{p-1} \left(\frac{n}{p}\right) \zeta^{an} \cdot \sum_{m=0}^{p-1} \left(\frac{m}{p}\right) \zeta^{-am} \\
&= \sum_{n=0}^{p-1} \sum_{m=0}^{p-1} \left(\frac{n}{p}\right) \left(\frac{m}{p}\right) \zeta^{an} \zeta^{-am} \\
&= \sum_{n=0}^{p-1} \sum_{m=0}^{p-1} \left(\frac{n}{p}\right) \left(\frac{m}{p}\right) \zeta^{an-am}.
\end{aligned}$$

Let $\delta(n, m) = 1$ if $n \equiv m \pmod{p}$ and 0 otherwise. By Lemma 4.4.8,

$$\begin{aligned}
\sum_{a=0}^{p-1} g_a g_{-a} &= \sum_{a=0}^{p-1} \sum_{n=0}^{p-1} \sum_{m=0}^{p-1} \left(\frac{n}{p}\right) \left(\frac{m}{p}\right) \zeta^{an-am} \\
&= \sum_{n=0}^{p-1} \sum_{m=0}^{p-1} \left(\frac{n}{p}\right) \left(\frac{m}{p}\right) \sum_{a=0}^{p-1} \zeta^{an-am} \\
&= \sum_{n=0}^{p-1} \sum_{m=0}^{p-1} \left(\frac{n}{p}\right) \left(\frac{m}{p}\right) p\delta(n, m) \\
&= \sum_{n=0}^{p-1} \left(\frac{n}{p}\right)^2 p \\
&= p(p-1).
\end{aligned}$$

Equate (4.4.2) and the above equality, then cancel $(p-1)$ to see that

$$g_1^2 = (-1)^{(p-1)/2} p.$$

Since $a \not\equiv 0 \pmod{p}$, we have $\left(\frac{a}{p}\right)^2 = 1$, so by Lemma 4.4.10,

$$g_a^2 = \left(\frac{a}{p}\right)^2 g_1^2 = g_1^2,$$

and the proposition is proved. □

4.4.1 Proof of Quadratic Reciprocity

We are now ready to prove Theorem 4.1.7 using Gauss sums.

Proof. Let q be an odd prime with $q \neq p$. Set $p^* = (-1)^{(p-1)/2} p$ and recall that Proposition 4.4.5 asserts that $p^* = g^2$, where $g = g_1 = \sum_{n=0}^{p-1} \left(\frac{n}{p}\right) \zeta^n$.

Proposition 4.2.1 implies that

$$(p^*)^{(q-1)/2} \equiv \left(\frac{p^*}{q}\right) \pmod{q}.$$

We have $g^{q-1} = (g^2)^{(q-1)/2} = (p^*)^{(q-1)/2}$, so multiplying both sides of the displayed equation by g yields a congruence

$$g^q \equiv g\left(\frac{p^*}{q}\right) \pmod{q}. \tag{4.4.3}$$

But wait, what does this congruence mean, given that g^q is not an integer? It means that the difference $g^q - g\left(\frac{p^*}{q}\right)$ is a multiple of q in the ring $\mathbf{Z}[\zeta]$ of all polynomials in ζ with coefficients in $\mathbf{Z}$.

The ring $\mathbf{Z}[\zeta]/(q)$ has characteristic q, so if $x, y \in \mathbf{Z}[\zeta]$, then $(x+y)^q \equiv x^q + y^q \pmod{q}$. Applying this to (4.4.3), we see that

$$g^q = \left(\sum_{n=0}^{p-1}\left(\frac{n}{p}\right)\zeta^n\right)^q \equiv \sum_{n=0}^{p-1}\left(\frac{n}{p}\right)^q \zeta^{nq} \equiv \sum_{n=0}^{p-1}\left(\frac{n}{p}\right)\zeta^{nq} \equiv g_q \pmod{q}.$$

By Lemma 4.4.10,

$$g^q \equiv g_q \equiv \left(\frac{q}{p}\right) g \pmod{q}.$$

Combining this with (4.4.3) yields

$$\left(\frac{q}{p}\right) g \equiv \left(\frac{p^*}{q}\right) g \pmod{q}.$$

Since $g^2 = p^*$ and $p \neq q$, we can cancel g from both sides to find that $\left(\frac{q}{p}\right) \equiv \left(\frac{p^*}{q}\right) \pmod{q}$. Since both residue symbols are ± 1 and q is odd, it follows that $\left(\frac{q}{p}\right) = \left(\frac{p^*}{q}\right)$. Finally, we note using Corollary 4.2.3 that

$$\left(\frac{p^*}{q}\right) = \left(\frac{(-1)^{(p-1)/2}p}{q}\right) = \left(\frac{-1}{q}\right)^{(p-1)/2}\left(\frac{p}{q}\right) = (-1)^{\frac{q-1}{2}\cdot\frac{p-1}{2}} \cdot \left(\frac{p}{q}\right).$$

□

4.5 Finding Square Roots

We return in this section to the question of computing square roots. If K is a field in which $2 \neq 0$, and $a, b, c \in K$, with $a \neq 0$, then the two solutions to the quadratic equation $ax^2 + bx + c = 0$ are

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

Now assume $K = \mathbf{Z}/p\mathbf{Z}$, with p an odd prime. Using Theorem 4.1.7, we can decide whether or not $b^2 - 4ac$ is a perfect square in $\mathbf{Z}/p\mathbf{Z}$, and hence whether or not $ax^2 + bx + c = 0$ has a solution in $\mathbf{Z}/p\mathbf{Z}$. However, Theorem 4.1.7 says nothing about how to actually find a solution when there is one. Also note that for this problem we do *not* need the full Quadratic Reciprocity Law; in practice, deciding whether an element of $\mathbf{Z}/p\mathbf{Z}$ is a perfect square with Proposition 4.2.1 is quite fast, in view of Section 2.3.

Suppose $a \in \mathbf{Z}/p\mathbf{Z}$ is a nonzero quadratic residue. If $p \equiv 3 \pmod 4$, then $b = a^{\frac{p+1}{4}}$ is a square root of a because

$$b^2 = a^{\frac{p+1}{2}} = a^{\frac{p-1}{2}+1} = a^{\frac{p-1}{2}} \cdot a = \left(\frac{a}{p}\right) \cdot a = a.$$

We can compute b in time polynomial in the number of digits of p using the powering algorithm of Section 2.3.

Suppose next that $p \equiv 1 \pmod 4$. Unfortunately, we do not know a deterministic algorithm that takes a and p as input, outputs a square root of a modulo p when one exists, and is polynomial-time in $\log(p)$.

Remark 4.5.1. There is an algorithm due to Schoof [Sch85] that computes the square root of a in time $O((\sqrt{(}|a|)^{1/2+\varepsilon} \cdot \log(p))^9)$. This beautiful algorithm (which makes use of elliptic curves) is not polynomial time in the sense described above, since for large a it takes exponentially longer than for small a.

We next describe a probabilistic algorithm to compute a square root of a modulo p, which is very quick in practice. Recall the notion of ring from Definition 2.1.3. We will also need the notion of ring homomorphism and isomorphism.

Definition 4.5.2 (Homomorphism of Rings)**.** Let R and S be rings. A *homomorphism of rings* $\varphi : R \to S$ is a map such that for all $a, b \in R$, we have

- $\varphi(ab) = \varphi(a)\varphi(b)$,
- $\varphi(a + b) = \varphi(a) + \varphi(b)$, and
- $\varphi(1) = 1$.

An *isomorphism* $\varphi : R \to S$ of rings is a ring homomorphism that is bijective.

Consider the ring

$$R = (\mathbf{Z}/p\mathbf{Z})[x]/(x^2 - a)$$

defined as follows. We have

$$R = \{u + v\alpha : u, v \in \mathbf{Z}/p\mathbf{Z}\}$$

with multiplication defined by

$$(u+v\alpha)(z+w\alpha) = (uz+awv) + (uw+vz)\alpha.$$

Here α corresponds to the class of x in R.

SAGE Example 4.5.3. We define and work with the ring R above in Sage as follows (for $p = 13$):

```
sage: S.<x> = PolynomialRing(GF(13))
sage: R.<alpha> = S.quotient(x^2 - 3)
sage: (2+3*alpha)*(1+2*alpha)
7*alpha + 7
```

Let b and c be the square roots of a in $\mathbf{Z}/p\mathbf{Z}$ (though we cannot easily compute b and c yet, we can consider them in order to deduce an algorithm to find them). We have ring homomorphisms $f : R \to \mathbf{Z}/p\mathbf{Z}$ and $g : R \to \mathbf{Z}/p\mathbf{Z}$ given by $f(u+v\alpha) = u+vb$ and $g(u+v\alpha) = u+vc$. Together, these define a ring isomorphism

$$\varphi : R \longrightarrow \mathbf{Z}/p\mathbf{Z} \times \mathbf{Z}/p\mathbf{Z}$$

given by $\varphi(u+v\alpha) = (u+vb, u+vc)$. Choose in some way a random element z of $(\mathbf{Z}/p\mathbf{Z})^*$, and define $u, v \in \mathbf{Z}/p\mathbf{Z}$ by

$$u + v\alpha = (1+z\alpha)^{\frac{p-1}{2}},$$

where we compute $(1+z\alpha)^{\frac{p-1}{2}}$ quickly using an analog of the binary powering algorithm of Section 2.3.2. If $v = 0$, we try again with another random z. If $v \neq 0$, we can quickly find the desired square roots b and c as follows. The quantity $u+vb$ is a $(p-1)/2$ power in $\mathbf{Z}/p\mathbf{Z}$, so it equals either 0, 1, or -1, so $b = -u/v$, $(1-u)/v$, or $(-1-u)/v$, respectively. Since we know u and v, we can try each of $-u/v$, $(1-u)/v$, and $(-1-u)/v$ and see which is a square root of a.

Example 4.5.4. Continuing Example 4.1.8, we find a square root of 69 modulo 389. We apply the algorithm described above in the case $p \equiv 1 \pmod 4$. We first choose the random $z = 24$ and find that $(1+24\alpha)^{194} = -1$. The coefficient of α in the power is 0, and we try again with $z = 51$. This time, we have $(1+51\alpha)^{194} = 239\alpha = u + v\alpha$. The inverse of 239 in $\mathbf{Z}/389\mathbf{Z}$ is 153, so we consider the following three possibilities for a square root of 69:

$$-\frac{u}{v} = 0 \qquad \frac{1-u}{v} = 153 \qquad -\frac{1-u}{v} = -153.$$

Thus, 153 and -153 are the square roots of 69 in $\mathbf{Z}/389\mathbf{Z}$.

SAGE Example 4.5.5. We implement the above algorithm in Sage and illustrate it with some examples.

```
sage: def find_sqrt(a, p):
...     assert (p-1)%4 == 0
...     assert legendre_symbol(a,p) == 1
...     S.<x> = PolynomialRing(GF(p))
...     R.<alpha> = S.quotient(x^2 - a)
...     while True:
...         z = GF(p).random_element()
...         w = (1 + z*alpha)^((p-1)//2)
...         (u, v) = (w[0], w[1])
...         if v != 0: break
...     if (-u/v)^2 == a: return -u/v
...     if ((1-u)/v)^2 == a: return (1-u)/v
...     if ((-1-u)/v)^2 == a: return (-1-u)/v
...
sage: b = find_sqrt(3,13)
sage: b                         # random: either 9 or 3
9
sage: b^2
3
sage: b = find_sqrt(3,13)
sage: b                         # see, it's random
4
sage: find_sqrt(5,389)          # random: either 303 or 86
303
sage: find_sqrt(5,389)          # see, it's random
86
```

4.6 Exercises

4.1 Calculate the following by hand: $\left(\frac{3}{97}\right)$, $\left(\frac{3}{389}\right)$, $\left(\frac{22}{11}\right)$, and $\left(\frac{5!}{7}\right)$.

4.2 Let G be an abelian group, and let n be a positive integer.

(a) Prove that the map $\varphi : G \to G$ given by $\varphi(x) = x^n$ is a group homomorphism.

(b) Prove that the subset H of G of squares of elements of G is a subgroup.

4.3 Use Theorem 4.1.7 to show that for $p \geq 5$ prime,

$$\left(\frac{3}{p}\right) = \begin{cases} 1 & \text{if } p \equiv 1, 11 \pmod{12}, \\ -1 & \text{if } p \equiv 5, 7 \pmod{12}. \end{cases}$$

4.4 (*) Use that $(\mathbf{Z}/p\mathbf{Z})^*$ is cyclic to give a direct proof that $\left(\frac{-3}{p}\right) = 1$ when $p \equiv 1 \pmod 3$. (Hint: There is an element $c \in (\mathbf{Z}/p\mathbf{Z})^*$ of order 3. Show that $(2c+1)^2 = -3$.)

4.5 (*) If $p \equiv 1 \pmod 5$, show directly that $\left(\frac{5}{p}\right) = 1$ by the method of Exercise 4.4. (Hint: Let $c \in (\mathbf{Z}/p\mathbf{Z})^*$ be an element of order 5. Show that $(c+c^4)^2 + (c+c^4) - 1 = 0$, etc.)

4.6 (*) Let p be an odd prime. In this exercise, you will prove that $\left(\frac{2}{p}\right) = 1$ if and only if $p \equiv \pm 1 \pmod 8$.

(a) Prove that
$$x = \frac{1-t^2}{1+t^2}, \qquad y = \frac{2t}{1+t^2}$$
is a parameterization of the set of solutions to $x^2 + y^2 \equiv 1 \pmod p$, in the sense that the solutions $(x, y) \in \mathbf{Z}/p\mathbf{Z}$ are in bijection with the $t \in \mathbf{Z}/p\mathbf{Z} \cup \{\infty\}$ such that $1+t^2 \not\equiv 0 \pmod p$. Here, $t = \infty$ corresponds to the point $(-1, 0)$. (Hint: if (x_1, y_1) is a solution, consider the line $y = t(x+1)$ through (x_1, y_1) and $(-1, 0)$, and solve for x_1, y_1 in terms of t.)

(b) Prove that the number of solutions to $x^2 + y^2 \equiv 1 \pmod p$ is $p+1$ if $p \equiv 3 \pmod 4$ and $p-1$ if $p \equiv 1 \pmod 4$.

(c) Consider the set S of pairs $(a, b) \in (\mathbf{Z}/p\mathbf{Z})^* \times (\mathbf{Z}/p\mathbf{Z})^*$ such that $a + b = 1$ and $\left(\frac{a}{p}\right) = \left(\frac{b}{p}\right) = 1$. Prove that $\#S = (p+1-4)/4$ if $p \equiv 3 \pmod 4$ and $\#S = (p-1-4)/4$ if $p \equiv 1 \pmod 4$. Conclude that $\#S$ is odd if and only if $p \equiv \pm 1 \pmod 8$.

(d) The map $\sigma(a, b) = (b, a)$ that swaps coordinates is a bijection of the set S. It has exactly one fixed point if and only if there is an $a \in \mathbf{Z}/p\mathbf{Z}$ such that $2a = 1$ and $\left(\frac{a}{p}\right) = 1$. Also, prove that $2a = 1$ has a solution $a \in \mathbf{Z}/p\mathbf{Z}$ with $\left(\frac{a}{p}\right) = 1$ if and only if $\left(\frac{2}{p}\right) = 1$.

(e) Finish by showing that σ has exactly one fixed point if and only if $\#S$ is odd, i.e., if and only if $p \equiv \pm 1 \pmod 8$.

Remark: The method of proof of this exercise can be generalized to give a proof of the full Quadratic Reciprocity Law.

4.7 How many natural numbers $x < 2^{13}$ satisfy the equation
$$x^2 \equiv 5 \pmod{2^{13} - 1}?$$
You may assume that $2^{13} - 1$ is prime.

4.8 Find the natural number $x < 97$ such that $x \equiv 4^{48} \pmod{97}$. Note that 97 is prime.

4.9 In this problem, we will formulate an analog of quadratic reciprocity for a symbol like $\left(\frac{a}{q}\right)$, but without the restriction that q be a prime. Suppose n is an odd positive integer, which we factor as $\prod_{i=1}^{k} p_i^{e_i}$. We define the Jacobi symbol $\left(\frac{a}{n}\right)$ as follows:

$$\left(\frac{a}{n}\right) = \prod_{i=1}^{k} \left(\frac{a}{p_i}\right)^{e_i}.$$

(a) Give an example to show that $\left(\frac{a}{n}\right) = 1$ need not imply that a is a perfect square modulo n.

(b) (*) Let n be odd and a and b be integers. Prove that the following holds:

i. $\left(\frac{a}{n}\right)\left(\frac{b}{n}\right) = \left(\frac{ab}{n}\right)$. (Thus $a \mapsto \left(\frac{a}{n}\right)$ induces a homomorphism from $(\mathbf{Z}/n\mathbf{Z})^*$ to $\{\pm 1\}$.)

ii. $\left(\frac{-1}{n}\right) \equiv n \pmod{4}$.

iii. $\left(\frac{2}{n}\right) = 1$ if $n \equiv \pm 1 \pmod{8}$ and -1 otherwise.

iv. Assume a is positive and odd. Then $\left(\frac{a}{n}\right) = (-1)^{\frac{a-1}{2}\cdot\frac{n-1}{2}}\left(\frac{n}{a}\right)$

4.10 (*) Prove that for any $n \in \mathbf{Z}$, the integer $n^2 + n + 1$ does not have any divisors of the form $6k - 1$.

5
Continued Fractions

The golden ratio $\frac{1+\sqrt{5}}{2}$ is equal to the infinite fraction

$$1+\cfrac{1}{1+\cfrac{1}{1+\cfrac{1}{1+\cdots,}}}$$

and the fraction

$$\frac{103993}{33102} = 3.14159265301190260407\ldots$$

is an excellent approximation to π. Both of these observations are explained by continued fractions.

Continued fractions are theoretically beautiful and provide tools that yield powerful algorithms for solving problems in number theory. For example, continued fractions provide a fast way to write a prime—even a hundred digit prime—as a sum of two squares, when possible.

Continued fractions are thus a beautiful algorithmic and conceptual tool in number theory that has many applications. For example, they provide a surprisingly efficient way to recognize a rational number given just the first few digits of its decimal expansion, and they give a sense in which e is “less complicated” than π (see Example 5.3.4 and Section 5.4).

In Section 5.2, we study continued fractions of finite length and lay the foundations for our later investigations. In Section 5.3, we give the continued fraction procedure, which associates to a real number x a continued fraction that converges to x. In Section 5.5, we characterize (eventually) periodic continued fractions as the continued fractions of nonrational roots of quadratic polynomials, then discuss an unsolved mystery concerning continued fractions of roots of irreducible polynomials of degree greater than 2. We conclude the chapter with applications of continued fractions to recognizing approximations to rational numbers (Section 5.6) and writing integers as sums of two squares (Section 5.7).

The reader is encouraged to read more about continued fractions in [HW79, Ch. X], [Khi63], [Bur89, §13.3], and [NZM91, Ch. 7].

5.1 The Definition

A *continued fraction* is an expression of the form

$$a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cdots\ .}}}$$

In this book, we will assume that the a_i are real numbers and $a_i > 0$ for $i \geq 1$, and the expression may or may not go on indefinitely. More general notions of continued fractions have been extensively studied, but they are beyond the scope of this book. We will be most interested in the case when the a_i are all integers.

We denote the continued fraction displayed above by

$$[a_0, a_1, a_2, \ldots].$$

For example,

$$[1, 2] = 1 + \frac{1}{2} = \frac{3}{2},$$

$$\begin{aligned} [3, 7, 15, 1, 292] &= 3 + \cfrac{1}{7 + \cfrac{1}{15 + \cfrac{1}{1 + \cfrac{1}{292}}}} \\ &= \frac{103993}{33102} = 3.14159265301190260407\ldots, \end{aligned}$$

and

$$\begin{aligned}[2,1,2,1,1,4,1,1,6] &= 2+\cfrac{1}{1+\cfrac{1}{2+\cfrac{1}{1+\cfrac{1}{1+\cfrac{1}{4+\cfrac{1}{1+\cfrac{1}{1+\cfrac{1}{6}}}}}}}}\\ &= \frac{1264}{465}\\ &= 2.71827956989247311827956989\ldots\end{aligned}$$

The second two examples were chosen to foreshadow that continued fractions can be used to obtain good rational approximations to irrational numbers. Note that the first approximates π, and the second e.

5.2 Finite Continued Fractions

This section is about continued fractions of the form $[a_0, a_1, \ldots, a_m]$ for some $m \geq 0$. We give an inductive definition of numbers p_n and q_n such that for all $n \leq m$

$$[a_0, a_1, \ldots, a_n] = \frac{p_n}{q_n}. \tag{5.2.1}$$

We then give related formulas for the determinants of the 2×2 matrices $\left(\begin{smallmatrix} p_n & p_{n-1} \\ q_n & q_{n-1}\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} p_n & p_{n-2} \\ q_n & q_{n-2}\end{smallmatrix}\right)$, which we will repeatedly use to deduce properties of the sequence of partial convergents $[a_0, \ldots, a_k]$. We will use Algorithm 1.1.13 to prove that every rational number is represented by a continued fraction, as in (5.2.1).

Definition 5.2.1 (Finite Continued Fraction)**.** A *finite continued fraction* is an expression

$$a_0+\cfrac{1}{a_1+\cfrac{1}{a_2+\cfrac{1}{\cdots+\frac{1}{a_n}}}}$$

where each a_m is a real number and $a_m > 0$ for all $m \geq 1$.

Definition 5.2.2 (Simple Continued Fraction)**.** A *simple continued fraction* is a finite or infinite continued fraction in which the a_i are all integers.

To get a feeling for continued fractions, observe that

$$\begin{aligned}
[a_0] &= a_0, \\
[a_0, a_1] &= a_0 + \frac{1}{a_1} = \frac{a_0a_1 + 1}{a_1}, \\
[a_0, a_1, a_2] &= a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2}} = \frac{a_0a_1a_2 + a_0 + a_2}{a_1a_2 + 1}.
\end{aligned}$$

Also,

$$\begin{aligned}
[a_0, a_1, \ldots, a_{n-1}, a_n] &= \left[a_0, a_1, \ldots, a_{n-2}, a_{n-1} + \frac{1}{a_n}\right] \\
&= a_0 + \frac{1}{[a_1, \ldots, a_n]} \\
&= [a_0, [a_1, \ldots, a_n]].
\end{aligned}$$

SAGE Example 5.2.3. The `continued_fraction` command computes continued fractions:

```
sage: continued_fraction(17/23)
[0, 1, 2, 1, 5]
sage: continued_fraction(e)
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1,
 12, 1, 1, 11]
```

Use the optional second argument `bits = n` to determine the precision (in bits) of the input number that is used to compute the continued fraction.

```
sage: continued_fraction(e, bits=20)
[2, 1, 2, 1, 1, 4, 1, 1, 6]
sage: continued_fraction(e, bits=30)
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1]
```

You can obtain the value of a continued fraction and even do arithmetic with continued fractions:

```
sage: a = continued_fraction(17/23); a
[0, 1, 2, 1, 5]
sage: a.value()
17/23
sage: b = continued_fraction(6/23); b
[0, 3, 1, 5]
sage: a + b
[1]
```

5.2.1 Partial Convergents

Fix a finite continued fraction $[a_0, \dots, a_m]$. We do not assume at this point that the a_i are integers.

Definition 5.2.4 (Partial convergents)**.** For $0 \leq n \leq m$, the nth *convergent* of the continued fraction $[a_0, \dots, a_m]$ is $[a_0, \dots, a_n]$. These convergents for $n < m$ are also called *partial convergents.*

For each n with $-2 \leq n \leq m$, define real numbers p_n and q_n as follows:

$$\begin{array}{llllll} p_{-2} = 0, & p_{-1} = 1, & p_0 = a_0, & \cdots & p_n = a_n p_{n-1} + p_{n-2} & \cdots, \\ q_{-2} = 1, & q_{-1} = 0, & q_0 = 1, & \cdots & q_n = a_n q_{n-1} + q_{n-2} & \cdots. \end{array}$$

Proposition 5.2.5 (Partial Convergents)**.** *For $n \geq 0$ with $n \leq m$ we have*

$$[a_0, \dots, a_n] = \frac{p_n}{q_n}.$$

Proof. We use induction. The assertion is obvious when $n = 0, 1$. Suppose the proposition is true for all continued fractions of length $n - 1$. Then

$$\begin{aligned} [a_0, \dots, a_n] &= [a_0, \dots, a_{n-2}, a_{n-1} + \frac{1}{a_n}] \\ &= \frac{\left(a_{n-1} + \frac{1}{a_n}\right) p_{n-2} + p_{n-3}}{\left(a_{n-1} + \frac{1}{a_n}\right) q_{n-2} + q_{n-3}} \\ &= \frac{(a_{n-1}a_n + 1)p_{n-2} + a_n p_{n-3}}{(a_{n-1}a_n + 1)q_{n-2} + a_n q_{n-3}} \\ &= \frac{a_n(a_{n-1}p_{n-2} + p_{n-3}) + p_{n-2}}{a_n(a_{n-1}q_{n-2} + q_{n-3}) + q_{n-2}} \\ &= \frac{a_n p_{n-1} + p_{n-2}}{a_n q_{n-1} + q_{n-2}} \\ &= \frac{p_n}{q_n}. \end{aligned}$$

□

SAGE Example 5.2.6. If `c` is a continued fraction, use `c.convergents()` to compute a list of the partial convergents of `c`.

```
sage: c = continued_fraction(pi,bits=33); c
[3, 7, 15, 1, 292, 2]
sage: c.convergents()
[3, 22/7, 333/106, 355/113, 103993/33102, 208341/66317]
```

As we will see, the convergents of a continued fraction are the best rational approximations to the value of the continued fraction. In the example above, the listed convergents are the best rational approximations of π with given denominator size.

Proposition 5.2.7. *For $n \geq 0$ with $n \leq m$ we have*

$$p_n q_{n-1} - q_n p_{n-1} = (-1)^{n-1} \tag{5.2.2}$$

and

$$p_n q_{n-2} - q_n p_{n-2} = (-1)^n a_n. \tag{5.2.3}$$

Equivalently,

$$\frac{p_n}{q_n} - \frac{p_{n-1}}{q_{n-1}} = (-1)^{n-1} \cdot \frac{1}{q_n q_{n-1}}$$

and

$$\frac{p_n}{q_n} - \frac{p_{n-2}}{q_{n-2}} = (-1)^n \cdot \frac{a_n}{q_n q_{n-2}}.$$

Proof. The case for $n = 0$ is obvious from the definitions. Now suppose $n > 0$ and the statement is true for $n - 1$. Then

$$\begin{aligned} p_n q_{n-1} - q_n p_{n-1} &= (a_n p_{n-1} + p_{n-2}) q_{n-1} - (a_n q_{n-1} + q_{n-2}) p_{n-1} \\ &= p_{n-2} q_{n-1} - q_{n-2} p_{n-1} \\ &= -(p_{n-1} q_{n-2} - p_{n-2} q_{n-1}) \\ &= -(-1)^{n-2} = (-1)^{n-1}. \end{aligned}$$

This completes the proof of (5.2.2). For (5.2.3), we have

$$\begin{aligned} p_n q_{n-2} - p_{n-2} q_n &= (a_n p_{n-1} + p_{n-2}) q_{n-2} - p_{n-2}(a_n q_{n-1} + q_{n-2}) \\ &= a_n (p_{n-1} q_{n-2} - p_{n-2} q_{n-1}) \\ &= (-1)^n a_n. \end{aligned}$$

□

Remark 5.2.8. Expressed in terms of matrices, the proposition asserts that the determinant of $\left(\begin{smallmatrix} p_n & p_{n-1} \\ q_n & q_{n-1} \end{smallmatrix}\right)$ is $(-1)^{n-1}$, and of $\left(\begin{smallmatrix} p_n & p_{n-2} \\ q_n & q_{n-2} \end{smallmatrix}\right)$ is $(-1)^n a_n$.

SAGE Example 5.2.9. We use Sage to verify Proposition 5.2.7 for the first few terms of the continued fraction of π.

```
sage: c = continued_fraction(pi); c
[3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, 14, 3]
sage: for n in range(-1, len(c)):
...    print c.pn(n)*c.qn(n-1) - c.qn(n)*c.pn(n-1),
1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1
sage: for n in range(len(c)):
...    print c.pn(n)*c.qn(n-2) - c.qn(n)*c.pn(n-2),
3 -7 15 -1 292 -1 1 -1 2 -1 3 -1 14 -3
```

Corollary 5.2.10 (Convergents in lowest terms)**.** *If $[a_0, a_1, \ldots, a_m]$ is a simple continued fraction, so each a_i is an integer, then the p_n and q_n are integers and the fraction p_n/q_n is in lowest terms.*

Proof. It is clear that the p_n and q_n are integers, from the formula that defines them. If d is a positive divisor of both p_n and q_n, then $d \mid (-1)^{n-1}$, so $d = 1$. □

SAGE Example 5.2.11. We illustrate Corollary 5.2.10 using Sage.

```
sage: c = continued_fraction([1,2,3,4,5])
sage: c.convergents()
[1, 3/2, 10/7, 43/30, 225/157]
sage: [c.pn(n) for n in range(len(c))]
[1, 3, 10, 43, 225]
sage: [c.qn(n) for n in range(len(c))]
[1, 2, 7, 30, 157]
```

5.2.2 The Sequence of Partial Convergents

Let $[a_0, \ldots, a_m]$ be a continued fraction and for $n \leq m$ let

$$c_n = [a_0, \ldots, a_n] = \frac{p_n}{q_n}$$

denote the nth convergent. Recall that by definition of continued fraction, $a_n > 0$ for $n > 0$, which gives the partial convergents of a continued fraction additional structure. For example, the partial convergents of $[2, 1, 2, 1, 1, 4, 1, 1, 6]$ are

$$2, 3, 8/3, 11/4, 19/7, 87/32, 106/39, 193/71, 1264/465.$$

To make the size of these numbers clearer, we approximate them using decimals. We also underline every other number, to illustrate some extra structure.

$$\underline{2}, 3, \underline{2.66667}, 2.75000, \underline{2.71429}, 2.71875, \underline{2.71795}, 2.71831, \underline{2.71828}$$

The underlined numbers are smaller than all of the nonunderlined numbers, and the sequence of underlined numbers is strictly increasing, whereas the nonunderlined numbers strictly decrease.

SAGE Example 5.2.12. Figure 5.1 illustrates the above pattern on another continued fraction using Sage.

```
sage: c = continued_fraction([1,1,1,1,1,1,1,1])
sage: v = [(i, c.pn(i)/c.qn(i)) for i in range(len(c))]
sage: P = point(v, rgbcolor=(0,0,1), pointsize=40)
sage: L = line(v, rgbcolor=(0.5,0.5,0.5))
sage: L2 = line([(0,c.value()),(len(c)-1,c.value())], \
...      thickness=0.5, rgbcolor=(0.7,0,0))
sage: (L+L2+P).show(xmin=0,ymin=1)
```

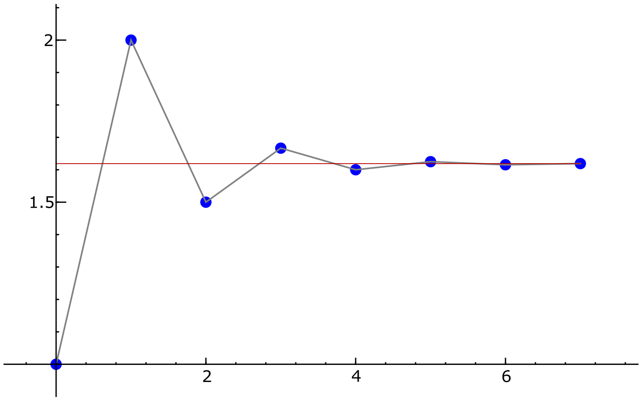

FIGURE 5.1. Graph of a Continued Fraction

We next prove that this extra structure is a general phenomenon.

Proposition 5.2.13 (How Convergents Converge)**.** *The even indexed convergents c_{2n} increase strictly with n, and the odd indexed convergents c_{2n+1} decrease strictly with n. Also, the odd indexed convergents c_{2n+1} are greater than all of the even indexed convergents c_{2m}.*

Proof. The a_n are positive for $n \geq 1$, so the q_n are positive. By Proposition 5.2.7, for $n \geq 2$,

$$c_n - c_{n-2} = (-1)^n \cdot \frac{a_n}{q_n q_{n-2}},$$

which proves the first claim.

Suppose for the sake of contradiction that there exist integers r and m such that $c_{2m+1} < c_{2r}$. Proposition 5.2.7 implies that for $n \geq 1$,

$$c_n - c_{n-1} = (-1)^{n-1} \cdot \frac{1}{q_n q_{n-1}}$$

has sign $(-1)^{n-1}$, so for all $s \geq 0$ we have $c_{2s+1} > c_{2s}$. Thus it is impossible that $r = m$. If $r < m$, then by what we proved in the first paragraph, $c_{2m+1} < c_{2r} < c_{2m}$, a contradiction (with $s = m$). If $r > m$, then $c_{2r+1} < c_{2m+1} < c_{2r}$, which is also a contradiction (with $s = r$). □

5.2.3 Every Rational Number is Represented

Proposition 5.2.14 (Rational Continued Fractions)**.** *Every nonzero rational number can be represented by a simple continued fraction.*

Proof. Without loss of generality, we may assume that the rational number is a/b, with $b \geq 1$ and $\gcd(a, b) = 1$. Algorithm 1.1.13 gives:

$$\begin{aligned} a &= b \cdot a_0 + r_1, & 0 < r_1 < b \\ b &= r_1 \cdot a_1 + r_2, & 0 < r_2 < r_1 \\ &\cdots \\ r_{n-2} &= r_{n-1} \cdot a_{n-1} + r_n, & 0 < r_n < r_{n-1} \\ r_{n-1} &= r_n \cdot a_n + 0. \end{aligned}$$

Note that $a_i > 0$ for $i > 0$ (also $r_n = 1$, since $\gcd(a, b) = 1$). Rewrite the equations as follows:

$$\begin{aligned} a/b &= a_0 + r_1/b = a_0 + 1/(b/r_1), \\ b/r_1 &= a_1 + r_2/r_1 = a_1 + 1/(r_1/r_2), \\ r_1/r_2 &= a_2 + r_3/r_2 = a_2 + 1/(r_2/r_3), \\ &\cdots \\ r_{n-1}/r_n &= a_n. \end{aligned}$$

It follows that

$$\frac{a}{b} = [a_0, a_1, \ldots, a_n].$$

□

The proof of Proposition 5.2.14 leads to an algorithm for computing the continued fraction of a rational number.

A nonzero rational number can be represented in exactly two ways; for example, $2 = [1, 1] = [2]$ (see Exercise 5.2).

5.3 Infinite Continued Fractions

This section begins with the continued fraction procedure, which associates a sequence $a_0, a_1, \ldots$ of integers to a real number x. After giving several examples, we prove that $x = \lim_{n\to\infty}[a_0, a_1, \ldots, a_n]$ by proving that the odd and even partial convergents become arbitrarily close to each other. We also show that if $a_0, a_1, \ldots$ is any infinite sequence of positive integers, then the sequence of $c_n = [a_0, a_1, \ldots, a_n]$ converges. More generally, if a_n is an arbitrary sequence of positive reals such that $\sum_{n=0}^{\infty} a_n$ diverges then (c_n) converges.

5.3.1 The Continued Fraction Procedure

Let $x \in \mathbf{R}$ and write

$$x = a_0 + t_0$$

with $a_0 \in \mathbf{Z}$ and $0 \leq t_0 < 1$. We call the number a_0 the *floor* of x, and we also sometimes write $a_0 = \lfloor x \rfloor$. If $t_0 \neq 0$, write

$$\frac{1}{t_0} = a_1 + t_1$$

with $a_1 \in \mathbf{N}$ and $0 \leq t_1 < 1$. Thus $t_0 = \frac{1}{a_1+t_1} = [0, a_1 + t_1]$, which is a continued fraction expansion of t_0, which need not be simple. Continue in this manner so long as $t_n \neq 0$ writing

$$\frac{1}{t_n} = a_{n+1} + t_{n+1}$$

with $a_{n+1} \in \mathbf{N}$ and $0 \leq t_{n+1} < 1$. We call this procedure, which associates to a real number x the sequence of integers $a_0, a_1, a_2, \ldots$, the *continued fraction process.*

Example 5.3.1. Let $x = \frac{8}{3}$. Then $x = 2 + \frac{2}{3}$, so $a_0 = 2$ and $t_0 = \frac{2}{3}$. Then $\frac{1}{t_0} = \frac{3}{2} = 1 + \frac{1}{2}$, so $a_1 = 1$ and $t_1 = \frac{1}{2}$. Then $\frac{1}{t_1} = 2$, so $a_2 = 2$, $t_2 = 0$, and the sequence terminates. Notice that

$$\frac{8}{3} = [2, 1, 2],$$

so the continued fraction procedure produces the continued fraction of $\frac{8}{3}$.

Example 5.3.2. Let $x = \frac{1+\sqrt{5}}{2}$. Then

$$x = 1 + \frac{-1+\sqrt{5}}{2},$$

so $a_0 = 1$ and $t_0 = \frac{-1+\sqrt{5}}{2}$. We have

$$\frac{1}{t_0} = \frac{2}{-1+\sqrt{5}} = \frac{-2-2\sqrt{5}}{-4} = \frac{1+\sqrt{5}}{2},$$

so $a_1 = 1$ and $t_1 = \frac{-1+\sqrt{5}}{2}$. Likewise, $a_n = 1$ for all n. As we will see below, the following exciting equality makes sense.

$$\frac{1+\sqrt{5}}{2} = 1 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{1 + \cdots}}}}}$$

SAGE Example 5.3.3. The equality of Example 5.3.2 is consistent with the following Sage calculation:

```
sage: def cf(bits):
...     x = (1 + sqrt(RealField(bits)(5))) / 2
...     return continued_fraction(x)
sage: cf(10)
[1, 1, 1, 1, 1, 1, 1, 3]
sage: cf(30)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
 1, 1, 1, 2]
sage: cf(50)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

Example 5.3.4. Suppose $x = e = 2.71828182\ldots$. Using the continued fraction procedure, we find that

$$a_0, a_1, a_2, \ldots = 2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, \ldots$$

For example, $a_0 = 2$ is the floor of 2. Subtracting 2 and inverting, we obtain $1/0.718\ldots = 1.3922\ldots$, so $a_1 = 1$. Subtracting 1 and inverting yields $1/0.3922\ldots = 2.5496\ldots$, so $a_2 = 2$. We will prove in Section 5.4 that the continued fraction of e obeys a simple pattern.

The 5th partial convergent of the continued fraction of e is

$$[a_0, a_1, a_2, a_3, a_4, a_5] = \frac{87}{32} = 2.71875,$$

which is a good rational approximation to e, in the sense that

$$\left|\frac{87}{32} - e\right| = 0.000468\ldots.$$

Note that $0.000468\ldots < 1/32^2 = 0.000976\ldots$, which illustrates the bound in Corollary 5.3.11.

Let's do the same thing with $\pi = 3.14159265358979\ldots$. Applying the continued fraction procedure, we find that the continued fraction of π is

$$a_0, a_1, a_2, \ldots = 3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, 14, \ldots$$

The first few partial convergents are

$$3, \frac{22}{7}, \frac{333}{106}, \frac{355}{113}, \frac{103993}{33102}, \cdots$$

These are good rational approximations to π; for example,

$$\frac{103993}{33102} = 3.14159265301\ldots.$$

Notice that the continued fraction of e exhibits a nice pattern (see Section 5.4 for a proof), whereas the continued fraction of π exhibits no pattern that is obvious to the author. The continued fraction of π has been extensively studied, and over 20 million terms have been computed. The data suggests that every integer appears infinitely often as a partial convergent. For much more about the continued fraction of π, or of any other sequence in this book, type the first few terms of the sequence into [Slo].

5.3.2 Convergence of Infinite Continued Fractions

Lemma 5.3.5. *For every n such that a_n is defined, we have*

$$x = [a_0, a_1, \ldots, a_n + t_n],$$

and if $t_n \neq 0$, then $x = [a_0, a_1, \ldots, a_n, \frac{1}{t_n}]$.

Proof. We use induction. The statements are both true when $n = 0$. If the second statement is true for $n - 1$, then

$$\begin{aligned} x &= \left[a_0, a_1, \ldots, a_{n-1}, \frac{1}{t_{n-1}}\right] \\ &= [a_0, a_1, \ldots, a_{n-1}, a_n + t_n] \\ &= \left[a_0, a_1, \ldots, a_{n-1}, a_n, \frac{1}{t_n}\right]. \end{aligned}$$

Similarly, the first statement is true for n if it is true for $n - 1$. □

Theorem 5.3.6 (Continued Fraction Limit)**.** *Let $a_0, a_1, \ldots$ be a sequence of integers such that $a_n > 0$ for all $n \geq 1$, and for each $n \geq 0$, set $c_n = [a_0, a_1, \ldots a_n]$. Then $\lim\limits_{n\to\infty} c_n$ exists.*

Proof. For any $m \geq n$, the number c_n is a partial convergent of $[a_0, \ldots, a_m]$. By Proposition 5.2.13, the even convergents c_{2n} form a strictly *increasing* sequence and the odd convergents c_{2n+1} form a strictly *decreasing* sequence. Moreover, the even convergents are all $\leq c_1$ and the odd convergents are all $\geq c_0$. Hence $\alpha_0 = \lim_{n\to\infty} c_{2n}$ and $\alpha_1 = \lim_{n\to\infty} c_{2n+1}$ both exist, and $\alpha_0 \leq \alpha_1$. Finally, by Proposition 5.2.7

$$|c_{2n} - c_{2n-1}| = \frac{1}{q_{2n} \cdot q_{2n-1}} \leq \frac{1}{2n(2n-1)} \to 0,$$

so $\alpha_0 = \alpha_1$. □

We define

$$[a_0, a_1, \ldots] = \lim_{n\to\infty} c_n.$$

Example 5.3.7. We illustrate the theorem with $x = \pi$. As in the proof of Theorem 5.3.6, let c_n be the nth partial convergent to π. The c_n with n odd converge down to π

$$c_1 = 3.1428571\ldots,\ c_3 = 3.1415929\ldots,\ c_5 = 3.1415926\ldots$$

whereas the c_n with n even converge up to π

$$c_2 = 3.1415094\ldots,\ c_4 = 3.1415926\ldots,\ c_6 = 3.1415926\ldots.$$

Theorem 5.3.8. *Let $a_0, a_1, a_2, \ldots$ be a sequence of real numbers such that $a_n > 0$ for all $n \geq 1$, and for each $n \geq 0$, set $c_n = [a_0, a_1, \ldots a_n]$. Then $\lim\limits_{n\to\infty} c_n$ exists if and only if the sum $\sum_{n=0}^{\infty} a_n$ diverges.*

Proof. We only prove that if $\sum a_n$ diverges, then $\lim_{n\to\infty} c_n$ exists. A proof of the converse can be found in [Wal48, Ch. 2, Thm. 6.1].

Let q_n be the sequence of "denominators" of the partial convergents, as defined in Section 5.2.1, so $q_{-2} = 1$, $q_{-1} = 0$, and for $n \geq 0$, we have

$$q_n = a_n q_{n-1} + q_{n-2}.$$

As we saw in the proof of Theorem 5.3.6, the limit $\lim_{n\to\infty} c_n$ exists provided that the sequence $\{q_n q_{n-1}\}$ diverges to positive infinity.

For n even,

$$\begin{aligned} q_n &= a_n q_{n-1} + q_{n-2} \\ &= a_n q_{n-1} + a_{n-2} q_{n-3} + q_{n-4} \\ &= a_n q_{n-1} + a_{n-2} q_{n-3} + a_{n-4} q_{n-5} + q_{n-6} \\ &= a_n q_{n-1} + a_{n-2} q_{n-3} + \cdots + a_2 q_1 + q_0 \end{aligned}$$

and for n odd,

$$q_n = a_n q_{n-1} + a_{n-2} q_{n-3} + \cdots + a_1 q_0 + q_{-1}.$$

Since $a_n > 0$ for $n > 0$, the sequence $\{q_n\}$ is increasing, so $q_i \geq 1$ for all $i \geq 0$. Applying this fact to the above expressions for q_n, we see that for n even

$$q_n \geq a_n + a_{n-2} + \cdots + a_2,$$

and for n odd

$$q_n \geq a_n + a_{n-2} + \cdots + a_1.$$

If $\sum a_n$ diverges, then at least one of $\sum a_{2n}$ or $\sum a_{2n+1}$ must diverge. The above inequalities then imply that at least one of the sequences $\{q_{2n}\}$ or $\{q_{2n+1}\}$ diverge to infinity. Since $\{q_n\}$ is an increasing sequence, it follows that $\{q_n q_{n-1}\}$ diverges to infinity. □

Example 5.3.9. Let $a_n = \frac{1}{n\log(n)}$ for $n \geq 2$ and $a_0 = a_1 = 0$. By the integral test, $\sum a_n$ diverges, so by Theorem 5.3.8, the continued fraction $[a_0, a_1, a_2, \ldots]$ converges. This convergence is very slow, since, e.g.

$$[a_0, a_1, \ldots, a_{9999}] = 0.5750039671012225425930\ldots$$

yet

$$[a_0, a_1, \ldots, a_{10000}] = 0.7169153932917378550424\ldots.$$

Theorem 5.3.10. *Let $x \in \mathbf{R}$ be a real number. Then x is the value of the (possibly infinite) simple continued fraction $[a_0, a_1, a_2, \ldots]$ produced by the continued fraction procedure.*

Proof. If the sequence is finite, then some $t_n = 0$ and the result follows by Lemma 5.3.5. Suppose the sequence is infinite. By Lemma 5.3.5,

$$x = [a_0, a_1, \ldots, a_n, \frac{1}{t_n}].$$

By Proposition 5.2.5 (which we apply in a case when the partial quotients of the continued fraction are not integers), we have

$$x = \frac{\dfrac{1}{t_n} \cdot p_n + p_{n-1}}{\dfrac{1}{t_n} \cdot q_n + q_{n-1}}.$$

Thus, if $c_n = [a_0, a_1, \ldots, a_n]$, then

$$\begin{aligned} x - c_n &= x - \frac{p_n}{q_n} \\ &= \frac{\frac{1}{t_n} p_n q_n + p_{n-1} q_n - \frac{1}{t_n} p_n q_n - p_n q_{n-1}}{q_n \left(\frac{1}{t_n} q_n + q_{n-1}\right)}. \\ &= \frac{p_{n-1} q_n - p_n q_{n-1}}{q_n \left(\frac{1}{t_n} q_n + q_{n-1}\right)} \\ &= \frac{(-1)^n}{q_n \left(\frac{1}{t_n} q_n + q_{n-1}\right)}. \end{aligned}$$

Thus

$$\begin{aligned} |x - c_n| &= \frac{1}{q_n \left(\frac{1}{t_n} q_n + q_{n-1}\right)} \\ &< \frac{1}{q_n (a_{n+1} q_n + q_{n-1})} \\ &= \frac{1}{q_n \cdot q_{n+1}} \leq \frac{1}{n(n+1)} \to 0. \end{aligned}$$

In the inequality, we use that a_{n+1} is the integer part of $\frac{1}{t_n}$, and is hence $\leq \frac{1}{t_n} < 1$, since $t_n < 1$. □

This corollary follows from the proof of Theorem 5.3.10.

Corollary 5.3.11 (Convergence of continued fraction)**.** *Let $a_0, a_1, \ldots$ define a simple continued fraction, and let $x = [a_0, a_1, \ldots] \in \mathbf{R}$ be its value. Then for all m,*

$$\left| x - \frac{p_m}{q_m} \right| < \frac{1}{q_m \cdot q_{m+1}}.$$

Proposition 5.3.12. *If x is a rational number, then the sequence $a_0, a_1, \ldots$ produced by the continued fraction procedure terminates.*

Proof. Let $[b_0, b_1, \ldots, b_m]$ be the continued fraction representation of x that we obtain using Algorithm 1.1.13, so the b_i are the partial quotients at each step. If $m = 0$, then x is an integer, so we may assume $m > 0$. Then

$$x = b_0 + 1/[b_1, \ldots, b_m].$$

If $[b_1, \ldots, b_m] = 1$, then $m = 1$ and $b_1 = 1$, which will not happen using Algorithm 1.1.13, since it would give $[b_0 + 1]$ for the continued fraction of the integer $b_0 + 1$. Thus $[b_1, \ldots, b_m] > 1$, so in the continued fraction algorithm we choose $a_0 = b_0$ and $t_0 = 1/[b_1, \ldots, b_m]$. Repeating this argument enough times proves the claim. □

5.4 The Continued Fraction of e

The continued fraction expansion of e begins $[2, 1, 2, 1, 1, 4, 1, 1, 6, \ldots]$. The obvious pattern in fact does continue, as Euler proved in 1737 (see [Eul85]), and we will prove in this section. As an application, Euler gave a proof that e is irrational by noting that its continued fraction is infinite.

The proof we give below draws heavily on the proof in [Coh], which describes a slight variant of a proof of Hermite (see [Old70]). The continued fraction representation of e is also treated in the German book [Per57], but the proof requires substantial background from elsewhere in that text.

5.4.1 Preliminaries

First, we write the continued fraction of e in a slightly different form. Instead of $[2, 1, 2, 1, 1, 4, \ldots]$, we can start the sequence of coefficients

$$[1, 0, 1, 1, 2, 1, 1, 4, \ldots]$$

to make the pattern the same throughout. (Everywhere else in this chapter we assume that the partial quotients a_n for $n \geq 1$ are positive, but temporarily relax that condition here and allow $a_1 = 0$.) The numerators and denominators of the convergents given by this new sequence satisfy a simple recurrence. Using r_i as a stand-in for p_i or q_i, we have

$$\begin{aligned} r_{3n} &= r_{3n-1} + r_{3n-2} \\ r_{3n-1} &= r_{3n-2} + r_{3n-3} \\ r_{3n-2} &= 2(n-1)r_{3n-3} + r_{3n-4}. \end{aligned}$$

Our first goal is to collapse these three recurrences into one recurrence that only makes mention of r_{3n}, r_{3n-3}, and r_{3n-6}. We have

$$\begin{aligned} r_{3n} &= r_{3n-1} + r_{3n-2} \\ &= (r_{3n-2} + r_{3n-3}) + (2(n-1)r_{3n-3} + r_{3n-4}) \\ &= (4n-3)r_{3n-3} + 2r_{3n-4}. \end{aligned}$$

This same method of simplification also shows us that

$$r_{3n-3} = 2r_{3n-7} + (4n-7)r_{3n-6}.$$

To get rid of $2r_{3n-4}$ in the first equation, we make the substitutions

$$\begin{aligned} 2r_{3n-4} &= 2(r_{3n-5} + r_{3n-6}) \\ &= 2((2(n-2)r_{3n-6} + r_{3n-7}) + r_{3n-6}) \\ &= (4n-6)r_{3n-6} + 2r_{3n-7}. \end{aligned}$$

Substituting for $2r_{3n-4}$ and then $2r_{3n-7}$, we finally have the needed collapsed recurrence,

$$r_{3n} = 2(2n-1)r_{3n-3} + r_{3n-6}.$$

5.4.2 Two Integral Sequences

We define the sequences $x_n = p_{3n}$, $y_n = q_{3n}$. Since the $3n$-convergents will converge to the same real number that the n convergents do, x_n/y_n also converges to the limit of the continued fraction. Each sequence $\{x_n\}$, $\{y_n\}$ will obey the recurrence relation derived in the previous section (where z_n is a stand-in for x_n or y_n):

$$z_n = 2(2n-1)z_{n-1} + z_{n-2}, \text{ for all } n \geq 2. \qquad (5.4.1)$$

The two sequences can be found in Table 5.1. (The initial conditions $x_0 = 1$, $x_1 = 3$, $y_0 = y_1 = 1$ are taken straight from the first few convergents of the original continued fraction.) Notice that since we are skipping several convergents at each step, the ratio x_n/y_n converges to e very quickly.

TABLE 5.1. Convergents

n	0	1	2	3	4	$\cdots$
x_n	1	3	19	193	2721	$\cdots$
y_n	1	1	7	71	1001	$\cdots$
x_n/y_n	1	3	2.714...	2.71830...	2.7182817...	$\cdots$

5.4.3 A Related Sequence of Integrals

Now, we define a sequence of real numbers $T_0, T_1, T_2, \ldots$ by the following integrals:

$$T_n = \int_0^1 \frac{t^n(t-1)^n}{n!}\ e^t dt.$$

Below, we compute the first two terms of this sequence explicitly. (When we compute T_1, we are doing the integration by parts $u = t(t-1)$, $dv = e^t dt$. Since the integral runs from 0 to 1, the boundary condition is 0 when evaluated at each of the endpoints. This vanishing will be helpful when we do the integral in the general case.)

$$\begin{aligned} T_0 &= \int_0^1 e^t dt = e - 1, \\ T_1 &= \int_0^1 t(t-1)e^t dt \\ &= -\int_0^1 ((t-1)+t)e^t dt \\ &= -(t-1)e^t \Big|_0^1 - te^t \Big|_0^1 + 2\int_0^1 e^t dt \\ &= -1 - e + 2(e-1) = e - 3. \end{aligned}$$

The reason that we defined this series now becomes apparent: $T_0 = y_0 e - x_0$ and $T_1 = y_1 e - x_1$. In general, it will be true that $T_n = y_n e - x_n$. We will now prove this fact.

It is clear that if T_n were to satisfy the same recurrence that the x_i and y_i do in (5.4.1), then the above statement holds by induction. (The initial conditions are correct, as needed.) So, we simplify T_n by integrating by parts twice in succession:

$$\begin{aligned}
T_n &= \int_0^1 \frac{t^n(t-1)^n}{n!}\ e^t dt \\
&= -\int_0^1 \frac{t^{n-1}(t-1)^n + t^n(t-1)^{n-1}}{(n-1)!}\ e^t dt \\
&= \int_0^1 \Big(\frac{t^{n-2}(t-1)^n}{(n-2)!} + n\frac{t^{n-1}(t-1)^{n-1}}{(n-1)!} \\
&\qquad\qquad + n\frac{t^{n-1}(t-1)^{n-1}}{(n-1)!} + \frac{t^n(t-1)^{n-2}}{(n-2)!}\Big)e^t dt \\
&= 2nT_{n-1} + \int_0^1 \frac{t^{n-2}(t-1)^{n-2}}{n-2!}(2t^2-2t+1)\ e^t dt \\
&= 2nT_{n-1} + 2\int_0^1 \frac{t^{n-1}(t-1)^{n-1}}{n-2!}\ e^t dt + \int_0^1 \frac{t^{n-2}(t-1)^{n-2}}{n-2!}\ e^t dt \\
&= 2nT_{n-1} + 2(n-1)T_{n-1} + T_{n-2} \\
&= 2(2n-1)T_{n-1} + T_{n-2},
\end{aligned}$$

which is the desired recurrence.

Therefore, $T_n = y_n e - x_n$. To conclude the proof, we consider the limit as n approaches infinity:

$$\lim_{n\to\infty} \int_0^1 \frac{t^n(t-1)^n}{n!}\ e^t dt = 0,$$

by inspection, and therefore

$$\lim_{n\to\infty} \frac{x_n}{y_n} = \lim_{n\to\infty} (e - \frac{T_n}{y_n}) = e.$$

Therefore, the ratio x_n/y_n approaches e, and the continued fraction expansion $[2, 1, 2, 1, 1, 4, 1, 1, \ldots]$ does in fact converge to e.

5.4.4 Extensions of the Argument

The method of proof of this section generalizes to show that the continued fraction expansion of $e^{1/n}$ is

$$[1,\ (n-1),\ 1,\ 1,\ (3n-1),\ 1,\ 1,\ (5n-1),\ 1,\ 1,\ (7n-1), \ldots]$$

for all $n \in \mathbf{N}$ (see Exercise 5.6).

5.5 Quadratic Irrationals

The main result of this section is that the continued fraction expansion of a number is eventually repeating if and only if the number is a quadratic irrational. This can be viewed as an analog for continued fractions of the familiar fact that the decimal expansion of x is eventually repeating if and only if x is rational. The proof that continued fractions of quadratic irrationals eventually repeats is surprisingly difficult and involves an interesting finiteness argument. Section 5.5.2 emphasizes our striking ignorance about continued fractions of real roots of irreducible polynomials over $\mathbf{Q}$ of degree bigger than 2.

Definition 5.5.1 (Quadratic Irrational)**.** A *quadratic irrational* is a real number $\alpha \in \mathbf{R}$ that is irrational and satisfies a quadratic polynomial with coefficients in $\mathbf{Q}$.

Thus, for example, $(1+\sqrt{5})/2$ is a quadratic irrational. Recall that

$$\frac{1+\sqrt{5}}{2} = [1, 1, 1, \ldots].$$

The continued fraction of $\sqrt{2}$ is $[1, 2, 2, 2, 2, 2, \ldots]$, and the continued fraction of $\sqrt{389}$ is

$$[19, 1, 2, 1, 1, 1, 1, 2, 1, 38, 1, 2, 1, 1, 1, 1, 2, 1, 38, \ldots].$$

Does the $[1, 2, 1, 1, 1, 1, 2, 1, 38]$ pattern repeat over and over again?

SAGE Example 5.5.2. We compute more terms of the continued fraction expansion of $\sqrt{389}$ using Sage:

```
sage: def cf_sqrt_d(d, bits):
...   x = sqrt(RealField(bits)(d))
...   return continued_fraction(x)
sage: cf_sqrt_d(389,50)
[19, 1, 2, 1, 1, 1, 1, 2, 1, 38, 1, 2, 1, 1, 1, 1, 2, 1, 38]
sage: cf_sqrt_d(389,100)
[19, 1, 2, 1, 1, 1, 1, 2, 1, 38, 1, 2, 1, 1, 1, 1, 2, 1, 38,
 1, 2, 1, 1, 1, 1, 2, 1, 38, 1, 2, 1, 1, 1, 1, 2, 1, 38, 1,
 2, 1, 1]
```

5.5.1 Periodic Continued Fractions

Definition 5.5.3 (Periodic Continued Fraction)**.** A *periodic continued fraction* is a continued fraction $[a_0, a_1, \ldots, a_n, \ldots]$ such that

$$a_n = a_{n+h}$$

for some fixed positive integer h and all sufficiently large n. We call the minimal such h the *period of the continued fraction.*

Example 5.5.4. Consider the periodic continued fraction $[1,2,1,2,\ldots] = [\overline{1,2}]$. What does it converge to? We have

$$[\overline{1,2}] = 1 + \cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{1}{1 + \cdots}}}},$$

so if $\alpha = [\overline{1,2}]$ then

$$\alpha = 1 + \cfrac{1}{2 + \cfrac{1}{\alpha}} = 1 + \cfrac{1}{\cfrac{2\alpha+1}{\alpha}} = 1 + \frac{\alpha}{2\alpha+1} = \frac{3\alpha+1}{2\alpha+1}$$

Thus $2\alpha^2 - 2\alpha - 1 = 0$, so

$$\alpha = \frac{1+\sqrt{3}}{2}.$$

Theorem 5.5.5 (Periodic Characterization)**.** *An infinite simple continued fraction is periodic if and only if it represents a quadratic irrational.*

Proof. ($\Longrightarrow$) First suppose that

$$[a_0, a_1, \ldots, a_n, \overline{a_{n+1}, \ldots, a_{n+h}}]$$

is a periodic continued fraction. Set $\alpha = [a_{n+1}, a_{n+2}, \ldots]$. Then

$$\alpha = [a_{n+1}, \ldots, a_{n+h}, \alpha],$$

so by Proposition 5.2.5

$$\alpha = \frac{\alpha p_{n+h} + p_{n+h-1}}{\alpha q_{n+h} + q_{n+h-1}}.$$

Here we use that α is the last partial quotient. Thus, α satisfies a quadratic equation with coefficients in $\mathbf{Q}$. Computing as in Example 5.5.4 and rationalizing the denominators, and using that the a_i are all integers, shows that

$$\begin{aligned}[a_0, a_1, \ldots] &= [a_0, a_1, \ldots, a_n, \alpha] \\ &= a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cdots + \cfrac{1}{\alpha}}}\end{aligned}$$

is of the form $c + d\alpha$, with $c, d \in \mathbf{Q}$, so $[a_0, a_1, \ldots]$ also satisfies a quadratic polynomial over $\mathbf{Q}$.

The continued fraction procedure applied to the value of an infinite simple continued fraction yields that continued fraction back, so by Proposition 5.3.12, $\alpha \notin \mathbf{Q}$ because it is the value of an infinite continued fraction.

($\Longleftarrow$) Suppose $\alpha \in \mathbf{R}$ is an irrational number that satisfies a quadratic equation

$$a\alpha^2 + b\alpha + c = 0 \tag{5.5.1}$$

with $a, b, c \in \mathbf{Z}$ and $a \neq 0$. Let $[a_0, a_1, \ldots]$ be the continued fraction expansion of α. For each n, let

$$r_n = [a_n, a_{n+1}, \ldots],$$

so

$$\alpha = [a_0, a_1, \ldots, a_{n-1}, r_n].$$

We will prove periodicity by showing that the set of r_n's is finite. If we have shown finiteness, then there exists $n, h > 0$ such that $r_n = r_{n+h}$, so

$$\begin{aligned}
[a_0, \ldots, a_{n-1}, r_n] &= [a_0, \ldots, a_{n-1}, a_n, \ldots, a_{n+h-1}, r_{n+h}] \\
&= [a_0, \ldots, a_{n-1}, a_n, \ldots, a_{n+h-1}, r_n] \\
&= [a_0, \ldots, a_{n-1}, a_n, \ldots, a_{n+h-1}, a_n, \ldots, a_{n+h-1}, r_{n+h}] \\
&= [a_0, \ldots, a_{n-1}, \overline{a_n, \ldots, a_{n+h-1}}].
\end{aligned}$$

It remains to show there are only finitely many distinct r_n. We have

$$\alpha = \frac{p_n}{q_n} = \frac{r_n p_{n-1} + p_{n-2}}{r_n q_{n-1} + q_{n-2}}.$$

Substituting this expression for α into the quadratic equation (5.5.1), we see that

$$A_n r_n^2 + B_n r_n + C_n = 0,$$

where

$$\begin{aligned}
A_n &= a p_{n-1}^2 + b p_{n-1} q_{n-1} + c q_{n-1}^2, \\
B_n &= 2a p_{n-1} p_{n-2} + b(p_{n-1} q_{n-2} + p_{n-2} q_{n-1}) + 2c q_{n-1} q_{n-2}, \text{ and} \\
C_n &= a p_{n-2}^2 + b p_{n-2} q_{n-2} + c p_{n-2}^2.
\end{aligned}$$

Note that $A_n, B_n, C_n \in \mathbf{Z}$, that $C_n = A_{n-1}$, and that

$$B_n^2 - 4A_n C_n = (b^2 - 4ac)(p_{n-1} q_{n-2} - q_{n-1} p_{n-2})^2 = b^2 - 4ac.$$

Recall from the proof of Theorem 5.3.10 that

$$\left| \alpha - \frac{p_{n-1}}{q_{n-1}} \right| < \frac{1}{q_n q_{n-1}}.$$

Thus,

$$|\alpha q_{n-1} - p_{n-1}| < \frac{1}{q_n} < \frac{1}{q_{n-1}},$$

so

$$p_{n-1} = \alpha q_{n-1} + \frac{\delta}{q_{n-1}} \qquad \text{with } |\delta| < 1.$$

Hence,

$$\begin{aligned} A_n &= a\left(\alpha q_{n-1} + \frac{\delta}{q_{n-1}}\right)^2 + b\left(\alpha q_{n-1} + \frac{\delta}{q_{n-1}}\right) q_{n-1} + c q_{n-1}^2 \\ &= (a\alpha^2 + b\alpha + c) q_{n-1}^2 + 2a\alpha\delta + a\frac{\delta^2}{q_{n-1}^2} + b\delta \\ &= 2a\alpha\delta + a\frac{\delta^2}{q_{n-1}^2} + b\delta. \end{aligned}$$

Thus,

$$|A_n| = \left|2a\alpha\delta + a\frac{\delta^2}{q_{n-1}^2} + b\delta\right| < 2|a\alpha| + |a| + |b|.$$

We conclude that there are only finitely many possibilities for the integer A_n. Also,

$$|C_n| = |A_{n-1}| \quad \text{and} \quad |B_n| = \sqrt{b^2 - 4(ac - A_n C_n)},$$

so there are only finitely many triples (A_n, B_n, C_n), and hence only finitely many possibilities for r_n as n varies, which completes the proof. (The proof above closely follows [HW79, Thm. 177, pg.144–145].) □

5.5.2 Continued Fractions of Algebraic Numbers of Higher Degree

Definition 5.5.6 (Algebraic Number)**.** An *algebraic number* is a root of a polynomial $f \in \mathbf{Q}[x]$.

Open Problem 5.5.7. *Give a simple description of the complete continued fractions expansion of the algebraic number $\sqrt[3]{2}$. It begins*

$$[1, 3, 1, 5, 1, 1, 4, 1, 1, 8, 1, 14, 1, 10, 2, 1, 4, 12, 2, 3, 2, 1, 3, 4, 1, 1, 2, 14, \\ 3, 12, 1, 15, 3, 1, 4, 534, 1, 1, 5, 1, 1, \ldots]$$

The author does not see a pattern, and the 534 reduces his confidence that he will. Lang and Trotter (see [LT72]) analyzed many terms of the continued fraction of $\sqrt[3]{2}$ statistically, and their work suggests that $\sqrt[3]{2}$ has an "unusual" continued fraction; later work in [LT74] suggests that maybe it does not.

Khintchine (see [Khi63, pg. 59])

> No properties of the representing continued fractions, analogous to those which have just been proved, are known for algebraic numbers of higher degree [as of 1963]. [...] It is of interest to point out that up till the present time *no continued fraction development of an algebraic number of higher degree than the second is known* [emphasis added]. It is not even known if such a development has bounded elements. Generally speaking the problems associated with the continued fraction expansion of algebraic numbers of degree higher than the second are extremely difficult and virtually unstudied.

Richard Guy (see [Guy94, pg. 260])

> Is there an algebraic number of degree greater than two whose simple continued fraction has unbounded partial quotients? Does every such number have unbounded partial quotients?

Baum and Sweet [BS76] answered the analog of Richard Guy's question, but with algebraic numbers replaced by elements of a field K other than $\mathbf{Q}$. (The field K is $\mathbf{F}_2((1/x))$, the field of Laurent series in the variable $1/x$ over the finite field with two elements. An element of K is a polynomial in x plus a formal power series in $1/x$.) They found an α of degree 3 over K whose continued fraction has all terms of bounded degree, and other elements of various degrees greater than 2 over K whose continued fractions have terms of unbounded degree.

5.6 Recognizing Rational Numbers

Suppose that somehow you can compute approximations to some rational number, and want to figure what the rational number probably is. Computing the approximation to high enough precision to find a period in the decimal expansion is not a good approach, because the period can be huge (see below). A much better approach is to compute the simple continued fraction of the approximation, and truncate it before a large partial quotient a_n, then compute the value of the truncated continued fraction. This results in a rational number that has a relatively small numerator and denominator, and is close to the approximation of the rational number, since the tail end of the continued fraction is at most $1/a_n$.

We begin with a contrived example, which illustrates how to recognize a rational number. Let

$$x = 9495/3847 = 2.46815700545879906420587470756433584611385\ldots.$$

The continued fraction of the truncation 2.468157005458799064 is

$$[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1, 328210621945, 2, 1, 1, 1, \ldots]$$

We have

$$[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1] = \frac{9495}{3847}.$$

Notice that no repetition is evident in the digits of x given above, though we know that the decimal expansion of x must be eventually periodic, since all decimal expansions of rational numbers are eventually periodic. In fact, the length of the period of the decimal expansion of $1/3847$ is 3846, which is the order of 10 modulo 3847 (see Exercise 5.7).

For a slightly less contrived application of this idea, suppose $f(x) \in \mathbf{Z}[x]$ is a polynomial with integer coefficients, and we know for some reason that one root of f is a rational number. We can find that rational number, by using Newton's method to approximate each root, and continued fractions to decide whether each root is a rational number (we can substitute the value of the continued fraction approximation into f to see if it is actually a root). One could also use the well-known Rational Root Theorem, which asserts that any rational root n/d of f, with $n, d \in \mathbf{Z}$ coprime, has the property that n divides the constant term of f and d the leading coefficient of f. However, using that theorem to find n/d would require factoring the constant and leading terms of f, which could be completely impractical if they have a few hundred digits (see Section 1.1.3). In contrast, Newton's method and continued fractions should quickly find n/d, assuming the degree of f isn't too large.

For example, suppose $f = 3847x^2 - 14808904x + 36527265$. To apply Newton's method, let x_0 be a guess for a root of f. Iterate using the recurrence

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$$

Choosing $x_0 = 0$, approximations of the first two iterates are

$$x_1 = 2.466574501394566404103909378,$$

and

$$x_2 = 2.466815700480740192304316684 6.$$

The continued fraction of the approximations x_1 and x_2 are

$$[2, 2, 6, 1, 47, 2, 1, 4, 3, 1, 5, 8, 2, 3]$$

and

$$[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1, 103, 8, 1, 2, 3, \ldots].$$

Truncating the continued fraction of x_2 before 103 gives

$$[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1],$$

which evaluates to $9495/3847$, which is a rational root of f.

SAGE Example 5.6.1. We do the above calculation using SAGE. First we implement the Newton iteration:

```
sage: def newton_root(f, iterates=2, x0=0, prec=53):
...     x = RealField(prec)(x0)
...     R = PolynomialRing(ZZ,'x')
...     f = R(f)
...     g = f.derivative()
...     for i in range(iterates):
...         x = x - f(x)/g(x)
...     return x
```

Next we run the Newton iteration, and compute the continued fraction of the result:

```
sage: a = newton_root(3847*x^2 - 14808904*x + 36527265); a
2.46815700480740
sage: cf = continued_fraction(a); cf
[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1, 103, 8, 1, 2, 3, 1, 1]
```

We truncate the continued fraction and compute its value.

```
sage: c = cf[:12]; c
[2, 2, 7, 2, 1, 5, 1, 1, 1, 1, 1, 1]
sage: c.value()
9495/3847
```

Another computational application of continued fractions, which we can only hint at, is that there are functions in certain parts of advanced number theory (that are beyond the scope of this book) that take rational values at certain points, and which can only be computed efficiently via approximations; using continued fractions as illustrated above to evaluate such functions is crucial.

5.7 Sums of Two Squares

In this section, we apply continued fractions to prove the following theorem.

Theorem 5.7.1. *A positive integer n is a sum of two squares if and only if all prime factors of $p \mid n$ such that $p \equiv 3 \pmod 4$ have even exponent in the prime factorization of n.*

We first consider some examples. Notice that $5 = 1^2 + 2^2$ is a sum of two squares, but 7 is not a sum of two squares. Since 2001 is divisible by 3 (because $2 + 1$ is divisible by 3), but not by 9 (since $2 + 1$ is not), Theorem 5.7.1 implies that 2001 is not a sum of two squares. The theorem also implies that $2 \cdot 3^4 \cdot 5 \cdot 7^2 \cdot 13$ is a sum of two squares.

SAGE Example 5.7.2. We use Sage to write a short program that *naively* determines whether or not an integer n is a sum of two squares, and if so returns a, b such that $a^2 + b^2 = n$.

```
sage: def sum_of_two_squares_naive(n):
...    for i in range(int(sqrt(n))):
...        if is_square(n - i^2):
...            return i, (Integer(n-i^2)).sqrt()
...    return "%s is not a sum of two squares"%n
```

We next use our function in a couple of cases.

```
sage: sum_of_two_squares_naive(23)
'23 is not a sum of two squares'
sage: sum_of_two_squares_naive(389)
(10, 17)
sage: sum_of_two_squares_naive(2007)
'2007 is not a sum of two squares'
sage: sum_of_two_squares_naive(2008)
'2008 is not a sum of two squares'
sage: sum_of_two_squares_naive(2009)
(28, 35)
sage: 28^2 + 35^2
2009
sage: sum_of_two_squares_naive(2*3^4*5*7^2*13)
(189, 693)
```

Definition 5.7.3 (Primitive)**.** A representation $n = x^2 + y^2$ is *primitive* if x and y are coprime.

Lemma 5.7.4. *If n is divisible by a prime $p \equiv 3 \pmod 4$, then n has no primitive representations.*

Proof. Suppose n has a primitive representation, $n = x^2 + y^2$, and let p be any prime factor of n. Then

$$p \mid x^2 + y^2 \quad \text{and} \quad \gcd(x, y) = 1,$$

so $p \nmid x$ and $p \nmid y$. Since $\mathbf{Z}/p\mathbf{Z}$ is a field, we may divide by y^2 in the equation $x^2 + y^2 \equiv 0 \pmod p$ to see that $(x/y)^2 \equiv -1 \pmod p$. Thus the Legendre symbol $\left(\frac{-1}{p}\right)$ equals $+1$. However, by Proposition 4.2.1,

$$\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$$

so $\left(\frac{-1}{p}\right) = 1$ if and only if $(p-1)/2$ is even, which is to say $p \equiv 1 \pmod 4$. $\square$

Proof of Theorem 5.7.1 ($\Longrightarrow$). Suppose that $p \equiv 3 \pmod 4$ is a prime, that $p^r \mid n$ but $p^{r+1} \nmid n$ with r odd, and that $n = x^2 + y^2$. Letting $d = \gcd(x, y)$, we have

$$x = dx', \quad y = dy', \quad \text{and} \quad n = d^2 n'$$

with $\gcd(x', y') = 1$ and

$$(x')^2 + (y')^2 = n'.$$

Because r is odd, $p \mid n'$, so Lemma 5.7.4 implies that $\gcd(x', y') > 1$, which is a contradiction. □

To prepare for our proof of the implication ($\Longleftarrow$) of Theorem 5.7.1, we reduce the problem to the case when n is prime. Write $n = n_1^2 n_2$, where n_2 has no prime factors $p \equiv 3 \pmod 4$. It suffices to show that n_2 is a sum of two squares, since

$$(x_1^2 + y_1^2)(x_2^2 + y_2^2) = (x_1x_2 - y_1y_2)^2 + (x_1y_2 + x_2y_1)^2, \tag{5.7.1}$$

so a product of two numbers that are sums of two squares is also a sum of two squares. Since $2 = 1^2 + 1^2$ is a sum of two squares, it suffices to show that any prime $p \equiv 1 \pmod 4$ is a sum of two squares.

Lemma 5.7.5. *If $x \in \mathbf{R}$ and $n \in \mathbf{N}$, then there is a fraction $\frac{a}{b}$ in lowest terms such that $0 < b \leq n$ and*

$$\left| x - \frac{a}{b} \right| \leq \frac{1}{b(n+1)}.$$

Proof. Consider the continued fraction $[a_0, a_1, \ldots]$ of x. By Corollary 5.3.11, for each m

$$\left| x - \frac{p_m}{q_m} \right| < \frac{1}{q_m \cdot q_{m+1}}.$$

Since $q_{m+1} \geq q_m + 1$ and $q_0 = 1$, either there exists an m such that $q_m \leq n < q_{m+1}$, or the continued fraction expansion of x is finite and n is larger than the denominator of the rational number x, in which case we take $\frac{a}{b} = x$ and are done. In the first case,

$$\left| x - \frac{p_m}{q_m} \right| < \frac{1}{q_m \cdot q_{m+1}} \leq \frac{1}{q_m \cdot (n+1)},$$

so $\dfrac{a}{b} = \dfrac{p_m}{q_m}$ satisfies the conclusion of the lemma. □

Proof of Theorem 5.7.1 ($\Longleftarrow$). As discussed above, it suffices to prove that any prime $p \equiv 1 \pmod 4$ is a sum of two squares. Since $p \equiv 1 \pmod 4$,

$$(-1)^{(p-1)/2} = 1,$$

Proposition 4.2.1 implies that -1 is a square modulo p; i.e., there exists $r \in \mathbf{Z}$ such that $r^2 \equiv -1 \pmod{p}$. Lemma 5.7.5, with $n = \lfloor\sqrt{p}\rfloor$ and $x = -\frac{r}{p}$, implies that there are integers a, b such that $0 < b < \sqrt{p}$ and

$$\left|-\frac{r}{p} - \frac{a}{b}\right| \leq \frac{1}{b(n+1)} < \frac{1}{b\sqrt{p}}.$$

Letting $c = rb + pa$, we have that

$$|c| < \frac{pb}{b\sqrt{p}} = \frac{p}{\sqrt{p}} = \sqrt{p}$$

so

$$0 < b^2 + c^2 < 2p.$$

But $c \equiv rb \pmod{p}$, so

$$b^2 + c^2 \equiv b^2 + r^2b^2 \equiv b^2(1 + r^2) \equiv 0 \pmod{p}.$$

Thus $b^2 + c^2 = p$. □

Remark 5.7.6. Our proof of Theorem 5.7.1 leads to an efficient algorithm to compute a representation of any $p \equiv 1 \pmod{4}$ as a sum of two squares.

SAGE Example 5.7.7. We next use Sage and Theorem 5.7.1 to give an efficient algorithm for writing a prime $p \equiv 1 \pmod{4}$ as a sum of two squares. First we implement the algorithm that comes out of the proof of the theorem.

```
sage: def sum_of_two_squares(p):
...     p = Integer(p)
...     assert p%4 == 1, "p must be 1 modulo 4"
...     r = Mod(-1,p).sqrt().lift()
...     v = continued_fraction(-r/p)
...     n = floor(sqrt(p))
...     for x in v.convergents():
...         c = r*x.denominator() + p*x.numerator()
...         if -n <= c and c <= n:
...             return (abs(x.denominator()),abs(c))
```

Next we use the algorithm to write the first 10-digit prime $\equiv 1 \pmod{4}$ as a sum of two squares:

```
sage: p = next_prime(next_prime(10^10))
sage: sum_of_two_squares(p)
(55913, 82908)
```

The above calculation was essentially instantanoues. If instead we use the naive algorithm from before, it takes several seconds to write p as a sum of two squares.

```
sage: sum_of_two_squares_naive(p)
(55913, 82908)
```

5.8 Exercises

5.1 If $c_n = p_n/q_n$ is the nth convergent of $[a_0, a_1, \ldots, a_n]$ and $a_0 > 0$, show that

$$[a_n, a_{n-1}, \ldots, a_1, a_0] = \frac{p_n}{p_{n-1}}$$

and

$$[a_n, a_{n-1}, \ldots, a_2, a_1] = \frac{q_n}{q_{n-1}}.$$

(Hint: In the first case, notice that $\frac{p_n}{p_{n-1}} = a_n + \frac{p_{n-2}}{p_{n-1}} = a_n + \frac{1}{\frac{p_{n-1}}{p_{n-2}}}$.)

5.2 Show that every nonzero rational number can be represented in exactly two ways by a finite simple continued fraction. (For example, 2 can be represented by $[1, 1]$ and $[2]$, and $1/3$ by $[0, 3]$ and $[0, 2, 1]$.)

5.3 Evaluate the infinite continued fraction $[2, \overline{1, 2, 1}]$.

5.4 Determine the infinite continued fraction of $\frac{1+\sqrt{13}}{2}$.

5.5 Let $a_0 \in \mathbf{R}$ and $a_1, \ldots, a_n$ and b be positive real numbers. Prove that

$$[a_0, a_1, \ldots, a_n + b] < [a_0, a_1, \ldots, a_n]$$

if and only if n is odd.

5.6 (*) Extend the method presented in the text to show that the continued fraction expansion of $e^{1/k}$ is

$$[1,\ (k-1),\ 1,\ 1,\ (3k-1),\ 1,\ 1,\ (5k-1),\ 1,\ 1,\ (7k-1), \ldots]$$

for all $k \in \mathbf{N}$.

(a) Compute p_0, p_3, q_0, and q_3 for the above continued fraction. Your answers should be in terms of k.

(b) Condense three steps of the recurrence for the numerators and denominators of the above continued fraction. That is, produce a simple recurrence for r_{3n} in terms of r_{3n-3} and r_{3n-6} whose coefficients are polynomials in n and k.

(c) Define a sequence of real numbers by

$$T_n(k) = \frac{1}{k^n} \int_0^{1/k} \frac{(kt)^n (kt-1)^n}{n!} \ e^t dt.$$

i. Compute $T_0(k)$, and verify that it equals $q_0 e^{1/k} - p_0$.

ii. Compute $T_1(k)$, and verify that it equals $q_3 e^{1/k} - p_3$.

iii. Integrate $T_n(k)$ by parts twice in succession, as in Section 5.4, and verify that $T_n(k)$, $T_{n-1}(k)$, and $T_{n-2}(k)$ satisfy the recurrence produced in part 6b, for $n \geq 2$.

(d) Conclude that the continued fraction

$$[1,\ (k-1),\ 1,\ 1,\ (3k-1),\ 1,\ 1,\ (5k-1),\ 1,\ 1,\ (7k-1), \ldots]$$

represents $e^{1/k}$.

5.7 Let d be an integer that is coprime to 10. Prove that the decimal expansion of $\frac{1}{d}$ has a period equal to the order of 10 modulo d. (Hint: For every positive integer r, we have $\frac{1}{1-10^r} = \sum_{n \geq 1} 10^{-rn}$.)

5.8 Find a positive integer that has at least three different representations as the sum of two squares, disregarding signs and the order of the summands.

5.9 Show that if a natural number n is the sum of two two rational squares it is also the sum of two integer squares.

5.10 (*) Let p be an odd prime. Show that $p \equiv 1, 3 \pmod 8$ if and only if p can be written as $p = x^2 + 2y^2$ for some choice of integers x and y.

5.11 Prove that of any four consecutive integers, at least one is not representable as a sum of two squares.

6
Elliptic Curves

Elliptic curves are number theoretic objects that are central to both pure and applied number theory. Deep problems in number theory such as the congruent number problem—which integers are the area of a right triangle with rational side lengths?—translate naturally into questions about elliptic curves. Other questions, such as the famous Birch and Swinnerton-Dyer conjecture, describe mysterious structure that mathematicians expect elliptic curves to have. One can also associate finite abelian groups to elliptic curves, and in many cases these groups are well suited to the construction of cryptosystems. In particular, elliptic curves are widely believed to provide good security with smaller key sizes, something that is useful in many applications, for example, if we are going to print an encryption key on a postage stamp, it is helpful if the key is short! Morover, there is a way to use elliptic curves to factor integers, which plays a crucial role in sophisticated attacks on the RSA public-key cryptosystem of Section 3.3.

This chapter is a brief introduction to elliptic curves that builds on the ideas of Chapters 1–3 and introduces several deep theorems and ideas that we will not prove. In Section 6.1, we define elliptic curves and draw some pictures of them, and then in Section 6.2 we describe how to put a group structure on the set of points on an elliptic curve. Sections 6.3 and 6.4 are about how to apply elliptic curves to two cryptographic problems—constructing public-key cryptosystems and factoring integers. Finally, in Section 6.5, we consider elliptic curves over the rational numbers, and explain a deep connection between elliptic curves and a 1,000-year old unsolved problem.

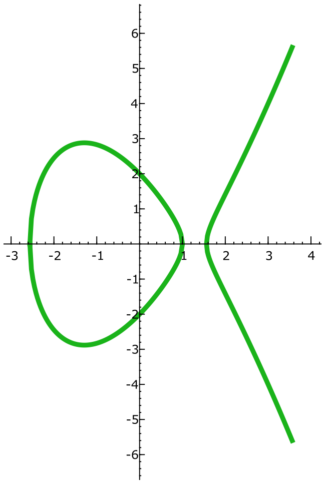

FIGURE 6.1. The elliptic curve $y^2 = x^3 - 5x + 4$ over $\mathbf{R}$

6.1 The Definition

Definition 6.1.1 (Elliptic Curve)**.** An *elliptic curve* over a field K is a curve defined by an equation of the form

$$y^2 = x^3 + ax + b,$$

where $a, b \in K$ and $-16(4a^3 + 27b^2) \neq 0$.

The condition that $-16(4a^3 + 27b^2) \neq 0$ implies that the curve has no "singular points," which will be essential for the applications we have in mind (see Exercise 6.1).

SAGE Example 6.1.2. We use the `EllipticCurve` command to create an elliptic curve over the rational field $\mathbf{Q}$ and draw the plot in Figure 6.1.

```
sage: E = EllipticCurve([-5, 4])
sage: E
Elliptic Curve defined by y^2  = x^3 - 5*x + 4
over Rational Field
sage: P = E.plot(thickness=4,rgbcolor=(0.1,0.7,0.1))
sage: P.show(figsize=[4,6])
```

We will use elliptic curves over finite fields to factor integers in Section 6.3 and to construct cryptosystems in Section 6.4. The following Sage code creates an elliptic curve over the finite field of order 37 and plots it, as illustrated in Figure 6.2.

```
sage: E = EllipticCurve(GF(37), [1,0])
sage: E
Elliptic Curve defined by y^2  = x^3 + x over
Finite Field of size 37
sage: E.plot(pointsize=45)
```

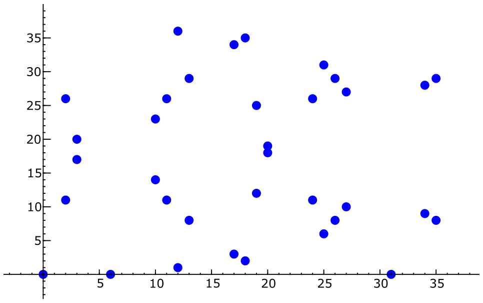

FIGURE 6.2. The elliptic curve $y^2 = x^3 + x$ over $\mathbf{Z}/37\mathbf{Z}$

In Section 6.2, we will put a natural abelian group structure on the set

$$E(K) = \{(x, y) \in K \times K : y^2 = x^3 + ax + b\} \cup \{\mathcal{O}\}$$

of K-rational points on an elliptic curve E over K. Here, $\mathcal{O}$ may be thought of as a point on E "at infinity." Figure 6.2 contains a plot of the points of $y^2 = x^3 + x$ over the finite field $\mathbf{Z}/37\mathbf{Z}$, though note that we do not explicitly draw the point at $\mathcal{O}$ at infinity.

Remark 6.1.3. If K has characteristic 2 (i.e., we have $1+1 = 0$ in K), then for any choice of a, b, the quantity $-16(4a^3 + 27b^2) \in K$ is 0, so according to Definition 6.1.1 there are no elliptic curves over K. There is a similar problem in characteristic 3. If we instead consider equations of the form

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6,$$

we obtain a more general definition of elliptic curves, which correctly allows for elliptic curves in characteristics 2 and 3; these elliptic curves are popular in cryptography because arithmetic on them is often easier to efficiently implement on a computer.

6.2 The Group Structure on an Elliptic Curve

Let E be an elliptic curve over a field K, given by an equation $y^2 = x^3 + ax + b$. We begin by defining a binary operation $+$ on $E(K)$.

Algorithm 6.2.1 (Elliptic Curve Group Law)**.** Given $P_1, P_2 \in E(K)$, this algorithm computes a third point $R = P_1 + P_2 \in E(K)$.

1. [Is $P_i = \mathcal{O}$?] If $P_1 = \mathcal{O}$ set $R = P_2$ or if $P_2 = \mathcal{O}$ set $R = P_1$ and terminate. Otherwise write $(x_i, y_i) = P_i$.
2. [Negatives] If $x_1 = x_2$ and $y_1 = -y_2$, set $R = \mathcal{O}$ and terminate.
3. [Compute λ] Set $\lambda = \begin{cases} (3x_1^2 + a)/(2y_1) & \text{if } P_1 = P_2, \\ (y_1 - y_2)/(x_1 - x_2) & \text{otherwise.} \end{cases}$
4. [Compute Sum] Then $R = \big(\lambda^2 - x_1 - x_2, -\lambda x_3 - \nu\big)$, where $\nu = y_1 - \lambda x_1$ and $x_3 = \lambda^2 - x_1 - x_2$ is the x-coordinate of R.

Note that in Step 3, if $P_1 = P_2$, then $y_1 \neq 0$; otherwise, we would have terminated in the previous step.

Theorem 6.2.2. *The binary operation + defined in Algorithm 6.2.1 endows the set $E(K)$ with an abelian group structure, with identity $\mathcal{O}$.*

Before discussing why the theorem is true, we reinterpret + geometrically, so that it will be easier for us to visualize. We obtain the sum $P_1 + P_2$ by finding the third point P_3 of intersection between E and the line L determined by P_1 and P_2, then reflecting P_3 about the x-axis. (This description requires suitable interpretation in cases 1 and 2, and when $P_1 = P_2$.) This is illustrated in Figure 6.3, in which $(0, 2) + (1, 0) = (3, 4)$ on $y^2 = x^3 - 5x + 4$.

SAGE Example 6.2.3. We create the elliptic curve $y^2 = x^3 - 5x + 4$ in Sage, then add together $P = (1, 0)$ and $Q = (0, 2)$. We also compute $P + P$, which is the point $\mathcal{O}$ at infinity, which is represented in Sage by $(0 : 1 : 0)$, and compute the sum $P + Q + Q + Q + Q$, which is surprisingly large.

```
sage: E = EllipticCurve([-5,4])
sage: P = E([1,0]); Q = E([0,2])
sage: P + Q
(3 : 4 : 1)
sage: P + P
(0 : 1 : 0)
sage: P + Q + Q + Q + Q
(350497/351649 : 16920528/208527857 : 1)
```

To further clarify the above geometric interpretation of the group law, we prove the following proposition.

Proposition 6.2.4 (Geometric Group Law)**.** *Suppose $P_i = (x_i, y_i)$, $i = 1, 2$ are distinct points on an elliptic curve $y^2 = x^3 + ax + b$, and that $x_1 \neq x_2$. Let L be the unique line through P_1 and P_2. Then L intersects the graph of E at exactly one other point*

$$Q = \big(\lambda^2 - x_1 - x_2, \quad \lambda x_3 + \nu\big),$$

where $\lambda = (y_1 - y_2)/(x_1 - x_2)$ and $\nu = y_1 - \lambda x_1$.

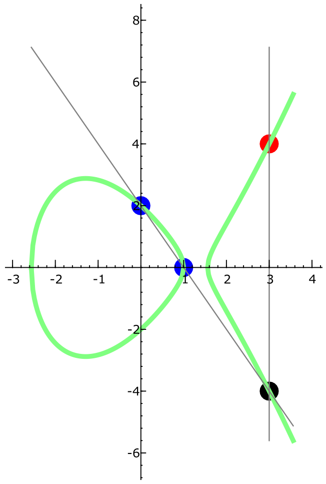

FIGURE 6.3. The Group Law: $(1,0)+(0,2)=(3,4)$ on $y^2=x^3-5x+4$

Proof. The line L through P_1, P_2 is $y=y_1+(x-x_1)\lambda$. Substituting this into $y^2=x^3+ax+b$, we get

$$(y_1+(x-x_1)\lambda)^2=x^3+ax+b.$$

Simplifying, we get $f(x)=x^3-\lambda^2x^2+\cdots=0$, where we omit the coefficients of x and the constant term since they will not be needed. Since P_1 and P_2 are in $L\cap E$, the polynomial f has x_1 and x_2 as roots. By Proposition 2.5.3, the polynomial f can have at most three roots. Writing $f=\prod(x-x_i)$ and equating terms, we see that $x_1+x_2+x_3=\lambda^2$. Thus, $x_3=\lambda^2-x_1-x_2$, as claimed. Also, from the equation for L we see that $y_3=y_1+(x_3-x_1)\lambda=\lambda x_3+\nu$, which completes the proof. □

To prove Theorem 6.2.2 means to show that $+$ satisfies the three axioms of an abelian group with $\mathcal{O}$ as identity element: existence of inverses, commutativity, and associativity. The existence of inverses follows immediately from the definition, since $(x,y)+(x,-y)=\mathcal{O}$. Commutativity is also clear from the definition of group law, since in Parts 1–3, the recipe is unchanged if we swap P_1 and P_2; in Part 4 swapping P_1 and P_2 does not change the line determined by P_1 and P_2, so by Proposition 6.2.4 it does not change the sum P_1+P_2.

It is more difficult to prove that $+$ satisfies the associative axiom, i.e., that $(P_1+P_2)+P_3=P_1+(P_2+P_3)$. This fact can be understood from at least three points of view. One is to reinterpret the group law geometrically (extending Proposition 6.2.4 to all cases), and thus transfer the problem to a question in plane geometry. This approach is beautifully explained with exactly the right level of detail in [ST92, §I.2]. Another approach is to use the formulas that define + to reduce associativity to checking specific algebraic identities; this is something that would be extremely tedious to do by hand, but can be done using a computer (also tedious). A third approach (see [Sil86] or [Har77]) is to develop a general theory of "divisors on algebraic curves," from which associativity of the group law falls out as a natural corollary. The third approach is the best, because it opens up many new vistas; however, we will not pursue it further because it is beyond the scope of this book.

SAGE Example 6.2.5. In the following Sage session, we use the formula from Algorithm 6.2.1 to verify that the group law holds for any choice of points P_1, P_2, P_3 on any elliptic curve over $\mathbf{Q}$ such that the points $P_1, P_2, P_3, P_1 + P_2, P_2 + P_3$ are all distinct and nonzero. We define a polynomial ring R in 8 variables.

```
sage: R.<x1,y1,x2,y2,x3,y3,a,b> = QQ[]
```

We define the relations the x_i will satisfy, and a quotient ring Q in which those relations are satisfied. (Quotients of polynomial rings are a generalization of the construction $\mathbf{Z}/n\mathbf{Z}$ that may be viewed as the quotient of the ring $\mathbf{Z}$ of integers by the relation that sets n to equal 0.)

```
sage: rels = [y1^2 - (x1^3 + a*x1 + b),
...           y2^2 - (x2^3 + a*x2 + b),
...           y3^2 - (x3^3 + a*x3 + b)]
...
sage: Q = R.quotient(rels)
```

We define the group operation, which assumes the points are distinct.

```
sage: def op(P1,P2):
...       x1,y1 = P1;  x2,y2 = P2
...       lam = (y1 - y2)/(x1 - x2); nu  = y1 - lam*x1
...       x3 = lam^2 - x1 - x2; y3 = -lam*x3 - nu
...       return (x3, y3)
```

We define three points, add them together via $P_1 + (P_2 + P_3)$ and $(P_1 + (P_2 + P_3))$, and observe that the results are the same modulo the relations.

```
sage: P1 = (x1,y1); P2 = (x2,y2); P3 = (x3,y3)
sage: Z = op(P1, op(P2,P3)); W = op(op(P1,P2),P3)
sage: (Q(Z[0].numerator()*W[0].denominator() -
...          Z[0].denominator()*W[0].numerator())) == 0
True
sage: (Q(Z[1].numerator()*W[1].denominator() -
...          Z[1].denominator()*W[1].numerator())) == 0
True
```

6.3 Integer Factorization Using Elliptic Curves

In 1987, Hendrik Lenstra published the landmark paper [Len87] that introduces and analyzes the Elliptic Curve Method (ECM), which is a powerful algorithm for factoring integers using elliptic curves. Lenstra's method is also described in [ST92, §IV.4], [Dav99, §VIII.5], and [Coh93, §10.3].

Lenstra's algorithm is well suited for finding "medium-sized" factors of an integer N, which today means between 10 to 40 decimal digits. The ECM method is not *directly* used for factoring RSA challenge numbers (see Section 1.1.3), but it is used on auxiliary numbers as a crucial step in the "number field sieve," which is the best known algorithm for hunting for such factorizations. Also, implementation of ECM typically requires little memory.

H. Lenstra

6.3.1 Pollard's $(p-1)$-Method

Lenstra's discovery of ECM was inspired by Pollard's $(p-1)$-method, which we describe in this section.

Definition 6.3.1 (Power Smooth)**.** Let B be a positive integer. If n is a positive integer with prime factorization $n = \prod p_i^{e_i}$, then n is *B-power smooth* if $p_i^{e_i} \leq B$ for all i.

For example, $30 = 2\cdot 3\cdot 5$ is B power smooth for $B = 5, 7$, but $150 = 2\cdot 3\cdot 5^2$ is not 5-power smooth (it is $B = 25$-power smooth).

We will use the following algorithm in both the Pollard $p-1$ and elliptic curve factorization methods.

Algorithm 6.3.2 (Least Common Multiple of First B Integers)**.** Given a positive integer B, this algorithm computes the least common multiple of the positive integers up to B.

1. [Sieve] Using, for example, the prime sieve (Algorithm 1.2.3), compute a list P of all primes $p \leq B$.
2. [Multiply] Compute and output the product $\prod_{p\in P} p^{\lfloor \log_p(B)\rfloor}$.

Proof. Set $m = \mathrm{lcm}(1, 2, \ldots, B)$. Then,

$$\mathrm{ord}_p(m) = \max(\{\mathrm{ord}_p(n) : 1 \leq n \leq B\}) = \mathrm{ord}_p(p^r),$$

where p^r is the largest power of p that satisfies $p^r \leq B$. Since $p^r \leq B < p^{r+1}$, we have $r = \lfloor \log_p(B)\rfloor$. □

SAGE Example 6.3.3. We implement Algorithm 6.3.2 in Sage and compute the least common multiple for $B = 100$ using both the above algorithm and a naive algorithm. We use `math.log` below so that $\log_p(B)$ is computed quickly using double precision numbers.

```
sage: def lcm_upto(B):
...       return prod([p^int(math.log(B)/math.log(p))
...                    for p in prime_range(B+1)])
sage: lcm_upto(10^2)
69720375229712477164533808935312303556800
sage: LCM([1..10^2])
69720375229712477164533808935312303556800
```

Algorithm 6.3.2 as implemented above in Sage takes about a second for $B = 10^6$.

Let N be a positive integer that we wish to factor. We use the Pollard $(p-1)$-method to look for a nontrivial factor of N as follows. First, we choose a positive integer B, usually with at most six digits. Suppose that there is a prime divisor p of N such that $p-1$ is B-power smooth. We try to find p using the following strategy. If $a > 1$ is an integer not divisible by p, then by Theorem 2.1.20,

$$a^{p-1} \equiv 1 \pmod{p}.$$

Let $m = \operatorname{lcm}(1, 2, 3, \ldots, B)$, and observe that our assumption that $p-1$ is B-power smooth implies that $p - 1 \mid m$, so

$$a^m \equiv 1 \pmod{p}.$$

Thus

$$p \mid \gcd(a^m - 1, N) > 1.$$

If $\gcd(a^m-1, N) < N$ also then $\gcd(a^m-1, N)$ is a nontrivial factor of N. If $\gcd(a^m - 1, N) = N$, then $a^m \equiv 1 \pmod{q^r}$ for every prime power divisor q^r of N. In this case, repeat the above steps but with a smaller choice of B or possibly a different choice of a. Also, it is a good idea to check from the start whether or not N is not a perfect power M^r and, if so, replace N by M. We formalize the algorithm as follows:

Algorithm 6.3.4 (Pollard $p-1$ Method)**.** Given a positive integer N and a bound B, this algorithm attempts to find a nontrivial factor g of N. (Each prime $p \mid g$ is likely to have the property that $p-1$ is B-power smooth.)

```
1. [Compute lcm] Use Algorithm 6.3.2 to compute $m = \operatorname{lcm}(1, 2, \ldots, B)$.
2. [Initialize] Set $a = 2$.
3. [Power and gcd] Compute $x = a^m - 1 \pmod{N}$ and $g = \gcd(x, N)$.
4. [Finished?] If $g \neq 1$ or $N$, output $g$ and terminate.
```

5. [Try Again?] If $a < 10$ (say), replace a by $a+1$ and go to step 3. Otherwise, terminate.

For fixed B, Algorithm 6.3.4 often splits N when N is divisible by a prime p such that $p-1$ is B-power smooth. Approximately 15 percent of primes p in the interval from 10^{15} and $10^{15}+10000$ are such that $p-1$ is 10^6 power smooth, so the Pollard method with $B = 10^6$ already fails nearly 85 percent of the time at finding 15-digit primes in this range (see also Exercise 6.10). We will not analyze Pollard's method further, since it was mentioned here only to set the stage for the elliptic curve factorization method.

The following examples illustrate the Pollard $(p-1)$-method.

Example 6.3.5. In this example, Pollard works perfectly. Let $N = 5917$. We try to use the Pollard $p-1$ method with $B = 5$ to split N. We have $m = \mathrm{lcm}(1,2,3,4,5) = 60$; taking $a = 2$, we have

$$2^{60} - 1 \equiv 3416 \pmod{5917}$$

and

$$\gcd(2^{60}-1, 5917) = \gcd(3416, 5917) = 61,$$

so 61 is a factor of 5917.

Example 6.3.6. In this example, we replace B with a larger integer. Let $N = 779167$. With $B = 5$ and $a = 2$, we have

$$2^{60} - 1 \equiv 710980 \pmod{779167},$$

and $\gcd(2^{60}-1, 779167) = 1$. With $B = 15$, we have

$$m = \mathrm{lcm}(1,2,\ldots,15) = 360360,$$

$$2^{360360} - 1 \equiv 584876 \pmod{779167},$$

and

$$\gcd(2^{360360}-1, N) = 2003,$$

so 2003 is a nontrivial factor of 779167.

Example 6.3.7. In this example, we replace B by a smaller integer. Let $N = 4331$. Suppose $B = 7$, so $m = \mathrm{lcm}(1,2,\ldots,7) = 420$,

$$2^{420} - 1 \equiv 0 \pmod{4331},$$

and $\gcd(2^{420}-1, 4331) = 4331$, so we do not obtain a factor of 4331. If we replace B by 5, Pollard's method works:

$$2^{60} - 1 \equiv 1464 \pmod{4331},$$

and $\gcd(2^{60}-1, 4331) = 61$, so we split 4331.

Example 6.3.8. In this example, $a = 2$ does not work, but $a = 3$ does. Let $N = 187$. Suppose $B = 15$, so $m = \mathrm{lcm}(1, 2, \ldots, 15) = 360360$,

$$2^{360360} - 1 \equiv 0 \pmod{187},$$

and $\gcd(2^{360360} - 1, 187) = 187$, so we do not obtain a factor of 187. If we replace $a = 2$ by $a = 3$, then Pollard's method works:

$$3^{360360} - 1 \equiv 66 \pmod{187},$$

and $\gcd(3^{360360} - 1, 187) = 11$. Thus $187 = 11 \cdot 17$.

SAGE Example 6.3.9. We implement the Pollard $(p - 1)$-method in Sage and use our implementation to do all of the above examples.

```
sage: def pollard(N, B=10^5, stop=10):
...       m = prod([p^int(math.log(B)/math.log(p))
...                 for p in prime_range(B+1)])
...       for a in [2..stop]:
...           x = (Mod(a,N)^m - 1).lift()
...           if x == 0: continue
...           g = gcd(x, N)
...           if g != 1 or g != N: return g
...       return 1
sage: pollard(5917,5)

```

6.3.2 Motivation for the Elliptic Curve Method

Fix a positive integer B. If $N = pq$ with p and q prime, and we assume that $p - 1$ and $q - 1$ are not B-power smooth, then the Pollard $(p - 1)$-method is unlikely to work. For example, let $B = 20$ and suppose that $N = 59 \cdot 101 = 5959$. Note that neither $59 - 1 = 2 \cdot 29$ nor $101 - 1 = 4 \cdot 25$ is B-power smooth. With $m = \mathrm{lcm}(1, 2, 3, \ldots, 20) = 232792560$, we have

$$2^m - 1 \equiv 5944 \pmod{N},$$

and $\gcd(2^m - 1, N) = 1$, so we do not find a factor of N.

As remarked above, the problem is that $p-1$ is not 20-power smooth for either $p = 59$ or $p = 101$. However, notice that $p - 2 = 3 \cdot 19$ is 20-power smooth. Lenstra's ECM replaces $(\mathbf{Z}/p\mathbf{Z})^*$, which has order $p - 1$, by the group of points on an elliptic curve E over $\mathbf{Z}/p\mathbf{Z}$. It is a theorem that

$$\#E(\mathbf{Z}/p\mathbf{Z}) = p + 1 \pm s$$

for some nonnegative integer $s < 2\sqrt{p}$ (see [Sil86, §V.1] for a proof). Also, every value of s subject to this bound occurs, as one can see using "complex multiplication theory." For example, if E is the elliptic curve

$$y^2 = x^3 + x + 54$$

over $\mathbf{Z}/59\mathbf{Z}$, then by enumerating points one sees that $E(\mathbf{Z}/59\mathbf{Z})$ is cyclic of order 57. The set of numbers $59 + 1 \pm s$ for $s \leq 15$ contains 14 numbers that are B-power smooth for $B = 20$, which illustrates that working with an elliptic curve gives us more flexibility. For example, $60 = 59 + 1 + 0$ is 5-power smooth and $70 = 59 + 1 + 10$ is 7-power smooth.

6.3.3 Lenstra's Elliptic Curve Factorization Method

Algorithm 6.3.10 (Elliptic Curve Factorization Method)**.** Given a positive integer N and a bound B, this algorithm attempts to find a nontrivial factor g of N or outputs "Fail."

1. [Compute lcm] Use Algorithm 6.3.2 to compute $m = \mathrm{lcm}(1, 2, \ldots, B)$.
2. [Choose Random Elliptic Curve] Choose a random $a \in \mathbf{Z}/N\mathbf{Z}$ such that $4a^3 + 27 \in (\mathbf{Z}/N\mathbf{Z})^*$. Then $P = (0, 1)$ is a point on the elliptic curve $y^2 = x^3 + ax + 1$ over $\mathbf{Z}/N\mathbf{Z}$.
3. [Compute Multiple] Attempt to compute mP using an elliptic curve analog of Algorithm 2.3.13. If at some point we cannot compute a sum of points because some denominator in Step 3 of Algorithm 6.2.1 is not coprime to N, we compute the greatest common divisor g of this denominator with N. If g is a nontrivial divisor, output it. If every denominator is coprime to N, output "Fail."

If Algorithm 6.3.10 fails for one random elliptic curve, there is an option that is unavailable with Pollard's $(p-1)$-method—we may repeat the above algorithm with a different elliptic curve. With Pollard's method we always work with the group $(\mathbf{Z}/N\mathbf{Z})^*$, but here we can try many groups $E(\mathbf{Z}/N\mathbf{Z})$ for many curves E. As mentioned above, the number of points on E over $\mathbf{Z}/p\mathbf{Z}$ is of the form $p + 1 - t$ for some t with $|t| < 2\sqrt{p}$; Algorithm 6.3.10 thus has a chance if $p + 1 - t$ is B-power smooth for some t with $|t| < 2\sqrt{p}$.

6.3.4 Examples

For simplicity, we use an elliptic curve of the form

$$y^2 = x^3 + ax + 1,$$

which has the point $P = (0, 1)$ already on it.

We factor $N = 5959$ using the elliptic curve method. Let

$$m = \mathrm{lcm}(1, 2, \ldots, 20) = 232792560 = 1101111000000010000111110000_2,$$

where x_2 means x is written in binary. First, we choose $a = 1201$ at random and consider $y^2 = x^3 + 1201x + 1$ over $\mathbf{Z}/5959\mathbf{Z}$. Using the formula for $P + P$ from Algorithm 6.2.1 we compute $2^i \cdot P = 2^i \cdot (0, 1)$ for $i \in B = \{4, 5, 6, 7, 8, 13, 21, 22, 23, 24, 26, 27\}$. Then $\sum_{i \in B} 2^i P = mP$. It turns out that during no step of this computation does a number not coprime to 5959 appear in any denominator, so we do not split N using $a = 1201$. Next, we try $a = 389$ and at some stage in the computation we add $P = (2051, 5273)$ and $Q = (637, 1292)$. When computing the group law explicitly, we try to compute $\lambda = (y_1 - y_2)/(x_1 - x_2)$ in $(\mathbf{Z}/5959\mathbf{Z})^*$, but we fail since $x_1 - x_2 = 1414$ and $\gcd(1414, 5959) = 101$. We thus find a nontrivial factor 101 of 5959.

SAGE Example 6.3.11. We implement elliptic curve factorization in Sage, then use it to do the above example and some other examples.

```
sage: def ecm(N, B=10^3, trials=10):
...       m = prod([p^int(math.log(B)/math.log(p))
...                 for p in prime_range(B+1)])
...       R = Integers(N)
...       # Make Sage think that R is a field:
...       R.is_field = lambda : True
...       for _ in range(trials):
...           while True:
...               a = R.random_element()
...               if gcd(4*a.lift()^3 + 27, N) == 1: break
...           try:
...               m * EllipticCurve([a, 1])([0,1])
...           except ZeroDivisionError, msg:
...               # msg: "Inverse of <int> does not exist"
...               return gcd(Integer(str(msg).split()[2]), N)
...       return 1
sage: set_random_seed(2)
sage: ecm(5959, B=20)
101
sage: ecm(next_prime(10^20)*next_prime(10^7), B=10^3)
10000019
```

6.3.5 A Heuristic Explanation

Let N be a positive integer and, for simplicity of exposition, assume that $N = p_1 \cdots p_r$ with the p_i distinct primes. It follows from Lemma 2.2.5 that there is a natural isomorphism

$$f : (\mathbf{Z}/N\mathbf{Z})^* \longrightarrow (\mathbf{Z}/p_1\mathbf{Z})^* \times \cdots \times (\mathbf{Z}/p_r\mathbf{Z})^*.$$

When using Pollard's method, we choose an $a \in (\mathbf{Z}/N\mathbf{Z})^*$, compute a^m, then compute $\gcd(a^m - 1, N)$. This gcd is divisible exactly by the primes p_i such that $a^m \equiv 1 \pmod{p_i}$. To reinterpret Pollard's method using the above isomorphism, let $(a_1, \ldots, a_r) = f(a)$. Then $(a_1^m, \ldots, a_r^m) = f(a^m)$, and the p_i that divide $\gcd(a^m - 1, N)$ are exactly the p_i such that $a_i^m = 1$. By Theorem 2.1.20, these p_i include the primes p_j such that $p_j - 1$ is B-power smooth, where $m = \operatorname{lcm}(1, \ldots, m)$.

We will not define $E(\mathbf{Z}/N\mathbf{Z})$ when N is composite, since this is not needed for the algorithm (where we assume that N is prime and hope for a contradiction). However, for the remainder of this paragraph, we pretend that $E(\mathbf{Z}/N\mathbf{Z})$ is meaningful and describe a heuristic connection between Lenstra and Pollard's methods. The significant difference between Pollard's method and the elliptic curve method is that the isomorphism f is replaced by an isomorphism (in quotes)

$$\text{“}g : E(\mathbf{Z}/N\mathbf{Z}) \to E(\mathbf{Z}/p_1\mathbf{Z}) \times \cdots \times E(\mathbf{Z}/p_r\mathbf{Z})\text{”}$$

where E is $y^2 = x^3 + ax + 1$, and the a of Pollard's method is replaced by $P = (0, 1)$. We put the isomorphism in quotes to emphasize that we have not defined $E(\mathbf{Z}/N\mathbf{Z})$. When carrying out the elliptic curve factorization algorithm, we attempt to compute mP, and if some components of $f(Q)$ are $\mathcal{O}$, for some point Q that appears during the computation, but others are nonzero, we find a nontrivial factor of N.

6.4 Elliptic Curve Cryptography

The idea to use elliptic curves in cryptography was independently proposed by Neil Koblitz and Victor Miller in the mid 1980s. In this section, we discuss an analog of Diffie-Hellman that uses an elliptic curve instead of $(\mathbf{Z}/p\mathbf{Z})^*$. We then discuss the ElGamal elliptic curve cryptosystem.

6.4.1 Elliptic Curve Analogs of Diffie-Hellman

The Diffie-Hellman key exchange from Section 3.2 works well on an elliptic curve with no serious modification. Michael and Nikita agree on a secret key as follows:

1. Michael and Nikita agree on a prime p, an elliptic curve E over $\mathbf{Z}/p\mathbf{Z}$, and a point $P \in E(\mathbf{Z}/p\mathbf{Z})$.
2. Michael secretly chooses a random m and sends mP.
3. Nikita secretly chooses a random n and sends nP.
4. The secret key is nmP, which both Michael and Nikita can compute.

Presumably, an adversary can not compute nmP without solving the discrete logarithm problem (see Problem 3.2.2 and Section 6.4.3 below) in $E(\mathbf{Z}/p\mathbf{Z})$. For well-chosen E, P, and p, experience suggests that the discrete logarithm problem in $E(\mathbf{Z}/p\mathbf{Z})$ is much more difficult than the discrete logarithm problem in $(\mathbf{Z}/p\mathbf{Z})^*$ (see Section 6.4.3 for more on the elliptic curve discrete log problem).

6.4.2 The ElGamal Cryptosystem and Digital Rights Management

This section is about the ElGamal cryptosystem, which works well on an elliptic curve. This section draws on a paper by a computer hacker named Beale Screamer who cracked a "Digital Rights Management" (DRM) system.

The elliptic curve used in the DRM is an elliptic curve over the finite field $k = \mathbf{Z}/p\mathbf{Z}$, where

$$p = 785963102379428822376694789446897396207498568951.$$

The number p in base 16 is

$$89\text{ABCDEF}012345672718281831415926141424\text{F}7,$$

which includes counting in hexadecimal, and digits of e, π, and $\sqrt{2}$. The elliptic curve E is

$$\begin{aligned} y^2 = x^3 &+ 317689081251325503476317476413827693272746955927x \\ &+ 79052896607878758718120572025718535432100651934. \end{aligned}$$

We have

$$\#E(k) = 785963102379428822376693024881714957612686157429,$$

and the group $E(k)$ is cyclic with generator

$$\begin{aligned} B = (&771507216262649826170648268565579889907769254176, \\ &390157510246556628525279459266514995562533196655). \end{aligned}$$

Our heroes Nikita and Michael share digital music when they are not out fighting terrorists. When Nikita installed the DRM software on her computer, it generated a private key

$$n = 670805031139910513517527207693060456300217054473,$$

which it hides in bits and pieces of files. In order for Nikita to play Juno Reactor's latest hit `juno.wma`, her web browser contacts a website that sells music. After Nikita sends her credit card number, that website allows Nikita to download a license file that allows her audio player to unlock and play `juno.wma`.

As we will see below, the license file was created using the ElGamal public-key cryptosystem in the group $E(k)$. Nikita can now use her license file to unlock `juno.wma`. However, when she shares both `juno.wma` and the license file with Michael, he is frustrated because even with the license, his computer still does not play `juno.wma`. This is because Michael's computer does not know Nikita's computer's private key (the integer n above), so Michael's computer can not decrypt the license file.

We now describe the ElGamal cryptosystem, which lends itself well to implementation in the group $E(\mathbf{Z}/p\mathbf{Z})$. To illustrate ElGamal, we describe how Nikita would set up an ElGamal cryptosystem that anyone could use to encrypt messages for her. Nikita chooses a prime p, an elliptic curve E over $\mathbf{Z}/p\mathbf{Z}$, and a point $B \in E(\mathbf{Z}/p\mathbf{Z})$, and publishes p, E, and B. She also chooses a random integer n, which she keeps secret, and publishes nB. Her public key is the four-tuple (p, E, B, nB).

Suppose Michael wishes to encrypt a message for Nikita. If the message is encoded as an element $P \in E(\mathbf{Z}/p\mathbf{Z})$, Michael computes a random integer r and the points rB and $P + r(nB)$ on $E(\mathbf{Z}/p\mathbf{Z})$. Then P is encrypted as the pair $(rB, P + r(nB))$. To decrypt the encrypted message, Nikita multiplies rB by her secret key n to find $n(rB) = r(nB)$, then subtracts this from $P + r(nB)$ to obtain

$$P = P + r(nB) - r(nB).$$

Remark 6.4.1. It also make sense to construct an ElGamal cryptosystem in the group $(\mathbf{Z}/p\mathbf{Z})^*$.

Returning to our story, Nikita's license file is an encrypted message to her. It contains the pair of points $(rB, P + r(nB))$, where

$$\begin{aligned} rB = (&1796710032183157463850266557330860449821944246 60,\\ &697834385359686368249301282675141830935176314718) \end{aligned}$$

and

$$\begin{aligned} P + r(nB) = (&1378510385482644673726451580930040003436391189 15,\\ &1108485892286762240572292302235808150242248756 99). \end{aligned}$$

When Nikita's computer plays `juno.wma`, it loads the secret key

$$n = 670805031139910513517527207693060456300217054473$$

into memory and computes

$$\begin{aligned} n(rB) = (&328901393518732637577115650601768681044040715701,\\ &586947838087815993601350565488788846203887988162). \end{aligned}$$

It then subtracts this from $P + r(nB)$ to obtain

$$\begin{aligned} P = (&14489646124220757767,\\ &669337780373284096274895136618194604469696830074). \end{aligned}$$

The x-coordinate 14489646124220757767 is the key that unlocks `juno.wma`.

If Nikita knew the private key n that her computer generated, she could compute P herself and unlock `juno.wma` and share her music with Michael. Beale Screamer found a weakness in the implementation of this system that allows Nikita to detetermine n, which is not a huge surprise since n is stored on her computer after all.

SAGE Example 6.4.2. We do the above examples in Sage:

```
sage: p = 785963102379428822376694789446897396207498568951
sage: E = EllipticCurve(GF(p), \
...    [317689081251325503476317476413827693272746955927,
...     79052896607878758718120572025718535432100651934])
sage: E.cardinality()
785963102379428822376693024881714957612686157429
sage: E.cardinality().is_prime()
True
sage: B = E([
...    771507216262649826170648268565579889907769254176,
...    390157510246556628525279459266514995562533196655])
sage: n=670805031139910513517527207693060456300217054473
sage: r=70674630913457179596452846564371866229568459543

...    669337780373284096274895136618194604469696830074])
sage: encrypt = (r*B, P + r*(n*B))
sage: encrypt[1] - n*encrypt[0] == P   # decrypting works
True
```

6.4.3 The Elliptic Curve Discrete Logarithm Problem

Problem 6.4.3 (Elliptic Curve Discrete Log Problem)**.** Suppose E is an elliptic curve over $\mathbf{Z}/p\mathbf{Z}$ and $P \in E(\mathbf{Z}/p\mathbf{Z})$. Given a multiple Q of P, the *elliptic curve discrete log problem* is to find $n \in \mathbf{Z}$ such that $nP = Q$.

For example, let E be the elliptic curve given by $y^2 = x^3 + x + 1$ over the field $\mathbf{Z}/7\mathbf{Z}$. We have

$$E(\mathbf{Z}/7\mathbf{Z}) = \{\mathcal{O}, (2,2), (0,1), (0,6), (2,5)\}.$$

If $P = (2,2)$ and $Q = (0,6)$, then $3P = Q$, so $n = 3$ is a solution to the discrete logarithm problem.

If $E(\mathbf{Z}/p\mathbf{Z})$ has order p or $p \pm 1$, or is a product of reasonably small primes, then there are some methods for attacking the discrete log problem on E, which are beyond the scope of this book. It is therefore important to be able to compute $\#E(\mathbf{Z}/p\mathbf{Z})$ efficiently, in order to verify that the elliptic curve one wishes to use for a cryptosystem doesn't have any obvious vulnerabilities. The naive algorithm to compute $\#E(\mathbf{Z}/p\mathbf{Z})$ is to try each value of $x \in \mathbf{Z}/p\mathbf{Z}$ and count how often x^3+ax+b is a perfect square mod p, but this is of no use when p is large enough to be useful for cryptography. Fortunately, there is an algorithm due to Schoof, Elkies, and Atkin for computing $\#E(\mathbf{Z}/p\mathbf{Z})$ efficiently (polynomial time in the number of digits of p), but this algorithm is beyond the scope of this book.

In Section 3.2.1, we discussed the discrete log problem in $(\mathbf{Z}/p\mathbf{Z})^*$. There are general attacks called "index calculus attacks" on the discrete log problem in $(\mathbf{Z}/p\mathbf{Z})^*$ that are slow, but still faster than the known algorithms for solving the discrete log in a "general" group (one with no extra structure). For most elliptic curves, there is no known analog of index calculus attacks on the discrete log problem. At present, it appears that given p, the discrete log problem in $E(\mathbf{Z}/p\mathbf{Z})$ is much harder than the discrete log problem in the multiplicative group $(\mathbf{Z}/p\mathbf{Z})^*$. This suggests that by using an elliptic curve-based cryptosystem instead of one based on $(\mathbf{Z}/p\mathbf{Z})^*$, one gets equivalent security with much smaller numbers, which is one reason why building cryptosystems using elliptic curves is attractive to some cryptographers. For example, Certicom, a company that strongly supports elliptic curve cryptography, claims:

> "[Elliptic curve crypto] devices require less storage, less power, less memory, and less bandwidth than other systems. This allows you to implement cryptography in platforms that are constrained, such as wireless devices, handheld computers, smart cards, and thin-clients. It also provides a big win in situations where efficiency is important."

For an up-to-date list of elliptic curve discrete log challenge problems that Certicom sponsors, see [Cer]. For example, in April 2004, a specific cryptosystem was cracked that was based on an elliptic curve over $\mathbf{Z}/p\mathbf{Z}$, where p has 109 bits. The first unsolved challenge problem involves an elliptic curve over $\mathbf{Z}/p\mathbf{Z}$, where p has 131 bits, and the next challenge after that is one in which p has 163 bits. Certicom claims at [Cer] that the 163-bit challenge problem is computationally infeasible.

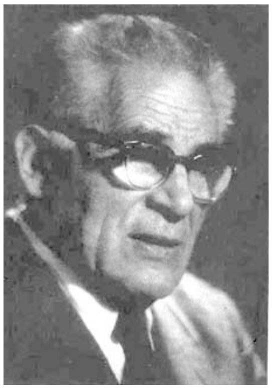

FIGURE 6.4. Louis J. Mordell

6.5 Elliptic Curves Over the Rational Numbers

Let E be an elliptic curve defined over $\mathbf{Q}$. The following is a deep theorem about the group $E(\mathbf{Q})$.

Theorem 6.5.1 (Mordell)**.** *The group $E(\mathbf{Q})$ is finitely generated. That is, there are points $P_1, \ldots, P_s \in E(\mathbf{Q})$ such that every element of $E(\mathbf{Q})$ is of the form $n_1P_1 + \cdots + n_sP_s$ for integers $n_1, \ldots n_s \in \mathbf{Z}$.*

Mordell's theorem implies that it makes sense to ask whether or not we can compute $E(\mathbf{Q})$, where by "compute" we mean find a finite set $P_1, \ldots, P_s$ of points on E that generate $E(\mathbf{Q})$ as an abelian group. There is a systematic approach to computing $E(\mathbf{Q})$ called "descent" (see, for example, [Cre97, Cre, Sil86]). It is widely believed that the method of descent will always succeed, but nobody has yet proved that it will. Proving that descent works for all curves is one of the central open problems in number theory, and is closely related to the Birch and Swinnerton-Dyer conjecture (one of the Clay Math Institute's million dollar prize problems). The crucial difficulty amounts to deciding whether or not certain explicitly given curves have any rational points on them or not (these are curves that have points over $\mathbf{R}$ and modulo n for all n).

The details of using descent to compute $E(\mathbf{Q})$ are beyond the scope of this book. In several places below, we will simply assert that $E(\mathbf{Q})$ has a certain structure or is generated by certain elements. In each case, we computed $E(\mathbf{Q})$ using a computer implementation of this method.

6.5.1 The Torsion Subgroup of $E(\mathbf{Q})$

For any abelian group G, let G_{tor} be the subgroup of elements of finite order. If E is an elliptic curve over $\mathbf{Q}$, then $E(\mathbf{Q})_{\text{tor}}$ is a subgroup of $E(\mathbf{Q})$, which must be finite because of Theorem 6.5.1 (see Exercise 6.6).

One can also prove that $E(\mathbf{Q})_{\mathrm{tor}}$ is finite by showing that there is a prime p and an injective reduction homomorphism $E(\mathbf{Q})_{\mathrm{tor}} \hookrightarrow E(\mathbf{Z}/p\mathbf{Z})$, then noting that $E(\mathbf{Z}/p\mathbf{Z})$ is finite. For example, if E is $y^2 = x^3 - 5x + 4$, then $E(\mathbf{Q})_{\mathrm{tor}} = \{\mathcal{O}, (1,0)\} \cong \mathbf{Z}/2\mathbf{Z}$.

The possibilities for $E(\mathbf{Q})_{\mathrm{tor}}$ are known.

Theorem 6.5.2 (Mazur, 1976)**.** *Let E be an elliptic curve over $\mathbf{Q}$. Then $E(\mathbf{Q})_{\mathrm{tor}}$ is isomorphic to one of the following 15 groups:*

$$\begin{aligned} \mathbf{Z}/n\mathbf{Z} &\qquad \textit{for } n \le 10 \textit{ or } n = 12,\\ \mathbf{Z}/2\mathbf{Z} \times \mathbf{Z}/2n &\qquad \textit{for } n \le 4. \end{aligned}$$

SAGE Example 6.5.3. We compute the structure of the torsion subgroups of some elliptic curves. In each case, the output of the function $T(a,b)$ below is a pair $c, d \in \mathbf{Z}$ (or integer c) such that the torsion subgroup of $y^3 = x^3 + ax + b$ is $\mathbf{Z}/c\mathbf{Z} \times \mathbf{Z}/d\mathbf{Z}$.

```
sage: T = lambda v: EllipticCurve(v
...           ).torsion_subgroup().invariants()
sage: T([-5,4])
[2]
sage: T([-43,166])
[7]
sage: T([-4,0])
[2, 2]
sage: T([-1386747, 368636886])
[8, 2]
```

6.5.2 The Rank of $E(\mathbf{Q})$

The quotient $E(\mathbf{Q})/E(\mathbf{Q})_{\mathrm{tor}}$ is a finitely generated free abelian group, so it is isomorphism to $\mathbf{Z}^r$ for some integer r, called the *rank* of $E(\mathbf{Q})$. For example, one can prove that if E is $y^2 = x^3 - 5x + 4$, then $E(\mathbf{Q})/E(\mathbf{Q})_{\mathrm{tor}}$ is generated by the point $(0,2)$.

SAGE Example 6.5.4. We use Sage to compute the ranks of some elliptic curves $y^2 = x^3 + ax + b$. The function $r(a,b)$ below returns the rank of this curve over $\mathbf{Q}$.

```
sage: r = lambda v: EllipticCurve(v).rank()
sage: r([-5,4])
1
sage: r([0,1])
0
sage: r([-3024, 46224])
2
sage: r([-112, 400])
```

```
3
sage: r([-102627, 12560670])
4
```

The following is a folklore conjecture, not associated with any particular mathematician:

Conjecture 6.5.5. *There are elliptic curves over* $\mathbf{Q}$ *of arbitrarily large rank.*

The world record is the following curve, whose rank is at least 28:

$$\begin{aligned} y^2 + &xy + y = x^3 - x^2 - \\ &20067762415575526585033208209338542750930230312178956502x + \\ &3448161179503055646703298569039072037485594435931918036126\ldots \\ &\ldots 6600829629193944873224342 9 \end{aligned}$$

It was discovered in May 2006 by Noam Elkies of Harvard University.

6.5.3 The Congruent Number Problem

Definition 6.5.6 (Congruent Number)**.** We call a nonzero rational number n a *congruent number* if $\pm n$ is the area of a right triangle with rational side lengths. Equivalently, n is a *congruent number* if the system of two equations

$$\begin{aligned} a^2 + b^2 &= c^2 \\ \frac{1}{2}ab &= n \end{aligned}$$

has a solution with $a, b, c \in \mathbf{Q}$.

For example, 6 is the area of the right triangle with side lengths 3, 4, and 5, so 6 is a congruent number. Less obvious is that 5 is also a congruent number; it is the area of the right triangle with side lengths 3/2, 20/3, and 41/6. It is nontrivial to prove that 1, 2, 3, and 4 are not congruent numbers. Here is a list of the integer congruent numbers up to 50:

$$5, 6, 7, 13, 14, 15, 20, 21, 22, 23, 24, 28, 29, 30, 31, 34, 37, 38, 39, 41, 45, 46, 47.$$

Every congruence class modulo 8 except 3 is represented in this list, which incorrectly suggests that if $n \equiv 3 \pmod 8$ then n is not a congruent number. Though no $n \leq 218$ with $n \equiv 3 \pmod 8$ is a congruent number, $n = 219$ is a congruent number congruent and $219 \equiv 3 \pmod 8$.

Deciding whether an integer n is a congruent number can be subtle, since the simplest triangle with area n can be very complicated. For example, as Zagier pointed out, the number 157 is a congruent number, and the "simplest" rational right triangle with area 157 has side lengths

$$a = \frac{6803298487826435051217540}{411340519227716149383203} \text{ and } b = \frac{411340519227716149383203}{21666555693714761309610}.$$

This solution would be difficult to find by a brute force search.

We call congruent numbers "congruent" because of the following proposition, which asserts that any congruent number is the common "congruence" between three perfect squares.

Proposition 6.5.7. *Suppose n is the area of a right triangle with rational side lengths a, b, c, with $a \leq b < c$. Let $A = (c/2)^2$. Then*

$$A - n, \quad A, \quad \text{and } A + n$$

are all perfect squares of rational numbers.

Proof. We have

$$\begin{aligned} a^2 + b^2 &= c^2 \\ \frac{1}{2}ab &= n \end{aligned}$$

Add or subtract 4 times the second equation to the first to get

$$\begin{aligned} a^2 \pm 2ab + b^2 &= c^2 \pm 4n \\ (a \pm b)^2 &= c^2 \pm 4n \\ \left(\frac{a \pm b}{2}\right)^2 &= \left(\frac{c}{2}\right)^2 \pm n \\ &= A \pm n \end{aligned}$$

□

The main motivating open problem related to congruent numbers is to give a systematic way to recognize them.

Open Problem 6.5.8. *Give an algorithm which, given n, outputs whether or not n is a congruent number.*

Fortunately, the vast theory developed about elliptic curves has something to say about the above problem. In order to understand this connection, we begin with an elementary algebraic proposition that establishes a link between elliptic curves and the congruent number problem.

Proposition 6.5.9 (Congruent numbers and elliptic curves)**.** *Let n be a rational number. There is a bijection between*

$$A = \left\{(a, b, c) \in \mathbf{Q}^3 \ : \ \frac{ab}{2} = n,\ a^2 + b^2 = c^2\right\}$$

and

$$B = \{(x,y) \in \mathbf{Q}^2 \,:\, y^2 = x^3 - n^2 x, \text{ with } y \neq 0\}$$

given explicitly by the maps

$$f(a,b,c) = \left(-\frac{nb}{a+c},\ \frac{2n^2}{a+c}\right)$$

and

$$g(x,y) = \left(\frac{n^2 - x^2}{y},\ -\frac{2xn}{y},\ \frac{n^2 + x^2}{y}\right).$$

The proof of this proposition is not deep, but involves substantial (elementary) algebra and we will not prove it in this book.

For $n \neq 0$, let E_n be the elliptic curve $y^2 = x^3 - n^2 x$.

Proposition 6.5.10 (Congruent number criterion)**.** *The rational number n is a congruent number if and only if there is a point $P = (x,y) \in E_n(\mathbf{Q})$ with $y \neq 0$.*

Proof. The number n is a congruent number if and only if the set A from Proposition 6.5.9 is nonempty. By the proposition A is nonempty if and only if B is nonempty. □

Example 6.5.11. Let $n = 5$. Then E_n is $y^2 = x^3 - 25x$, and we notice that $(-4,-6) \in E_n(\mathbf{Q})$. We next use the bijection of Proposition 6.5.9 to find the corresponding right triangle:

$$g(-4,-6) = \left(\frac{25-16}{-6}, -\frac{-40}{-6}, \frac{25+16}{-6}\right) = \left(-\frac{3}{2}, -\frac{20}{3}, -\frac{41}{6}\right).$$

Multiplying through by -1 yields the side lengths of a rational right triangle with area 5. *Are there any others?*

Observe that we can apply g to any point in $E_n(\mathbf{Q})$ with $y \neq 0$. Using the group law, we find that $2(-4,-6) = (1681/144, 62279/1728)$ and

$$g(2(-4,-6)) = \left(-\frac{1519}{492}, -\frac{4920}{1519}, \frac{3344161}{747348}\right).$$

This example foreshadows Theorem 6.5.14.

Example 6.5.12. Let $n = 1$, so E_1 is defined by $y^2 = x^3 - x$. Since 1 is not a congruent number, the elliptic curve E_1 has no point with $y \neq 0$. See Exercise 6.11.

SAGE Example 6.5.13. We implement the `cong` function in Sage, which returns a triple (a,b,c) whose entries are the sides of a rational right triangle of area n if one exists, and returns False if there are no such triangles.

```
sage: def cong(n):
...       G = EllipticCurve([-n^2,0]).gens()
...       if len(G) == 0: return False
...       x,y,_ = G[0]
...       return ((n^2-x^2)/y,-2*x*n/y,(n^2+x^2)/y)
sage: cong(6)
(3, 4, 5)
sage: cong(5)
(3/2, 20/3, 41/6)
sage: cong(1)
False
sage: cong(13)
(323/30, 780/323, 106921/9690)
sage: (323/30 * 780/323)/2
13
sage: (323/30)^2 + (780/323)^2 == (106921/9690)^2
True
```

Theorem 6.5.14 (Infinitely Many Triangles). *If n is a congruent number, then there are infinitely many distinct right triangles with rational side lengths and area n.*

We will not prove this theorem, except to note that one proves it by showing that $E_n(\mathbf{Q})_{\mathrm{tor}} = \{\mathcal{O}, (0,0), (n,0), (-n,0)\}$, so the elements of the set B in Proposition 6.5.9 all have infinite order. Hence, B is infinite so A is infinite.

Tunnell has proved that the Birch and Swinnerton-Dyer conjecture (alluded to above), implies the existence of an elementary way to decide whether or not an integer n is a congruent number. We state Tunnell's elementary way in the form of a conjecture.

Conjecture 6.5.15. *Let a, b, c denote integers. If n is an even square-free integer, then n is a congruent number if and only if*

$$\#\left\{(a,b,c) \in \mathbf{Z}^3 : 4a^2 + b^2 + 8c^2 = \frac{n}{2} : c \text{ is even}\right\}$$
$$= \#\left\{(a,b,c) : 4a^2 + b^2 + 8c^2 = \frac{n}{2} : c \text{ is odd}\right\}.$$

If n is odd and square free then n is a congruent number if and only if

$$\#\left\{(a,b,c) : 2a^2 + b^2 + 8c^2 = n : c \text{ is even}\right\}$$
$$= \#\left\{(a,b,c) : 2a^2 + b^2 + 8c^2 = n : c \text{ is odd}\right\}.$$

Enough of the Birch and Swinnerton-Dyer conjecture is known to prove one direction of Conjecture 6.5.15. In particular, it is a very deep theorem that if we do not have equality of the displayed cardinalities, then n is not a congruent number.

The even more difficult (and still open!) part of Conjecture 6.5.15 is the converse: If one has equality of the displayed cardinalities, prove that n is a congruent number. The difficulty in this direction, which appears to be very deep, is that we must somehow construct (or prove the existence of) elements of $E_n(\mathbf{Q})$. This has been accomplished in some cases due to the groundbreaking work of Gross and Zagier ([GZ86]) but much work remains to be done.

The excellent book [Kob84] is about congruent numbers and Conjecture 6.5.15, and we encourage the reader to consult it. The Birch and Swinnerton-Dyer conjecture is a Clay Math Institute million dollar millennium prize problem (see [Cla, Wil00]).

6.6 Exercises

6.1 Write down an equation $y^2 = x^3 + ax + b$ over a field K such that $-16(4a^3+27b^2) = 0$. Precisely what goes wrong when trying to endow the set $E(K) = \{(x, y) \in K \times K : y^2 = x^3 + ax + b\} \cup \{\mathcal{O}\}$ with a group structure?

6.2 One rational solution to the equation $y^2 = x^3 - 2$ is $(3, 5)$. Find a rational solution with $x \neq 3$ by drawing the tangent line to $(3, 5)$ and computing the second point of intersection.

6.3 Let E be the elliptic curve over the finite field $K = \mathbf{Z}/5\mathbf{Z}$ defined by the equation

$$y^2 = x^3 + x + 1.$$

(a) List all 9 elements of $E(K)$.

(b) What is the structure of $E(K)$, as a product of cyclic groups?

6.4 Let E be the elliptic curve defined by the equation $y^2 = x^3 + 1$. For each prime $p \geq 5$, let N_p be the cardinality of the group $E(\mathbf{Z}/p\mathbf{Z})$ of points on this curve having coordinates in $\mathbf{Z}/p\mathbf{Z}$. For example, we have that $N_5 = 6, N_7 = 12, N_{11} = 12, N_{13} = 12, N_{17} = 18, N_{19} = 12, , N_{23} = 24,$ and $N_{29} = 30$ (you do not have to prove this).

(a) For the set of primes satisfying $p \equiv 2 \pmod 3$, can you see a pattern for the values of N_p? Make a general conjecture for the value of N_p when $p \equiv 2 \pmod 3$.

(b) (*) Prove your conjecture.

6.5 Let E be an elliptic curve over the real numbers $\mathbf{R}$. Prove that $E(\mathbf{R})$ is not a finitely generated abelian group.

6.6 (*) Suppose G is a finitely generated abelian group. Prove that the subgroup G_{tor} of elements of finite order in G is finite.

6.7 Suppose $y^2 = x^3 + ax + b$ with $a, b \in \mathbf{Q}$ defines an elliptic curve. Show that there is another equation $Y^2 = X^3 + AX + B$ with $A, B \in \mathbf{Z}$ whose solutions are in bijection with the solutions to $y^2 = x^3 + ax + b$.

6.8 Suppose a, b, c are relatively prime integers with $a^2 + b^2 = c^2$. Then there exist integers x and y with $x > y$ such that $c = x^2 + y^2$ and either $a = x^2 - y^2$, $b = 2xy$ or $a = 2xy$, $b = x^2 - y^2$.

6.9 (*) Fermat's Last Theorem for exponent 4 asserts that any solution to the equation $x^4 + y^4 = z^4$ with $x, y, z \in \mathbf{Z}$ satisfies $xyz = 0$. Prove Fermat's Last Theorem for exponent 4, as follows.

(a) Show that if the equation $x^2 + y^4 = z^4$ has no integer solutions with $xyz \neq 0$, then Fermat's Last Theorem for exponent 4 is true.

(b) Prove that $x^2 + y^4 = z^4$ has no integer solutions with $xyz \neq 0$ as follows. Suppose $n^2 + k^4 = m^4$ is a solution with $m > 0$ minimal among all solutions. Show that there exists a solution with m smaller using Exercise 6.8 (consider two cases).

6.10 This problem requires a computer.

(a) Show that the set of numbers $59 + 1 \pm s$ for $s \leq 15$ contains 14 numbers that are B-power smooth for $B = 20$.

(b) Find the proportion of primes p in the interval from 10^{12} and $10^{12} + 1000$ such that $p - 1$ is $B = 10^5$ power smooth.

6.11 (*) Prove that 1 is not a congruent number by showing that the elliptic curve $y^2 = x^3 - x$ has no rational solutions except $(0, \pm 1)$ and $(0, 0)$, as follows:

(a) Write $y = \frac{p}{q}$ and $x = \frac{r}{s}$, where p, q, r, s are all positive integers and $\gcd(p, q) = \gcd(r, s) = 1$. Prove that $s \mid q$, so $q = sk$ for some $k \in \mathbf{Z}$.

(b) Prove that $s = k^2$, and substitute to see that $p^2 = r^3 - rk^4$.

(c) Prove that r is a perfect square by supposing that there is a prime ℓ such that $\mathrm{ord}_\ell(r)$ is odd, and analyzing ord_ℓ of both sides of $p^2 = r^3 - rk^4$.

(d) Write $r = m^2$, and substitute to see that $p^2 = m^6 - m^2k^4$. Prove that $m \mid p$.

(e) Divide through by m^2 and deduce a contradiction to Exercise 6.9.

Answers and Hints

• Chapter 1. Prime Numbers

2. They are $2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97$.
3. Emulate the proof of Proposition 1.2.5.

• Chapter 2. The Ring of Integers Modulo n

2. They are 5, 13, 3, and 8.
3. For example, $x = 22$, $y = -39$.
4. Hint: Use the binomial theorem and prove that if $r \geq 1$, then p divides $\binom{p}{r}$.
7. For example, $S_1 = \{0, 1, 2, 3, 4, 5, 6\}$, $S_2 = \{1, 3, 5, 7, 9, 11, 13\}$, $S_3 = \{0, 2, 4, 6, 8, 10, 12\}$, and $S_4 = \{2, 3, 5, 7, 11, 13, 29\}$. In each we find S_i by listing the first seven numbers satisfying the ith condition, then adjust the last number if necessary so that the reductions will be distinct modulo 7.
8. An integer is divisible by 5 if and only if the last digits is 0 or 5. An integer is divisible by 9 if and only if the sum of the digits is divisible by 9. An integer is divisible by 11 if and only if the alternating sum of the digits is divisible by 11.
9. Hint for part (a): Use the divisibility rule you found in Exercise 1.8.

10. 71
11. 8
12. As explained on page 23, we know that $\mathbf{Z}/n\mathbf{Z}$ is a ring for any n. Thus to show that $\mathbf{Z}/p\mathbf{Z}$ is a field it suffices to show that every nonzero element $\overline{a} \in \mathbf{Z}/p\mathbf{Z}$ has an inverse. Lift a to an element $a \in \mathbf{Z}$, and set $b = p$ in Proposition 2.3.1. Because p is prime, $\gcd(a, p) = 1$, so there exists x, y such that $ax+py = 1$. Reducing this equality modulo p proves that $\overline{a}$ has an inverse $x \pmod{p}$. Alternatively, one could argue just like after Definition 2.1.16 that $\overline{a}^m = 1$ for some m, so some power of $\overline{a}$ is the inverse of $\overline{a}$.
13. 302
15. Only for $n = 1, 2$. If $n > 2$, then n is either divisible by an odd prime p or 4. If $4 \mid n$, then $2^e - 2^{e-1}$ divides $\varphi(n)$ for some $e \geq 2$, so $\varphi(n)$ is even. If an odd p divides n, then the even number $p^e - p^{e-1}$ divides $\varphi(n)$ for some $e \geq 1$.
16. The map ψ is a homomorphism since both reduction maps

$$\mathbf{Z}/mn\mathbf{Z} \to \mathbf{Z}/m\mathbf{Z} \quad \text{and} \quad \mathbf{Z}/mn\mathbf{Z} \to \mathbf{Z}/n\mathbf{Z}$$

are homomorphisms. It is injective because if $a \in \mathbf{Z}$ is such that $\psi(a) = 0$, then $m \mid a$ and $n \mid a$, so $mn \mid a$ (since m and n are coprime), so $a \equiv 0 \pmod{mn}$. The cardinality of $\mathbf{Z}/mn\mathbf{Z}$ is mn and the cardinality of the product $\mathbf{Z}/m\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$ is also mn, so ψ must be an isomorphism. The units $(\mathbf{Z}/mn\mathbf{Z})^*$ are thus in bijection with the units $(\mathbf{Z}/m\mathbf{Z})^* \times (\mathbf{Z}/n\mathbf{Z})^*$.

For the second part of the exercise, let $g = \gcd(m, n)$ and set $a = mn/g$. Then $a \not\equiv 0 \pmod{mn}$, but $m \mid a$ and $n \mid a$, so $a \ker(\psi)$.

17. We express the question as a system of linear equations modulo various numbers, and use the Chinese remainder theorem. Let x be the number of books. The problem asserts that

$$\begin{aligned} x &\equiv 6 \pmod{7} \\ x &\equiv 2 \pmod{6} \\ x &\equiv 1 \pmod{5} \\ x &\equiv 0 \pmod{4} \end{aligned}$$

Applying CRT to the first pair of equations, we find that $x \equiv 20 \pmod{42}$. Applying CRT to this equation and the third, we find that $x \equiv 146 \pmod{210}$. Since 146 is not divisible by 4, we add multiples of 210 to 146 until we find the first x that is divisible by 4. The first multiple works, and we find that the aspiring mathematicians have 356 math books.

18. Note that $p = 3$ works, since $11 = 3^2 + 2$ is prime. Now suppose $p \neq 3$ is any prime such that p and $p^2 + 2$ are both prime. We must have $p \equiv 1 \pmod{3}$ or $p \equiv 2 \pmod{3}$. Then $p^2 \equiv 1 \pmod{3}$, so $p^2 + 2 \equiv 0 \pmod{3}$. Since $p^2 + 2$ is prime, we must have $p^2 + 2 = 3$, so $p = 1$, a contradiction as p is assumed prime.
19. For (a) $n = 1, 2$, see solution to Exercise 2.15. For (b), yes there are many such examples. For example, $m = 2$, $n = 4$.
20. By repeated application of multiplicativity and Equation (2.2.2) on page 31, we see that if $n = \prod_i p_i^{e_i}$ is the prime factorization of n, then

$$\varphi(n) = \prod_i (p_i^{e_i} - p_i^{e_i - 1}) = \prod_i p_i^{e_i - 1} \cdot \prod_i (p_i - 1).$$

23. 1, 6, 29, 34
24. Let $g = \gcd(12n+1, 30n+2)$. Then $g \mid 30n+2-2\cdot(12n+1) = 6n$. For the same reason, g also divides $12n + 1 - 2 \cdot (6n) = 1$, so $g = 1$, as claimed.
27. There is no primitive root modulo 8, since $(\mathbf{Z}/8\mathbf{Z})^*$ has order 4, but every element of $(\mathbf{Z}/8\mathbf{Z})^*$ has order 2. Prove that if ζ is a primitive root modulo 2^n, for $n \geq 3$, then the reduction of ζ mod 8 is a primitive root, a contradiction.
28. 2 is a primitive root modulo 125.
29. Let $\prod_{i=1}^m p_i^{e_i}$ be the prime factorization of n. Slightly generalizing Exercise 16, we see that

$$(\mathbf{Z}/n\mathbf{Z})^* \cong \prod (\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*.$$

Thus $(\mathbf{Z}/n\mathbf{Z})^*$ is cyclic if and only if the product $(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$ is cyclic. If $8 \mid n$, then there is no chance $(\mathbf{Z}/n\mathbf{Z})^*$ is cyclic, so assume $8 \nmid n$. Then by Exercise 2.28, each group $(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$ is itself cyclic. A product of cyclic groups is cyclic if and only the orders of the factors in the product are coprime (this follows from Exercise 2.16). Thus $(\mathbf{Z}/n\mathbf{Z})^*$ is cyclic if and only if the numbers $p_i(p_i - 1)$, for $i = 1, \ldots, m$ are pairwise coprime. Since $p_i - 1$ is even, there can be at most one odd prime in the factorization of n, and we see that $(\mathbf{Z}/n\mathbf{Z})^*$ is cyclic if and only if n is an odd prime power, twice an odd prime power, or $n = 4$.

• Chapter 3. Public-Key Cryptography

1. The best case is that each letter is A. Then the question is to find the largest n such that $1 + 27 + \cdots + 27^n \leq 10^{20}$. By computing

$\log_{27}(10^{20})$, we see that $27^{13} < 10^{20}$ and $27^{14} > 10^{20}$. Thus $n \leq 13$, and since $1+27+\cdots+27^{n-1} < 27^n$, and $2\cdot 27^{13} < 10^{20}$, it follows that $n = 13$.

2. This is not secure, since it is just equivalent to a "Ceaser Cipher," that is a permutation of the letters of the alphabet, which is well-known to be easily broken using a frequency analysis.

3. If we can compute the polynomial

$$f = (x-p)(x-q)(x-r) = x^3-(p+q+r)x^2+(pq+pr+qr)x-pqr,$$

then we can factor n by finding the roots of f, for example, using Newton's method (or Cardona's formula for the roots of a cubic). Because p, q, r, are distinct odd primes, we have

$$\varphi(n) = (p-1)(q-1)(r-1) = pqr - (pq+pr+qr) + p + q + r,$$

and

$$\sigma(n) = 1 + (p+q+r) + (pq+pr+qr) + pqr.$$

Since we know n, $\varphi(n)$, and $\sigma(n)$, we know

$$\begin{aligned} \sigma(n) - 1 - n &= (p+q+r) + (pq+pr+qr), \quad \text{and} \\ \varphi(n) - n &= (p+q+r) - (pq+pr+qr). \end{aligned}$$

We can thus compute both $p+q+r$ and $pq+pr+qr$, hence deduce f and find p, q, r.

• Chapter 4. Quadratic Reciprocity

1. They are all 1, −1, 0, and 1.

3. By Proposition 4.3.4, the value of $\left(\frac{3}{p}\right)$ depends only on the reduction $\pm p \pmod{12}$. List enough primes p such that $\pm p$ reduce to $1, 5, 7, 11$ modulo 12 and verify that the asserted formula holds for each of them.

7. Since $p = 2^{13} - 1$ is prime, there are either two solutions or no solutions to $x^2 \equiv 5 \pmod{p}$, and we can decide which using quadratic reciprocity. We have

$$\left(\frac{5}{p}\right) = (-1)^{(p-1)/2\cdot(5-1)/2}\left(\frac{p}{5}\right) = \left(\frac{p}{5}\right),$$

so there are two solutions if and only if $p = 2^{13}-1$ is ± 1 mod 5. In fact, $p \equiv 1 \pmod{5}$, so there are two solutions.

8. We have $4^{48} = 2^{96}$. By Euler's Theorem, $2^{96} = 1$, so $x = 1$.

9. For (a), take $a = 19$ and $n = 20$. We found this example using the Chinese remainder theorem applied to 4 (mod 5) and 3 (mod 4), and used that $\left(\frac{19}{20}\right) = \left(\frac{19}{5}\right) \cdot \left(\frac{19}{4}\right) = (-1)(-1) = 1$, yet 19 is not a square modulo either 5 or 4, so is certainly not a square modulo 20.

10. Hint: First reduce to the case that $6k - 1$ is prime, by using that if p and q are primes not of the form $6k - 1$, then neither is their product. If $p = 6k - 1$ divides $n^2 + n + 1$, it divides $4n^2 + 4n + 4 = (2n + 1)^2 + 3$, so -3 is a quadratic residue modulo p. Now use quadratic reciprocity to show that -3 is not a quadratic residue modulo p.

• Chapter 5. Continued Fractions

9. Suppose $n = x^2 + y^2$, with $x, y \in \mathbf{Q}$. Let d be such that $dx, dy \in \mathbf{Z}$. Then $d^2n = (dx)^2 + (dy)^2$ is a sum of two integer squares, so by Theorem 5.7.1, if $p \mid d^2n$ and $p \equiv 3 \pmod{4}$, then $\mathrm{ord}_p(d^2n)$ is even. We have $\mathrm{ord}_p(d^2n)$ is even if and only if $\mathrm{ord}_p(n)$ is even, so Theorem 5.7.1 implies that n is also a sum of two squares.

11. The squares modulo 8 are $0, 1, 4$, so a sum of two squares reduces modulo 8 to one of $0, 1, 2, 4$, or 5. Four consecutive integers that are sums of squares would reduce to four consecutive integers in the set $\{0, 1, 2, 4, 5\}$, which is impossible.

• Chapter 6. Elliptic Curves

2. The second point of intersection is $(129/100, 383/1000)$.

3. The group is cyclic of order 9, generated by $(4, 2)$. The elements of $E(K)$ are
$$\{\mathcal{O}, (4,2), (3,4), (2,4), (0,4), (0,1), (2,1), (3,1), (4,3)\}.$$

4. In part (a), the pattern is that $N_p = p + 1$. For part (b), a hint is that when $p \equiv 2 \pmod{3}$, the map $x \mapsto x^3$ on $(\mathbf{Z}/p\mathbf{Z})^*$ is an automorphism, so $x \mapsto x^3 + 1$ is a bijection. Now use what you learned about squares in $\mathbf{Z}/p\mathbf{Z}$ from Chapter 4.

5. For all sufficiently large real x, the equation $y^2 = x^3 + ax + b$ has a real solution y. Thus, the group $E(\mathbf{R})$ is not countable, since $\mathbf{R}$ is not countable. But any finitely generated group is countable.

6. In a course on abstract algebra, one often proves the nontrivial fact that every subgroup of a finitely generated abelian group is finitely generated. In particular, the torsion subgroup G_{tor} is

finitely generated. However, a finitely generated abelian torsion group is finite.

7. Hint: Multiply both sides of $y^2 = x^3 + ax + b$ by a power of a common denominator, and "absorb" powers into x and y.

8. Hint: see Exercise 4.6.

ABSTRACT

This paper is about how to compute the Hermite normal form of a *random* integer matrix in practice. We propose significant improvements to the algorithm by Micciancio and Warinschi, and extend these techniques to the computation of the saturation of a matrix. We describe the fastest implementation for computing Hermite normal form for large matrices with large entries.

1. Introduction

This paper is about how to compute the Hermite normal form of a *random* integer matrix in practice. We describe the best known algorithm for random matrices, due to Micciancio and Warinschi [MW01] and explain some new ideas that make it practical. We also apply these techniques to give a new algorithm for computing the saturation of a module, and present timings.

In this paper we do not concern ourselves with nonrandom matrices, and instead refer the reader to [SL96,Sto98] for the state of the art for worse case complexity results. Our motivation for focusing on the random case is that it comes up frequently in algorithms for computing with modular forms.

Among the numerous notions of Hermite normal form, we use the following one, which is the closest to the familiar notion of reduced row echelon form.

Definition 1.1 *(Hermite normal form).* For any $n \times m$ integer matrix A the *Hermite normal form* (HNF) of A is the unique matrix $H = (h_{i,j})$ such that there is a unimodular $n \times n$ matrix U with $UA = H$, and such that H satisfies the following two conditions:

doi:10.1016/j.jnt.2010.01.017

- there exist a sequence of integers $j_1 < \cdots < j_n$ such that for all $0 \leqslant i \leqslant n$ we have $h_{i,j} = 0$ for all $j < j_i$ (row echelon structure),
- for $0 \leqslant k < i \leqslant n$ we have $0 \leqslant h_{k,j_i} < h_{i,j_i}$ (the pivot element is the greatest along its column and the coefficients above are nonnegative).

Thus the Hermite normal form is a generalization over $\mathbb{Z}$ of the reduced row echelon form of a matrix over $\mathbb{Q}$. Just as computation of echelon forms is a building block for many algorithms for computing with vector spaces, Hermite normal form is a building block for algorithms for computing with modules over $\mathbb{Z}$ (see, e.g., [Coh93, Chapter 2]).

Example 1.2. The HNF of the matrix

$$A = \begin{pmatrix} -5 & 8 & -3 & -9 & 5 & 5 \\ -2 & 8 & -2 & -2 & 8 & 5 \\ 7 & -5 & -8 & 4 & 3 & -4 \\ 1 & -1 & 6 & 0 & 8 & -3 \end{pmatrix}$$

is

$$H = \begin{pmatrix} 1 & 0 & 3 & 237 & -299 & 90 \\ 0 & 1 & 1 & 103 & -130 & 40 \\ 0 & 0 & 4 & 352 & -450 & 135 \\ 0 & 0 & 0 & 486 & -627 & 188 \end{pmatrix}.$$

Notice how the entries in the answer are quite large compared to the input.

Heuristic observations: For a random $n \times m$ matrix A with $n \leqslant m$, the number of digits of each entry of the rightmost $m - n + 1$ columns of H are similar in size to the determinant of the left $n \times n$ submatrix of A. For example, a random 250×250 matrix with entries in $[-2^{32}, 2^{32}]$ has HNF with entries in the last column all having about 2590 digits and determinant with about 2590 digits, but all other entries are likely to be very small (e.g., a single digit).

There are numerous algorithms for the computing HNF's, including [KB79,DKLET87,Bra89,MW01]. We describe an algorithm that is based on the heuristically fast algorithm by Micciancio and Warinschi [MW01], updated with several practical improvements.

In the rest of this paper, we mainly address computation of the HNF of a square nonsingular matrix A. We also briefly explain how to reduce the general case to the square case, discuss computation of saturation, and give timings. We give an outline of the algorithm in Section 2 and present more details in Sections 3, 5 and 6. The cases of more rows than columns and more columns than rows is discussed in the Section 7. In Section 9, we sketch the main features of our implementation in Sage, and compare the computation time for various class of matrices.

2. Outline of the algorithm when A is square

For the rest of this section, let $A = (a_{i,j})_{i,j=0,\ldots,n-1}$ be an $n \times n$ matrix with integer entries. There are two key ideas behind the algorithm of [MW01] for computing the HNF of A.

1. Every entry in the HNF H of a square matrix A is at most the absolute value of the determinant $\det(A)$, so one can compute H be working modulo the determinant of H. This idea was first introduced and developed in [DKLET87].
2. The determinant of A may of course still be extremely large. Micciancio and Warinschi's clever idea is to instead compute the Hermite form H' of a small-determinant matrix constructed

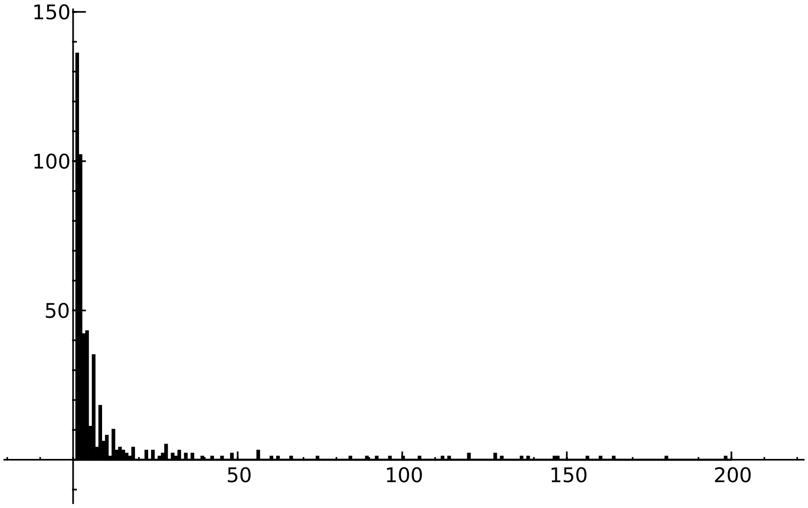

Fig. 2.1. Distribution of the determinants in (2.1), for 500 random matrices with $n = 100$ and entries uniformly chosen to satisfy $\log_2 \|A\| = 100$. Only 9 elements had a determinant larger than 200, and the largest one was 6816.

from A using the Euclidean algorithm and properties of determinants. Then we recover H from H' via three update steps.

We now explain the second key idea in more detail. Consider the following block decomposition of A:

$$A = \begin{bmatrix} B & b \\ c^T & a_{n-1,n} \\ d^T & a_{n,n} \end{bmatrix},$$

where B is the upper left $(n-2) \times (n-1)$ submatrix of A, and b, c, d are column vectors. Let $d_1 = \det\left(\begin{bmatrix} B \; c^T \end{bmatrix}\right)$ and $d_2 = \det\left(\begin{bmatrix} B \; d^T \end{bmatrix}\right)$. Use the extended Euclidean algorithm to find integers s, t such that

$$g = sd_1 + td_2,$$

where $g = \gcd(d_1, d_2)$.

Since the determinant is linear in row operations, we have

$$\det\left(\begin{bmatrix} B \\ sc^T + td^T \end{bmatrix}\right) = g. \tag{2.1}$$

For random matrices, g is likely to be very small. Fig. 2.1 illustrates the distribution of such gcd's, on a set of 500 random integer matrices of dimension 100 with 100-bit coefficients.

Algorithm 1 (on page 4) is essentially the algorithm of Micciancio and Warinschi. Our main improvement over their work is to greatly optimize Steps 3, 4 and 8. Step 8 is performed by a procedure they call `AddColumn` (see Algorithm 3 in Section 5 below), and steps 9 and 10 by a procedure they call `AddRow` (see Algorithm 4 in Section 6 below).

3. Double determinant computation

There are many algorithms for computing the determinant of an integer matrix A. One algorithm involves computing the Hadamard bound on $\det(A)$, then computing the determinant modulo p for

Algorithm 1: Hermite Normal Form [MW01]

```
    Data: $A$: an $n \times n$ nonsingular matrix over $\mathbb{Z}$
    Result: $H$: the Hermite normal form of $A$
1   begin
2       Write $A = \begin{bmatrix} B & b \\ c^T & a_{n-1,n} \\ d^T & a_{n,n} \end{bmatrix}$
3       Compute $d_1 = \det\left(\begin{bmatrix} B \\ c^T \end{bmatrix}\right)$
4       Compute $d_2 = \det\left(\begin{bmatrix} B \\ d^T \end{bmatrix}\right)$
5       Compute the extended gcd of $d_1$ and $d_2$: $g = sd_1 + td_2$
6       Let $C = \begin{bmatrix} B \\ sc^T + td^T \end{bmatrix}$
7       Compute $H_1$, the Hermite normal form of $C$, by working modulo $g$ as explained in Section 4
        below. (NOTE: In the unlikely case that $g = 0$ or $g$ is large, we compute $H_1$ using any HNF
        algorithm applied to $C$, e.g., by recursively applying the main algorithm of this paper to $C$.)
8       Obtain from $H_1$ the Hermite form $H_2$ of $\begin{bmatrix} B & b \\ sc^T + td^T & sa_{n-1,n} + ta_{n,n} \end{bmatrix}$
9       Obtain from $H_2$ the hermite form $H_3$ of $\begin{bmatrix} B & b \\ c^T & a_{n-1,n} \end{bmatrix}$
10      Obtain from $H_3$ the Hermite form $H$ of $\begin{bmatrix} B & b \\ c^T & a_{n-1,n} \\ d^T & a_{n,n} \end{bmatrix}$
11  end
```

sufficiently many p using an (asymptotically fast) Gaussian elimination algorithm, and finally using a Chinese remainder theorem reconstruction. This algorithm has bit complexity

$$\mathcal{O}\left(n^4\left(\log n + \log\|A\|\right) + n^3 \log^2 \|A\|\right),$$

or $\mathcal{O}(n^{\omega+1}(\log n + \log\|A\|))$ with fast matrix arithmetic (see [GG99, Chapter 5]).

Abbott, Bronstein and Mulders [ABM99] propose another determinant algorithm based on solving $Ax = v$ for a random integer vector v using an iterative p-adic solving algorithm (e.g., [Dix82,MC79]). In particular, by Cramer's rule the greatest common divisor of the denominators of the entries of x is a divisor d of $D = \det(A)$. The unknown integer D/d can be recovered by computing it modulo p for several primes and using the Chinese remainder theorem; usually D/d is very small, so this is fast. This approach has a similar worst case bit complexity: $\mathcal{O}(n^4 + n^3(\log n + \log\|A\|)^2)$ but a better average case complexity of $\mathcal{O}(n^3(\log^2 n + \log\|A\|)^2)$.

The computation time can also be improved by allowing early termination in the Chinese remainder algorithm: once a reconstruction stabilizes modulo several primes, the result is likely to remain the same with a certified probability, and one can avoid the remaining modular computations.

Further details on practical implementations for computing determinants of integer matrices can be found in [DU06].

Storjohann [Sto05] obtains the best known bit complexity for computing determinants using a Las Vegas algorithm. He obtains a complexity of $\mathcal{O}\tilde{}(n^\omega \log\|A\|)$, where ω is the exponent for matrix multiplication. However, no implementation of this algorithm is known that is better in practice than the p-adic lifting based method for practical problem sizes. Consequently, we based our implementation on this latter algorithm by [ABM99].

The computation of the two determinants (Steps 3 and 4) therefore involves the solving of two systems, with very similar matrices. We reduce it to only one system solution *in the generic case* using the following lemma. Since this is a bottleneck in the algorithm, this factor of two savings is huge in practice.

Please cite this article in press as: C. Pernet, W. Stein, Fast computation of Hermite normal forms of random integer matrices, J. Number Theory (2010), doi:10.1016/j.jnt.2010.01.017

Algorithm 2: Double determinant computation

```
Data: $B$: an $(n-1) \times n$ matrix over $\mathbb{Z}$
Data: $c, d$: two vectors in $\mathbb{Z}^n$
Result: $(d_1, d_2) = (\det(\begin{bmatrix} B^T & c \end{bmatrix}), \det(\begin{bmatrix} B^T & d \end{bmatrix}))$
begin
    Solve the system $\begin{bmatrix} B^T & c \end{bmatrix} x = d$ using Dixon's $p$-adic lifting
    Then $y_i = -x_i/x_n$, $y_n = 1/x_n$ solves $\begin{bmatrix} B^T & d \end{bmatrix} y = c$ by Lemma 3.1, unless $x_n = 0$, in which case
    we use the usual determinant algorithm to compute the determinants of the two matrices
    $u_1 = \mathrm{lcm}(\mathrm{denominators}(x))$
    $u_2 = \mathrm{lcm}(\mathrm{denominators}(y))$
    Compute Hadamard's bounds $h_1$ and $h_2$ on the determinants of $\begin{bmatrix} B^T & c \end{bmatrix}$ and $\begin{bmatrix} B^T & d \end{bmatrix}$
    Select a set of primes $(p_i)$ s.t. $\prod_i p_i > \max(h_1/u_1, h_2/u_2)$
    foreach $p_i$ do
        compute $B^T = LUP$, the LUP decomposition of $B^T \bmod p_i$
        $q = \prod_{i=1}^{n-1} U_{i,i} \bmod p_i$
        $x = L^{-1} c \bmod p_i$
        $y = L^{-1} d \bmod p_i$
        $v_1^{(i)} = q x_n \bmod p_i$
        $v_2^{(i)} = q y_n \bmod p_i$
    reconstruct $v_1$ and $v_2$ from $(v_1^{(i)})$ and $(v_2^{(i)})$ using CRT
    return $(d_1, d_2) = (u_1 v_1, u_2 v_2)$
end
```

Lemma 3.1. *Let A be an $n \times (n-1)$ matrix and c and d column vectors of degree n, and assume that the augmented matrices $[A|c]$ and $[A|d]$ are both invertible. Let $x = (x_i)$ be the solution of $[A|c]x = d$. If $x_n \neq 0$, then the solution $y = (y_i)$ to $[A|d]y = c$ is*

$$y = \left(-\frac{x_1}{x_n}, -\frac{x_2}{x_n}, \ldots, -\frac{x_{n-1}}{x_n}, \frac{1}{x_n}\right).$$

Proof. Write a_i for the ith column of A. The equation $[A|c]x = d$ is thus $(\sum_{i=1}^{n-1} a_i x_i) + c x_n = d$, so $(\sum_{i=1}^{n-1} a_i x_i) - d = -x_n c$. Dividing both sides by $-x_n$ yields $(\sum_{i=1}^{n-1}(-\frac{x_i}{x_n})a_i) + \frac{1}{x_n} d = c$, which proves the lemma. □

Example 3.2. Let $A = \begin{bmatrix} 1 & 2 \\ -4 & 3 \\ 2 & -5 \end{bmatrix}$, $c = (-1, 3, 5)^T$, and $d = (2, -3, 4)^T$. The solution to $[A|c]x = d$ is

$$x = \left(\frac{111}{68}, \frac{35}{68}, \frac{45}{68}\right).$$

Thus

$$y = \left(-\frac{x_1}{x_3}, -\frac{x_2}{x_3}, \frac{1}{x_3}\right) = \left(-\frac{37}{15}, -\frac{7}{9}, \frac{68}{45}\right).$$

Algorithm 2 (on page 5) describes how the two determinants are computed using Lemma 3.1.

4. Hermite form modulo g

Recall that C is a square nonsingular matrix with "small" determinant g. Step 7 of Algorithm 1 (on page 4) is to compute the HNF of C as explained in [DKLET87, §3]. There it is proved that since $g = \det(C)$, the Hermite normal form of $\left[\begin{smallmatrix} C \\ gI \end{smallmatrix}\right]$ is $\left[\begin{smallmatrix} H \\ 0 \end{smallmatrix}\right]$ where H is the Hermite normal form of C. Using this result, to compute H, we apply the standard row reduction Hermite normal form algorithm to C, always reducing all numbers modulo g. Conceptually, think of this as adding multiples of the rows of gI, which does not change the resulting Hermite form. At the end of this process we obtain a matrix $H = (h_{ij})$ with $0 \leqslant h_{ij} < g$ for all ij. There is one special case; since the product of the diagonal entries of the Hermite form of C is g, if the lower right entry of H is 0, then we replace it by g. Then the resulting matrix H is the Hermite normal form of C.

For additional discussion of the modular Hermite form algorithm, see [Coh93, §2.4, p. 71] which describes the algorithm in detail, including a discussion of our above remark about replacing 0 by g.

Example 4.1. Let $C = \left[\begin{smallmatrix} 5 & 26 \\ 2 & 11 \end{smallmatrix}\right]$. Then $g = \det(C) = 3$, and the reduction mod g of C is $\left[\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right]$. Subtracting the second row from the first yields $\left[\begin{smallmatrix} 2 & 2 \\ 0 & 0 \end{smallmatrix}\right]$, which is already reduced modulo 3. Then multiplying through the first row by -1 and reducing modulo 3 again, we obtain $\left[\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right]$. Then, as mentioned above, since the lower right entry is 0, we replace it by $g = 3$, obtaining the Hermite normal form $H = \left[\begin{smallmatrix} 1 & 1 \\ 0 & 3 \end{smallmatrix}\right]$.

5. Add a column

Step 8 of Algorithm 1 is to find a column vector e such that

$$[\, H_1 \quad e \,] = U \begin{bmatrix} B & b \\ sc^T + td^T & a_{n-1,n} \end{bmatrix} \tag{5.1}$$

is in Hermite form, for a unimodular matrix U.

By hypothesis $C = \left[\begin{smallmatrix} B \\ sc^T + td^T \end{smallmatrix}\right]$ is invertible, so from (5.1), one gets

$$\begin{aligned} e &= U \begin{bmatrix} b \\ a_{n-1,n-1} \end{bmatrix} \\ &= H_1 \begin{bmatrix} B \\ sc^T + td^T \end{bmatrix}^{-1} \begin{bmatrix} b \\ a_{n-1,n-1} \end{bmatrix}. \end{aligned}$$

In [MW01], the column e is computed using multi-modular computations and a tight bound on the size of the entries of e. We instead use the p-adic lifting algorithm of [Dix82,MC79] to solve the system

$$\begin{bmatrix} B \\ sc^T + td^T \end{bmatrix} x = \begin{bmatrix} b \\ a_{n-1,n-1} \end{bmatrix}.$$

However, the last row $sc^T + td^T$ typically has much larger coefficients than the rest of the matrix, thus unduly penalizing the complexity of finding a solution. Our key idea is to replace the row $sc^T + td^T$ by a random row u that has small entries such that the resulting matrix is still invertible, find the solution y of this modified system, then recover x as follows. Let $\{k\}$ be a basis of the 1-dimensional kernel of B. Then the sought for solution of the original system is

$$x = y + \alpha k,$$

```
Algorithm 3: AddColumn
Data: $B = \begin{bmatrix} B_1 & b_2 \\ b_3^T & b_4 \end{bmatrix}$: an $n \times n$ matrix over $\mathbb{Z}$, where $B_1$ is $(n-1) \times (n-1)$ and $b_2, b_3$ are vectors
Data: $H_1$: the Hermite normal form of $\begin{bmatrix} B_1 \\ b_3^T \end{bmatrix}$
Result: $H$: the Hermite normal form of $B$
begin
    Pick a random vector $u$ such that $|u_i| \leqslant \|B\|\ \forall i$
    Solve $\begin{bmatrix} B_1 \\ u \end{bmatrix} y = \begin{bmatrix} b_2 \\ b_4 \end{bmatrix}$
    Compute a kernel basis vector $k$ of $B_1$
    $\alpha = b_4 - \frac{b_3^T \cdot y}{b_3^T \cdot k}$
    $x = y + \alpha k$
    $e = H_1 x$
    return $[H_1\ e]$
end
```

where α satisfies

$$\left(sc^T + td^T\right) \cdot (y + \alpha k) = a_{n-1,n-1}.$$

By linearity of the dot product, we have

$$\alpha = \frac{a_{n-1,n-1} - (sc^T + td^T) \cdot y}{(sc^T + td^T) \cdot k}.$$

Note that if $(sc^T + td^T) \cdot k = 0$, then $Ck = 0$, which would contradict our assumption that $C = \begin{bmatrix} B \\ sc^T + td^T \end{bmatrix}$ is invertible.

6. Add a row

Steps 9 and 10 of Algorithm 1 consist of adding a new row to the current Hermite form and updating it to obtain a new matrix in Hermite form.

The principle is to eliminate the new row with all existing pivots and update the already computed parts when necessary. Algorithm 4 (on page 8) describes this in more detail.

7. The nonsquare case

In the case where the matrix is rectangular, with dimensions $m \times n$, we reduce to the case of a square nonsingular matrix as follows: first compute the column and row rank profile (pivot columns and subset of independent rows) of A modulo a random word-size prime. With high probability, the matrix A has the same column and row rank profile over $\mathbb{Q}$, so we can now apply Algorithm 1 to the square nonsingular $r \times r$ matrix obtained by picking the row and column rank profile submatrix of A over $\mathbb{Z}$.

The additional rows and columns are then incorporated as follows:

additional columns: use Algorithm 3 (`AddColumn`) with a block of column vectors instead of just one column. If this fails, then we computed the rank profile incorrectly, in which case we start over with a different random prime.

additional rows: use Algorithm 4 (`AddRow`) for each additional row.

```
Algorithm 4: AddRow
Data: $A$: an $m \times n$ matrix in Hermite normal form
Data: $b$: a vector of degree $n$
Result: $H$: the Hermite normal form of $\begin{bmatrix} A \\ b \end{bmatrix}$
begin
    forall pivots $a_{i,j_i}$ of $A$ do
        if $b_{j_i} = 0$ then
            continue
        if $A_{i,j_i} | b_{j_i}$ then
            $b := b - b_{j_i}/A_{i,j_i} A_{i,1\dots n}$
        else
            /* Extended gcd based elimination */
            $(g, s, t) = \mathrm{XGCD}(a_{i,j_i}, b_{j_i})$ ;        /* so $g = sa_{i,j_i} + tb_{j_i}$ */
            $A_{i,1\dots n} := sA_{i,1\dots n} + tb_{j_i}$
            $b := b_{j_i}/gA_{i,1\dots n} - A_{i,j_i}/gb$
            for $k = 1$ to $i - 1$ do
                /* Reduces row $k$ with row $i$ */
                $A_{k,1\dots n} := A_{k,1\dots n} - \lfloor A_{k,j_i}/A_{i,j_i} \rfloor A_{i,1\dots n}$
    if $b \neq 0$ then
        let $j$ be the index of the first nonzero element of $b$
        insert $b^T$ between rows $i$ and $i + 1$ such that $j_i < j < j_{i+1}$
    Return $H = \begin{bmatrix} A \\ b \end{bmatrix}$
end
```

8. Saturation

If M is a submodule of $\mathbb{Z}^n$ for some n, then the saturation of M is $\mathbb{Z}^n \cap (\mathbb{Q}M)$, i.e., the intersection with $\mathbb{Z}^n$ of the $\mathbb{Q}$-span of any basis of M. For example, if M has rank n, then the saturation of M just equals $\mathbb{Z}^n$. Also, kernels of homomorphisms of free $\mathbb{Z}$-modules are saturated. Saturation comes up in many number theoretic algorithms, e.g., saturation is an important step in computing a basis over $\mathbb{Z}$ for the space of q-expansions of cuspidal modular forms of given weight and level, and comes up in explicit computation with homology of modular curves using modular symbols.

There is a well-known connection between saturation and Hermite form. If A is a basis matrix for M, and H is the Hermite form of the transpose of A with any 0 rows at the bottom deleted (so H is square), then $H^{-1}A$ is a matrix whose rows are a basis for the saturation of M. Thus computation of a saturation of a matrix reduces to computation of one Hermite form and solving a system $HX = A$.

If A is sufficiently random, then the Hermite form matrix H has a very large last column and all other entries are small, so we exploit the trick in Section 6 and instead solve a much easier system.

9. Implementation

Our implementation of the algorithms described in this paper are included in Sage [Ste]. This implementation relies on `IML` [SC] for the solution of integer systems using p-adic lifting, and on `LinBox` [Lin] for the computation of determinants modulo p (the `IML` and `LinBox` libraries are both part of Sage). Our implementation is primarily optimized for the square case.

We illustrate computing a Hermite normal form and saturation in Sage.

```
sage: A = matrix(ZZ,3,5,[-1,2,5,65,2,4,-1,-3,1,-2,-1,-2,1,-1,1])
sage: A
[-1  2  5 65  2]
```

```
[ 4 -1 -3  1 -2]
[-1 -2  1 -1  1]
sage: A.hermite_form()
[  1   0  17 259   7]
[  0   1  31 453  13]
[  0   0  40 582  17]
sage: A.saturation()
[-1  2  5 65  2]
[ 4 -1 -3  1 -2]
[-1 -2  1 -1  1]
```

There are implementations of Hermite normal form algorithms in NTL [Sho], PARI [PAR], GAP [GAP], Maple and Mathematica. The algorithm in this paper is asymptotically better than these standard implementations.

Acknowledgments

We thank Allan Steel for providing us with notes from a talk he gave on his implementation of [MW01]. Steel's implementation was much faster than any other available (e.g., PARI, NTL, Mathematica, Maple, and GAP), which was the motivation for this paper. We would also like to thank Burcin Erocal for implementing mod n computation of Hermite form in Sage, Robert Bradshaw for help benchmarking our implementation, Arne Storjohann for helpful conversations about the nonrandom case, and Andrew Crites and Michael Goff for discussions.

Toward a Generalization of the Gross-Zagier Conjecture

William Stein[1]*
[1] *Department of Mathematics, University of Washington, Web:* `http://wstein.org`*, Email:* `wstein@uw.edu`

Abstract: We review some of Kolyvagin's results and conjectures about elliptic curves, then make a new conjecture that slightly refines Kolyvagin's conjectures. We introduce a definition of finite index subgroups $W_p \subset E(K)$, one for each prime p that is inert in a fixed imaginary quadratic field K. These subgroups generalize the group $\mathbb{Z}y_K$ generated by the Heegner point $y_K \in E(K)$ in the case $r_{\rm an} = 1$. For any curve with $r_{\rm an} \geq 1$, we give a description of W_p, which is conditional on truth of the Birch and Swinnerton-Dyer conjecture and our conjectural refinement of Kolyvagin's conjecture. We then deduce the following conditional theorem, up to an explicit finite set of primes: (a) the set of indexes $[E(K) : W_p]$ is finite, and (b) the subgroups W_p with $[E(K) : W_p]$ maximal satisfy a higher-rank generalization of the Gross-Zagier formula. We also investigate a higher-rank generalization of a conjecture of Gross-Zagier.

1 Introduction

Let E be an elliptic curve defined over $\mathbb{Q}$. The order of vanishing $r_{\rm an}$ at $s = 1$ of the Hasse-Weil L-series $L(E/\mathbb{Q}, s)$ of E is defined because E is modular (see [BCDT01, Wil95]). The Birch and Swinnerton-Dyer (BSD) rank conjecture [Bir65] asserts that $r_{\rm an}$ is equal to the algebraic rank $r_{\rm alg}$ of $E(\mathbb{Q})$. The BSD formula then gives a conjectural formula for the leading coefficient of the Taylor expansion about $s = 1$ of $L(E/\mathbb{Q}, s)$; this formula resembles the analytic class number formula. The BSD rank conjecture is known for curves with $r_{\rm an} \leq 1$, but there has been relatively little progress toward the BSD rank conjecture when $r_{\rm an} \geq 2$.

In the late 1980s, Kolyvagin wrote several landmark papers that combined the Gross-Zagier theorem [GZ86] about heights of Heegner points over quadratic imaginary fields K, a theorem [BFH90] about nonvanishing of special values of twists of L-functions, and relations involving Hecke operators between Heegner points over ring class fields of K to prove that if $r_{\rm an} \leq 1$, then the BSD rank conjecture is true for E. Kolyvagin wrote [Kol91a] on the case of general rank, in which he computes the elementary invariants of the Selmer groups of any elliptic curve E of any rank in terms of properties of Heegner points, assuming a certain nontriviality hypothesis. It was until recently unclear whether or not this hypothesis was ever satisfied for any curve with $r_{\rm an} \geq 2$. Fortunately, this hypothesis has now been confirmed numerically (with high probability) in one case of a rank 2 curve [JLS08].

We review some of Kolyvagin's results and conjectures from [Kol91a], then make a new conjecture that refines Kolyvagin's conjectures. Using reduction modulo p of Heegner points, we introduce a definition of finite index subgroups $W_p \subset E(K)$, one for each prime p that is inert in K. Let $y_K \in E(K)$ be the associated Heegner point as in Equation (1) below. Then these subgroups W_p generalize the group $\mathbb{Z}y_K$ in the case $r_{\rm an} = 1$. For any $r_{\rm an} \geq 1$, we give a description of W_p, which is conditional on truth of the BSD conjecture and our conjectural refinement of Kolyvagin's conjecture. We then deduce the following conditional theorem (see Theorems 7.5 and 7.7), up to an explicit finite set of primes: (a) the set of indexes $[E(K) : W_p]$ is finite, and (b) the subgroups W_p with $[E(K) : W_p]$ maximal satisfy a higher-rank generalization of the Gross-Zagier formula (see (5) below). We also give numerical data and a new conjecture about the existence of Gross-Zagier subgroups.

We leave open far more questions than we answer, and we intend to follow up on these questions in subsequent papers. For example, perhaps the definition of the groups W_p can be refined and generalized in various ways, and results similar to those in this paper proved about them. It would be interesting to find a practical algorithm that can provably compute the groups W_p for a particular p, assuming that $E(K)$ has already been computed. We also hope to find a higher-rank analogue of the Gross-Zagier formula over the Hilbert class field of K, involving the Petersson inner product, modular forms, and Rankin-Selberg convolutions $L_{\mathcal{A}}(f, s)$, as in [GZ86], which is consistent with the results we prove about the groups W_p in this paper. It would also be

*Supported by NSF grant 0555776.

Copyright © 0000 Oxford University Press

valuable to give proofs of the results of [Kol91a] building on [McC91] instead of [Kol91b], possibly using results from the present paper.

We briefly outline the structure of this paper. In the first few sections, we state the BSD conjecture and Gross-Zagier formula, define Kolyvagin points, state Kolyvagin's conjectures, and then define certain finite index subgroups W_p of $E(K)$. In the rest of the paper, we study reduction mod p, conditionally deduce the structure of W_p, and give some numerical examples.

More precisely, we do the following. In Section 2 we state the full Birch and Swinnerton-Dyer conjecture over an imaginary quadratic field K, and state a generalized Gross-Zagier formula for elliptic curves of any rank. In Section 3, we introduce the Kolyvagin points P_λ on E over ring class fields of K, and deduce some key properities of these points. We state Kolvagin's conjectures from [Kol91a] along with some of their consequences in Section 4. We also state a conjecture that refines Kolyvagin's conjectures and also refines a conjecture of Gross-Zagier. In Section 5 we use reductions of Kolyvagin points to define, for every prime p that is inert in K, a finite index subgroup W_p of $E(K)$. Section 6 lays some general foundations for our later determination of the structure of W_p by studying the image of a fixed $Q \in E(K)$ in $E(\mathbb{F}_{p^2})/(p+1)$. Section 7 presents a conditional proof that (up to primes not in the set $B(E)$) maximal index subgroups exist and that they satisfy our generalized Gross-Zagier formula. Finally, in Section 8 we numerically investigate the existence of Gross-Zagier subgroups of $E(K)$, and give evidence for a higher-rank generalization of a conjecture of Gross-Zagier.

1.1 Notation and Conventions

Let A be an abelian group. Let $A_{\rm tor}$ be the subgroup of elements of A of finite order and let $A_{/\,{\rm tor}} = A/A_{\rm tor}$ denote the quotient of A by its torsion subgroup. Let $A[n]$ be the subgroup of elements of A of order n, and for any prime ℓ, let $A(\ell)$ be the subgroup of elements of ℓ-power order. For $z \in A$, let $e = \mathrm{ord}_\ell(z)$ be the largest integer e such that $z = \ell^e y$ for some $y \in A$, or $\mathrm{ord}_\ell(z) = \infty$ if the set of e is unbounded. If $a_1, \ldots, a_n$ are elements of an additive or multiplicative group A, we let $\langle a_1, \ldots, a_n\rangle$ denote the subgroup of A generated by the a_i.

Throughout this paper, E denotes an elliptic curve defined over $\mathbb{Q}$ of conductor N, and K is a quadratic imaginary field with $D = \mathrm{disc}(K)$ coprime to N that satisfies the *Heegner hypothesis*—each prime dividing N splits in K. We fix an ideal $\mathcal{N}$ in $\mathcal{O}_K$ such that $\mathcal{O}_K/\mathcal{N}$ is cyclic of order N. Let H be the Hilbert class field of K, let $\pi : X_0(N) \to E$ be a fixed choice of modular parametrization (see Section 3 below), and let

$$y_K = \mathrm{Tr}_{H/K}(\pi((\mathbb{C}/\mathcal{O}_K, \mathcal{N}^{-1}/\mathcal{O}_K))) \in E(K) \tag{1}$$

be the Heegner point associated to K.

Let c denote the Manin constant of E (see Section 2), and c_q the Tamagawa numbers of E at primes $q \mid N$. Unless otherwise stated, everywhere in this paper p denotes a prime that is inert in K.

2 Gross-Zagier Subgroups

In this section, we fix our notation and conventions, and define the Manin constant. Then we recall the statement of the full Birch and Swinnerton-Dyer conjecture over an imaginary quadratic field K. We give a new definition of *Gross-Zagier subgroups* of $E(K)$ and prove that they all satisfy a Gross-Zagier style formula. When $r_{\rm an} = 1$, we prove that $\mathbb{Z}y_K$ is the unique Gross-Zagier subgroup, up to torsion.

Let E be an elliptic curve over $\mathbb{Q}$ and let K be a quadratic imaginary field that satisfies the Heegner hypothesis – so K has discriminant $D < -4$, each prime dividing the conductor N of E splits in K, and $\gcd(D, N) = 1$. Let $\mathcal{O}_K$ be the ring of integers of K. Let E^D denote the quadratic twist of E by D. Throughout this paper, except briefly in Section 8, we *always* assume that

$$r_{\rm an}(E/\mathbb{Q}) > r_{\rm an}(E^D/\mathbb{Q}) \leq 1 \tag{2}$$

Recall that under the Heegner hypothesis the sign of the functional equation of

$$L(E/K, s) = L(E/\mathbb{Q}, s) \cdot L(E^D/\mathbb{Q}, s)$$

is -1, so the sign in the functional equations for $L(E/\mathbb{Q},s)$ and $L(E^D/\mathbb{Q},s)$ are different, hence

$$\operatorname{ord}_{s=1} L(E/\mathbb{Q},s) \not\equiv \operatorname{ord}_{s=1} L(E^D/\mathbb{Q},s) \pmod 2.$$

Proposition 2.1. *Suppose E is an elliptic curve with $r_{\mathrm{an}}(E/\mathbb{Q}) > 0$. Then there exist infinitely many D satisfying the Heegner hypothesis with*

$$r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1.$$

Proof. The main theorem of [BFH90] implies the existence of infinitely many D with $r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$. Since $r_{\mathrm{an}}(E/\mathbb{Q}) > 0$ and $r_{\mathrm{an}}(E/\mathbb{Q}) \not\equiv r_{\mathrm{an}}(E^D/\mathbb{Q}) \pmod 2$, the inequality $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q})$ also holds.

Let $\omega = 2\pi i c f(z) dz$ be the pullback of a minimal invariant differential on E, where $f(z) \in S_2(\Gamma_0(N))$ is a cuspidal newform, and c is the Manin constant of E (see [ARS06]). For each prime $q \mid N$, let c_q be the Tamagawa number of E at q. Set $r = r_{\mathrm{an}}(E/K) = \operatorname{ord}_{s=1} L(E/K,s)$, which is defined since every elliptic curve over $\mathbb{Q}$ is modular. Let $\|\omega\|^2 = \int_{E(\mathbb{C})} \omega \wedge \overline{i\omega} = 2 \cdot \operatorname{Vol}(\mathbb{C}/\Lambda)$. The Shafarevich-Tate group of E over a number field M is

$$Ш(E/M) = \ker\left(\mathrm{H}^1(M,E) \to \bigoplus_v H^1(M_v,E)\right).$$

The following is a formulation of the Birch and Swinnerton-Dyer conjecture [GZ86, pg. 311] over K.

Conjecture 2.2 (Birch and Swinnerton-Dyer)**.** *The Mordell-Weil group $E(K)$ has rank $r = \operatorname{ord}_{s=1} L(E/K,s)$, the Shafarevich-Tate group $Ш(E/K)$ is finite, and*

$$\frac{L^{(r)}(E/K,1)}{r!} = \frac{\#Ш(E/K) \cdot \|\omega\|^2 \cdot \operatorname{Reg}(E/K) \cdot \left(\prod_{q|N} c_q\right)^2}{\#E(K)_{\mathrm{tor}}^2 \cdot \sqrt{|D|}}. \tag{3}$$

Let $Ш_{\mathrm{an}}$ be the order of $Ш(E/K)$ that is predicted by Conjecture 2.2. The existence of the Cassels-Tate pairing implies that if $Ш(E/K)$ is finite, then $\#Ш(E/K)$ is a perfect square, so Conjecture 2.2 implies that $\sqrt{Ш_{\mathrm{an}}}$ is an integer. Recall from Section 1.1 that $A_{/\mathrm{tor}} = A/A_{\mathrm{tor}}$.

Definition 2.3 (Gross-Zagier subgroup)**.** *A* Gross-Zagier subgroup *$W \subset E(K)$ is a torsion-free subgroup such that $E^D(\mathbb{Q}) \subset W + E(K)_{\mathrm{tor}}$, the quotient $E(K)_{/\mathrm{tor}}/W$ is cyclic, and*

$$[E(K) : W] = c \cdot \prod c_q \cdot \sqrt{Ш_{\mathrm{an}}}. \tag{4}$$

For any set S of primes, we say that a subgroup $W \subset E(K)$ is a *Gross-Zagier subgroup up to primes not in S* if W has no p-torsion for $p \notin S$ and all the conditions of Definition 2.3 holds up to primes not in S.

We will numerically investigate the existence of Gross-Zagier subgroups in Section 8, assuming that Conjecture 2.2 is true. Even the existence of Gross-Zagier subgroups of every $E(K)$ is far from clear, since if they exist, then $\#E(K)_{\mathrm{tor}}$ divides $c \prod c_q \cdot \sqrt{Ш_{\mathrm{an}}}$. In fact, we will give an example of an $E(K)$ that does not have any Gross-Zagier subgroups (this example does not satisfy (2)).

In the following proposition we do not assume the Conjecture 2.2. Thus $Ш_{\mathrm{an}}$ *a priori* could just be some meaningless transcendental number. Also, for any subgroup $H \subset E(K)$, we write $\operatorname{Reg}(H)$ for the absolute value of the determinant of the height pairing matrix on any basis for H modulo torsion.

Proposition 2.4. *If W is a Gross-Zagier subgroup, then W satisfies the* generalized Gross-Zagier formula*:*

$$\frac{L^{(r)}(E/K,1)}{r!} = \frac{\|\omega\|^2}{c^2 \cdot \sqrt{|D|}} \cdot \operatorname{Reg}(W). \tag{5}$$

More generally, a torsion-free subgroup $W \subset E(K)$ satisfies the generalized Gross-Zagier formula if and only if it has index $c \cdot \prod c_q \cdot \sqrt{Ш_{\mathrm{an}}}$ in $E(K)$.

Proof. The BSD formula (3) with $\#Ш(E/K)$ replaced by $Ш_{\mathrm{an}}$ implies that (5) holds if and only if

$$\frac{\|\omega\|^2}{c^2 \cdot \sqrt{|D|}} \cdot \operatorname{Reg}(W) = \frac{Ш_{\mathrm{an}} \cdot \|\omega\|^2 \cdot \operatorname{Reg}(E/K) \cdot \left(\prod_{p|N} c_q\right)^2}{\#E(K)_{\mathrm{tor}}^2 \cdot \sqrt{|D|}}. \tag{6}$$

Our hypotheses that $[E(K) : W]$ is finite and that W is torsion free imply that

$$[E(K) : W]^2 = \frac{\operatorname{Reg}(W) \cdot \#E(K)_{\mathrm{tor}}^2}{\operatorname{Reg}(E/K)} \tag{7}$$

Manipulate (6) by cancelling everything in common on both sides and putting the regulators and torsion on the left, and everything else on the right. The substitution (7) then shows that $[E(K) : W]^2 = c^2 \cdot \left(\prod_{q|N} c_q\right)^2 \cdot Ш_{\mathrm{an}}$ if and only if (5) holds. Taking square roots proves the proposition. □

Corollary 2.5. *Let $y_K \in E(K)$ be the Heegner point after fixing a choice of ideal $\mathcal{N}$ as in Equation* (1)*, and assume that E has analytic rank* 1*. Then the Gross-Zagier subgroups of $E(K)$ are the cyclic groups $\langle y_K + P\rangle$, for all $P \in E(K)_{\mathrm{tor}}$.*

Proof. By [Kol88], $E(K)$ is of rank 1, and by Proposition 2.4 the Gross-Zagier formula [GZ86, Thm. 2.1, pg. 311] implies that $[E(K) : \langle y_K\rangle] = c \prod c_q \sqrt{\text{Ш}_{\mathrm{an}}}$ (see also, [GZ86, Conj. 2.2, pg. 311]). Since $E(K)_{/\,\mathrm{tor}}$ is free of rank 1 and $\langle y_K\rangle$ is torsion free, $E(K)_{/\,\mathrm{tor}}/\langle y_K\rangle$ is cyclic, so $\langle y_K\rangle$ is a Gross-Zagier subgroup. The same argument proves this with y_K replaced by $y_K + P$ for any $P \in E(K)_{\mathrm{tor}}$, since y_K and $y_K + P$ have the same height. If W is any Gross-Zagier subgroup, then since $E(K)$ has rank one we must have $W \equiv \langle y_K\rangle \pmod{E(K)_{\mathrm{tor}}}$, so $W = \langle y_K + P\rangle$ for some $P \in E(K)_{\mathrm{tor}}$.

3 Heegner and Kolyvagin Points

In this section, we define certain subsets $\Lambda^k_{\ell^n} \subset \mathbb{Z}$ of positive square-free integers. For each integer $\lambda \in \Lambda^k_{\ell^n}$, we consider the corresponding ring class field K_λ, and we define elements $I_\lambda, J_\lambda \in \mathbb{Z}[\mathrm{Gal}(K_\lambda/K)]$. We then apply these group ring elements to the Heegner points $y_\lambda \in E(K_\lambda)$ to obtain the Kolyvagin points $P_\lambda \in E(K_\lambda)$. Finally, we prove the $\mathrm{Gal}(K_\lambda/K)$-equivariance of the equivalence class $P_\lambda + \ell^n E(K)$ in $E(K)/\ell^n E(K)$.

For any integer m, let $a_m = a_m(E)$ be the mth coefficient of the L-series $\sum a_m/m^s$ attached to E. Let ℓ be any prime and n any positive integer. For any nonnegative integer k, let $\Lambda^k_{\ell^n}$ be the set of squarefree positive integers $\lambda = p_1 \dots p_k$ coprime to N, where each p_i is inert in K and

$$a_{p_i} \equiv p_i + 1 \equiv 0 \pmod{\ell^n}.$$

When $k = 0$, we set $\Lambda^0_{\ell^n} = \{1\}$. The Chebotarev density theorem implies that $\Lambda^k_{\ell^n}$ is infinite for any $k \geq 1$.

Recall from Section 1.1 that we fixed an ideal $\mathcal{N}$ in $\mathcal{O}_K$ such that $\mathcal{O}_K/\mathcal{N}$ is cyclic of order N, and let $\mathcal{O}_\lambda = \mathbb{Z} + \lambda\mathcal{O}_K$ be the order in $\mathcal{O}_K$ of conductor λ. Let $X_0(N)$ be the compact modular curve defined over $\mathbb{Q}$ that classifies isomorphism classes of elliptic curves equipped with a cyclic subgroup of order N. Fix a choice of minimal modular parametrization $\pi : X_0(N) \to E$, which exists by the modularity theorem [BCDT01, Wil95]. For each $\lambda \in \Lambda^k_{\ell^n}$, the *Heegner point*

$$x_\lambda = [(\mathbb{C}/\mathcal{O}_\lambda, (\mathcal{N} \cap \mathcal{O}_\lambda)^{-1}/\mathcal{O}_\lambda)] \in X_0(N)(K_\lambda)$$

is defined over the ring class field K_λ of K of conductor λ.

Definition 3.1 (Heegner point)**.** *The Heegner point y_λ associated to $\lambda \in \Lambda^k_{\ell^n}$ is*

$$y_\lambda = \pi(x_\lambda) \in E(K_\lambda).$$

We emphasize that that y_λ depends on the choice of modular parametrization π_E and the ideal $\mathcal{N}$ in $\mathcal{O}_K$ with $\mathcal{O}_K/\mathcal{N} = \mathbb{Z}/N\mathbb{Z}$. However, once we fix that data, the Heegner points for all λ are defined.

For $\lambda \in \Lambda^k_{\ell^n}$, let $G_\lambda = \mathrm{Gal}(K_\lambda/K_1)$ and note that we have a canonical isomorphism

$$G_\lambda \cong \prod_{p\mid\lambda} G_p,$$

where the group $G_p = \mathrm{Gal}(K_p/K_1) = \langle t_p\rangle$ is cyclic of order $p+1$, with some (non-canonical) choice t_p of generator. Let

$$I_p = \sum_{i=1}^{p} i t_p^i \in \mathbb{Z}[G_p] \quad \text{and} \quad I_\lambda = \prod_{p\mid\lambda} I_p \in \mathbb{Z}[G_\lambda].$$

Let R be a set of representatives in $\mathrm{Gal}(K_\lambda/K)$ for the quotient group $\mathrm{Gal}(K_\lambda/K)/\mathrm{Gal}(K_\lambda/K_1) \cong \mathrm{Gal}(K_1/K)$, and let

$$J_\lambda = \sum_{g\in R} g \in \mathbb{Z}[G_\lambda].$$

Definition 3.2 (Kolyvagin Point)**.** *The Kolyvagin point P_λ associated to $\lambda \in \Lambda^k_{\ell_n}$ is*

$$P_\lambda = J_\lambda I_\lambda y_\lambda \in E(K_\lambda).$$

Note that $P_1 = y_K \in E(K)$.

Let $R = \mathrm{End}(E/\mathbb{C})$ and let $B(E)$ be the set of *odd* primes ℓ that do not divide $\mathrm{disc}(R)$ and such that the ℓ-adic representation $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}_R(\mathrm{Tate}_\ell(E))$ is surjective. By a theorem of Serre [Ser72], the set $B(E)$ contains all but finitely many primes (see [GJP+09] for algorithms to bound $B(E)$). Let T_p be the pth Hecke operator on the Jacobian $J_0(N)$ of $X_0(N)$, and for each prime $p \mid \lambda$, let Tr_p be the trace $J_0(N)(K_\lambda) \to J_0(N)(K_{\lambda/p})$.

Proposition 3.3. *The points y_λ form an Euler system, in the sense that if $\lambda = p\lambda'$ for a prime p and $\lambda \in \Lambda_\ell$, then $y_\lambda = \mathrm{Frob}_\wp(y_{\lambda'}) \pmod{\wp}$ for all primes $\wp$ of K_λ over p, and $\mathrm{Tr}_p(x_\lambda) = T_p(x_{\lambda'})$ in $J_0(N)$.*

Proof. See [Gro91, Prop. 3.7].

Proposition 3.4. *We have*

$$[I_\lambda y_\lambda] \in (E(K_\lambda)/\ell^n E(K_\lambda))^{G_\lambda} \qquad \textit{and} \qquad [P_\lambda] \in (E(K_\lambda)/\ell^n E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)}$$

Proof. Though standard (see, e.g., [Gro91, Prop. 3.6]) this proposition plays a key role in Section 5, so we give a proof here for the convenience of the reader. The first statement implies the second, since $[P_\lambda]$ is the $\mathrm{Gal}(K_1/K)$ trace of $[I_\lambda y_\lambda]$. It remains to prove the first inclusion. For this, it suffices to show that $[I_\lambda y_\lambda]$ is fixed by t_p for all primes $p \mid \lambda$, as these elements generate G_λ. We will prove this by showing that $(t_p - 1)I_\lambda y_\lambda$ lies in $\ell^n E(K_\lambda)$.

Write $\lambda = p\lambda'$. We have

$$(t_p - 1)I_p = (t_p - 1) \cdot \left(\sum_{i=1}^{p} i t_p^i\right) = p + 1 - \mathrm{Tr}_p, \tag{8}$$

where as above $\mathrm{Tr}_p = \mathrm{Tr}_{K_\lambda/K_{\lambda'}}$. Note that this is the only place in the proof where we use the explicit definition of I_p as $\sum_{i=1}^{p} i t_p^i$, and in fact we could instead replace I_p by any element I of $\mathbb{Z}[G_\lambda]$ such that

$$(t_p - 1)I = p + 1 - \mathrm{Tr}_p,$$

but doing so does not seem to lead to anything interesting. Note that the Euler system relation (see Proposition 3.3) and our hypothesis that $a_p \equiv 0 \pmod{\ell^n}$ together imply that

$$\mathrm{Tr}_p I_{\lambda'} y_\lambda = I_{\lambda'} \mathrm{Tr}_p y_\lambda = I_{\lambda'} a_p y_{\lambda'} \in \ell^n E(K_\lambda).$$

We have

$$(t_p - 1)I_\lambda = (t_p - 1)I_p I_{\lambda'} = (p + 1 - \mathrm{Tr}_p)I_{\lambda'}$$

in $\mathbb{Z}[G_\lambda]$, so since $p + 1 \equiv 0 \pmod{\ell^n}$

$$(t_p - 1)I_\lambda y_\lambda = (p + 1)I_{\lambda'} y_\lambda - \mathrm{Tr}_p I_{\lambda'} y_\lambda \in \ell^n E(K_\lambda).$$

□

4 Kolyvagin's Conjectures and their Consequences

For any prime ℓ and positive integer n, let

$$\Lambda_{\ell^n} = \bigcup_{\text{all } k \geq 0} \Lambda_{\ell^n}^k$$

be the set of square-free positive integers λ such that $\ell^n \mid \gcd(a_p, p+1)$ for each $p \mid \lambda$. In this section, we define maps $n, m : \Lambda_\ell \to \mathbb{Z} \cup \{\infty\}$ that measure ℓ-divisibility properties of λ and P_λ for all $\lambda \in \Lambda_\ell$. We state Kolyvagin's "Conjecture A" that there exists λ with $m(\lambda) \neq \infty$, then state Kolyvagin's structure theorem, which describes the structure of $\mathrm{Sel}^{(\ell^b)}(E/K)$, for b sufficiently large, in terms of the maps n and m. Finally, we state Kolyvagin's stronger "Conjecture D", which basically asserts that if f is the smallest nonnegative integer such that $m(\lambda) \neq \infty$ for some $\lambda \in \Lambda_\ell^f$, then for sufficiently large k the cohomology classes τ_{λ,ℓ^n} with $\lambda \in \Lambda_{\ell^n+k}^f$ generate a subgroup of $\mathrm{Sel}^{(\ell^n)}(E/K)$ that equals the image of a subgroup V of $E(K)$. To motivate Conjecture 4.9, we prove that it implies that $\mathrm{rank}(E(\mathbb{Q})) = f + 1$ and $Ш(E/K)(\ell)$ is finite for each $\ell \in B(E)$ and determine the structure of V (see Proposition 4.11).

Recall that we defined ord_ℓ in Section 1.1. Define two set-theoretic maps

$$n, m : \Lambda_\ell \to \mathbb{Z} \cup \{\infty\}$$

by

$$n(\lambda) = \max\{e : \lambda \in \Lambda_{\ell^e}\} \qquad \text{and} \qquad m(\lambda) = \mathrm{ord}_\ell([P_\lambda]),$$

where $[P_\lambda]$ denotes the equivalence class of P_λ in $E(K_\lambda)/\ell^{n(\lambda)}E(K_\lambda)$. For each integer $k \geq 0$, let

$$m_{\ell,k} = \min(m(\Lambda_\ell^k)) \qquad \text{and} \qquad m_\ell = \min(m(\Lambda_\ell)) = \min(\{m_{\ell,k} : k \geq 0\}).$$

Also, let

$$f_\ell = \min\{k : m_{\ell,k} < \infty\} \leq \infty, \tag{9}$$

where we let $f_\ell = \infty$ if $m_\ell = \infty$.

Kolyvagin proves [Kol91b, Thm. C] that $m_{\ell,0} \geq m_{\ell,1} \geq m_{\ell,2} \geq \dots$.

Conjecture 4.1 (Kolyvagin's Conjecture A_ℓ)**.** *$m_\ell < \infty$. Equivalently, there exists $\lambda \in \Lambda_\ell$ such that $[P_\lambda] \neq 0$.*

See [JLS08] for the first computational evidence for Conjecture 4.1. For example, for a specific rank 2 elliptic curve, that paper shows that $m_3 = m_{3,1} = 0$ and $f_3 = 1$, assuming that the numerical computation of a certain Heegner point y_λ was done to sufficient precision. (If the computation were not done to sufficient precision it is highly likely that we would haved detected this.)

Conjecture 4.1 is quite powerful, as the following theorem shows. For an abelian group A of odd order with an action of complex conjugation, let A^+ denote the $+1$ eigenspace for conjugation and A^- the minus eigenspace, so $A = A^+ \oplus A^-$. As always, we continue to assume our minimality hypothesis that

$$r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1.$$

Theorem 4.2 (Kolyvagin)**.** *Let $\ell \in B(E)$, suppose Conjecture 4.1 is true for ℓ, and let $f = f_\ell$. For every k, let $b_k = \ell^{m_{\ell,k} - m_{\ell,k+1}}$. Then for every $n \geq m_{\ell,f}$, we have*

$$\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q}) = \mathrm{Sel}^{(\ell^n)}(E/K)^+ \approx (\mathbb{Z}/\ell^n\mathbb{Z})^{f+1} \oplus (\mathbb{Z}/b_{f+1}\mathbb{Z})^2 \oplus (\mathbb{Z}/b_{f+3}\mathbb{Z})^2 \oplus \cdots$$

and

$$\mathrm{Sel}^{(\ell^n)}(E^D/\mathbb{Q}) = \mathrm{Sel}^{(\ell^n)}(E/K)^- \approx (\mathbb{Z}/\ell^n\mathbb{Z})^{h} \oplus (\mathbb{Z}/b_{f}\mathbb{Z})^2 \oplus (\mathbb{Z}/b_{f+2}\mathbb{Z})^2 \oplus \cdots$$

where $h = \mathrm{rank}(E^D(\mathbb{Q})) \leq 1$.

Proof. The leftmost equality in the above two equations is true because ℓ is odd, and Theorem 1 of [Kol91a] implies both of the rightmost equalities, but possibly with $\mathrm{Sel}^{(\ell^n)}(E/K)^+$ and $\mathrm{Sel}^{(\ell^n)}(E/K)^-$ swapped and a different value for h. Theorem 1 of [Kol91a] is proved by inductively constructing cohomology classes with good properties with respect to certain localization homomorphisms. To finish the proof, we establish that these two Selmer groups are not swapped and that $h = \mathrm{rank}(E^D(\mathbb{Q}))$.

First note that by [Kol88, BFH90], our hypothesis that $r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$ implies that $r_{\mathrm{an}}(E^D/\mathbb{Q}) = \mathrm{rank}(E^D(\mathbb{Q}))$ and $Ш(E^D/\mathbb{Q})$ is finite.

If $f = 0$, then the Heegner point y_K has infinite order, so by [GZ86] we have $r_{\mathrm{an}}(E/K) = 1$ and by [Kol88], $E(K)$ has rank 1 and $Ш(E/K)$ is finite. By our minimality hypothesis, we have $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q})$, so $r_{\mathrm{an}}(E/\mathbb{Q}) = \mathrm{rank}(E(\mathbb{Q})) = 1$ and $r_{\mathrm{an}}(E^D/\mathbb{Q}) = \mathrm{rank}(E^D(\mathbb{Q})) = 0$. Thus the two displayed Selmer groups $\mathrm{Sel}^{(\ell^n)}(E/K)^\pm$ are in the claimed order. Moreover, $h = 0 = \mathrm{rank}(E^D(\mathbb{Q}))$.

Next assume $f > 0$. Then one of the two Selmer groups contained $(\mathbb{Z}/\ell^n\mathbb{Z})^{f+1}$ for arbitrarily large n. Since we know that $Ш(E^D/\mathbb{Q})$ is finite and $\mathrm{rank}(E^D(\mathbb{Q})) \leq 1$ but $f + 1 \geq 2$, the Selmer group that contains $(\mathbb{Z}/\ell^n\mathbb{Z})^{f+1}$ must be $\mathrm{Sel}^{(\ell^n)}(E/K)^+$. Thus again we see that the two displayed Selmer groups are in the claimed order. Also, again $h = \mathrm{rank}(E^D(\mathbb{Q}))$ follows.

□

Remark 4.3. *Suppose the hypotheses of Theorem 4.2 are satisfied. Then comparing the conclusion about the choice of signs in Theorem 4.2 with the statement of Theorem 1 in [Kol91a] shows that $f + 1 \equiv r_{\mathrm{an}}(E/\mathbb{Q}) \pmod 2$, which implies the parity conjecture for the Selmer group of E at ℓ.*

Proposition 4.4. *Let $\ell \in B(E)$. Then $f_\ell = \mathrm{rank}(E(\mathbb{Q})) - 1$ if and only if $Ш(E/\mathbb{Q})(\ell)$ is finite and Conjecture 4.1 holds for ℓ.*

Proof. First suppose $f_\ell = \mathrm{rank}(E(\mathbb{Q})) - 1$. Then $f_\ell \neq \infty$, so Conjecture 4.1 holds. To prove that $\text{Ш}(E/\mathbb{Q})(\ell)$ is finite, use Theorem 4.2 and that by our rank hypothesis the image of $E(\mathbb{Q})$ in $\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q})$ is $(\mathbb{Z}/\ell^n\mathbb{Z})^{f+1}$. Thus $\text{Ш}(E/\mathbb{Q})[\ell^n]$ is a quotient of the ℓ^n-torsion subgroup of the finite group $(\mathbb{Z}/b_{f+1}\mathbb{Z})^2 \oplus (\mathbb{Z}/b_{f+3}\mathbb{Z})^2 \oplus \cdots$, so $\text{Ш}(E/\mathbb{Q})(\ell)$ is finite.

Conversely, suppose the ℓ-primary group $\text{Ш}(E/\mathbb{Q})(\ell)$ is finite and that Conjecture 4.1 holds. Let b be a positive integer such that $\ell^b\text{Ш}(E/\mathbb{Q})(\ell) = 0$. Then the map $\mathrm{Sel}^{(\ell^b)}(E/\mathbb{Q}) \to \text{Ш}(E/\mathbb{Q})(\ell)$ is surjective, and for every integer $n \geq b$, the map $\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q})[\ell^b] \to \text{Ш}(E/\mathbb{Q})(\ell)$ is also surjective, since $\mathrm{Sel}^{(\ell^b)}(E/\mathbb{Q}) \to \mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q})[\ell^b]$. The image of $\ell^b\,\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q})$ in $\text{Ш}(E/\mathbb{Q})(\ell)$ is trivial. Since $\ell \in B(E)$ we have $E(\mathbb{Q})_{\mathrm{tor}}[\ell] = 0$, so exactness of the sequence

$$0 \to E(\mathbb{Q})/\ell^n E(\mathbb{Q}) \to \mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q}) \to \text{Ш}(E/\mathbb{Q})(\ell) \to 0$$

implies that $\ell^b\,\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q}) \approx \ell^b(\mathbb{Z}/\ell^n\mathbb{Z})^r$, where $r = \mathrm{rank}(E(\mathbb{Q}))$. On the other hand, if we also choose $\ell^b \geq b_{f+1}$, then Theorem 4.2 implies that $\ell^b\,\mathrm{Sel}^{(\ell^n)}(E/\mathbb{Q}) \approx \ell^b(\mathbb{Z}/\ell^n\mathbb{Z})^{f+1}$. We conclude that $r = f+1$.

□

Kolyvagin's other conjectures involve $\mathrm{H}^1(K, E[\ell^\infty]) = \varinjlim_m \mathrm{H}^1(K, E[\ell^m])$.

Lemma 4.5. *Suppose $E(K)[\ell] = 0$. Then for every $m \geq 1$, the natural map $\mathrm{H}^1(K, E[\ell^m]) \to \mathrm{H}^1(K, E[\ell^\infty])$ is injective.*

Proof. This lemma is of course very well known, but we give a proof for completeness. It suffices to show that for any pair a, b of nonnegative integers that the map

$$\mathrm{H}^1(K, E[\ell^a]) \to \mathrm{H}^1(K, E[\ell^{a+b}]) \tag{10}$$

is injective. Taking Galois cohomology of $0 \to E[\ell^a] \to E[\ell^{a+b}] \to E[\ell^{a+b}]/E[\ell^a] \to 0$ we see that $\mathrm{H}^0(K, E[\ell^{a+b}]/E[\ell^a])$ surjects onto the kernel of (10). We have an exact sequence of Galois modules

$$0 \to E[\ell^a] \to E[\ell^{a+b}] \xrightarrow{\ell^a} E[\ell^b] \to 0,$$

so $\mathrm{H}^0(K, E[\ell^{a+b}]/E[\ell^a]) \cong \mathrm{H}^0(K, E[\ell^b]) = E(K)[\ell^b] = 0$, since $E(K)[\ell] = 0$.

□

We now define Galois cohomology classes associated to the Kolyvagin points P_λ. For $\lambda \in \Lambda_{\ell^n}$ with $\ell \in B(E)$, let $\tau_{\lambda,\ell^n} \in \mathrm{H}^1(K, E[\ell^n])$ be the image of P_λ under the map

$$(E(K_\lambda)/\ell^n E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)} \hookrightarrow \mathrm{H}^1(K_\lambda, E[\ell^n])^{\mathrm{Gal}(K_\lambda/K)} \cong \mathrm{H}^1(K, E[\ell^n]),$$

where the last map is an isomorphism because $\ell \in B(E)$ (see, e.g., [Gro91, §4]). Kolyvagin also remarks that one can define Galois cohomology classes τ_{λ,ℓ^n} for $\ell \notin B(E)$ and all $\lambda \in \Lambda_{\ell^{k_0+n}}$, where k_0 is the smallest nonnegative even integer such that $\ell^{k_0/2}E(\mathbf{K})(\ell) = 0$ and $\mathbf{K}$ is the compositum of all K_λ for $\lambda \in \Lambda$. Of course, for all $\ell \in B(E)$ we have $k_0 = 0$.

Let τ'_{λ,ℓ^n} be the image in $H^1(K, E[\ell^\infty])$ of τ_{λ,ℓ^n} (note that for the moment we are not assuming that $\ell \in B(E)$, so the natural map $\mathrm{H}^1(K, E[\ell^m]) \to \mathrm{H}^1(K, E[\ell^\infty])$ need not be injective). For any integers $a \geq 0$, $k \geq k_0$ and $n \geq 1$, let

$$V^a_{k,\ell^n} = \langle \tau'_{\lambda,\ell^n} : \lambda \in \Lambda^a_{\ell^{n+k}} \rangle \subset H^1(K, E[\ell^\infty])$$

Since $\Lambda^a_{\ell^{n+k+1}} \subset \Lambda^a_{\ell^{n+k}}$, we have

$$V^a_{0,\ell^n} \supset V^a_{1,\ell^n} \supset V^a_{2,\ell^n} \supset \cdots .$$

We have $\ell\tau_{\lambda,\ell^{n+1}} = \tau_{\lambda,\ell^n}$, because the following diagram commutes, with $G = \mathrm{Gal}(K_\lambda/K)$:

$$\begin{tikzcd}
(E(K_\lambda)/\ell^{k+n+1}E(K_\lambda))^G \arrow[r, hook] & \mathrm{H}^1(K_\lambda, E[\ell^{k+n+1}])^G \\
(E(K_\lambda)/\ell^{k+n}E(K_\lambda))^G \arrow[r, hook] \arrow[u, "{[\ell]}"] & \mathrm{H}^1(K_\lambda, E[\ell^{k+n}])^G \arrow[u]
\end{tikzcd}$$

Thus $\ell V^a_{k,\ell^{n+1}} \subset V^a_{k,\ell^n}$.

We say $\{\tau_{\lambda,\ell^n}\}$ is a *strong nonzero system* if there exists $a \geq 0$ such that for all $k \geq k_0$ there exists n such that $V^a_{k,\ell^n} \neq 0$. In other words, if one continues the grid of subgroups of $\mathrm{H}^1(K, E[\ell^\infty])$ below infinitely far to the right and up in the obvious way, then it is *not* the case that sufficiently far to the right every single group is 0.

$$\begin{tikzcd}
\vdots & \vdots & \vdots & \\
V^a_{0,\ell^3} & V^a_{1,\ell^3} \arrow[l] & V^a_{2,\ell^3} \arrow[l] & \cdots \arrow[l] \\
V^a_{0,\ell^2} & V^a_{1,\ell^2} \arrow[l] & V^a_{2,\ell^2} \arrow[l] & \cdots \arrow[l] \\
V^a_{0,\ell} & V^a_{1,\ell} \arrow[l] & V^a_{2,\ell} \arrow[l] & \cdots \arrow[l]
\end{tikzcd}$$

Conjecture 4.6 (Kolyvagin's Conjecture B_ℓ)**.** *$\{\tau_{\lambda,\ell^n}\}$ is a strong nonzero system.*

Remark 4.7. *Kolyvagin remarks [Kol91a, pg. 258] that if $\ell \in B(E)$, then $\{\tau_{\lambda,\ell^n}\}$ is a strong nonzero system if and only if there exists n such that $V^a_{0,\ell^n} \neq 0$. By Lemma 4.5, this is the case if and only if some τ is nonzero. So for $\ell \in B(E)$, Conjectures 4.1 is true if and only if Conjecture 4.6 is true.*

The following conjecture is motivated by Theorem 4.2 and the conjecture that $Ш(E/K)$ is finite.

Conjecture 4.8 (Kolyvagin's Conjecture C)**.** *The set of primes ℓ such that $m_\ell \neq 0$ is finite.*

Let $r_{\mathrm{an}} = \mathrm{ord}_{s=1} L(E,s)$, and let $\varepsilon = (-1)^{r_{\mathrm{an}}-1}$. For any module A with an action of complex conjugation σ, and $\nu \in \{0,1\}$, let $A^\nu = (1-(-1)^\nu \varepsilon\sigma)A$.

Conjecture 4.9 (Kolyvagin's Conjecture D_ℓ)**.** *There exists $\nu \in \{0,1\}$ and a subgroup $V \subset (E(K)/E(K)_{\mathrm{tor}})^\nu$ such that $1 \leq \mathrm{rank}(V) \equiv \nu \pmod 2$ and for all $n \geq 1$ and all sufficiently large k, one has*

$$V^a_{k,\ell^n} \equiv V \pmod{\ell^n(E(K)_{/\,\mathrm{tor}})},$$

where $a = \mathrm{rank}(V) - 1$.

The following conjecture is the natural generalization to higher rank of the hypothesis when $r_{\mathrm{an}}(E/\mathbb{Q}) = 1$ that the Hegner point y_K has infinite order.

Conjecture 4.10 (Kolyvagin's Conjecture D)**.** *There exists a single subgroup V of $E(K)$ such that Conjecture 4.9 holds simultaneously for all ℓ with that V.*

Conjecture 4.9 has numerous consequences. Much of the following proposition is implicitly stated without any proofs in [Kol91a, pg. 258–259], so we give complete proofs below.

Proposition 4.11. *Assume our running minimality hypothesis that $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$. Suppose Conjecture 4.9 is true for $\ell \in B(E)$ and let $f = f_\ell$. Then*

1. *$(E(K)/E(K)_{\mathrm{tor}})^\nu = (E(K)/E(K)_{\mathrm{tor}})^+$,*
2. *$a = f$,*
3. *$\mathrm{rank}(E(\mathbb{Q})) = f + 1$,*
4. *$Ш(E/K)(\ell)$ is finite,*
5. *$r_{\mathrm{an}}(E/\mathbb{Q}) \equiv \mathrm{rank}(E(\mathbb{Q})) \pmod 2$, and*
6. *$V \otimes \mathbb{Z}_\ell = \ell^{m_f} E(\mathbb{Q}) \otimes \mathbb{Z}_\ell$.*

Proof. By Conjecture 4.9, there exists $\nu \in \{0,1\}$ and a subgroup $V \subset (E(K)/E(K)_{\mathrm{tor}})^\nu$ such that $1 \leq \mathrm{rank}(V) \equiv \nu \pmod 2$ and for all $n > 0$ and all sufficiently large k we have

$$V^a_{k,\ell^n} \equiv V \pmod{\ell^n E(K)_{\mathrm{tor}}},$$

where $a = \mathrm{rank}(V) - 1$.

If $\mathrm{rank}(V) = 1$, then $a = 0$, so $V^0_{k,\ell^n} \neq 0$ for some k, so since f is the smallest integer such that $V^f_{k,\ell^n} \neq 0$, this implies that $f = 0$ giving Part 2; thus the Heegner point y_K has infinite order and $r_{\mathrm{an}}(E/K) = 1$. Since $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q})$, we have $r_{\mathrm{an}}(E/\mathbb{Q}) = 1$ and $r_{\mathrm{an}}(E^D/\mathbb{Q}) = 0$, so Parts 1,3,4, 5 follows. Finally, Part 6 follows since V^0_{k,ℓ^n} is just the image of the Heegner point y_K under the connecting homomorphism, and $\mathrm{ord}_\ell(y_K) = m_f$.

Next assume that $\mathrm{rank}(V) > 1$. By our minimality hypothesis, $r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$, so $\mathrm{rank}(E^D(\mathbb{Q})) \leq 1$, hence $V \not\subset (E(K)/E(K)_{\mathrm{tor}})^-$, so $V \subset (E(K)/E(K)_{\mathrm{tor}})^+$, which proves Part 1. We have $f \leq a$ since $V^a_{k,\ell^n} \neq 0$ for some $k \geq 0$. Also, since $f < \infty$, Theorem 4.2 implies that $\mathrm{rank}(E(\mathbb{Q})) \leq f + 1$. Since $\mathrm{rank}((E(K)/E(K)_{\mathrm{tor}})^+) = \mathrm{rank}(E(\mathbb{Q}))$, we have

$$a + 1 = \mathrm{rank}(V) \leq \mathrm{rank}(E(\mathbb{Q})) \leq f + 1 \leq a + 1.$$

We conclude that the above inequalities are equalities, so $a = f$ which proves Part 2, and $\mathrm{rank}(E(\mathbb{Q})) = f + 1$, which proves Part 3. Also because $\mathrm{rank}(E(\mathbb{Q})) = f + 1$, Theorem 4.2 implies that $Ш(E/\mathbb{Q})(\ell)$ is finite, so since $Ш(E^D/\mathbb{Q}))$ is also finite, Part 4 is true. Considering the definition of the A^ν before the statement of Conjecture 4.9, we see that $1 - (-1)^\nu(-1)^{r_{\mathrm{an}}-1}\sigma = 1 + \sigma$, so $\nu \equiv r_{\mathrm{an}} \pmod 2$. Since part of Conjecture 4.9 is that $\mathrm{rank}(V) \equiv \nu \pmod 2$, and we proved that $\mathrm{rank}(V) = \mathrm{rank}(E(\mathbb{Q}))$, we conclude that $r_{\mathrm{an}} \equiv \mathrm{rank}(E(\mathbb{Q}))$ (mod 2), which is Part 5. By [Kol91a, Thm. 3], for all $k \geq m_f$ the subgroup $V^f_{k,\ell^n} \subset \mathrm{H}^1(K, E[\ell^\infty])$ contains $(\ell^{m_f}\mathbb{Z}/\ell^n\mathbb{Z})^{f+1} = \delta(\ell^{m_f}E(\mathbb{Q}))$, so $\ell^{m_f}E(\mathbb{Q}) \otimes \mathbb{Z}_\ell \subset V \otimes \mathbb{Z}_\ell$. On the other hand, by definition of m_f, every cohomology class τ_{λ,ℓ^n} is contained in $\ell^{m_f}\,\mathrm{H}^1(K, E[\ell^n])$. Thus $\delta(V) \subset \ell^{m_f}\,\mathrm{H}^1(K, E[\ell^\infty])$, so $V \subset \ell^{m_f}E(\mathbb{Q})$. This proves Part 6.

□

Recall from Section 2 that c is the Manin constant of E and the c_q are the Tamagawa numbers of E. We make the following new refinement of Kolyvagin's Conjecture 4.8.

Conjecture 4.12. *We have* $m_\ell = \mathrm{ord}_\ell(c \cdot \prod_{q|N} c_q)$.

Theorem 7.5 and Theorem 7.7 below serve as our motivation to make Conjecture 4.12. In particular, Kolyvagin proved that at primes $\ell \in B(E)$, Conjecture 4.12 is equivalent to [GZ86, Conj 2.2, pg 311] in the special case when E has analytic rank 1 over K.

5 Mod p Kolyvagin Points and Kolyvagin Subgroups

As always, we assume E is an elliptic curve over $\mathbb{Q}$, that K is a quadratic imaginary field satisfying the Heegner hypothesis, and p is a prime that is inert in K. The Heegner hypothesis implies that the primes of bad reduction for E split in K, so p must be a prime of good reduction. For each such prime, we define a finite-index subgroup W_p of $E(K)$. We do this by extending Kolyvagin's construction of points P_λ to obtain a new well-defined construction of elements of the quotient group

$$E(\mathbb{F}_p)/(p+1) = E(\mathbb{F}_p)/(p+1)E(\mathbb{F}_p)$$

for any inert prime p. Thus this section takes Kolyvagin's definition of points P_λ one step further to define elements of $E(\mathbb{F}_p)/(p+1)$. We first compute the structure of the odd part of the group $E(\mathbb{F}_p)/(p+1)$ for any good prime p. We then use properties of splitting of primes in certain ring class fields to define the canonical reduction $R_{p,\lambda} \in E(\mathbb{F}_p)/(p+1)$ of the Kolyvagin points P_λ, and consider the subgroup X_p of $E(\mathbb{F}_p)/(p+1)$ generated by the $R_{p,\lambda}$ for certain λ. We then define W_p to be the inverse image of X_p and finish with some results about the structure of W_p.

If A is a finite abelian group, the *odd part* of A is the subgroup of A of all elements of odd order, and if n is an integer, the odd part of n is $n/2^{\mathrm{ord}_2(n)}$.

Lemma 5.1. *The odd part of* $E(\mathbb{F}_p)/(p+1)$ *is cyclic of order the odd part of* $\gcd(p+1, a_p)$.

Proof. Suppose ℓ is an odd prime divisor of $\#(E(\mathbb{F}_p)/(p+1))$. If the ℓ-primary subgroup of $E(\mathbb{F}_p)/(p+1)$ is not cyclic, then since $\ell \neq p$ we have $E(\mathbb{F}_p)[\ell] \approx (\mathbb{Z}/\ell\mathbb{Z})^2$. The Weil pairing induces an isomorphism of Galois modules $\bigwedge^2 E[\ell] \cong \mu_\ell$ and $E[\ell] \subset E(\mathbb{F}_p)$, so $\mu_\ell \subset \mathbb{F}_p^*$, hence $\ell \mid (p-1)$. Since ℓ divides $\#(E(\mathbb{F}_p)/(p+1))$ and ℓ is prime, we have $\ell \mid (p+1)$, so $\ell \mid \gcd(p-1, p+1) = 2$, a contradiction, since ℓ is odd.

The group $E(\mathbb{F}_p)$ has order $p + 1 - a_p$, and we just proved above that $E(\mathbb{F}_p)(\ell)$ is cyclic for any odd prime divisor ℓ of $p+1$. Thus the quotient ℓ-primary group $(E(\mathbb{F}_p)/(p+1))(\ell) = (E(\mathbb{F}_p)(\ell))/(p+1)$ has order ℓ^m, where

$$m = \mathrm{ord}_\ell(\gcd(p+1, \#E(\mathbb{F}_p))) = \mathrm{ord}_\ell(\gcd(p+1, p+1-a_p)) = \mathrm{ord}_\ell(\gcd(p+1, a_p)).$$

Taking the product over all odd primes ℓ, shows that the odd part of $E(\mathbb{F}_p)/(p+1)$ has order the odd part of $\gcd(p+1, a_p)$. □

Remark 5.2. 1. *Lemma 5.1 is true even if p is a good prime that is not inert in K (in fact, the lemma and proof have nothing to do with K).*

2. *Lemma 5.1 is false if we do not restrict to odd parts. For example, if E is $y^2 = x^3 - x$ and $p = 3$, then $E(\mathbb{F}_3) \approx (\mathbb{Z}/2\mathbb{Z})^2$, so $E(\mathbb{F}_3)/4 \approx (\mathbb{Z}/2\mathbb{Z})^2$ is not cyclic.*
3. *For every prime ℓ, there exists infinitely many primes p such that $E(\mathbb{F}_p)(\ell)$ is not cyclic. Indeed, by the Chebotarev density theorem there are infinitely many p that split completely in the field $\mathbb{Q}(E[\ell])$, and for these p we have $(\mathbb{Z}/\ell\mathbb{Z})^2 \subset E(\mathbb{F}_p)$.*

Lemma 5.3. *If p is inert in K and does not divide λ, then the prime ideal $p\mathcal{O}_K$ of K splits completely in K_λ. In particular, if $p \in \Lambda^1_{\ell^n}$ and $\lambda \in \Lambda_{\ell^n}$ with $p \nmid \lambda$, then $p\mathcal{O}_K$ splits completely in K_λ.*

Proof. (Compare line -3 on page 103 of [Kol91b].) Since p is inert, the ideal $p\mathcal{O}_K$ is a prime principal ideal of $\mathcal{O}_K$, hence splits completely in the Hilbert class field K_1. As explained in [Gro91, pg. 238], class field theory identifies $\mathrm{Gal}(K_\lambda/K_1)$ with $C = (\mathcal{O}_K/\lambda\mathcal{O}_K)^*/(\mathbb{Z}/\lambda\mathbb{Z})^*$. The image of p is trivial in C, so the Frobenius element attached to $p\mathcal{O}_K$ is trivial, hence $p\mathcal{O}_K$ splits completely in the ring of integers of K_λ, as claimed. □

Define the reduction map $E(K) \to E(\mathbb{F}_{p^2})$ by reducing the Néron model $\mathcal{E}$ of E over $\mathcal{O}_K$ modulo $p\mathcal{O}_K$, and using the natural maps $E(K) \cong \mathcal{E}(\mathcal{O}_K) \to \mathcal{E}_{\mathbb{F}_{p^2}}(\mathbb{F}_{p^2}) \cong E(\mathbb{F}_{p^2})$. Let $\pi_p : E(K) \to E(\mathbb{F}_p)/(p+1)$ be the composition of reduction modulo the prime ideal $p\mathcal{O}_K$ with $\mathrm{Tr}_{\mathbb{F}_{p^2}/\mathbb{F}_p} : E(\mathbb{F}_{p^2}) \to E(\mathbb{F}_p)$ followed by quotienting out by the subgroup $(p+1)E(\mathbb{F}_p)$. Fix a *choice* $\wp$ of prime ideal of K_λ over $p\mathcal{O}_K$. Extend π_p to a map $\pi_\wp : E(K_\lambda) \to E(\mathbb{F}_p)/(p+1)$ by quotienting out by $\wp$, as illustrated in the following diagram:

$$\begin{tikzcd}
E(K_\lambda) \arrow[drr, "\text{mod } \wp"] & & \\
E(K) \arrow[u] \arrow[r, "\cong"] \arrow[ddrr, dotted, "\pi_p"'] & \mathcal{E}(\mathcal{O}_K) \arrow[r] & E(\mathbb{F}_{p^2}) \arrow[d, "\text{trace}"] \\
& & E(\mathbb{F}_p) \arrow[d] \\
& & E(\mathbb{F}_p)/(p+1)
\end{tikzcd}$$

For each $\ell \mid (p+1)$, let $v_\ell = \mathrm{ord}_\ell(\gcd(a_p, p+1))$, and define $\pi_{\wp,\ell} : E(K_\lambda) \to (E(\mathbb{F}_p)/(p+1))(\ell)$ by

$$\pi_{\wp,\ell}(S) = \pi_\wp\left(\frac{p+1}{\ell^{v_\ell}} S\right).$$

We now study how the homomorphism $\pi_{\wp,\ell}$ depends on our choice of prime of $\wp$ over $p\mathcal{O}_K$.

Proposition 5.4. *The map $\pi_{\wp,\ell}$ induces a well-defined (independent of choice of $\wp$) homomorphism*

$$\vartheta : (E(K_\lambda)/\ell^{v_\ell}E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)} \to E(\mathbb{F}_p)/(p+1).$$

Proof. Let $[S] \in (E(K_\lambda)/\ell^{v_\ell}E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)}$ with $S \in E(K_\lambda)$. If $\wp'$ is another prime of K_λ over $p\mathcal{O}_K$, then because the Galois group acts transitively on the primes over a given prime, there is $\sigma \in \mathrm{Gal}(K_\lambda/K)$ such that $\pi_{\wp',\ell}(S) = \pi_{\wp,\ell}(\sigma(S))$. Since $[S]$ is $\mathrm{Gal}(K_\lambda/K)$-equivariant, we have $\sigma(S) = S + \ell^{v_\ell} \cdot Q$, for some $Q \in E(K_\lambda)$, so

$$\begin{aligned}
\vartheta([\sigma(S)]) &= \pi_{\wp,\ell}(\sigma(S)) \\
&= \pi_\wp\left(\frac{p+1}{\ell^{v_\ell}}\sigma(S)\right) \\
&= \pi_\wp\left(\frac{p+1}{\ell^{v_\ell}}S\right) + \pi_\wp((p+1)Q) \\
&= \pi_{\wp,\ell}(S) + 0 = \vartheta([S]),
\end{aligned}$$

where $\pi_\wp((p+1)Q) = (p+1)\pi_\wp(Q)$ is 0, since the group $E(\mathbb{F}_p)/(p+1)$ is killed by $p+1$. □

By Proposition 3.4, $[P_\lambda]$ is in the domain of the homomorphism ϑ of Proposition 5.4.

Definition 5.5 (Mod p Kolyvagin Point)**.** *The* mod p Kolyvagin point *associated to $p \in \Lambda^1_{\ell^n}$ and $\lambda \in \Lambda_{\ell^n}$ is*

$$R_{p,\lambda} = \vartheta([P_\lambda]) \in E(\mathbb{F}_p)/(p+1),$$

where ϑ is as in Proposition 5.4.

As above, let $v_\ell = \mathrm{ord}_\ell(\gcd(a_p, p+1))$. For each $k \geq 0$, let

$$X_{k,p} = \left\langle R_{p,\lambda} : \lambda \in \bigcup_\ell \Lambda^{f_\ell}_{\ell^{v_\ell+k}} \right\rangle \subset E(\mathbb{F}_p)/(p+1) \tag{11}$$

be the subgroup generated by all mod p Kolyvagin points associated to λ that are a product of f_ℓ primes, where f_ℓ is from Equation (9). Note that the subscript of Λ in (11) is $\ell^{v_\ell+k}$, and we take the union over *all* ℓ thus obtaining a subgroup $X_{k,p}$ that need not be ℓ-primary for any ℓ, despite $R_{p,\lambda}$ being ℓ-primary. Let

$$X_p = \bigcap_{k \geq 0} X_{k,p}.$$

Let $W_{k,p}$ be the inverse image of $X_{k,p}$ under the map π_p:

$$W_{k,p} = \pi_p^{-1}(X_{k,p}) \subset E(K),$$

and

$$W_p = \pi_p^{-1}(X_p) \subset E(K).$$

Since $E(\mathbb{F}_p)/(p+1)$ is finite, $W_{k,p}$ and W_p have finite index in $E(K)$; also, by Lemma 5.1, the odd part of this index divides $\gcd(p+1, a_p)$.

Remark 5.6. *Note that $E^D(\mathbb{Q})$ is in the kernel of the trace map, hence in the kernel of π_p, so $E^D(\mathbb{Q}) \subset W_p$. Thus it is possible that W_p contains torsion, hence W_p in general need not be a Gross-Zagier subgroup as in Definition 2.3. In a future paper, we intend to give a more refined definition of a sequence of groups W_p^a, for each $a \geq 0$, which better accounts for torsion. We would then search for a Gross-Zagier style formula for each group W_p^a for $a \leq f+1$, in order to more closely relate $r_{\mathrm{an}}(E/\mathbb{Q})$ to $f+1$.*

6 Controlling the Reduction Map

The main result of this section is a proof that under certain hypothesis, if a point Q has infinite order and n is a positive integer, then there are infinitely many primes p such that the image of Q in $E(\mathbb{F}_{p^2})/(p+1)$ has order divisible by n. We prove this using Galois cohomology and by converting a condition on ℓ-divisibility of points into a Chebotarev condition. We will use this result later to study the maximum index $[E(K) : W_p]$ that can occur and prove a generalized Gross-Zagier formula for such W_p.

Let E, K, etc., be as above, and let $\ell \in B(E)$, where $B(E)$ is the set of primes defined on page 5. Suppose $Q \in E(K)$ has infinite order, and let n be an odd positive integer. Suppose that for each prime $\ell \mid n$, the set of cardinalities $\{\# \mathrm{H}^1(K(E[\ell^j])/K, E[\ell^j]) : j \geq 1\}$ is bounded. This hypothesis is satisfied if $\ell \in B(E)$, since then $\mathrm{H}^1(K(E[\ell^j])/K, E[\ell^j]) = 0$ for all j (see [Gro91, pg. 241] and [GJP$^+$09, Prop. 5.2]).

Proposition 6.1. *Let Q and n be as above. Let S be the set of primes p such that p is inert in K, p splits completely in $K(E[n])/K$, and the image of Q in $E(\mathbb{F}_{p^2})/(p+1)E(\mathbb{F}_{p^2})$ has order divisible by n. Then S has positive (Dirichlet) density.*

Proof. Let $m = \prod \ell_i^{e_i}$ with ℓ_i the distinct primes that divide n, and e_i any positive integers, which we will fix later in the argument. Fix any i, and let $L = K(E[\prod_{j \neq i} \ell_j])$, which is a Galois extension of K. Define homomorphisms Ψ_i, f, g, and h as in the following commutative diagram:

$$\begin{tikzcd}
E(K(E[m]))/\ell_i^{e_i} E(K(E[m])) \arrow[r, hook] & \mathrm{H}^1(K(E[m]), E[\ell_i^{e_i}]) \\
 & \mathrm{H}^1(L(E[\ell_i^{e_i}]), E[\ell_i^{e_i}]) \arrow[u, "f"'] \\
 & \mathrm{H}^1(K(E[\ell_i^{e_i}]), E[\ell_i^{e_i}]) \arrow[u, "h"'] \\
E(K)/\ell_i^{e_i} E(K) \arrow[uuu] \arrow[r, hook] \arrow[uuur, dotted, "\psi_i"] & \mathrm{H}^1(K, E[\ell_i^{e_i}]) \arrow[u, "g"']
\end{tikzcd}$$

The horizontal maps above are induced by the short exact sequence coming from multiplication by $\ell_i^{e_i}$, and the vertical maps on the right are the restriction maps. The diagram commutes so the order of the image of Q in $E(K(E[m]))/\ell_i^{e_i}E(K(E[m]))$ is the same as the order of $\Psi_i(Q)$.

By hypothesis and the inflation restriction sequence the cardinality of $\ker(g)$ is bounded independently of i and e_i. Also, $[L : K]$ depends only on the set of prime divisors ℓ_i of n, not their exponents, so

$$\#\ker(h) = \#\mathrm{H}^1(L(E[\ell_i^{e_i}])/K(E[\ell_i^{e_i}]), E[\ell_i^{e_i}]) = \#\mathrm{Hom}(\mathrm{Gal}(L(E[\ell_i^{e_i}])/K(E[\ell_i^{e_i}])), E[\ell_i^{e_i}])$$

is also bounded independent of e_i, because every homomorphism has image in the fixed subset $E[\ell_i^d]$, where d is the exponent of the group $\mathrm{Gal}(L/K)$. Finally, the map f is injective, since

$$\ker(f) \cong \mathrm{H}^1(K(E[m])/L(E[\ell_i^{e_i}]), E[\ell_i^{e_i}])$$

and $\#\mathrm{Gal}(K(E[m])/L(E[\ell_i^{e_i}]))$ is divisible only by the primes ℓ_j for $j \neq i$ and these are all coprime to $\#E[\ell_i^{e_i}] = \ell_i^{2e_i}$. We conclude that there is an integer b such that $\#\ker(\Psi_i) \leq \ell_i^b$, and this bound holds no matter how we increase the numbers e_i and e_j (for all j).

The above proof that $\ker(\Psi_i)$ is uniformly bounded is completely general. See Remark 6.3 for a sketch of an alternative proof of this bound in the special case when $\ell \in B(E)$ for all $\ell \mid n$, which is the only case we will use in this paper.

Because $\ker(\Psi_i)$ is uniformly bounded independent of our choice of e_i, for each i, we can choose e_i large enough so that $\Psi_i(Q)$ has order divisible by $\ell_i^{\mathrm{ord}_{\ell_i}(n)}$. Then for each i, let d_i be maximal such that $\ell_i^{d_i}$ divides Q in $E(K(E[m]))$. Note that $d_i < e_i$ for each i, since $\Psi_i(Q) \neq 0$ and $\Psi(Q)$ is an element of a group that is killed by $\ell_i^{e_i}$. Since $m = \prod \ell_i^{e_i}$, we have $\ell_i^{d_i+1} \mid m$, so

$$M_i = K\left(E[m],\ \frac{1}{\ell_i^{d_i+1}}Q\right)$$

does not depend on the choice of $\ell_i^{d_i+1}$th root of Q, is a Galois extension of $K(E[m])$, and $[M_i : K(E[m])]$ is a nontrivial power of ℓ_i. Thus the M_i for all i are linearly disjoint as extensions of $K(E[m])$.

Let M be the compositum of the fields M_i defined above. Since the M_i are linearly disjoint nontrivial extensions of $K(E[m])$, there exists an automorphism $\sigma \in \mathrm{Gal}(M/\mathbb{Q})$ such that $\sigma|_{K(E([m]))}$ is complex conjugation, and $\sigma|_{M_i}$ has order divisible by ℓ_i for each i. By the Chebotarev density theorem, there is a positive density of primes $p \in \mathbb{Z}$ that are unramified in M and have Frobenius the class of σ. Such primes are inert in K since complex conjugation acts nontrivially on K, split completely in $K(E[m])/K$ since complex conjugation has order 2, and each prime over p in $K(E[m])$ does not split completely in any of the extensions $M_i/K(E[m])$ since $[\mathrm{Frob}_p]|_{M_i} = \sigma|_{M_i}$ has order divisible by $\ell_i > 2$. Note that this is the only place in the argument where we use that n is odd.

Let p be any prime as in the previous paragraph. We have

$$E(\mathbb{F}_{p^2})/\ell_i^{e_i}E(\mathbb{F}_{p^2}) \cong (\mathbb{Z}/\ell_i^{e_i}\mathbb{Z})^2$$

since $p\mathcal{O}_K$ splits completely in $K(E[m])$ and $\ell_i^{e_i} \mid m$. Also, the Frobenius condition implies that the primes of M_i over $p\mathcal{O}_K$ do not have residue class degree 1, so since M_i is generated by any choice of $\frac{1}{\ell^{d_i+1}}Q$, the reduction $\overline{Q}$ of Q modulo any prime over $p\mathcal{O}_K$ is not divisible by $\ell_i^{d_i+1}$ in $E(\mathbb{F}_{p^2})$. Note that $\ell_i^{d_i}$ divides $\overline{Q}$, because the prime $p\mathcal{O}_K$ splits completely in $K(E[m])/K$ and $\ell_i^{d_i}$ divides Q in $K(E[m])$, so d_i is the largest integer such that $\ell_i^{d_i}$ divides the image of $\overline{Q}$ in $E(\mathbb{F}_{p^2})$. We conclude that for each i the image of Q in $E(\mathbb{F}_{p^2})/\ell_i^{e_i}E(\mathbb{F}_{p^2})$ has order the same as the order of $\Psi_i(Q)$.

By hypothesis, $e_i \geq \mathrm{ord}_{\ell_i}(n)$ and $\Psi_i(Q)$ has order divisible by $\ell_i^{\mathrm{ord}_{\ell_i}(n)}$ for each i, so the image of Q in $E(\mathbb{F}_{p^2})/mE(\mathbb{F}_{p^2})$ has order divisible by n. For any such p, we also have that the characteristic polynomial of the class of Frob_p in $\mathrm{Gal}(\mathbb{Q}(E[m])/\mathbb{Q})$ acting on $E[m]$ is $x^2 - a_px + p \pmod{m}$. On the other hand, since $[\mathrm{Frob}_p]$ on $E[m]$ is the class of complex conjugation and complex conjugation acts nontrivially (since m is odd) hence has characteristic polynomial $x^2 - 1$, we have $x^2 - a_px + p \equiv x^2 - 1 \pmod{m}$. Thus $m \mid (p+1)$, so the image of Q in $E(\mathbb{F}_{p^2})/(p+1)E(\mathbb{F}_{p^2})$ also has order divisible by n, which completes the proof. □

Remark 6.2. *Proposition 6.1 is analogous to the statement that if $x, n \in \mathbb{Z}$ with $\gcd(n, x) = 1$ and $\mathbb{Q}(\zeta_n, \sqrt[n]{x})$ is an extension of $\mathbb{Q}(\zeta_n)$ of degree n, then there exist a positive density of primes p such that the multiplicative order of x modulo p is divisible by n. The proof of this statement resembles the proof of Proposition 6.1, except we work with the field $\mathbb{Q}(\zeta_n, \sqrt[n]{x})$. The idea of the proof of Proposition 6.1 is well-known to experts who study questions such as the Lang-Trotter conjecture about reduction of points on elliptic curves.*

Remark 6.3. *If for every prime $\ell \mid n$ we have $\ell \in B(E)$, we can alternatively use that $K(E[\ell_1^\infty])$ and $K(E[\ell_2^\infty])$ are linearly disjoint for distinct odd primes ℓ_1 and ℓ_2 in $B(E)$ to give a different proof that the maps Ψ_i have uniformly bounded kernel in Proposition 6.1. In that case we have that* $\mathrm{Gal}(K(E[n])/K) \approx \mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})$, *so*

$$\ker\Big(\mathrm{H}^1(K, E[n]) \to \mathrm{H}^1(K(E[n]), E[n])\Big) \cong \mathrm{H}^1(K(E[n])/K, E[n]) = \mathrm{H}^1(\mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z}), (\mathbb{Z}/n\mathbb{Z})^2) = 0,$$

where the last group is 0 *by a standard group cohomology argument (see, e.g., [Ste02, §5.1]). This implies that the maps Ψ_i are all injective. The linear disjointness of $K(E[\ell_1^\infty])$ and $K(E[\ell_2^\infty])$ for the distinct* odd *primes ℓ_1 and ℓ_2 follows by a Galois theory argument using the structure of* $\mathrm{GL}_2(\mathbb{Z}/\ell^n\mathbb{Z})$. *We thank R. Greenberg for this observation.*

7 Maximal Index Subgroups W_p

As above, we assume that E is an elliptic curve over $\mathbb{Q}$ with positive analytic rank and that $K = \mathbb{Q}(\sqrt{D})$ is a quadratic imaginary field that satisfies the Heegner hypothesis and the minimality hypothesis that $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$.

Recall that for each inert prime p of K we defined a subgroup $X_p \subset E(\mathbb{F}_p)/(p+1)$ in Equation (11) of Section 5. This was a group got by reducing Kolyvagin points associated to all primes ℓ modulo a choice of prime over p. In this section, for all $\ell \in B(E)$ we conditionally compute, in terms of $m_{\ell,f}$, the ℓ-primary part $X_p(\ell)$ of this subgroup $X_p \subset E(\mathbb{F}_p)/(p+1)$. We relate our refinement of Kolyvagin's conjectures to the generalized Gross-Zagier formula (5). We also conditionally compute X_p in terms of $c \cdot \prod c_q \cdot \sqrt{\#\text{Ш}(E/K)}$ using Theorem 4.2. We apply our description of X_p to prove that, up to primes not in $B(E)$, the subgroups W_p with $[E(K) : W_p]$ maximal are all Gross-Zagier subgroups of $E(K)$.

Proposition 7.1. *Conjecture 4.9 implies that for every $\ell \in B(E)$,*

$$X_p(\ell) = \frac{p+1}{\ell^{v_\ell}} \cdot \pi_p(\ell^{m_{\ell,f}} E(\mathbb{Q})),$$

where $v_\ell = \mathrm{ord}_\ell(p+1)$.

Proof. Let Φ be the composite homomorphism

$$(E(K_\lambda)/\ell^{v_\ell}E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)} \hookrightarrow \mathrm{H}^1(K_\lambda, E[\ell^{v_\ell}])^{\mathrm{Gal}(K_\lambda/K)} \cong \mathrm{H}^1(K, E[\ell^{v_\ell}]),$$

and let $\delta : E(K) \to \mathrm{H}^1(K, E[\ell^{v_\ell}])$. We are assuming Conjecture 4.9, so we may apply Proposition 4.11 Part 6 (taking into account Lemma 4.5), to see that for all k sufficiently large we have $\delta(\ell^{m_{\ell,f}}E(\mathbb{Q})) = V^f_{k,\ell^{v_\ell}}$. Thus

$$\delta(\ell^{m_{\ell,f}}E(\mathbb{Q})) = \langle \Phi([P_\lambda]) : \lambda \in \Lambda^f_{\ell^{v_\ell+k}} \rangle.$$

Let $i : E(K) \to (E(K_\lambda)/\ell^{v_\ell}E(K_\lambda))^{\mathrm{Gal}(K_\lambda/K)}$. For any $Q \in E(K)$ we have $\frac{p+1}{\ell^{v_\ell}} \cdot \pi_p(Q) = \vartheta(i(Q))$ where ϑ is as in Proposition 5.4. Since $\delta = \Phi \circ i$ and Φ is injective, the group $X_{k,p}(\ell)$ generated by all $\vartheta([P_\lambda])$ is equal to $\vartheta(i(\ell^{m_{\ell,f}}E(\mathbb{Q})))$. Since this is true for all sufficiently large k, the proposition follows for X_p. □

Theorem 7.5 below generalizes [Kol91b, Thm. E] to arbitrary rank. To prove it we first prove some lemmas and make a definition.

Lemma 7.2. *Suppose A is a nonzero finitely generated free abelian group and $\varphi : A \to \mathbb{Z}/d\mathbb{Z}$ is a surjective homomorphism. For every nonzero integer c we have $[A : \varphi^{-1}(\varphi(cA))] = \gcd(c, d)$.*

Proof. Let $B = \varphi^{-1}(\varphi(cA))$. We have $\varphi(\ker(\varphi)) = 0 \subset \varphi(cA)$, so $\ker(\varphi) \subset B$. Since $\ker(\varphi) \subset B$, the isomorphism $A/\ker(\varphi) \cong \mathbb{Z}/d\mathbb{Z}$ induces an isomorphism $A/B \cong (\mathbb{Z}/d\mathbb{Z})/\varphi(B)$. But φ is surjective, so $\varphi(B) = \varphi(\varphi^{-1}(\varphi(cA))) = \varphi(cA) = c\varphi(A) = c(\mathbb{Z}/d\mathbb{Z})$, so $A/B \cong (\mathbb{Z}/d\mathbb{Z})/(c(\mathbb{Z}/d\mathbb{Z})) \cong \mathbb{Z}/\gcd(d,c)\mathbb{Z}$. □

Recall (see page 5) that $B(E)$ is a set of primes that have certain good properties for E. Below, for any integer n we either let $n' = \ell^{\mathrm{ord}_\ell(n)}$ be the ℓ-part of n or the maximal divisor of n divisible only by primes in $B(E)$, depending on whether we are considering the first or second part of the following lemma.

Lemma 7.3. *Assume $E(\mathbb{Q})$ has positive rank and let t be a positive integer.*

1. *If $\ell \in B(E)$ is such that $X_p(\ell) = \frac{p+1}{\ell^{v_\ell}} \cdot \pi_p(tE(\mathbb{Q}))$ for all inert primes p, then*

$$\max\{\mathrm{ord}_\ell([E(K) : W_p]) : \textit{ all inert } p\} = \mathrm{ord}_\ell(t).$$

2. If for all $\ell \in B(E)$ we have $X_p(\ell) = \frac{p+1}{\ell^{v_\ell}} \cdot \pi_p(tE(\mathbb{Q}))$ for all inert primes p, then

$$\max\{[E(K) : W_p]' : \text{ all inert } p\} = t'.$$

Proof. Let p be any inert prime, and recall that p is a prime of good reduction, since all bad primes split in K. By Lemma 5.1, the odd part of the image of $\pi_p : E(K) \to E(\mathbb{F}_p)/(p+1)$ is a cyclic group $\mathbb{Z}/n\mathbb{Z}$ for some integer n. Since $\pi_p(E^D(\mathbb{Q})) = 0$ (see Remark 5.6), we have

$$\pi_p(tE(\mathbb{Q}))' = \pi_p(tE(\mathbb{Q}) + tE^D(\mathbb{Q}))' = \pi_p(tE(K))',$$

so by Proposition 7.6, $W_p' = \pi_p^{-1}(X_p)' = \pi_p^{-1}(\pi_p(tE(K))')$. Thus Lemma 7.2 implies that $[E(K)' : W_p']$ is $\gcd(t,n)'$. This proves that set of indexes $[E(K)' : W_p']$ all divide t'.

We show the maximum equals t' by proving that there is a positive density of primes p such that the n above is divisible by t'. By hypothesis, there is a point $P \in E(\mathbb{Q})$ of infinite order. By Proposition 6.1, there exists a positive density of primes p that are inert in K such that $\pi_p(P) \in E(\mathbb{F}_p)/(p+1)$ has order divisible by t'. For such p, the n above is thus divisible by t', so $\gcd(t,n)' = t'$, which completes the proof. □

Let

$$w_\ell = \sup(\{\mathrm{ord}_\ell([E(K) : W_p]) : \text{ all inert } p\}) \le \infty. \tag{12}$$

Lemma 7.4. *Suppose $\ell \in B(E)$, that Conjecture 4.9 is true for E, and assume that p is an inert prime such that $\mathrm{ord}_\ell([E(K) : W_p])$ is maximal in the sense that it equals w_ℓ. Then $m_{\ell,f} = \mathrm{ord}_\ell([E(K) : W_p])$.*

Proof. We are assuming that Conjecture 4.9 is true, so Proposition 7.1 applies and gives an explicit formula for $X_p(\ell)$. Namely, we may take $t = m_{\ell,f}$ in Lemma 7.3. Also, by Conjecture 4.9 (and Proposition 4.11) we have $E(\mathbb{Q})$ has rank at least 1. The lemma then follows from Lemma 7.3. □

Theorem 7.5. *Suppose $\ell \in B(E)$, that Conjectures 2.2 and 4.9 are true for E, and that p is an inert prime such that $w_\ell = \mathrm{ord}_\ell([E(K) : W_p])$, where w_ℓ is as in (12) above. Then W_p satisfies the generalized Gross-Zagier formula (5) up to a rational factor that is coprime to ℓ if and only if Conjecture 4.12 is true for ℓ.*

Proof. We are assuming Conjecture 4.9, which implies Conjecture 4.1, so we may apply Theorem 4.2, which has Conjecture 4.1 as a hypothesis. Let b_k be as in Theorem 4.2 for our given prime ℓ. Theorem 4.2 implies that

$$\begin{aligned}\#Ш(E/K)(\ell) &= \#((\mathbb{Z}/b_f\mathbb{Z})^2 \oplus (\mathbb{Z}/b_{f+1}\mathbb{Z})^2 \oplus (\mathbb{Z}/b_{f+2}\mathbb{Z})^2 \oplus \cdots) \\ &= (b_f \cdot b_{f+1} \cdots)^2 \\ &= \ell^{2(m_{\ell,f} - m_{\ell,f+1} + m_{\ell,f+1} - m_{\ell,f+2} + m_{\ell,f+2} - \cdots)} \cdots \\ &= \ell^{2(m_{\ell,f} - m_\ell)},\end{aligned}$$

so $m_{\ell,f} - m_\ell = \mathrm{ord}_\ell(\sqrt{\#Ш(E/K)(\ell)})$.

We will now show that the generalized Gross-Zagier formula (5) holds up to a rational factor that is coprime to ℓ if and only if Conjecture 4.12 that $m_\ell = \mathrm{ord}_\ell(c\prod c_q)$ is true for ℓ. We will repeatedly use Lemma 7.4 that $m_{\ell,f} = \mathrm{ord}_\ell([E(K) : W_p])$.

First, suppose that the generalized Gross-Zagier formula (5) holds up to a rational factor that is coprime to ℓ. Proposition 2.4 combined with Conjecture 2.2 (that $Ш_{\mathrm{an}} = \#Ш$), implies that this hypothesis means that $\mathrm{ord}_\ell([E(K) : W_p]) = \mathrm{ord}_\ell\left(c\prod c_q \cdot \sqrt{\#Ш(E/K)(\ell)}\right)$. Thus:

$$\begin{aligned}m_{\ell,f} &= \mathrm{ord}_\ell([E(K) : W_p]) \\ &= \mathrm{ord}_\ell\left(c\prod c_q \cdot \sqrt{\#Ш(E/K)(\ell)}\right) \\ &= \mathrm{ord}_\ell\left(c\prod c_q\right) + \mathrm{ord}_\ell(\sqrt{\#Ш(E/K)(\ell)}) \\ &= \mathrm{ord}_\ell\left(c\prod c_q\right) + m_{\ell,f} - m_\ell,\end{aligned}$$

where in the last equality we use the formula for $\#Ш(E/K)(\ell)$ that we derived above using Theorem 4.2. Subtracting $m_{\ell,f}$ from both sides shows that $m_\ell = \mathrm{ord}_\ell(c\prod c_q)$.

Conversely, suppose that $m_\ell = \mathrm{ord}_\ell(c\prod c_q)$. From Theorem 4.2 we have

$$m_{\ell,f} - m_\ell = \mathrm{ord}_\ell(\sqrt{\#Ш(E/K)(\ell)}),$$

so

$$\mathrm{ord}_\ell([E(K) : W_p]) = m_{\ell,f} = \mathrm{ord}_\ell\left(c\prod c_q\right) + m_{\ell,f} - m_\ell = \mathrm{ord}_\ell\left(c\prod c_q \cdot \sqrt{\#Ш(E/K)(\ell)}\right).$$

Proposition 2.4 then implies that W_p satisfies the generalized Gross-Zagier formula up to a rational factor coprime to ℓ. □

For any integer n, let n' denote the maximal divisor of n that is divisible only by primes in $B(E)$, and for any abelian group A, let $A' = A \otimes \mathbb{Z}[1/b]$, where b is the product of the finitely many primes not in $B(E)$. Let

$$T = c \cdot \prod_{q|N} c_q \cdot \sqrt{\#\text{Ш}(E/K)}.$$

Proposition 7.6. *Conjectures 4.9 and 4.12 together imply that* $X_p' = \pi_p(TE(\mathbb{Q}))'$.

Proof. Using the calculation in the first paragraph of the proof of Theorem 7.5 along with Conjecture 4.12 combined with Theorem 4.2, shows that for every $\ell \in B(E)$, we have

$$m_{\ell,f} = \text{ord}_\ell(T).$$

Since the integers $T/\ell^{m_{\ell,f}}$ and $(p+1)/\ell^{v_\ell}$, for $v_\ell = \text{ord}_\ell(p+1)$, both act as automorphisms on any ℓ-primary group,

$$\begin{aligned}\pi_p(TE(\mathbb{Q}))(\ell) &= \left(\frac{T}{\ell^{m_{\ell,f}}} \cdot \pi_p(\ell^{m_{\ell,f}} E(\mathbb{Q}))\right)(\ell)\\ &= \pi_p(\ell^{m_{\ell,f}} E(\mathbb{Q}))(\ell)\\ &= \frac{p+1}{\ell^{v_\ell}} \cdot \pi_p(\ell^{m_{\ell,f}} E(\mathbb{Q})) = X_p(\ell),\end{aligned}$$

where the last equality uses Proposition 7.1 (which assumes that Conjecture 4.9 is true). We conclude that $X_p' = \pi(TE(\mathbb{Q}))'$.

Theorem 7.7 is a partial converse to Theorem 7.5.

Theorem 7.7. *Assume that $E(\mathbb{Q})$ has positive rank. Then Conjectures 4.9 and 4.12 together imply that the maximum index $[E(K)' : W_p']$ over all inert p is $(c \cdot \prod c_q \cdot \sqrt{\#\text{Ш}(E/K)})'$.*

Proof. The conjectures we're assuming allow us to use Proposition 7.6 and hence take $t = T$ in Lemma 7.3. This proves the theorem. □

Conclusion: By Proposition 2.4, if W_p' has maximal index in $E(K)'$, then imply that we have an equality

$$\frac{L^{(r)}(E,1)}{r!} = \frac{\|\omega\|^2}{c \cdot \sqrt{|D|}} \cdot \text{Reg}(W_p),$$

up to powers of primes not in $B(E)$. Thus the W_p' of maximal index satisfy this generalized Gross-Zagier formula.

Conjecture 7.8. *If $W \subset E(K)$ is* any *Gross-Zagier subgroup of index ℓ^{w_ℓ}, then there exists an inert prime p such that W_p' equals W'.*

8 Existence of Gross-Zagier Subgroups

Let E, K, etc., be as in Section 1.1, and let

$$t = c \cdot \prod_{q|N} c_q \cdot \sqrt{\#\text{Ш}(E/K)_{\text{an}}}.$$

In this section we investigate the analogue of the conjectures on pages 311–312 of [GZ86]. In particular, the existence of any Gross-Zagier subgroup for $E(K)$ combined with the BSD conjecture implies that $\#E(K)_{\text{tor}} \mid t$. The main theorem of [GZ86] thus led Gross-Zagier to make the following conjecture.

Conjecture 8.1 (Gross-Zagier)**.** *If $E(K)$ has rank 1, then the integer t is divisible by $\#E(\mathbb{Q})_{\text{tor}}$.*

Proposition 8.2. *Assume the BSD formula. If there exists any subgroup W of $E(K)$ such that the generalized Gross-Zagier formula (5) holds for W, then $\#E(K)_{\text{tor}} \mid t$. Note that we do not assume W is torsion free.*

Proof. Let W be such a subgroup. Arguing as in the proof of Proposition 2.4, we see that

$$\#E(K)_{\text{tor}}^2 \cdot (\text{Reg}(W)/\text{Reg}(E/K)) = c^2 \cdot \left(\prod_{q|N} c_q\right)^2 \cdot \text{Ш}_{\text{an}} = t^2.$$

The quotient $\text{Reg}(W)/\text{Reg}(E/K)$ is a square integer, so taking square roots of both sides yields the claim.

□

Because of Proposition 8.2, we view the divisibility $\#E(K)_{\mathrm{tor}} \mid t$ as a sort of *"litmus test"* for whether there could be a generalization of the Gross-Zagier formula in general. First, we observe that the most naive generalization of Conjecture 8.1 to higher rank is *false* (!), as the following example shows.

Example 8.3. *Let E be the curve 65a of rank 1 over $\mathbb{Q}$ given by $y^2 + xy = x^3 - x$ and let $D = -56$. Then $\#\text{Ш}_{\mathrm{an}}(E/K) = \prod c_q = c = 1$, so $t = 1$, but $\#E(\mathbb{Q})_{\mathrm{tor}} = 2$. Here $E^D(\mathbb{Q})$ has rank 2, so $\mathrm{rank}(E(K)) = 3$, and the rank hypothesis of Conjecture 8.1 is not satisfied.*

Proposition 8.4. *Suppose $\mathrm{rank}(E(\mathbb{Q})) > 0$ and that t is a positive integer. Then there exists a Gross-Zagier subgroup $W \subset E(K)$ if and only if $\#E(K)_{\mathrm{tor}} \mid t$.*

Proof. Suppose $W \subset E(K)$ is a Gross-Zagier subgroup. Then $[E(K) : W] = t$. By hypothesis W is torsion free, so $E(K)_{\mathrm{tor}} \hookrightarrow E(K)/W$, so $\#E(K)_{\mathrm{tor}} \mid \#(E(K)/W) = t$.

Conversely, suppose that $\#E(K)_{\mathrm{tor}} \mid t$, and note that by hypothesis $E(\mathbb{Q})$ has positive rank. The group $E(K)/(E^D(\mathbb{Q}) + E(K)_{\mathrm{tor}})$ is thus a finitely generated infinite abelian group, so has subgroups of all index. In particular, it has a subgroup W' such that the quotient by W' is cyclic of order $t/\#E(K)_{\mathrm{tor}}$. Let $\tilde{W}$ be the inverse image of W' in $E(K)$, so $E(K)_{\mathrm{tor}}, E^D(\mathbb{Q}) \subset \tilde{W}$, and $[E(K) : \tilde{W}] = t/\#E(K)_{\mathrm{tor}}$. Since $\tilde{W}$ is finitely generated, there exists a torsion free subgroup $W \subset \tilde{W}$ such that $W \oplus E(K)_{\mathrm{tor}} = \tilde{W}$. Then

$$[E(K) : W] = \#E(K)_{\mathrm{tor}} \cdot [E(K) : \tilde{W}] = \#E(K)_{\mathrm{tor}} \cdot \frac{t}{\#E(K)_{\mathrm{tor}}} = t.$$

□

Elsewehere in this paper, for technical reasons in order to apply Kolyvagin's theorems, we made a minimality hypothesis on $r_{\mathrm{an}}(E^D/\mathbb{Q})$, and based on extensive numerical data, we conjecture that this is the right hypothesis to guarantee the existence of Gross-Zagier subgroups $W \subset E(K)$.

Conjecture 8.5. *If $r_{\mathrm{an}}(E/\mathbb{Q}) > r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$, then $\#E(K)_{\mathrm{tor}} \mid t$. In particular, there exists a Gross-Zagier subgroup $W \subset E(K)$.*

We obtain evidence for Conjecture 8.5 using Sage[†] [S$^+$09, Creb, PAR], Cremona's tables [Crea], Proposition 8.4, and assuming the Birch and Swinnerton-Dyer conjecture. More precisely, we check that Conjecture 8.5 is "probably true" for every elliptic curve of rank ≥ 2 and conductor $\leq 130,000$ and the first three D that satisfy the Heegner hypothesis, except possibly for the triples $(E, D, \#E(K)_{\mathrm{tor}})$ in Table 1 where the computation of the conjectural order of $\#\text{Ш}(E/K)$ took too long.

Table 1: All triples up to conductor 130,000 where we did not yet verify Conjecture 8.5

$(8320e1, -191, 2), (9842d1, -223, 3), (9842d1, -255, 3), (9842d1, -447, 3), (74655j1, -251, 3),$
$(87680a1, -119, 2), (87680a1, -151, 2), (87680b1, -119, 2), (87680b1, -151, 2), (89465a1, -51, 2),$
$(89465a1, -59, 2), (89465a1, -71, 2), (95545b1, -191, 2), (95545b1, -219, 2), (104585b1, -139, 2),$
$(104585b1, -179, 2), (104585b1, -191, 2), (114260a1, -231, 2), (114260a1, -239, 2), (114260a1, -431, 2),$
$(122486a1, -103, 3), (122486a1, -55, 3), (122486a1, -87, 3), (126672r1, -335, 2), (126672r1, -647, 2),$
$(126672r1, -719, 2), (129940a1, -111, 2), (129940a1, -71, 2), (129940a1, -79, 2)$

In our computations, we considered the first three Heegner D, *without* making the condition $r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$. The conjecture is *false* without the hypothesis that $r_{\mathrm{an}}(E^D/\mathbb{Q}) \leq 1$, as Example 8.3 above shows. Moreover, we found two further similar examples in which, however, E has rank 2 and E^D has rank 3. First, for the curve E with Cremona label 20672m1, equation $y^2 = x^3 - 431x - 3444$ and $D = -127$, we have $\mathrm{rank}(E(\mathbb{Q})) = 2$, $\mathrm{rank}(E^D(\mathbb{Q})) = 3$, and $\#E(K)_{\mathrm{tor}} = 2$, but $t = 1$. A second example is E given by 18560c1 and $D = -151$, in which again $\mathrm{rank}(E(\mathbb{Q})) = 2$, $\mathrm{rank}(E^D(\mathbb{Q})) = 3$, $\#E(K)_{\mathrm{tor}} = 2$, but $t = 1$.

This was a large computation that relies on a range of nontrivial computer code, which we carried out as follows. First we computed $\#E(K)_{\mathrm{tor}}$ for each of the 78,420 elliptic curve of conductor $\leq$130,000 with rank ≥ 2 and the first three Heegner D. We then determined whether $\#E(K)_{\mathrm{tor}}$ divides $c \cdot \prod c_q$. Since we are verifying that something divides $c \cdot \prod c_q$, there is no loss at all in assuming Manin's conjecture that $c = 1$ for the optimal quotient of $X_0(N)$. We then computed the Manin constant c for non-optimal curves by finding a shortest isogeny path from the optimal curve in the isogeny graph of E (there is unfortunately a small possibility of error in computation of the isogeny graph, due to numerical precision used in the implementation). We found only 37 remaining curves E of rank ≥ 2 such that $\#E(K)_{\mathrm{tor}} \nmid c \cdot \prod c_q$, and $37 \cdot 3 = 111$ corresponding pairs (E, D). It

[†] Running on hardware purchased using National Science Foundation Grant No. DMS-0821725.

turns out that all of these curves are optimal hence have $c = 1$. For each of these pairs (E, D) we attempted to compute $\#Ш(E/K)_{\mathrm{an}}$ using Conjecture 2.2 and some results of [GJP+09], and the computation finished in all but 29 cases. The main difficulty was computing $\mathrm{Reg}(E/K)$ in terms of $\mathrm{Reg}(E/\mathbb{Q})$ and $\mathrm{Reg}(E^D/\mathbb{Q})$ by saturating the sum of $E(\mathbb{Q})$ and $E^D(\mathbb{Q})$ in $E(K)$. Computing $E^D(\mathbb{Q})$ was sometimes very difficult, since E^D has huge conductor and rank 1, and this sometimes took as long as a day when it completed. For more details, the reader is urged to read the source code of the Sage command `heegner_sha_an` in Sage-3.4.1 and later.

The Modular Degree, Congruence Primes and Multiplicity One

Amod Agashe Kenneth A. Ribet William A. Stein

Abstract.

The modular degree and congruence number are two fundamental invariants of an elliptic curve over the rational field. Frey and Müller have asked whether these invariants coincide. Although this question has a negative answer, we prove a theorem about the relation between the two invariants: one divides the other, and the ratio is divisible only by primes whose squares divide the conductor of the elliptic curve. We discuss the ratio even in the case where the square of a prime does divide the conductor, and we study analogues of the two invariants for modular abelian varieties of arbitrary dimension.

1 Introduction

Let E be an elliptic curve over $\mathbf{Q}$. By [BCDT01], we may view E as an abelian variety quotient over $\mathbf{Q}$ of the modular Jacobian $J_0(N)$, where N is the conductor of E. After possibly replacing E by an isogenous curve, we may assume that the kernel of the map $J_0(N) \to E$ is connected, i.e., that E is an *optimal quotient* of $J_0(N)$.

Let $f_E = \sum a_n q^n \in S_2(\Gamma_0(N))$ be the newform attached to E. The *congruence number* r_E of E is the largest integer such that there is an element $g = \sum b_n q^n \in S_2(\Gamma_0(N))$ with integer Fourier coefficients b_n that is orthogonal to f_E with respect to the Peterson innner product, and congruent to f_E modulo r_E (i.e., $a_n \equiv b_n \pmod{r_E}$ for all n). The *modular degree* m_E is the degree of the composite map $X_0(N) \to J_0(N) \to E$, where we map $X_0(N)$ to $J_0(N)$ by sending $P \in X_0(N)$ to $[P] - [\infty] \in J_0(N)$.

Section 2 is about relations between r_E and m_E. For example, $m_E \mid r_E$. In [FM99, Q. 4.4], Frey and Müller asked whether $r_E = m_E$. We give examples in which $r_E \neq m_E$, then conjecture that for any prime p, $\mathrm{ord}_p(r_E/m_E) \leq \frac{1}{2}\mathrm{ord}_p(N)$. We prove this conjecture when $\mathrm{ord}_p(N) \leq 1$.

In Section 3, we consider analogues of congruence primes and the modular degree for optimal quotients that are not necessarily elliptic curves; these are quotients of $J_0(N)$ and $J_1(N)$ of any dimension associated to ideals of the relevant Hecke algebras. In Section 4 we prove the main theorem of this paper, and in Section 5 we give some new examples of failure of multiplicity one motivated by the arguments in Section 4.

Acknowledgment. The authors are grateful to A. Abbes, R. Coleman, B. Conrad, J. Cremona, H. Lenstra, E. de Shalit, B. Edixhoven, L. Merel, and R. Taylor for several discussions and advice regarding this paper.

2 Congruence Primes and the Modular Degree

Let N be a positive integer and let $X_0(N)$ be the modular curve over $\mathbf{Q}$ that classifies isomorphism classes of elliptic curves with a cyclic subgroup of order N. The Hecke algebra $\mathbf{T}$ of level N is the subring of the ring of endomorphisms of $J_0(N) = \mathrm{Jac}(X_0(N))$ generated by the Hecke operators T_n for all $n \geq 1$. Let f be a newform of weight 2 for $\Gamma_0(N)$ with integer Fourier coefficients, and let I_f be kernel of the homomorphism $\mathbf{T} \to \mathbf{Z}[\ldots, a_n(f), \ldots]$ that sends T_n to a_n. Then the quotient $E = J_0(N)/I_f J_0(N)$ is an elliptic curve over $\mathbf{Q}$. We call E the *optimal quotient* associated to f. Composing the embedding $X_0(N) \hookrightarrow J_0(N)$ that sends ∞ to 0 with the quotient map $J_0(N) \to E$, we obtain a surjective morphism of curves $\phi_{E} : X_0(N) \to E$.

Definition 2.1. The *modular degree m_{E}* of E is the degree of ϕ_{E}.

Congruence primes have been studied by Doi, Hida, Ribet, Mazur and others (see, e.g., [Rib83, §1]), and played an important role in Wiles's work [Wil95] on Fermat's last theorem. Frey and Mai-Murty have observed that an appropriate asymptotic bound on the modular degree is equivalent to the *abc*-conjecture (see [Fre97, p.544] and [Mur99, p.180]). Thus, results that relate congruence primes and the modular degree are of great interest.

Theorem 2.2. *Let E be an elliptic curve over $\mathbf{Q}$ of conductor N, with modular degree m_{E} and congruence number r_{E}. Then $m_{E} \mid r_{E}$ and if $\mathrm{ord}_p(N) \leq 1$ then $\mathrm{ord}_p(r_{E}) = \mathrm{ord}_p(m_{E})$.*

We will prove a generalization of Theorem 2.2 in Section 4 below.

The divisibility $m_{E} \mid r_{E}$ was first discussed in [Zag85, Th. 3], where it is attributed to the second author (Ribet); however in [Zag85] the divisibility was mistakenly written in the opposite direction. For some other expositions of the proof, see [AU96, Lem 3.2] and [CK04]. We generalize this divisibility in Proposition 4.5. The second part of Theorem 2.2, i.e., that if $\mathrm{ord}_p(N) \leq 1$ then $\mathrm{ord}_p(r_{E}) = \mathrm{ord}_p(m_{E})$, follows from the more general Theorem 3.7 below. Note that [AU96, Prop. 3.3–3.4] implies the weaker statement that if $p \nmid N$ then $\mathrm{ord}_p(r_{E}) = \mathrm{ord}_p(m_{E})$, since [AU96, Prop. 3.3] implies

$$\mathrm{ord}_p(r_{E}) - \mathrm{ord}_p(m_{E}) = \mathrm{ord}_p(\#\mathcal{C}) - \mathrm{ord}_p(c_{E}) - \mathrm{ord}_p(\#\mathcal{D}),$$

Table 1: Differing Modular Degree and Congruence Number

Curve	m_E	r_E
54B1	2	6
64A1	2	4
72A1	4	8
80A1	4	8
88A1	8	16
92B1	6	12

135A1	12	36
144A1	4	8
144B1	8	16

and by [AU96, Prop. 3.4] $\mathrm{ord}_p(\#\mathcal{C}) = 0$. (Here c_E is the Manin constant of E, which is an integer by results of Edixhoven and Katz-Mazur; see e.g., [ARS06] for more details.)

Frey and Müller [FM99, Ques. 4.4] asked whether $r_E = m_E$ in general. After implementing an algorithm to compute r_E in Magma [BCP97], we quickly found that the answer is no. The counterexamples at conductor $N \leq 144$ are given in Table 1, where the curve is given using the notation of [Cre97]:

For example, the elliptic curve 54B1, given by the equation $y^2 + xy + y = x^3 - x^2 + x - 1$, has $r_E = 6$ and $m_E = 2$. To see explicitly that $3 \mid r_E$, observe that the newform corresponding to E is $f = q + q^2 + q^4 - 3q^5 - q^7 + \cdots$ and the newform corresponding to $X_0(27)$ if $g = q - 2q^4 - q^7 + \cdots$, so $g(q) + g(q^2)$ appears to be congruent to f modulo 3. To prove this congruence, we checked it for 18 Fourier coefficients, where the sufficiency of precision to degree 18 was determined using [Stu87].

In our computations, there appears to be no absolute bound on the p that occur. For example, for the curve 242B1 of conductor $N = 2 \cdot 11^2$ we have[1]

$$m_E = 2^4 \neq r_E = 2^4 \cdot 11.$$

We propose the following replacement for Question 4.4 of [FM99]:

Conjecture 2.3. *Let E be an optimal elliptic curve of conductor N and p be any prime. Then*

$$\mathrm{ord}_p\left(\frac{r_E}{m_E}\right) \leq \frac{1}{2}\,\mathrm{ord}_p(N).$$

We verified Conjecture 2.3 using Magma for every optimal elliptic curve quotient of $J_0(N)$, with $N \leq 539$.

If $p \geq 5$ then $\mathrm{ord}_p(N) \leq 2$, so a special case of the conjecture is

$$\mathrm{ord}_p\left(\frac{r_E}{m_E}\right) \leq 1 \qquad \text{for any } p \geq 5.$$

[1] The curve 242a1 in "modern notation."

Remark 2.4. It is often productive to parametrize elliptic curves by $X_1(N)$ instead of $X_0(N)$ (see, e.g., [Ste89] and [Vat05]). Suppose E is an optimal quotient of $X_1(N)$, let m'_E be the degree of the modular parametrization, and let r'_E be the $\Gamma_1(N)$-congruence number, which is defined as above but with $S_2(\Gamma_0(N))$ replaced by $S_2(\Gamma_1(N))$. For the optimal quotient of $X_1(N)$ isogenous to 54B1, we find using Magma that $m'_E = 18$ and $r'_E = 6$. Thus the equality $m'_E = r'_E$ fails, and the analogous divisibility $m'_E \mid r'_E$ no longer holds. Also, for a curve of conductor 38 we have $m'_E = 18$ and $r'_E = 6$, so equality need not hold even if the level is square free. We hope to investigate this in a future paper.

3 Modular abelian varieties of arbitrary dimension

For $N \geq 4$, let Γ be a fixed choice of either $\Gamma_0(N)$ or $\Gamma_1(N)$, let X be the modular curve over $\mathbf{Q}$ associated to Γ, and let J be the Jacobian of X. Let I be a *saturated* ideal of the corresponding Hecke algebra $\mathbf{T} \subset \mathrm{End}(J)$, so $\mathbf{T}/I$ is torsion free. Then $A = A_I = J/IJ$ is an optimal quotient of J since IJ is an abelian subvariety.

Definition 3.1. If $f = \sum a_n(f)q^n \in S_2(\Gamma)$ and $I_f = \ker(\mathbf{T} \to \mathbf{Z}[\ldots, a_n(f), \ldots])$, then $A = A_f = J/I_f J$ is the *newform quotient* associated to f. It is an abelian variety over $\mathbf{Q}$ of dimension equal to the degree of the field $\mathbf{Q}(\ldots, a_n(f), \ldots)$.

In this section, we generalize the notions of the congruence number and the modular degree to quotients $A = A_I$, and state a theorem relating the two numbers, which we prove in Sections 4.1–4.2.

Let ϕ_2 denote the quotient map $J \to A$. By Poincare reducibility over $\mathbf{Q}$ there is a unique abelian subvariety $A^\vee$ of J that projects isogenously to the quotient A (equivalently, which has finite intersection with $\ker(\phi_2)$), and so by Hecke equivariance of $J \to A$ it follows that $A^\vee$ is $\mathbf{T}$-stable. Let ϕ be the composite isogeny

$$\phi : A^\vee \xrightarrow{\phi_1} J \xrightarrow{\phi_2} A.$$

Remark 3.2. Note that $A^\vee$ is the dual abelian variety of A. More generally, if C is any abelian variety, let $C^\vee$ denote the dual of C. There is a canonical principal polarization $J \cong J^\vee$, and dualizing ϕ_2, we obtain a map $\phi_2^\vee : A^\vee \to J^\vee$, which we compose with $\theta^{-1} : J^\vee \cong J$ to obtain a map $\phi_1 : A^\vee \to J$. Note also that φ is a polarization (induced by pullback of the theta divisor).

The *exponent* of a finite group G is the smallest positive integer n such that every element of G has order dividing n.

Definition 3.3. The *modular exponent* of A is the exponent of the kernel of the isogeny ϕ, and the *modular number* of A is the degree of ϕ.

We denote the modular exponent of A by $\tilde{n}_{A}$ and the modular number by n_{A}. When A is an elliptic curve, the modular exponent is equal to the modular degree of A, and the modular number is the square of the modular degree (see, e.g., [AU96, p. 278]).

If R is a subring of $\mathbf{C}$, let $S_2(R) = S_2(\Gamma; R)$ denote the subgroup of $S_2(\Gamma)$ consisting of cups forms whose Fourier expansions at the cusp ∞ have coefficients in R. (Note that Γ is fixed for this whole section.) Let $S_2(\Gamma;\mathbf{Z})[I]^{\perp}$ denote the orthogonal complement of $S_2(\Gamma;\mathbf{Z})[I]$ in $S_2(\Gamma;\mathbf{Z})$ with respect to the Petersson inner product.

The following is well known, but we had difficulty finding a good reference.

Proposition 3.4. *The group $S_2(\Gamma;\mathbf{Z})$ is of finite rank as a $\mathbf{Z}$-module.*

Proof. Using the standard pairing between $\mathbf{T}$ and $S_2(\Gamma,\mathbf{Z})$ (see also [Rib83, Theorem 2.2]) we see that $S_2(\Gamma,\mathbf{Z}) \cong \mathrm{Hom}(\mathbf{T},\mathbf{Z})$. Thus $S_2(\Gamma,\mathbf{Z})$ is finitely generated over $\mathbf{Z}$ if and only if $\mathbf{T}$ is finitely generated over $\mathbf{Z}$. But the action of $\mathbf{T}$ on $\mathrm{H}_1(J,\mathbf{Z})$ is a faithful representation that embeds $\mathbf{T}$ into $\mathrm{Mat}_{2d}(\mathbf{Z}) \cong \mathbf{Z}^{(2d)^2}$. But $\mathbf{Z}$ is Noetherian, so $\mathbf{T}$ is finitely generated over $\mathbf{Z}$. □

Definition 3.5. The exponent of the quotient group

$$\frac{S_2(\Gamma;\mathbf{Z})}{S_2(\Gamma;\mathbf{Z})[I] + S_2(\Gamma;\mathbf{Z})[I]^{\perp}} \tag{1}$$

is the *congruence exponent* $\tilde{r}_{A}$ of A and its order is the *congruence number* r_{A}.

Remark 3.6. Note that $S_2(\Gamma,\mathbf{Z}) \otimes_{\mathbf{Z}} R = S_2(\Gamma,R)$; see, e.g., the discussion in [DI95, §12]. Thus the analogue of Definition 3.5 with $\mathbf{Z}$ replaced by an algebraic integer ring (or even $\overline{\mathbf{Z}}$) gives a torsion module whose annihilator ideal meets $\mathbf{Z}$ in the ideal generated by the congruence exponent.

Our definition of r_{A} generalizes the definition in Section 2 when A is an elliptic curve (see [AU96, p. 276]), and the following generalizes Theorem 2.2:

Theorem 3.7. *If $f \in S_2(\mathbf{C})$ is a newform, then*

(a) We have $\tilde{n}_{A_f} \mid \tilde{r}_{A_f}$, and

(b) If $p^2 \nmid N$, then $\mathrm{ord}_p(\tilde{r}_{A_f}) = \mathrm{ord}_p(\tilde{n}_{A_f})$.

Remark 3.8. When A_f is an elliptic curve, Theorem 3.7 implies that the modular degree divides the congruence number (since for an elliptic curve the modular degree and modular exponent are the same), i.e., $\sqrt{n_{A_f}} \mid r_{A_f}$. In general, the divisibility $n_{A_f} \mid r_{A_f}^2$ need not hold. For example, there is a newform of degree 24 in $S_2(\Gamma_0(431))$ such that

$$n_{A_f} = (2^{11}\cdot 6947)^2 \nmid r_{A_f}^2 = (2^{10}\cdot 6947)^2.$$

Note that 431 is prime and mod 2 multiplicity one fails for $J_0(431)$ (see [Kil02]).

4 Proof of the Main Theorem

In this section we prove Theorem 3.7. We continue using the notation introduced so far.

4.1 Proof of Theorem 3.7 (a)

We begin with a remark about compatibilities. In general, the polarization of J induced by the theta divisor need not be Hecke equivariant, because if T is a Hecke operator on J, then on $J^\vee$ it acts as $W_N T W_N$, where W_N is the Atkin-Lehner involution (see e.g., [DI95, Rem. 10.2.2]). However, on J^{new} the action of the Hecke operators commutes with that of W_N, so if the quotient map $J \to A$ factors through J^{new}, then the Hecke action on $A^\vee$ induced by the embedding $A^\vee \to J^\vee$ and the action on $A^\vee$ induced by $\phi_1 : A^\vee \to J$ are the same. Hence $A^\vee$ is isomorphic to $\phi_1(A^\vee)$ as a $\mathbf{T}$-module.

Recall that f is a newform, $I_f = \mathrm{Ann}_{\mathbf{T}}(f)$, and $J = J_0(N)$. Let $B = I_f J$, so that $A^\vee + B = J$, and $J/B \cong A$. The following lemma is well known, but we prove it here for the convenience of the reader.

Lemma 4.1. $\mathrm{Hom}_{\mathbf{Q}}(A^\vee, B) = 0$.

Proof. Pick a prime ℓ. Then $\overline{\mathbf{Q}}_\ell \otimes V_\ell(J)^{\mathrm{ss}}$ as a $\overline{\mathbf{Q}}_\ell[G_{\mathbf{Q}}]$-module is a direct sum of copies of the representations ρ_g as g ranges through all normalized eigenforms of weight 2 and level N with coefficients in $\overline{\mathbf{Q}}$; by a well-known result of the second author, these representations are absolutely irreducible. Now since f is a newform and $A^\vee \to A$ is an isogeny, $\overline{\mathbf{Q}}_\ell \otimes V_\ell(A^\vee)^{\mathrm{ss}}$ is a direct sum of copies of $\rho_{\sigma(f)}$ as σ ranges over all embeddings of K_f into $\overline{\mathbf{Q}}$. Thus, by the analytic theory of multiplicity one (see [Li75, Cor. 3, pg. 300]), the Galois modules $V_\ell(A^\vee)$ and $V_\ell(B) = V_\ell(J)/V_\ell(A^\vee)$ share no common Jordan-Hölder factors even when coefficients are extended to $\overline{\mathbf{Q}}_\ell$, so $\mathrm{Hom}_{\mathbf{Q}}(A', B) = 0$. □

Let $\mathbf{T}_1$ be the image of $\mathbf{T}$ in $\mathrm{End}(A^\vee)$, and let $\mathbf{T}_2$ be the image of $\mathbf{T}$ in $\mathrm{End}(B)$. We have the following commutative diagram with exact rows:

$$\begin{tikzcd}
0 \arrow[r] & \mathbf{T} \arrow[r] \arrow[d] & \mathbf{T}_1 \oplus \mathbf{T}_2 \arrow[r] \arrow[d] & \dfrac{\mathbf{T}_1 \oplus \mathbf{T}_2}{\mathbf{T}} \arrow[r] \arrow[d, dotted] & 0 \\
0 \arrow[r] & \mathrm{End}(J) \arrow[r] & \mathrm{End}(A^\vee) \oplus \mathrm{End}(B) \arrow[r] & \dfrac{\mathrm{End}(A^\vee) \oplus \mathrm{End}(B)}{\mathrm{End}(J)} \arrow[r] & 0.
\end{tikzcd} \tag{2}$$

Let

$$e = (1, 0) \in \mathbf{T}_1 \oplus \mathbf{T}_2,$$

and let e_1 and e_2 denote the images of e in the groups $(\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}$ and $(\mathrm{End}(A^\vee) \oplus \mathrm{End}(B))/\mathrm{End}(J)$, respectively. It follows from Lemma 4.1 that the two quotient groups on the right hand side of (2) are finite, so e_1 and e_2

have finite order. Note that because e_2 is the image of e_1, the order of e_2 is a divisor of the order of e_1.

The *denominator* of any $\varphi \in \mathrm{End}(J) \otimes \mathbf{Q}$ is the smallest positive integer n such that $n\varphi \in \mathrm{End}(J)$.

Let $\pi_{A^\vee}, \pi_B \in \mathrm{End}(J) \otimes \mathbf{Q}$ be projection onto $A^\vee$ and B, respectively. Note that the denominator of $\pi_{A^\vee}$ equals the denominator of π_B, since $\pi_{A^\vee} + \pi_B = 1_J$, so that $\pi_B = 1_J - \pi_{A^\vee}$.

Lemma 4.2. *The element $e_2 \in (\mathrm{End}(A^\vee) \oplus \mathrm{End}(B))/\mathrm{End}(J)$ defined above has order $\tilde{n}_A$.*

Proof. Let n be the order of e_2, so n is the denominator of $\pi_{A^\vee}$, which, as mentioned above, is also the denominator of π_B. We want to show that n is equal to $\tilde{n}_A$, the exponent of $A^\vee \cap B$.

Let $i_{A^\vee}$ and i_B be the embeddings of $A^\vee$ and B into J, respectively. Then

$$\varphi = (n\pi_{A^\vee}, n\pi_B) \in \mathrm{Hom}(J, A^\vee \times B)$$

and $\varphi \circ (i_{A^\vee} + i_B) = [n]_{A^\vee \times B}$. We have an exact sequence

$$0 \to A^\vee \cap B \xrightarrow{x \mapsto (x,-x)} A^\vee \times B \xrightarrow{i_{A^\vee} + i_B} J \to 0.$$

Let Δ be the image of $A^\vee \cap B$. Then by exactness,

$$[n]\Delta = (\varphi \circ (i_{A^\vee} + i_B))(\Delta) = \varphi \circ ((i_{A^\vee} + i_B)(\Delta)) = \varphi(\{0\}) = \{0\},$$

so n is a multiple of the exponent $\tilde{n}_A$ of $A^\vee \cap B$.

To show the opposite divisibility, consider the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & A^\vee \cap B \arrow[r, "x \mapsto (x,-x)"] \arrow[d, "{[\tilde{n}_A]}"] & A^\vee \times B \arrow[r] \arrow[d, "{([\tilde{n}_A],0)}"] & J \arrow[r] \arrow[d, dotted, "\psi"] & 0 \\
0 \arrow[r] & A^\vee \cap B \arrow[r, "x \mapsto (x,-x)"] & A^\vee \times B \arrow[r] & J \arrow[r] & 0,
\end{tikzcd}$$

where the middle vertical map is $(a, b) \mapsto (\tilde{n}_A a, 0)$ and the map ψ exists because $[\tilde{n}_A](A^\vee \cap B) = 0$. But $\psi = \tilde{n}_A \pi_{A^\vee}$ in $\mathrm{End}(J) \otimes \mathbf{Q}$. This shows that $\tilde{n}_A \pi_{A^\vee} \in \mathrm{End}(J)$, i.e., that $\tilde{n}_A$ is a multiple of the denominator n of $\pi_{A^\vee}$.

□

Let $\mathrm{Ext}^1 = \mathrm{Ext}^1_{\mathbf{Z}}$ denote the first Ext functor in the category of $\mathbf{Z}$-modules.

Lemma 4.3. *The group $(\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}$ is isomorphic to the quotient (1) in Definition 3.5, so $r_A = \#((\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T})$ and $\tilde{r}_A$ is the exponent of $(\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}$. More precisely, $\mathrm{Ext}^1((\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}, \mathbf{Z})$ is isomorphic as a $\mathbf{T}$-module to the quotient (1).*

Proof. Apply the $\mathrm{Hom}(-, \mathbf{Z})$ functor to the first row of (2) to obtain a three-term exact sequence

$$0 \to \mathrm{Hom}(\mathbf{T}_1 \oplus \mathbf{T}_2, \mathbf{Z}) \to \mathrm{Hom}(\mathbf{T}, \mathbf{Z}) \to \mathrm{Ext}^1((\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}, \mathbf{Z}) \to 0. \qquad (3)$$

There is a $\mathbf{T}$-equivariant bilinear pairing $\mathbf{T} \times S_2(\mathbf{Z}) \to \mathbf{Z}$ given by $(t, g) \mapsto a_1(t(g))$, which is perfect by [AU96, Lemma 2.1] (see also [Rib83, Theorem 2.2]). Using this pairing, we transform (3) into an exact sequence

$$0 \to S_2(\mathbf{Z})[I_f] \oplus S_2(\Gamma; \mathbf{Z})[I_f]^{\perp} \to S_2(\mathbf{Z}) \to \mathrm{Ext}^1((\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}, \mathbf{Z}) \to 0$$

of $\mathbf{T}$-modules. Here we use that $\mathrm{Hom}(\mathbf{T}_2, \mathbf{Z})$ is the unique saturated Hecke-stable complement of $S_2(\mathbf{Z})[I_f]$ in $S_2(\mathbf{Z})$, hence must equal $S_2(\mathbf{Z})[I_f]^{\perp}$. Finally note that if G is any finite abelian group, then $\mathrm{Ext}^1(G, \mathbf{Z}) \approx G$ as groups, which gives the desired result. □

LEMMA 4.4. *The element $e_1 \in (\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}$ has order $\tilde{r}_A$.*

Proof. By Lemma 4.3, the lemma is equivalent to the assertion that the order r of e_1 equals the exponent of $M = (\mathbf{T}_1 \oplus \mathbf{T}_2)/\mathbf{T}$. Since e_1 is an element of M, the exponent of M is divisible by r.

To obtain the reverse divisibility, consider any element x of M. Let $(a, b) \in \mathbf{T}_1 \oplus \mathbf{T}_2$ be such that its image in M is x. By definition of e_1 and r, we have $(r, 0) \in \mathbf{T}$, and since $1 = (1, 1) \in \mathbf{T}$, we also have $(0, r) \in \mathbf{T}$. Thus $(\mathbf{T}r, 0)$ and $(0, \mathbf{T}r)$ are both subsets of $\mathbf{T}$ (i.e., in the image of $\mathbf{T}$ under the map $\mathbf{T} \to \mathbf{T}_1 \oplus \mathbf{T}_2$), so $r(a, b) = (ra, rb) = (ra, 0) + (0, rb) \in \mathbf{T}$. This implies that the order of x divides r. Since this is true for every $x \in M$, we conclude that the exponent of M divides r. □

PROPOSITION 4.5. *If $f \in S_2(\mathbf{C})$ is a newform, then $\tilde{n}_{A_f} \mid \tilde{r}_{A_f}$.*

Proof. Since e_2 is the image of e_1 under the right-most vertical homomorphism in (2), the order of e_2 divides that of e_1. Now apply Lemmas 4.2 and 4.4. □

This finishes the proof of the first statement in Theorem 3.7.

4.2 PROOF OF THEOREM 3.7 (B)

Let $\mathbf{T}'$ be the saturation of $\mathbf{T} = \mathbf{Z}[\ldots, T_n, \ldots]$ in $\mathrm{End}(J_0(N))$, i.e., the set of elements of $\mathrm{End}(J_0(N)) \otimes \mathbf{Q}$ some positive multiple of which lie in $\mathbf{T}$. The quotient $\mathbf{T}'/\mathbf{T}$ is a finitely generated abelian group because both $\mathbf{T}$ and $\mathrm{End}(J_0(N))$ are finitely generated over $\mathbf{Z}$. Since $\mathbf{T}'/\mathbf{T}$ is also a torsion group, it is finite.

In Section 4.2.1, we will give some conditions under which $\mathbf{T}$ and $\mathbf{T}'$ agree locally at maximal ideal of $\mathbf{T}$. In Section 4.2.2, we will explain how the ratio of the congruence number to the modular degree is closely related to the order of $\mathbf{T}'/\mathbf{T}$, and finally deduce that this ratio is 1 (for quotients associated to newforms) locally at a prime p such that $p^2 \nmid N$.

4.2.1 Multiplicity One

Fixt an integer N and a prime $p \mid N$. Suppose for a moment that N is prime, so $p = N$. In [Maz77], Mazur proves that $\mathbf{T} = \mathbf{T}'$; he combines this result with the equality

$$\mathbf{T} \otimes \mathbf{Q} = \mathrm{End}(J_0(p)) \otimes \mathbf{Q},$$

to deduce that $\mathbf{T} = \mathrm{End}(J_0(p))$. This result, combined with Ribet's result [Rib75] or [Rib81] to the effect that $\mathbf{T} \otimes \mathbf{Q} = (\mathrm{End}_{\overline{\mathbf{Q}}} J_0(N)) \otimes \mathbf{Q}$, shows that $\mathbf{T}$ is the full ring of endomorphisms of $J_0(N)$ over $\overline{\mathbf{Q}}$. When N is no longer necessarily prime, the method of [Maz77] shows that $\mathbf{T}$ and $\mathbf{T}'$ agree locally at a maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ that satisfies a simple condition involving differentials form mod ℓ, where ℓ is the residue characteristic of $\mathfrak{m}$.

For the sake of completeness, we state and prove a lemma that can be easily extracted from [Maz77]. Let m be the largest square dividing N and let $R = \mathbf{Z}[\frac{1}{m}]$. Let $X_0(N)_R$ denote the minimal regular model of $X_0(N)$ over R. Let $\Omega = \Omega_{X_0(N)/R}$ denote the sheaf of regular differentials on $X_0(N)_R$, as in [Maz78, §2(e)]. If ℓ is a prime such that $\ell^2 \nmid N$, then $X_0(N)_{\mathbf{F}_\ell}$ denotes the special fiber of $X_0(N)_R$ at the prime ℓ.

Lemma 4.6 (Mazur). *Let $\mathfrak{m}$ be a maximal ideal of $\mathbf{T}$ of residue characteristic ℓ such that $\ell^2 \nmid N$. Suppose that*

$$\dim_{\mathbf{T}/\mathfrak{m}} \mathrm{H}^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}] \leq 1.$$

Then $\mathbf{T}$ and $\mathbf{T}'$ agree locally at $\mathfrak{m}$.

Proof. Let M denote the group $H^1(X_0(N)_R, \mathcal{O}_{X_0(N)})$, where $\mathcal{O}_{X_0(N)}$ is the structure sheaf of $X_0(N)$. As explained in [Maz77, p. 95], we have an action of $\mathrm{End}_{\mathbf{Q}} J_0(N)$ on M, and the action of $\mathbf{T}$ on M via the inclusion $\mathbf{T} \subseteq \mathrm{End}_{\mathbf{Q}} J_0(N)$ is faithful, so likewise for the action by $\mathbf{T}'$. Hence we have an injection $\phi : \mathbf{T}' \hookrightarrow \mathrm{End}_{\mathbf{T}} M$. Suppose $\mathfrak{m}$ is a maximal ideal of $\mathbf{T}$ that satisfies the hypotheses of the lemma. To prove that $\mathbf{T}_{\mathfrak{m}} = \mathbf{T}'_{\mathfrak{m}}$ it suffices to prove the following claim:

Claim: The map $\phi|_{\mathbf{T}}$ is surjective locally at $\mathfrak{m}$.

Proof. By Nakayama's lemma, to show that M is generated as a single element over $\mathbf{T}$ locally at $\mathfrak{m}$, it suffices to check that the dimension of the $\mathbf{T}/\mathfrak{m}$-vector space $M/\mathfrak{m}M$ is at most one. Since $\ell^2 \nmid N$, $M/\mathfrak{m}M$ is dual to $H^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}]$ (see, e.g., [Maz78, §2]). Since we are assuming that $\dim_{\mathbf{T}/\mathfrak{m}} H^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}] \leq 1$, we have $\dim_{\mathbf{T}/\mathfrak{m}}(M/\mathfrak{m}M) \leq 1$, which proves the claim. □

□

If $\mathfrak{m}$ is a maximal ideal of the Hecke algebra $\mathbf{T}$ of residue characteristic ℓ, we say that $\mathfrak{m}$ satisfies *multiplicity one for differentials* if

$$\dim(\mathrm{H}^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}]) \leq 1.$$

By Lemma 4.6, multiplicity one for $\mathrm{H}^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}]$ implies that $\mathbf{T}$ and $\mathbf{T}'$ agree at $\mathfrak{m}$.

There is quite a bit of literature on the question of multiplicity 1 for $\mathrm{H}^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}]$. The easiest case is that ℓ is prime to the level N:

LEMMA 4.7 (Mazur). *If* $\mathfrak{m}$ *is a maximal ideal of* $\mathbf{T}$ *of residue characteristic* ℓ *such that* $\ell \nmid N$*, then*

$$\dim_{\mathbf{T}/\mathfrak{m}} \mathrm{H}^0(X_0(N)_{\mathbf{F}_\ell}, \Omega)[\mathfrak{m}] \leq 1.$$

Proof. Mazur deduces this lemma from injectivity of the q-expansion map. The reader may find the following alternative approach to part of the argument easier to follow than the one on p. 95 of [Maz77]. We have an $\mathbf{F}_\ell$-vector space that embeds in $\mathbf{F}_\ell[[q]]$, for example a space V of differentials that is killed by a maximal ideal $\mathfrak{m}$. This space is a $\mathbf{T}/\mathfrak{m}$-vector space, and we want to see that its dimension over $\mathbf{T}/\mathfrak{m}$ is at most 1. Mazur invokes tensor products and eigenvectors; alternatively, we note that V embeds in $\mathrm{Hom}_{\mathbf{F}_\ell}(\mathbf{T}/\mathfrak{m}, \mathbf{F}_\ell)$ via the standard duality that sends $v \in V$ to the linear form whose value on a Hecke operator T is the qth coefficient of $v|T$. The group $\mathrm{Hom}_{\mathbf{F}_\ell}(\mathbf{T}/\mathfrak{m}, \mathbf{F}_\ell)$ has the same size as $\mathbf{T}/\mathfrak{m}$, which completes the argument because $\mathrm{Hom}_{\mathbf{F}_\ell}(\mathbf{T}/\mathfrak{m}, \mathbf{F}_\ell)$ has dimension 1 as a $\mathbf{T}/\mathfrak{m}$-vector space. □

In the context of Mazur's paper, where the level N is prime, we see from Lemma 4.7 that $\mathbf{T}$ and $\mathbf{T}'$ agree away from N. Locally at N, Mazur proved that $\mathbf{T} = \mathbf{T}'$ by an analogue of the arguments that he used away from N; see Chapter II of [Maz77] (and especially Prop. 9.4 and 9.5 of that chapter) as well as [MR91], where these arguments are taken up in a context where the level is no longer necessarily prime (and where one works locally at a prime whose square does not divide the level). Thus in the prime level case, $\mathbf{T} = \mathbf{T}'$, as we asserted above.

Now let p be a prime such that $p \parallel N$, and let $M = N/p$. The question of multiplicity 1 at p for $\mathrm{H}^0(X_0(pM)_{\mathbf{F}_p}, \Omega)[\mathfrak{m}]$ is discussed in [MR91], where the authors establish multiplicity 1 for maximal ideals $\mathfrak{m} \mid p$ for which the associated mod p Galois representation is irreducible and *not* p-old. (A representation of level pM is p-old if it arises from $S_2(\Gamma_0(M))$.)

If $\mathfrak{m}$ is a maximal ideal of $\mathbf{T}$ of residue characteristic ℓ, then we say that $\mathfrak{m}$ is ordinary if $T_\ell \notin \mathfrak{m}$ (note that T_ℓ is often denoted U_ℓ if $\ell \mid N$). For our purposes, the following lemma is convenient:

LEMMA 4.8 (Wiles). *If* $\mathfrak{m}$ *is an ordinary maximal ideal of* $\mathbf{T}$ *of characteristic* p*, then*

$$\dim_{\mathbf{T}/\mathfrak{m}} \mathrm{H}^0(X_0(pM)_{\mathbf{F}_p}, \Omega)[\mathfrak{m}] \leq 1.$$

This is essentially Lemma 2.2 in [Wil95, pg. 485]; we make a few comments about how it applies on our situation:

1. Wiles considers $X_1(M,p)$ instead of $X_0(pM)$, which means that he is using $\Gamma_1(M)$-structure instead of $\Gamma_0(M)$-structure. This surely has no relevance to the issue at hand.

2. Wiles assumes (on page 480) that p is an odd prime, but again this assumption is not relevant to our question.

3. The condition that $\mathfrak{m}$ is ordinary does not appear explicitly in the statement of Lemma 2.2 in [Wil95]; instead it is a reigning assumption in the context of his discussion.

4. We see by example that Wiles's "ordinary" assumption is less stringent than the assumption in [MR91]; note that [MR91] rule out cases where $\mathfrak{m}$ is both old and new at p, whereas Wiles is happy to include such cases. (On the other hand, Wiles's assumption is certainly nonempty, since it rules out maximal ideals $\mathfrak{m}$ that arise from non-ordinary (old) forms of level M. Here is an example with $p = 2$ and $M = 11$, so $N = 22$: There is a unique newform $f = \sum a_n q^n$ of level 11, and $\mathbf{T} = \mathbf{Z}[T_2] \subset \mathrm{End}(J_0(22))$, where $T_2^2 - a_2 T_2 + 2 = 0$. Since $a_2 = -2$, we have $\mathbf{T} \cong \mathbf{Z}[\sqrt{-1}]$. We can choose the square root of -1 to be $T_2 + 1$. Then T_2 is a generator of the unique maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ with residue characteristic 2, and this maximal ideal is not ordinary.)

We now summarize the conclusions we can make from the lemmas so far:

Proposition 4.9. *The modules $\mathbf{T}$ and $\mathbf{T}'$ agree locally at each maximal ideal $\mathfrak{m}$ that is either prime to N or that satisfies the following supplemental hypothesis: the residue characteristic of $\mathfrak{m}$ divides N only to the first power and $\mathfrak{m}$ is ordinary.*

Proof. This follows easily from Lemmas 4.6, 4.7, and 4.8. □

In Mazur's original context, where the level N is prime, we have $T_N^2 = 1$ because there are no forms of level 1. Accordingly, each $\mathfrak{m}$ dividing N is ordinary, and we recover Mazur's equality $\mathbf{T} = \mathbf{T}'$ in this special case.

4.2.2 Degrees and Congruences

Let $e \in \mathbf{T} \otimes \mathbf{Q}$ be as in Section 4.1, and let p, N, M be as before Lemma 4.8. The image of e in $J_0(pM)$ is the $\mathbf{T}$-stable abelian subvariety denoted $A^\vee$ in Section 4.1, but since we shall now exclusively work with this subvariety rather than the corresponding optimal quotient of $J_0(pM)$ (which was denoted A earlier), we will now write A to denote the image of e (without risk of confusion). We also write B to denote the unique $\mathbf{T}$-stable abelian subvariety of $J_0(pM)$ complementary to A.

For $t \in \mathbf{T}$, let t_A be the restriction of t to A, and let t_B be the image of t in $\mathrm{End}(B)$. Let $\mathbf{T}_A$ be the subgroup of $\mathrm{End}(A)$ consisting of the various t_A, and define $\mathbf{T}_B$ similarly. As before, we obtain an injection $j : \mathbf{T} \hookrightarrow \mathbf{T}_A \times \mathbf{T}_B$ with finite cokernel. Because j is an injection, we refer to the maps $\pi_A : \mathbf{T} \to \mathbf{T}_A$ and $\pi_B : \mathbf{T} \to \mathbf{T}_B$, given by $t \mapsto t_A$ and $t \mapsto t_B$, respectively, as "projections".

Definition 4.10. The *congruence ideal* associated with the projector e is $I = \pi_A(\ker(\pi_B)) \subset \mathbf{T}_A$.

Viewing $\mathbf{T}_A$ as $\mathbf{T}_A \times \{0\}$, we may view $\mathbf{T}_A$ as a subgroup of $\mathbf{T} \otimes \mathbf{Q} \cong (\mathbf{T}_A \times \mathbf{T}_B) \otimes \mathbf{Q}$. Also, we may view $\mathbf{T}$ as embedded in $\mathbf{T}_A \times \mathbf{T}_B$, via the map j.

Lemma 4.11. *We have* $I = \mathbf{T}_A \cap \mathbf{T}$.

A larger ideal of $\mathbf{T}_A$ is $J = \mathrm{Ann}_{\mathbf{T}_A}(A \cap B)$; it consists of restrictions to A of Hecke operators that vanish on $A \cap B$.

Lemma 4.12. *We have* $I \subset J$.

Proof. The image in $\mathbf{T}_A$ of an operator that vanishes on B also vanishes on $A \cap B$. □

Lemma 4.13. *We have* $J = \mathbf{T}_A \cap \mathrm{End}(J_0(pM)) = \mathbf{T}_A \cap \mathbf{T}'$.

Proof. This is elementary; it is an analogue of Lemma 4.11. □

Proposition 4.14. *There is a natural inclusion* $J/I \hookrightarrow \mathbf{T}'/\mathbf{T}$ *of* $\mathbf{T}$*-modules.*

Proof. Consider the map $\mathbf{T} \to \mathbf{T} \otimes \mathbf{Q}$ given by $t \mapsto te$. This homomorphism factors through $\mathbf{T}_A$ and yields an injection $\iota_A : \mathbf{T}_A \hookrightarrow \mathbf{T} \otimes \mathbf{Q}$. Symmetrically, we also obtain $\iota_B : \mathbf{T}_B \hookrightarrow \mathbf{T} \otimes \mathbf{Q}$. The map $(t_A, t_B) \mapsto \iota_A(t_A) + \iota_B(t_B)$ is an injection $\mathbf{T}_A \times \mathbf{T}_B \hookrightarrow \mathbf{T} \otimes \mathbf{Q}$. The composite of this map with the inclusion $j : \mathbf{T} \hookrightarrow \mathbf{T}_A \times \mathbf{T}_B$ defined above is the natural map $\mathbf{T} \hookrightarrow \mathbf{T} \otimes \mathbf{Q}$. We thus have a sequence of inclusions

$$\mathbf{T} \hookrightarrow \mathbf{T}_A \times \mathbf{T}_B \hookrightarrow \mathbf{T} \otimes \mathbf{Q} \subset \mathrm{End}(J_0(pM)) \otimes \mathbf{Q}.$$

By Lemma 4.11 and Lemma 4.13, we have $I = \mathbf{T}_A \cap \mathbf{T}$ and $J = \mathbf{T}_A \cap \mathbf{T}'$. Thus $I = J \cap \mathbf{T}$, where the intersection is taken inside $\mathbf{T}'$. Thus

$$J/I = J/(J \cap \mathbf{T}) \cong (J + \mathbf{T})/\mathbf{T} \hookrightarrow \mathbf{T}'/\mathbf{T}.$$

□

Corollary 4.15. *If* $\mathfrak{m}$ *is a maximal ideal not in* $\mathrm{Supp}_{\mathbf{T}}(\mathbf{T}'/\mathbf{T})$*, then* $\mathfrak{m}$ *is not in the support of* J/I*, i.e., if* $\mathbf{T}$ *and* $\mathbf{T}'$ *agree locally at* $\mathfrak{m}$*, then* I *and* J *also agree locally at* $\mathfrak{m}$*.*

Note that the Hecke algebra $\mathbf{T}$ acts on J/I through its quotient $\mathbf{T}_A$, since the action of $\mathbf{T}$ on I and on J factors through this quotient.

Now we specialize to the case where A is ordinary at p, in the sense that the image of T_p in $\mathbf{T}_A$, which we denote $T_{p,A}$, is invertible modulo every maximal ideal of $\mathbf{T}_A$ that divides p. (This case occurs when A is a subvariety of the p-new subvariety of $J_0(pM)$, since the square of $T_{p,A}$ is the identity.)

If $\mathfrak{m} \mid p$ is a maximal ideal of $\mathbf{T}$ that arises by pullback from a maximal ideal of $\mathbf{T}_A$, then $\mathfrak{m}$ is ordinary in the sense used above. When A is ordinary at p, it follows from Proposition 4.9 and Corollary 4.15 that $I = J$ locally at p. The reason is simple: regarding I and J as $\mathbf{T}_A$-modules, we realize that we need to test that $I = J$ at maximal ideals of $\mathbf{T}_A$ that divide p. These ideals correspond to maximal ideals $\mathfrak{m} \mid p$ of $\mathbf{T}$ that are automatically ordinary, so we have $I = J$ locally at $\mathfrak{m}$ because of Proposition 4.9. By Proposition 4.9, we have $\mathbf{T} = \mathbf{T}'$ locally at primes away from the level pM. Thus we conclude that $I = J$ locally at all primes $\ell \nmid pM$ and also at p, a prime that divides the level pM exactly once.

Suppose, finally, that A is the abelian variety associated to a newform f of level pM. The ideal $I \subset \mathbf{T}_A$ measures congruences between f and the space of forms in $S_2(\Gamma_0(pM))$ that are orthogonal to the space generated by f. Also, $A \cap B$ is the kernel in A of the map "multiplication by the modular element e". In this case, the inclusion $I \subset J$ corresponds to the divisibility $\tilde{n}_A \mid \tilde{r}_A$, and we have equality at primes at which $I = J$ locally. We conclude that the congruence exponent and the modular exponent agree both at p and at primes not dividing pM, which completes our proof of Theorem 3.7(b).

Remark 4.16. The ring

$$R = \mathrm{End}(J_0(pM)) \cap (\mathbf{T}_A \times \mathbf{T}_B)$$

is often of interest, where the intersection is taken in $\mathrm{End}(J_0(pM)) \otimes \mathbf{Q}$. We proved above that there is a natural inclusion $J/I \hookrightarrow \mathbf{T}'/\mathbf{T}$. This inclusion yields an isomorphism $J/I \xrightarrow{\sim} R/\mathbf{T}$. Indeed, if (t_A, u_B) is an endomorphism of $J_0(pM)$, where $t, u \in \mathbf{T}$, then $(t_A, u_B) - u = (t_A, 0)$ is an element of J. The ideals I and J are equal to the extent that the rings $\mathbf{T}$ and R coincide. Even when $\mathbf{T}'$ is bigger than $\mathbf{T}$, its subring R may be not far from $\mathbf{T}$.

5 Failure of Multiplicity One

In this section, we discuss examples of failure of multiplicity one (in two different but related senses). The notion of multiplicity one, originally due to Mazur [Maz77], has played an important role in several places (e.g., in Wiles's proof of Fermat's last theorem [Wil95]). This notion is closely related to Gorensteinness of certain Hecke algebras (e.g., see [Til97]). Kilford [Kil02] found examples of failure of Gorensteinness (and multiplicity one) at the prime 2 for certain prime levels. Motivated by the arguments in Section 4, in this section we give examples of failure of multiplicity one for primes (including odd primes) whose square divides the level.

5.1 Multiplicity One for Differentials

In connection with the arguments in Section 4, especially Lemmas 4.6 and 4.8, it is of interest to compute the index $[\mathbf{T}' : \mathbf{T}]$ for various N. We can compute this index in Magma, e.g., the following commands compute the index for $N = 54$: “`J := JZero(54); T := HeckeAlgebra(J); Index(Saturation(T), T);`” We obtain Table 2, where the first column contains N and the second column contains $[\mathbf{T}' : \mathbf{T}]$:

Let $\mathfrak{m}$ be a maximal ideal of the Hecke algebra $\mathbf{T} \subset \mathrm{End}(J_0(N))$ of residue characteristic p. Recall that we say that $\mathfrak{m}$ satisfies *multiplicity one for differentials* if $\dim(\mathrm{H}^0(X_0(N)_{\mathbf{F}_p}, \Omega)[\mathfrak{m}]) \leq 1$.

In each case in which $[\mathbf{T}' : \mathbf{T}] \neq 1$, Lemma 4.6 implies that there is some maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ such that $\dim(\mathrm{H}^0(X_0(N)_{\mathbf{F}_p}, \Omega)[\mathfrak{m}]) > 1$, which is an example of failure of multiplicity one for differentials.

In Table 2, whenever $p \mid [\mathbf{T}' : \mathbf{T}]$, then $p^2 \mid 2N$. This is a consequence of Proposition 4.9, which moreover asserts that when 2 exactly divides N and $2 \mid [\mathbf{T}' : \mathbf{T}]$ then there is a non-ordinary (old) maximal ideal of characteristic 2 in the support of $\mathbf{T}'/\mathbf{T}$.

Moreover, notice that Theorem 3.7(b) (whose proof is in Section 4.2) follows formally from two key facts: that A_f is new and that multiplicity one for differentials holds for ordinary maximal ideals with residue characteristic $p \mid\mid N$ and for all maximal ideals with residue characteristic $p \nmid N$. The conclusion of Theorem 3.7(b) does not hold for the counterexamples in Section 2 (e.g., for 54B1), which are all new elliptic curves, so multiplicity one for differentials does not hold for certain maximal ideals that arise from the new quotient of the Hecke algebra. Note that in all examples we have $p \mid (r/m)$ with $p^2 \mid N$, which raises the question: are there non-ordinary counterexamples with $p \mid\mid N$?

5.2 Multiplicity One for Jacobians

We say that a maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ satisfies *multiplicity one* if $J_0(N)[\mathfrak{m}]$ is of dimension two over $\mathbf{T}/\mathfrak{m}$. We sometimes use the phrase “multiplicity one for $J_0(N)$” in order to distinguish this notion from the notion of multiplicity one for differentials.

Proposition 5.1. *Suppose E is an optimal elliptic curve over $\mathbf{Q}$ of conductor N and p is a prime such that $p \mid r_E$ but $p \nmid m_E$. Let $\mathfrak{m}$ be the annihilator in $\mathbf{T}$ of $E[p]$. Then multiplicity one fails for $\mathfrak{m}$, i.e., $\dim_{\mathbf{T}/\mathfrak{m}} J_0(N)[\mathfrak{m}] > 2$.*

Proof. Using the principal polarization $E \cong E^\vee$ we view E as an abelian subvariety of $J = J_0(N)$ and consider the complementary $\mathbf{T}$-stable abelian subvariety A of E (thus A is the kernel of the modular parametrization map $J \to E$). In this setup, $J = E + A$, and the intersection of E and A is $E[m_E]$. Here we use that the composite map $E \simeq E^\vee \to J^\vee \to J \to E$ is a polarization, and hence is multiplication by a positive integer m_E. Because $p \nmid m_E$, we have $E[p] \cap A = 0$. On the other hand, let $\mathfrak{m}$ be the annihilator of $E[p]$ inside $\mathbf{T}$.

Table 2: The Index $[\mathbf{T}' : \mathbf{T}]$

11	1	51	1	91	1	131	1	171	9

40	1	80	4	120	32	160	256	200	80
41	1	81	1	121	1	161	1	201	1
42	1	82	1	122	1	162	81	202	1
43	1	83	1	123	1	163	1	203	1
44	2	84	2	124	16	164	8	204	32
45	1	85	1	125	25	165	1	205	1
46	2	86	1	126	18	166	2	206	4
47	1	87	1	127	1	167	1	207	81
48	1	88	8	128	64	168	128	208	256
49	1	89	1	129	1	169	13	209	1
50	1	90	1	130	1	170	1	210	2

Then $J[\mathfrak{m}]$ contains $E[p]$ and also $A[\mathfrak{m}]$, and because p is a congruence prime, the submodule $A[\mathfrak{m}] \subset J[\mathfrak{m}]$ is nonzero. Thus the sum $E[p] + A[\mathfrak{m}]$ is a direct sum and is larger than $E[p]$, which is of dimension 2 over $\mathbf{T}/\mathfrak{m} = \mathbf{Z}/p\mathbf{Z}$. Hence the dimension of $J[\mathfrak{m}]$ over $\mathbf{T}/\mathfrak{m}$ is bigger than 2, as claimed. □

Proposition 5.1 implies that any example in which simultaneously $p \nmid m_E$ and $\mathrm{ord}_p(r_E) \neq \mathrm{ord}_p(m_E)$ produces an example in which multiplicity one for $J_0(N)$ fails. For example, for the curve 54B1 and $p = 3$, we have $\mathrm{ord}_3(r_E) = 1$ but $\mathrm{ord}_3(m_E) = 0$, so multiplicity one at 3 fails for $J_0(54)$.

Abstract. Sage is a free, open source, self-contained distribution of mathematical software, including a large library that provides a unified interface to the components of this distribution. This library also builds on the components of Sage to implement novel algorithms covering a broad range of mathematical functionality from algebraic combinatorics to number theory and arithmetic geometry.

Keywords: Python, Cython, Sage, Open Source, Interfaces

1 Introduction

In order to use mathematical software for exploration, we often push the boundaries of available computing resources and continuously try to improve our implementations and algorithms. Most mathematical algorithms require basic building blocks, such as multiprecision numbers, fast polynomial arithmetic, exact or numeric linear algebra, or more advanced algorithms such as Gröbner basis computation or integer factorization. Though implementing some of these basic foundations from scratch can be a good exercise, the resulting code may be slow and buggy. Instead, one can build on existing optimized implementations of these basic components, either by using a general computer algebra system, such as Magma, Maple, Mathematica or MATLAB, or by making use of the many high quality open source libraries that provide the desired functionality. These two approaches both have significant drawbacks. This paper is about Sage,[3] which provides an alternative approach to this problem.

[3] http://www.sagemath.org

Having to rely on a closed propriety system can be frustrating, since it is difficult to gain access to the source code of the software, either to correct a bug or include a simple optimization in an algorithm. Sometimes this is by design:

> “Indeed, in almost all practical uses of Mathematica, issues about how Mathematica works inside turn out to be largely irrelevant. You might think that knowing how Mathematica works inside would be necessary [...]” (See [Wol].)

Even if we manage to contact the developers, and they find time to make the changes we request, it might still take months or years before these changes are made available in a new release.

Fundamental questions of correctness, reproducibility and scientific value arise when building a mathematical research program on top of proprietary software (see, e.g., [SJ07]). There are many published refereed papers containing results that rely on computations performed in Magma, Maple, or Mathematica.[4] In some cases, a specific version of Magma is the only software that can carry out the computation. This is not the infrastructure on which we want to build the future of mathematical research.

In sharp contrast, open source libraries provide a great deal of flexibility, since anyone can see and modify the source code as they wish. However, functionality is often segmented into different specialized libraries and advanced algorithms are hidden behind custom interpreted languages. One often runs into trouble trying to install dependencies before being able use an open source software package. Also, converting the output of one package to the input format of another package can present numerous difficulties and introduce subtle errors.

Sage, which started in 2005 (see [SJ05]), attacks this problem by providing:

1. a *self-contained distribution* of mathematical software that installs from source easily, with the only dependency being compiler tools,
2. *unified interfaces* to other mathematical software to make it easier to use all these programs together, and
3. a *new library* that builds on the included software packages and implements a broad range of mathematical functionality.

The rest of this paper goes into more detail about Sage. In Section 1.1, we describe the Sage graphical user interface. Section 1.2 is about the Sage development process, Sage days workshops, mailing lists, and documentation. The subject of Section 2 is the sophisticated way in which Sage is built out of a wide range of open source libraries and software. In Section 2.1 we explain how we use Python and Cython as the glue that binds the compendium of software included in Sage into a unified whole. We then delve deeper into Python, Cython and the Sage preparser in Section 2.2, and illustrate some applications to mathematics in Section 2.3. Sage is actively used for research, and in Section 3 we describe some capabilities of Sage in advanced areas of mathematics.

```
plot(x*sin(1/x), (x,0,1/3), figsize=[8,2])
```

```
integrate(x*cos(x)^2*sin(x), x)
```

$-\frac{1}{12}\,x\cos\left(3\,x\right) - \frac{1}{4}\,x\cos\left(x\right) + \frac{1}{36}\,\sin\left(3\,x\right) + \frac{1}{4}\,\sin\left(x\right)$

Fig. 1. The Sage Notebook

1.1 The Notebook

As illustrated in Figure 1, the graphical user interface for Sage is a web application, inspired by Google Documents [Goo], which provides convenient access to all capabilities of Sage, including 3D graphics. In single user mode, Sage works like a regular application whose main window happens to be your web browser. In multiuser mode, this architecture allows users to easily set up servers for accessing their work over the Internet as well as sharing and collaborating with colleagues. One can try the Sage notebook by visiting `www.sagenb.org`, where there are over 30,000 user accounts and over 2,000 published worksheets.

Users also download Sage to run it directly on their computers. We track all downloads from `www.sagemath.org`, though there are several other high-profile sites that provide mirrors of our binaries. Recently, people download about 6,000 copies of Sage per month directly from the Sage website.

1.2 The Sage Development Process

There are over 200 developers from across the world who have contributed to the Sage project. People often contribute because they write code using Sage as part of a research project, and in this process find and fix bugs, speed up parts of Sage, or want the code portion of their research to be peer reviewed. Each contribution to Sage is first posted to the Sage Trac server `trac.sagemath.org`; it is then peer reviewed, and finally added to Sage after all issues have been sorted out and all requirements are met. Nothing about this process is anonymous; every step of the peer review process is recorded indefinitely for all to see.

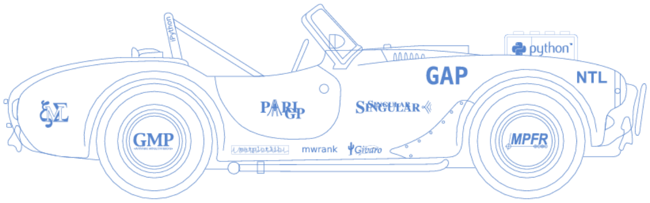
[4] Including by the second author of this paper, e.g., [CES03]!

The Sage Developer's Guide begins with an easy-to-follow tutorial that guides developers through each step involved in contributing code to Sage. Swift feedback is available through the `sage-devel` mailing list, and the `#sage-devel` IRC chat room on `irc.freenode.net` (see `www.sagemath.org/development.html`).

Much development of Sage has taken place at the Sage Days workshops. There have been two dozen Sage Days [Sagb] and many more are planned. These are essential to sustaining the momentum of the Sage project and also help ensure that developers work together toward a common goal, rather than competing with each other and fragmenting our limited community resources.

A major goal is ensuring that there will be many Sage Days workshops for the next couple of years. The topics will depend on funding, but will likely include numerical computation, large-scale bug fixing, L-functions and modular forms, function fields, symbolic computation, topology, and combinatorics. The combination of experienced developers with a group of enthusiastic mathematicians at each of these workshops has rapidly increased the developer community, and we hope that it will continue to do so.

2 Building the Car...



With the motto "building the car instead of reinventing the wheel," Sage brings together numerous open source software packages (see Table 1 and [Saga]).

Many applications of Sage require using these libraries together. Sage handles the conversion of data behind the scenes, automatically using the best tool for the job, and allows the user to concentrate on the problem at hand.

In the following example, which we explain in detail below, Sage uses the FLINT library [HH] for univariate polynomials over the ring $\mathbb{Z}$ of integers, whereas Singular [DGPS10] is used for multivariate polynomials. The option to use the NTL library [Sho] for univariate polynomials is still available, if the user so chooses.

```
sage: R.<x> = ZZ[]
sage: type(R.an_element())
<type 'sage.rings...Polynomial_integer_dense_flint'>
sage: R.<x,y> = ZZ[]
sage: type(R.an_element())
<type 'sage.rings...MPolynomial_libsingular'>
sage: R = PolynomialRing(ZZ, 'x', implementation='NTL')
sage: type(R.an_element())
<type 'sage.rings...Polynomial_integer_dense_ntl'>
```

Table 1. Packages Included With Every Copy of Sage-4.4.2

atlas	gap	libgcrypt	palp	scipy_sandbox
blas	gd	libgpg_error	pari	scons
boehm_gc	gdmodule	libm4ri	pexpect	setuptools
boost	genus2reduction	libpng	pil	singular
cddlib	gfan	linbox	polybori	sphinx
cliquer	ghmm	matplotlib	pycrypto	sqlalchemy
cvxopt	givaro	maxima	pygments	sqlite
cython	gnutls	mercurial	pynac	symmetrica
docutils	gsl	moin	python	sympow
ecl	iconv	mpfi	python_gnutls	sympy
eclib	iml	mpfr	r	tachyon
ecm	ipython	mpir	ratpoints	termcap
f2c	jinja	mpmath	readline	twisted
flint	jinja2	networkx	rubiks	weave
flintqs	lapack	ntl	sagenb	zlib
fortran	lcalc	numpy	sagetex	zn_poly
freetype	libfplll	opencdk	scipy	zodb3

The first line in the example above constructs the univariate polynomial ring `R` $= \mathbb{Z}[x]$, and assigns the variable `x` to be the generator of this ring. Note that $\mathbb{Z}$ is represented by `ZZ` in Sage. The expression `R.<x> = ZZ[]` is not valid Python, but can be used in Sage code as a shorthand as explained in Section 2.2. The next line asks the ring `R` for an element, using the `an_element` function, then uses the builtin Python function `type` to query its type. We learn that it is an instance of the class `Polynomial_integer_dense_flint`. Similarly line 4 constructs `R` $= \mathbb{Z}[x, y]$ and line 7 defines `R` $= \mathbb{Z}[x]$, but this time using the `PolynomialRing` constructor explicitly and specifying that we want the underlying implementation to use the NTL library.

Often these interfaces are used under the hood, without the user having to know anything about the corresponding systems. Nonetheless, there are easy ways to find out what is used by inspecting the source code, and users are strongly encouraged to cite components they use in published papers. The following example illustrates another way to get a list of components used when a specific command is run.

```
sage: from sage.misc.citation import get_systems
sage: get_systems(’integrate(x^2, x)’)
[’ginac’, ’Maxima’]
sage: R.<x,y,z> = QQ[]
sage: I = R.ideal(x^2+y^2, z^2+y)
sage: get_systems(’I.primary_decomposition()’)
[’Singular’]
```

2.1 Interfaces

Sage makes it possible to use a wide range of mathematical software packages together by providing a unified interface that handles data conversion automatically. The complexity and functionality of these interfaces varies greatly, from simple text-based interfaces that call external software for an individual computation, to using a library as the basis for an arithmetic type. The interfaces can also run code from libraries written in the interpreted language of another program. Table 2 lists the interfaces provided by Sage.

Table 2. Sage Interfaces to the above Mathematical Software

Pexpect	axiom, ecm, fricas, frobby, gap, g2red, gfan, gnuplot, gp, kash, lie, lisp, macaulay2, magma, maple, mathematica, matlab, maxima, mupad, mwrank, octave, phc, polymake, povray, qepcad, qsieve, r, rubik, scilab, singular, tachyon
C Library	eclib, fplll, gap (in progress), iml, linbox, maxima, ratpoints, r (via rpy2), singular, symmetrica
C Library arithmetic	flint, mpir, ntl, pari, polybori, pynac, singular

The above interfaces are the result of many years writing Python and Cython [BBS] code to adapt Singular [DGPS10], GAP [L$^+$], Maxima [D$^+$], Pari [PAR], GiNaC/Pynac [B$^+$], NTL [Sho], FLINT [HH], and many other libraries, so that they can be used smoothly and efficiently in a unified way from Python [Ros]. Some of these programs were originally designed to be used only through their own interpreter and made into a library by Sage developers. For example libSingular was created by Martin Albrecht in order to use the fast multivariate polynomial arithmetic in Singular from Sage. The libSingular interface is now used by other projects, including Macaulay2 [GS] and GFan [Jen].

There are other approaches to linking mathematical software together. The recent paper [LHK$^+$] reports on the state of the art using OpenMath. Sage takes a dramatically different approach to this problem. Instead of using a general string-based XML protocol to communicate with other mathematical software, Sage interfaces are tailor made to the specific software and problem at hand. This results in far more efficient and flexible interfaces. The main disadvantage compared to OpenMath is that the interfaces all go through Sage.

Having access to many programs which can perform the same computation, without having to worry about data conversion, also makes it easier to double check results. For example, below we first use Maxima, an open source symbolic computation package distributed with Sage, to integrate a function, then perform the same computation using Maple and Mathematica.

```
sage: var('x')
sage: integrate(sin(x^2), x)
1/8*((I - 1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) + \
  (I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sqrt(2)*x))*sqrt(pi)
sage: maple(sin(x^2)).integrate(x)
1/2*2^(1/2)*Pi^(1/2)*FresnelS(2^(1/2)/Pi^(1/2)*x)
sage: mathematica(sin(x^2)).Integrate(x)
Sqrt[Pi/2]*FresnelS[Sqrt[2/Pi]*x]
```

The most common type of interface, called a pexpect interface, communicates with another command line program by reading and writing strings to a text console, as if another user was in front of the terminal. Even though these are relatively simple to develop, the overhead of having to print and parse strings to represent the data makes this process potentially cumbersome and inefficient. This is the default method of communication with most high level mathematics software, including commercial and open source programs, such as Maple, Mathematica, Magma, KASH or GAP.

Sage provides a framework to represent elements over these interfaces, perform arithmetic with them or apply functions to the given object, as well as using a file to pass the data if the string representation is too big. The following demonstrates arithmetic with GAP elements.

```
sage: a = gap('22')
sage: a*a
484
```

It is also possible to use pexpect interfaces over remote consoles. In the following code, we connect to the localhost as a different user and call Mathematica functions. Note that the interface can handle indexing vectors as well.

```
sage: mma = Mathematica(server="rmma60@localhost")
sage: mma("2+2")
4
sage: t = mma("Cos[x]")
sage: t.Integrate('x')
Sin[x]
sage: t = mma('{0,1,2,3}')
sage: t[2]
1
```

Sage also includes specialized libraries that are linked directly from compiled code written in Cython. These are used to handle specific problems, such as the characteristic polynomial computation in the example below.

```
sage: M = Matrix(GF(5), 10, 10)
sage: M.randomize()
sage: M.charpoly(algorithm='linbox')
x^10 + 4*x^9 + 4*x^7 + 3*x^4 + 3*x^3 + 3*x^2 + 4*x + 3
```

Many basic arithmetic types also use Cython to directly utilize data structures from efficient arithmetic libraries, such as MPIR or FLINT. An example of this can be seen at the beginning of this section, where elements of the ring $\mathbb{Z}[x]$ are represented by the class Polynomial_integer_dense_flint.

The Singular interface is one of the most advanced included in Sage. Singular has a large library of code written in its own language. Previously the only way to access these functions, which include algorithms for Gröbner basis and primary decomposition, was to call Singular through a pexpect interface, passing data back and forth using strings. Recently, due to work of Michael Brickenstein and Martin Albrecht, Sage acquired the ability to call these functions directly.

In the example below, we import the function primdecSY from primdec.lib, and call it the same way we would call a Python function. The interface handles the conversion of the data to Singular's format and back. Since Sage already uses Singular data structures directly to represent multivariate polynomials and ideals over multivariate polynomial rings, there are no conversion costs. It is only a matter of passing the right pointer.

```
sage: pr = sage.libs.singular.ff.primdec__lib.primdecSY
sage: R.<x,y,z> = QQ[]
sage: p = z^2+1; q = z^3+2
sage: I = R.ideal([p*q^2,y-z^2])
sage: pr(I)
[[[z^2 - y, y^3 + 4*y*z + 4], \
    [z^2 - y, y*z + 2, y^2 + 2*z]], \
    [[y + 1, z^2 + 1], [y + 1, z^2 + 1]]]
```

Efforts are under way to extend these capabilities to other programs, for example to GAP which provides Sage's underlying group theory functionality. Up to now, GAP was only available through its interpreter, through a pexpect interface that was written by Steve Linton. As the following example demonstrates, the performance of this interface is far from ideal.[5]

```
sage: b = gap('10')
sage: b*b
100
sage: timeit('b*b')
625 loops, best of 3: 289 microseconds per loop
```

The code snippet above constructs the element b in GAP using the pexpect interface, and measures the time it takes to square b. Compare these numbers to the following example, which uses the library interface to GAP, recently developed by the second author (but *not* included in Sage yet).

```
sage: import sage.libs.gap.gap as g
sage: a = g.libgap('10'); a
10
sage: type(a)
<type 'sage.libs.gap.gap.GapElement'>
sage: a*a
100
sage: timeit('a*a')
625 loops, best of 3: 229 nanoseconds per loop
```

The library interface is about 1,000 times faster than the pexpect interface.

[5] All timings in this paper were performed on an 2.66GHz Intel Xeon X7460 based computer.

2.2 Python - a mainstream language

In line with the principle of not reinventing the wheel, Sage is built on the mainstream programming language Python, both as the main development language and the user language. This frees the Sage developers, who are mainly mathematicians, from the troubles of language design, and gives access to an immense array of general purpose Python libraries and tools.

Python is an interpreted language with a clear, easy to read and learn syntax. Since it is dynamically typed, it is ideal for rapid prototyping, providing an environment to easily test new ideas and algorithms.

A fast interpreter In the following Singular session, we first declare the ring `r` $= \mathbb{Q}[x, y, z]$ and the polynomial `f` $\in$ `r`, then measures the time to square `f` repeatedly, 10,000 times.

```
singular: int t = timer; ring r = 0,(x,y,z), dp;
singular: def f = y^2*z^2-x^2*y^3-x*z^3+x^3*y*z;
singular: int j; def g = f;
singular: for (j = 1; j <= 10^5; j++) { g = f*f; }
singular: (timer-t), system("--ticks-per-sec");
990 1000
```

The elapsed time is 990 milliseconds. Next we use Sage to do the same computation, using the same Singular data structures directly, but without going through the interpreter.

```
sage: R.<x,y,z> = QQ[]
sage: f = y^2*z^2 - x^2*y^3 - x*z^3 + x^3*y*z;  type(f)
<type 'sage.rings.polynomial...MPolynomial_libsingular'>
sage: timeit('for j in xrange(10^5): g = f*f')
5 loops, best of 3: 91.8 ms per loop
```

Sage takes only 91.8 milliseconds for the same operation. This difference is because the Python interpreter is more efficient at performing `for` loops.

Cython - compiled extensions Python alone is too slow to implement a serious mathematical software system. Fortunately, Cython [BBS] makes it easy to optimize parts of your program or access existing C/C++ libraries. It can translate Python code with annotations containing static type information to C/C++ code, which is then compiled as a Python extension module.

Many of the basic arithmetic types in Sage are provided by Cython wrappers of C libraries, such as FLINT for univariate polynomials over $\mathbb{Z}$, Singular for multivariate polynomials, and Pynac for symbolic expressions.

The code segment below defines a Python function to add integers from 0 to N and times the execution of this function with the argument `10^7`.

```
sage: def mysum(N):
....:     s = int(0)
....:     for k in xrange(1,N): s += k
....:     return s
....:
```

```
sage: time mysum(10^7)
CPU times: user 0.52 s, sys: 0.00 s, total: 0.52 s
49999995000000
```

Here is the same function, but the loop index `k` is declared to be a C integer and the accumulator `s` is a C `long long`.

```
sage: cython("""
....: def mysum_cython(N):
....:     cdef int k
....:     cdef long long s = 0
....:     for k in xrange(N): s += k
....:     return s
....: """)
sage: time mysum_cython(10^7)
CPU times: user 0.01 s, sys: 0.00 s, total: 0.01 s
49999995000000L
```

The code is compiled and linked to the interpreter on the fly, and the function `mysum_cython` is available immediately. Note that the run time for the Cython function is 60 times faster than the Python equivalent.

Cython also handles the conversion of Python types to C types automatically. In the following example, we call the C function `sinl` using Cython to wrap it in a Python function named `sin_c_wrap`.

```
sage: cython("""
....: cdef extern from "math.h":
....:         long double sinl(long double)
....: def sin_c_wrap(a):
....:         return sinl(a)
....: """)
sage: sin_c_wrap(3.14)
0.0015926529164868282
sage: sin_c_wrap(1)
0.8414709848078965
sage: sin_c_wrap(1r)
0.8414709848078965
```

Note that the conversion of Sage types in the first two calls to `sin_c_wrap` or the Python type integer in the last call is performed transparently by Cython.

The Preparser While Python has many advantages as a programming and glue language, it also has some undesirable features. Sage hides these problems by using a preparser to change the commands passed to Python in an interactive session (or when running a script with the `.sage` extension). In order to maintain compatibility with Python, changes performed by the preparser are kept to a minimum. Moreover, the Sage library code is not preparsed, and is written in Cython or Python directly.

Python, like C and many other programming languages, performs integer floor division. This means typing `1/2` results in 0, not the rational number 1/2. Sage wraps all numeric literals entered in the command line or the notebook with its own type declarations, which behave as expected with respect to arithmetic and have the advantage that they are backed by efficient multiprecision arithmetic libraries such as MPIR [H+] and MPFR [Z+], which are thousands of times faster than Python for large integer arithmetic.

To call the preparser directly on a given string, use the preparse function.

```
sage: preparse("1/2")
'Integer(1)/Integer(2)'
sage: preparse("1.5")
"RealNumber('1.5')"
```

Adding a trailing r after a number indicates that the preparser should leave that as the “raw” literal. The following illustrates division with Python integers.

```
sage: preparse("1r/2r")
'1/2'
sage: 1r/2r
0
```

Here is the result of performing the same division in Sage.

```
sage: 1/2
1/2
sage: type(1/2)
<type 'sage.rings.rational.Rational'>
sage: (1/2).parent()
Rational Field
```

The preparser also changes the ^ sign to the exponentiation operator ** and provides a shorthand to create new mathematical domains and name their generator in one command.

```
sage: preparse("2^3")
'Integer(2)**Integer(3)'
sage: preparse("R.<x,y> = ZZ[]")
"R = ZZ['x, y']; (x, y,) = R._first_ngens(2)"
```

2.3 Algebraic, Symbolic and Numerical Tools

Sage combines algebraic, symbolic and numerical computation tools under one roof, enabling users to choose the tool that best suits the problem. This combination also makes Sage more accessible to a wide audience—scientists, engineers, pure mathematicians and mathematics teachers can all use the same platform for scientific computation.

While not concentrating on only one of these domains might seem to divide development resources unnecessarily, it actually results in a better overall experience for everyone, since users do not have to come up with makeshift solutions to compensate for the lack of functionality from a different field. Moreover, because Sage is a distributed mostly-volunteer open source project, widening our focus results in substantially more developer resources.

Algebraic Tools: The Coercion System An algebraic framework, similar to that of Magma or Axiom, provides access to efficient data structures and specialized algorithms associated to particular mathematical domains. The Python language allows classes to define how arithmetic operations like `+` and `*` will be handled, in a similar way to how C++ allows overloading of operators. However, the built-in support for overloading in Python is too simple to support operations with a range of objects in a mathematical type hierarchy.

Sage abstracts the process of deciding what an arithmetic operation means, or equivalently, in which domain the operation should be performed, in a framework called the *coercion system*, which was developed and implemented by Robert Bradshaw, David Roe, and many others. Implementations of new mathematical objects only need to define which other domains have a natural embedding to their domain. When performing arithmetic with objects, the coercion system will find a common domain where both arguments can be canonically mapped, perform the necessary type conversions automatically, thus allowing the implementation to only handle the case where both objects have the same parent.

In the following example, the variable `t` is an element of $\mathbb{Z}$ whereas `u` is in $\mathbb{Q}$. In order to perform the addition, the coercion system first deduces that the result should be in $\mathbb{Q}$ from the fact that `t` can be converted to the domain of `u`, namely $\mathbb{Q}$, but canonical conversion in the other direction is not possible. Then the addition is performed with both operands having the same domain $\mathbb{Q}$.

```
sage: t = 1
sage: t.parent()
Integer Ring
sage: u = 1/2
sage: u.parent()
Rational Field
sage: v = t + u; v
3/2
sage: v.parent()
Rational Field
```

Similarly, in the following example, the common domain $\mathbb{Q}[x]$ is found for arguments from $\mathbb{Z}[x]$ and $\mathbb{Q}$. Note that in this case, the result is not in the domain of either of the operands.

```
sage: R.<x> = ZZ[]
sage: r = x + 1/2
sage: r.parent()
Univariate Polynomial Ring in x over Rational Field
sage: 5*r
5*x + 5/2
```

Algebraic Tools: The Category Framework Another abstraction to make implementing mathematical structures easier is the *category framework*, whose development was spearheaded by Nicolas Thiéry and Florent Hivert. Similar in spirit to the mathematical programming facilities developed in Axiom and encapsulated in Aldor, the category framework uses Python's dynamic class creation capabilities to combine functions relevant for a mathematical object, inherited through a mathematical hierarchy, into a class at run time.

This process greatly simplifies the troubles of having to combine object-oriented programming concepts with mathematical structural concerns, while keeping efficiency in mind. Efficient implementations can keep the inheritance hierarchy imposed by the data structures, while generic methods to compute basic properties are implemented in the *category* and automatically attached to the element classes when they are needed.

Symbolic Tools The symbolic subsystem of Sage provides an environment similar to Maple or Mathematica, where the input is treated only as an expression without any concern about the underlying mathematical structure.

Sage uses Pynac [ES], a hybrid C++ and Cython library built on top of GiNaC [B$^+$], to work with symbolic expressions. High level symbolic calculus problems including symbolic integration, solution of differential equations and Laplace transforms are solved using Maxima behind the scenes.

Here is an example of how to use the symbolic computation facilities in Sage. Note that in contrast to other symbolic software such as Maple, variables must be declared before they are used.

```
sage: x,y,z = var(’x,y,z’)
sage: sin(x).diff(x)
cos(x)
sage: psi(x).series(x,4)
(-1)*x^(-1) + (-euler_gamma) + (1/6*pi^2)*x + \
    (-zeta(3))*x^2 + (1/90*pi^4)*x^3 + Order(x^4)
sage: w = SR.wild()  # wildcard for symbolic substitutions
sage: ((x^2+y^2+z^2)*zeta(x)).subs({w^2:5})
15*zeta(x)
```

Numerical Tools In addition to code for symbolic computation, the standard numerical Python packages NumPy, SciPy, and Matplotlib are included in Sage, along with the numerical libraries cvxopt, GSL, Mpmath, and R.

For numerical applications, Robert Bradshaw and Carl Witty developed a compiler for Sage that converts symbolic expressions into an internal format suitable for blazingly fast floating point evaluation.

```
sage: f(x,y) = sqrt(x^2 + y^2)
sage: a = float(2)
sage: timeit(’float(f(a,a))’)
625 loops, best of 3: 216 microseconds per loop
sage: g = fast_float(f)
sage: timeit(’float(g(a,a))’)
625 loops, best of 3: 0.406 microseconds per loop
```

The `fast_float` feature is automatically used by the `minimize` command.

```
sage: minimize(f, (a,a))
(-5.65756135618e-05, -5.65756135618e-05)
```

Performance is typically within a factor of two from what one gets using a direct implementation in C or Fortran.

3 Afterword

In this article, we have showed that Sage is a powerful platform for developing sophisticated mathematical software. Sage is actively used in research mathematics, and people use Sage to develop state-of-the-art algorithms. Sage is particularly strong in number theory, algebraic combinatorics, and graph theory. For further examples, see the 53 published articles, 11 Ph.D. theses, 10 books, and 30 preprints at `www.sagemath.org/library-publications.html`.

For example, Sage has extensive functionality for computations related to the Birch and Swinnerton-Dyer conjecture. In addition to Mordell-Weil group computations using [Cre] and point counting over large finite fields using the SEA package in [PAR], there is much novel elliptic curve code written directly for Sage. This includes the fastest known algorithm for computation of p-adic heights [Har07,MST06], and code for computing p-adic L-series of elliptic curves at ordinary, supersingular, and split multiplicative primes. Sage combines these capabilities to compute explicitly bounds on Shafarevich-Tate groups of elliptic curves [SW10]. Sage also has code for computation with modular forms, modular abelian varieties, and ideal class groups in quaternion algebras.

The MuPAD-combinat project, which was started by Florent Hivert and Nicolas M. Thiéry in 2000, built the world's preeminent system for algebraic combinatorics on top of MuPAD (see [Des06] and [HT05]). Page 54 of [HT05]: "They [MuPAD] also have promised to release the code source of the library under a well known open-source license, some day." In 2008, MuPAD was instead purchased by MathWorks (makers of MATLAB), so MuPAD is no longer available as a separate product, and will probably never be open source. Instead it now suddenly costs $3000 (commercial) or $700 (academic).

As a result, the MuPAD-combinat group has spent several years reimplementing everything in Sage (see [T$^+$] for the current status). The MuPAD-combinat group was not taken by surprise by the failure of MuPAD, but instead were concerned from the beginning by the inherent risk in building their research program on top of MuPAD. In fact, they decided to switch to Sage two months before the bad news hit, and have made tremendous progress porting:

> "It has been such a relief during the last two years not to have this Damocles sword on our head!"

40 Heegner Points and the Arithmetic of Elliptic Curves over Ring Class Extensions, with R. Bradshaw

Heegner Points and the Arithmetic of Elliptic Curves Over Ring Class Extensions

Robert Bradshaw and William Stein[1a,b]

[a] *Google, Seattle*
[b] *University of Washington*

Abstract

Let E be an elliptic curve over $\mathbb{Q}$ and let K be a quadratic imaginary field that satisfies the Heegner hypothesis. We study the arithmetic of E over ring class extensions of K, with particular focus on the case when E has analytic rank at least 2 over $\mathbb{Q}$. We also point out an issue in the literature regarding generalizing the Gross-Zagier formula, and offer a conjecturally correct formula.

Keywords: elliptic curve, Gross-Zagier formula, Birch and Swinnerton-Dyer conjecture, Shafarevich-Tate groups
2000 MSC: 11G05

1. Introduction

Let E be an elliptic curve over $\mathbb{Q}$. By [Wil95, BCDT01], $L(E,s)$ extends to an entire function on $\mathbb{C}$, so $r_{\mathrm{an}}(E/\mathbb{Q}) = \mathrm{ord}_{s=1} L(E,s)$ is defined. Let $r_{\mathrm{alg}}(E/\mathbb{Q}) = \mathrm{rank}(E(\mathbb{Q}))$.

Conjecture 1 (Birch and Swinnerton-Dyer (see [Wil00]))**.** *We have*

$$r_{\mathrm{an}}(E/\mathbb{Q}) = r_{\mathrm{alg}}(E/\mathbb{Q}).$$

Let K be a quadratic imaginary field such that all primes dividing the conductor N of E split in K, and let $u = \#\mathcal{O}_K^\times/2$, which is 1 unless $K = \mathbb{Q}(\sqrt{-1})$ or $\mathbb{Q}(\sqrt{-3})$. For each squarefree product c of primes that are inert

[1] This work was supported by NSF grants DMS-0757627, DMS-0653968 and the Mathematical Sciences Research Institute.

in K, let K_c denote the ring class field of conductor c, which is an abelian extension of K ramified exactly at primes dividing c. Moroever, K_1 is the Hilbert class field of K, and (see [Gro91, §3])

$$\mathrm{Gal}(K_c/K_1) \cong (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times.$$

Heegner points are certain points in $E(K_c)$ that are constructed using complex multiplication and a fixed choice of modular parametrization $\phi_E : X_0(N) \to E$ of minimal degree. In this paper, we study the subgroup of $E(K_c)$ generated by Galois conjugates of Heegner points, and relate it to $\#Ш(E/K_c)$.

Our motivation for this paper is that the subgroup W of any Mordell-Weil group generated by Heegner points typically fits into an analogue of the BSD conjecture, but with the "difficult" factors such as the Shafarevich-Tate group and Tamagawa numbers removed (see [Ste10b]). Thus according to the BSD formula (see Conjecture 12 below), we expect that the index of W in its saturation (or the closely related index of $E(K) + W$ in $E(K_c)$) in the Mordell-Weil group is related to the order of Ш and Tamagawa numbers. In Theorem 13 below, which is conditional on the BSD formula (see Conjecture 12 below), we compute this index in terms of other invariants of E. Intriguingly, in order for our result to satisfy certain consistency checks, we discover that the previously published explicit generalizations of the Gross-Zagier formula to ring class fields appear to be wrong, e.g., they do not properly take into account either the conductor of the ring class character or the degree of the ring class field.

Our hypothesis that every prime dividing N splits in K implies that there is a factorization of the ideal $N\mathcal{O}_K$ as $\mathcal{N}\bar{\mathcal{N}}$ with $\mathcal{O}_K/\mathcal{N} \cong \mathbb{Z}/N\mathbb{Z}$. Fix an embedding $K \hookrightarrow \mathbb{C}$ and view $\mathcal{O}_K$ as a lattice in $\mathbb{C}$, so $\mathbb{C}/\mathcal{O}_K$ is a CM elliptic curve, and $\mathcal{N}^{-1}/\mathcal{O}_K$ defines a cyclic subgroup of order N. Let $X_0(N)$ be the standard modular curve whose affine points over $\mathbb{C}$ parameterize isomorphism classes of pairs (F, C), where F is an elliptic curve over $\mathbb{C}$ and C is a cyclic subgroup of F of order N. Let x_1 be the point in $X_0(N)(K_1)$ defined by the isomorphism class of $(\mathbb{C}/\mathcal{O}_K, \mathcal{N}^{-1}/\mathcal{O}_K)$. Using the modular parameterization $\phi_E : X_0(N) \to E$, we obtain a point $y_1 = \phi_E(x_1) \in E(K_1)$. Let $y_K = \mathrm{Tr}_{K_1/K}(y_1)$ be the trace of y_1. After fixing our choice of ϕ_E, the point y_K is well defined up to sign, since making a different choice of $\mathcal{N}$ replaces y_K by its image under an Atkin-Lehner involution, as explained in [Wat06, §2] or [Coh07, Thm. 8.7.7], and Atkin-Lehner acts as ±1 on E.

In addition to their central importance to explicit computation of rational points on elliptic curves, Heegner points play an essential role in results toward Conjecture 1 (see, e.g., [Gro91]):

Theorem 2 (Gross-Zagier, Kolyvagin, et al.)**.** *Let $E/\mathbb{Q}$ be an elliptic curve with $r_{\mathrm{an}}(E/\mathbb{Q}) \leq 1$. Then $r_{\mathrm{an}}(E/\mathbb{Q}) = r_{\mathrm{alg}}(E/\mathbb{Q})$ and $Ш(E/\mathbb{Q})$ is finite.*

The proof that $Ш(E/\mathbb{Q})$ is finite also yields an explicit computable upper bound on the p-part of $\#Ш(E/\mathbb{Q})$ (see [GJP$^+$09, Thm. 3.4]) at primes p where $\overline{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(E[p])$ has sufficiently large image (see [Cha05, GJP$^+$09, Jet08, SW11]). The bound is in terms of $[E(K) : \mathbb{Z}y_K]$, for any choice of K. This bound plays an essential role in verifying the full BSD formula (Conjecture 12) for specific elliptic curves, as in [GJP$^+$09, Mil10, MS10].

If M is any number field, let $\hat{h}_M$ denote the Néron-Tate canonical height on $E(M)$ over M. If S is an extension of M and $P \in E(M)$, then $\hat{h}_S(P) = [S : M] \cdot \hat{h}_M(P)$ (see [Sil92, Prop. VIII.5.4]). Following [GZ86, §I.6 and §V.2], we have

$$\|\omega_E\|^2 = \frac{8\pi^2 \cdot (f,f) \cdot c_E^2}{\deg(\phi_E)}, \tag{1}$$

where ω_E is a minimal differential on E, c_E is the Manin constant, $\deg(\phi_E)$ is the modular degree, f is the newform corresponding to E, and (f,f) is the Petersson inner product of f with itself (see also [GJP$^+$09, §3]).

Remark 3. We assume that $c_E = 1$ in the rest of this paper. As explained in [ARS06] this should be a harmless assumption, and conjecturally amounts to working with the optimal elliptic curve isogenous to E.

The following theorem is in [GZ86, §V.2, pg. 311]:

Theorem 4 (Gross-Zagier)**.** *We have*

$$L'(E/K,1) = \frac{\|\omega_E\|^2}{u^2 \cdot \sqrt{|D_K|}} \cdot \hat{h}_K(y_K).$$

Let E be an elliptic curve over $\mathbb{Q}$ and assume that $r_{\mathrm{an}}(E/K) = 1$. The subgroup of $E(K)$ generated by the Heegner point plays an essential role in the proof of Theorem 2. One uses the nontorsion point $y_K = \mathrm{Tr}_{K_1/K}(y_1)$ to bound the rank of $E(K)$ from below. There are also higher Heegner points $y_c = \phi_E(x_c)$ (see Section 2) that are used to construct elements of various Selmer groups associated to E, which one then uses to bound the rank of $E(K)$ from above.

Assume $L'(E/K,1) \neq 0$. Then, as explained in [Ste10b, §2], the Gross-Zagier formula and the BSD formula for $L'(E/K,1)$ together imply that

$$[E(K) : \mathbb{Z}y_K]^2 = \#Ш(E/K) \cdot \prod c_{v,K},$$

where the $c_{v,K}$ are the Tamagawa numbers of E/K. Note that since each prime divisor $p \mid N$ splits in K, the product of the Tamagawa numbers of E/K is the square of $\prod_{p|N} c_p$, where the c_p are the Tamagawa numbers of $E/\mathbb{Q}$. See the proof of Proposition 14 for related remarks, and [Ste10b, Prop. 2.4] for a discussion of what happens when E has rank ≥ 2.

In Section 2, we recall the definition of Heegner points over ring class fields, set up some notation involving characters and corresponding idempotent projectors, and discuss generalization of the Gross-Zagier formula to higher Heegner points. In Section 3, we introduce the subgroup W of $E(K_c)$ generated by Galois conjugates of Heegner points and describe a theorem of Bertolini-Darmon that allows us to deduce conditions under which $W+E(K)$ has finite index in $E(K_c)$. In Section 4, we use a generalization of the Gross-Zagier formula to derive a formula for $\mathrm{Reg}(W)$, then use the BSD formula to compute the index of $W+E(K)$ in $E(K_c)$. We also compute the index of W in its saturation. Section 5 gives an example that illustrates the results of Section 4. Finally, Section 6 suggests some avenues for future investigation.

2. Higher Heegner Points

Fix a positive squarefree integer c whose prime divisors are inert in K and coprime to N. Let $\mathcal{O}_c = \mathbb{Z} + c\mathcal{O}_K$ and $\mathcal{N}_c = \mathcal{N} \cap \mathcal{O}_c$. Then the pair $(\mathbb{C}/\mathcal{O}_c, \mathcal{N}_c^{-1}/\mathcal{O}_c)$ defines a CM elliptic curve equipped with a cyclic subgroup of order N, and the isomorphism class of this pair defines a point $x_c \in X_0(N)(K_c)$. We use the modular parameterization ϕ_E to map x_c to a point $y_c = \phi_E(x_c) \in E(K_c)$.

Let $G = \mathrm{Gal}(K_c/K)$ and let

$$h_c = [K_c : K] = \#\,\mathrm{Cl}(\mathcal{O}_c) = \#G$$

be the class number of the order $\mathcal{O}_c$. For any character $\chi : G \to \mathbb{C}^\times$, let e_χ be the idempotent

$$e_\chi = \frac{1}{h_c}\sum_{\sigma \in G} \chi^{-1}(\sigma)\sigma \in \mathbb{C}[G],$$

which projects to the χ-isotypical component of any module. Note that if $\sigma \in G$, then $\sigma e_\chi = \chi(\sigma) e_\chi$; also, $1 = \sum_{\chi : G \to \mathbb{C}^\times} e_\chi$.

Following [Gro84, (10.1)], we extend the Néron-Tate height pairing $\langle\ ,\ \rangle_{K_c}$ on $E(K_c)$ defined by h_{K_c} to a Hermitian inner product on the complex vector space $V = E(K_c) \otimes_{\mathbb{Z}} \mathbb{C}$ by letting

$$\langle \alpha P,\, \beta Q \rangle = \alpha \overline{\beta} \langle P,\, Q \rangle_{K_c} \tag{2}$$

and extending linearly. We also view V as a $\mathbb{C}[G]$-module by making $\sigma \in G$ act by $\sigma(P \otimes \alpha) = \sigma(P) \otimes \alpha$. Since E is defined over $\mathbb{Q}$, the height pairing on V is $\mathrm{Gal}(K_c/\mathbb{Q})$-equivariant (see [Sil92, Lem. VIII.5.10]), in the sense that for any $\sigma \in \mathrm{Gal}(K_c/\mathbb{Q})$ and $P, Q \in E(K_c)$, we have $\langle \sigma(P), \sigma(Q) \rangle = \langle P, Q \rangle$.

Lemma 5. *The χ eigenspaces of V are orthogonal with respect to the height pairing.*

Proof. This is standard, but for the convenience of the reader we give a proof. If χ, χ' are two characters of G, then for any $P, Q \in E(K_c)$ and $\sigma \in G$, we have

$$\begin{aligned} \langle e_\chi P,\, e_{\chi'} Q \rangle &= \langle \sigma(e_\chi P),\, \sigma(e_{\chi'} Q) \rangle \\ &= \langle \chi(\sigma) e_\chi P,\, \chi'(\sigma) e_{\chi'} Q \rangle \\ &= \chi(\sigma) \chi'(\sigma)^{-1} \langle e_\chi P,\, e_{\chi'} Q \rangle. \end{aligned}$$

Thus if $\langle e_\chi P,\, e_{\chi'} Q \rangle \neq 0$ for some P, Q, then $\chi(\sigma)\chi'(\sigma)^{-1} = 1$ for all σ, hence $\chi = \chi'$. □

We next explain how the heights $\hat{h}_{K_c}(e_\chi y_c)$ are related to the special values of certain L-functions. Let $f = \sum a_n q^n \in S_2(\Gamma_0(N))$ be the newform corresponding to E, let χ be a character of G, and let $L(f, \chi, s)$ be the Rankin-Selberg L-series $L(f \otimes g_\chi, s)$, as described in [Gro84, §III]. According to [Gro84, Prop. 21.2], the sign in the functional equation for $L(f, \chi, s)$ is -1, so $L(f, \chi, s)$ vanishes to odd order at $s = 1$. In [Zha01a, Thm. 1.2.1], Zhang proves a generalization of the Gross-Zagier formula (Theorem 4 above) that relates the height of $e_\chi y_c$ to $L'(f, \chi, 1)$. Unfortunately, the literature on this formula is inconsistent. For nontrival χ, [JLS09, §A.2] asserts that Zhang's theorem implies that

$$L'(f, \chi, 1) = \frac{4(f, f)}{u^2 \sqrt{|D_K|}} \cdot \hat{h}_{K_c}(e_\chi y_c). \tag{3}$$

The earlier paper [Hay95, Thm. 2] conjectures that the formula is

$$L'(f,\chi,1) = \frac{8\pi^2(f,f)}{u^2\sqrt{|D_K|}} \cdot \hat{h}_{K_c}(e_\chi y_c). \tag{4}$$

However, somewhat bizarrely, immediately after stating the above, [Hay95] then states that the formula is instead

$$L'(f,\chi,1) = \frac{h_c \cdot 8\pi^2(f,f)}{u^2\sqrt{|D_K|}} \cdot \hat{h}_{K_c}(e_\chi y_c). \tag{5}$$

which is closer to what we expect (see Conjecture 6).

Consistency checks with the BSD formula (see Proposition 14 and the discussion on page 14 right after the proof of Theorem 13) very strongly suggest that Equations (3), (4) and (5) are all incorrect. Zhang remarks at the end of Section 1 of [Zha04], "I would like to thank N. Vatsal and H. Xue for pointing out many inaccuracies in our previous paper [Zha01a]," and in an email to the authors: "You are right that my formula cited in your paper is not accurate. A correct version is in my paper [Zha04]."

Instead, we propose the following closely related formula, which also features the *conductor* of the character $\chi : \mathrm{Gal}(K_c/K) \to \mathbb{C}^\times$, which is the smallest integer divisor $c' \mid c$ such that χ factors through the natural quotient map $\mathrm{Gal}(K_c/K) \to \mathrm{Gal}(K_{c'}/K)$.

Conjecture 6. *If χ is a nontrivial character of G, then*

$$L'(f,\chi,1) = \frac{h_c \cdot 8\pi^2(f,f)}{\mathrm{cond}(\chi) \cdot u^2 \cdot \sqrt{|D_K|}} \cdot \hat{h}_{K_c}(e_\chi y_c).$$

Remark 7. Zhang has explained to us that one can deduce the above conjecture from his [Zha04, Thm 6.1]. Zhang and his students intend to give the details in a future paper.

3. The Heegner Point Subgroup

In this section we state a theorem of Bertolini-Darmon, and use it to understand when $W + E(K)$ generates a finite index subgroup of $E(K_c)$. We also give equivalent conditions under which W and $E(K)$ are orthogonal.

Let E and K be as above. We continue to fix an integer c whose prime divisors are inert in K and coprime to N, and let a_c be the cth Fourier coefficient of the newform attached to the elliptic curve E. Consider the subgroup $W = \mathbb{Z}[G]y_c$ of $E(K_c)$ spanned by the G-conjugates of y_c.

Recall from Section 2 the vector space $V = E(K_c) \otimes_{\mathbb{Z}} \mathbb{C}$, which is a finite-dimensional $\mathbb{C}[G]$-module equipped with a G-invariant bilinear Hermitian height pairing (2). For any character χ of G, let $V^\chi = e_\chi V$ be the subspace of V on which G acts via χ. Because $1 = \sum_\chi e_\chi$, we have

$$V = \bigoplus_{\chi : G \to \mathbb{C}^\times} V^\chi,$$

and Lemma 5 asserts that the V^χ are mutually orthogonal. Let $y_{c,\chi} = e_\chi(y_c) \in V^\chi$.

Theorem 8 (Bertolini-Darmon [BD90])**.** *If $y_{c,\chi} \neq 0$ then $V^\chi = \mathbb{C}y_{c,\chi}$.*

Remark 9. The converse of Theorem 8 is the assertion that if $y_{c,\chi} = 0$ then $V^\chi \neq \mathbb{C}y_{c,\chi} = 0$. As explained in [BD90], this is consistent with a natural refinement of the BSD rank conjecture (Conjecture 1), which asserts that V^χ has odd rank (see also [YZZ10, Conj. 1.4.1]). It is a difficult open problem to come up with any way to construct points in V^χ when $\mathbb{C}y_{c,\chi} = 0$.

Proposition 10. *If for* all *nontrivial characters χ of G we have $L'(f, \chi, 1) \neq 0$, then the index $[E(K_c) : W + E(K)]$ is finite.*

Proof. By tensoring with $\mathbb{C}$, we see that the claim is equivalent to showing that the $\mathbb{C}$ span of $W + E(K)$ is V. Let χ_1 denote the trivial character. Then

$$V = \bigoplus_{\chi : G \to \mathbb{C}^\times} V^\chi = V^{\chi_1} \oplus \bigoplus_{\chi \neq \chi_1} V^\chi.$$

We have $V^{\chi_1} = E(K) \otimes \mathbb{C}$. Theorem 8 and our hypothesis that $L'(f, \chi, 1) \neq 0$ for all nontrivial χ imply that $W \otimes \mathbb{C} = \oplus_{\chi \neq \chi_1} V^\chi$, □

As explained in [Gro84, §6] and [Gro91, Prop. 3.7], we have $\mathrm{Tr}_{K_c/K}(y_c) = a_c y_K$, which motivates the appearance of $a_c y_K$ in the following proposition.

Proposition 11. *The following are equivalent:*

1. *The two subgroups W and $E(K)$ of $E(K_c)$ are mutually orthogonal.*
2. *The point $a_c y_K$ is torsion.*
3. $a_c = 0$ *or* $r_{\mathrm{an}}(E/K) > 1$.

Proof. To prove that 1 implies 2, suppose that W is orthogonal to $E(K)$. The height pairing on $E(K_c)$ is 0 only on torsion points, so $W \cap E(K)$ is a torsion group. But $a_c y_K = \mathrm{Tr}_{K_c/K}(y_c) \in W \cap E(K)$, so $a_c y_K$ is torsion, as claimed.

To prove that 2 implies 1, assume that $a_c y_K$ is torsion. Choose $P \in E(K)$ and $Q \in W$. For any $\sigma \in G$, we have

$$\mathrm{Tr}_{K_c/K}(\sigma(y_c)) = \sigma(\mathrm{Tr}_{K_c/K}(y_c)) = \sigma(a_c y_K) = a_c y_K \in E(K)_{\mathrm{tor}}. \tag{6}$$

Since Q is a linear combination of $\sigma(y_c)$ for various σ, Equation (6) implies that $\mathrm{Tr}_{K_c/K}(Q)$ is torsion. The height pairing is Galois equivariant, so for all $\sigma \in G$, we have $\langle P, Q\rangle = \langle \sigma P, \sigma Q\rangle = \langle P, \sigma Q\rangle$. Thus

$$\langle P, Q\rangle = \frac{1}{h_c}\sum_{\sigma\in G}\langle P, \sigma Q\rangle = \frac{1}{h_c}\langle P, \mathrm{Tr}_{K_c/K} Q\rangle = 0.$$

Finally we observe that 2 and 3 are equivalent. If $a_c = 0$ then $a_c y_K = 0$. If $r_{\mathrm{an}}(E/K) > 1$, then Theorem 4 implies that y_K is torsion. Conversely, suppose $a_c y_K$ is torsion. If $a_c \neq 0$, then y_K is also torsion, so Theorem 4 implies that $r_{\mathrm{an}}(E/K) > 1$. □

4. Regulators and Indexes

In this section we study the index $[E(K_c) : W + E(K)]$, and under certain hypotheses, conjecturally relate it to various arithmetic invariants of E. In particular, we prove Theorem 13, which is a conjectural formula for the index $[E(K_c)_{/\mathrm{tor}} : (E(K) + W)_{/\mathrm{tor}}]$ under any of the equivalent hypotheses of Proposition 11.

If H is any subgroup of a Mordell-Weil group $E(M)$, let $\mathrm{Reg}_M(H)$ be the absolute value of the determinant of the height pairing $\langle\, , \rangle_M$ on a basis of H. We emphasize here that we use the height relative to M and not the absolute height on $E(\overline{\mathbb{Q}})$.

Theorem 13 below is conditional on the BSD formula over number fields.

Conjecture 12 (Birch and Swinnerton-Dyer Formula)**.** *If E is an elliptic curve of rank r over a number field F then*

$$\frac{L^{(r)}(E/F, 1)}{r!} = \frac{\Omega_{E/F} \cdot \mathrm{Reg}_F(E(F)) \cdot \#Ш(E/F) \cdot \prod_v c_{v,F}}{\sqrt{|D_F|} \cdot \#E(F)_{\mathrm{tor}}^2},$$

where $D_F \in \mathbb{Z}$ is the discriminant of F, and the other quantities are as in [Lan91, III, §5].

If E is defined over $\mathbb{Q}$ and F is totally imaginary, as it is in our application in which $F = K$ or $F = K_c$, we have $\Omega_{E/F} = \|\omega_E\|^{[F:\mathbb{Q}]}$, where $\|\omega_E\|$ is as in Equation (1) (see also [GZ86, §6]).

Much of the rest of this section is devoted to proving the following theorem.

Theorem 13. *Assume Conjectures 6 and 12 for E, that $\mathrm{ord}_{s=1} L(E/K, \chi, s) = 1$ for each nontrivial ring class character χ of conductor dividing c, and that $a_c y_K$ is torsion. Let $r = r_{\mathrm{an}}(E/K) = \mathrm{ord}_{s=1} L(E/K, s)$ and assume that $r = \mathrm{rank}(E(K))$, as predicted by Conjecture 1. Then*

$$[E(K_c)_{/\mathrm{tor}} : (E(K)+W)_{/\mathrm{tor}}]^2 = \frac{\#\text{Ш}(E/K_c)}{\#\text{Ш}(E/K)} \cdot \frac{\prod_w c_{w,K_c}}{\prod_v c_{v,K}} \cdot \frac{\#E(K)_{\mathrm{tor}}^2}{\#E(K_c)_{\mathrm{tor}}^2} \cdot h_c^{r-1} \cdot u^{2h_c}.$$

Because of the the Cassels-Tate pairing, we expect that $\#\text{Ш}(E/K_c)$ and $\#\text{Ш}(E/K)$ are both perfect squares (see, e.g., [Ste04, Thm. 1.2]). The following Proposition is thus an important consistency check for Theorem 13.

Proposition 14. *Theorem 13 predicts that $\frac{\#\text{Ш}(E/K_c)}{\#\text{Ш}(E/K)}$ is a perfect square.*

Proof. We check that each factor, except the quotient of Shafarevich-Tate groups appearing in the theorem, is a perfect square, especially the Tamagawa number factors. Each prime of bad reduction for E splits in K, and for the two primes v and v' over a split prime p of $\mathbb{Q}$, we have $c_{v,K} = c_{v',K}$, so

$$\prod_v c_{v,K} = \left(\prod_{p|N} c_{p,\mathbb{Q}}\right)^2.$$

The extension K_c/K is unramified at each prime of bad reduction for E, and the formation of Néron models commutes with unramified base change (see [BLR90, §1.2, Prop. 2]), so for each prime v of K and each prime w of K_c with $w \mid v$, we have $c_{w,K_c} = c_{v,K}$. Let g_v be the number of primes of K_c over the prime v of K. Then

$$\prod_{w \text{ of } K_c} c_{w,K_c} = \prod_{v \text{ of } K} c_{v,K}^{g_v} = \prod_{p|N} c_{p,\mathbb{Q}}^{2g_v} = \left(\prod_{p|N} c_{p,\mathbb{Q}}^{g_v}\right)^2.$$

Finally, the factor h_c^{r-1} is a perfect square since the sign of the functional equation for $L(E/K, s)$ is odd, so r is odd. □

Lemma 15. *With hypotheses as in Theorem 13, $L(E/K_c, s)$ vanishes to order exactly $r + h_c - 1$ and*

$$\frac{L^{(r+h_c-1)}(E/K_c, 1)}{(r + h_c - 1)!} = \frac{L^{(r)}(E/K, 1)}{r!} \cdot \prod_{\chi \neq \chi_1} L'(E/K, \chi, 1). \tag{7}$$

Proof. The L-function of E over K_c factors as

$$L(E/K_c, s) = \prod_{\chi} L(f, \chi, s) = L(E/K, s) \cdot \prod_{\chi \neq \chi_1} L(f, \chi, s),$$

where the first product is over characters $\chi : G \to \mathbb{C}^\times$, and χ_1 is the trivial character. This implies the order of vanishing statement. The leading coefficient of the product of power series is the product of the leading coefficients of those series, which gives the formula for the leading coefficient. □

In using Conjecture 12 to deduce Theorem 13, we will make use of an explicit formula for the discriminant D_{K_c}.

Lemma 16. *We have*

$$D_{K_c} = D_K^{h_c} \cdot \prod_{p \mid c} p^{\frac{2 \cdot p \cdot h_c}{p+1}}$$

Proof. Consider a prime divisor $p \mid c$, and write $c = pc'$. The prime $p\mathcal{O}_K$ above p splits completely in $K_{c'}/K$ (as explained in [Ste10b, Lem. 5.3]). Going from $K_{c'}$ to K_c, the primes above $p\mathcal{O}_K$ are totally ramified, with ramification index $[K_c : K_{c'}] = [K_p : K_1] = p+1$. Combining this information for all $p \mid c$ and applying [FT93, Thm. 26, Ch. III], implies that the different $\delta_{K_c/K}$ is $\prod_{p|c} \prod_{\mathfrak{p}|p} \mathfrak{p}^p$. Let $\mathfrak{p}$ be any prime of K_c over p. As explained above, since p is inert in $K/\mathbb{Q}$, the prime $p\mathcal{O}_K$ splits completely in $K_{c'}/K$, then totally and tamely ramifies in K_c/K_c', so $\mathrm{norm}_{K_c/\mathbb{Q}}(\mathfrak{p}) = p^2$, and the number of primes $\mathfrak{p}$ over a given p is $h_c/(p + 1)$. The different ideal is multiplicative in towers, and the discriminant is the norm of the different, so

$$\begin{aligned} D_{K_c} &= \mathrm{norm}_{K_c/\mathbb{Q}}(\delta_{K_c/\mathbb{Q}}) \\ &= \mathrm{norm}_{K_c/\mathbb{Q}}(\delta_{K/\mathbb{Q}} \cdot \delta_{K_c/K}) \\ &= \mathrm{norm}_{K_c/\mathbb{Q}}(\delta_{K/\mathbb{Q}}) \cdot \prod_{p|c} \prod_{\mathfrak{p}|p} \mathrm{norm}_{K_c/\mathbb{Q}}(\mathfrak{p})^p \\ &= D_K^{h_c} \cdot \prod_{p|c} p^{\frac{2h_c p}{p+1}}. \end{aligned}$$

□

The product of prime divisors of c in Lemma 16 can be expressed in terms of conductors as follows:

Lemma 17. *We have*

$$D_{K_c} = D_K^{h_c} \cdot \prod_{\chi \neq \chi_1} \operatorname{cond}(\chi)^2. \tag{8}$$

Proof. Consider the set of characters $\chi : G \to \mathbb{C}^\times$. A character χ has conductor not divisible by p precisely if it factors through $\operatorname{Gal}(K_{c'}/K)$, so the number of characters χ with conductor not divisible by p is the number of characters of $\operatorname{Gal}(K_{c'}/K)$, which is $\#\operatorname{Gal}(K_{c'}/K) = h_c/(p+1)$. Thus the number of characters with conductor divisible by p is $h_c - h_c/(p+1)$. As $\operatorname{cond}(\chi) \mid c$ we have

$$\prod_{\chi \neq \chi_1} \operatorname{cond}(\chi) = \prod_{p \mid c} p^{h_c - h_c/(p+1)} = \prod_{p \mid c} p^{h_c p/(p+1)},$$

which, combined with Lemma 16, implies the claimed formula. □

We will use the following lemma in computing a certain regulator in the proof of Proposition 19 below.

Lemma 18. *Let $M_m(a,b)$ be the $m \times m$ matrix with $a+b$ along the diagonal and all other entries equal to b. Then* $\det M_m(a,b) = (a+mb)a^{m-1}$.

Proof. The case for $m = 1, 2$ is clear. For $m > 2$, first consider the determinant of the matrix $M'_m(a,b)$ of size $m \times m$ whose entries are all b except for the first upper off diagonal whose entries are all $a+b$ (see Equation (9) below). We claim that $\det M'_m(a,b) = (-a)^{m-1}b$. For $m = 1, 2$ this is clear. For larger m we perform a row operation (subtract row 2 from row 1) and expand by minors, as follows:

$$\det M'_m(a,b) = \begin{vmatrix} b & a+b & \cdots & b \\ b & b & \ddots & \vdots \\ \vdots & & \ddots & a+b \\ b & \cdots & b & b \end{vmatrix} = \begin{vmatrix} 0 & a & \cdots & 0 \\ b & b & \ddots & \vdots \\ \vdots & & \ddots & a+b \\ b & \cdots & b & b \end{vmatrix} \tag{9}$$

$$= -a \cdot \det M'_{m-1}(a,b) = -a(-a)^{m-2}b = (-a)^{m-1} \cdot b. \tag{10}$$

Using this formula for $\det M'_m(a,b)$ allows us to compute $\det M_m(a,b)$ as follows, where in the first step we subtract the last row from the first row:

$$\det M_m(a,b) = \begin{vmatrix} a+b & b & \cdots & b \\ b & a+b & & \vdots \\ \vdots & & \ddots & b \\ b & \cdots & b & a+b \end{vmatrix} = \begin{vmatrix} a & 0 & \cdots & -a \\ b & a+b & & \vdots \\ \vdots & & \ddots & b \\ b & \cdots & b & a+b \end{vmatrix}$$
$$= a \cdot \det M_{m-1}(a,b) \;+\; (-1)^m(-a)\det M'_{m-1}(a,b)$$
$$= (a+mb)\cdot a^{m-1}.$$

□

Proposition 19. *With hypotheses as in Theorem 13 (but without assuming any conjectures!), we have*

$$\mathrm{Reg}_{K_c}(W) = h_c^{h_c-2} \cdot \prod_{\chi\neq\chi_1} \hat{h}_{K_c}(y_{c,\chi}).$$

Proof. In this proof we will work everywhere with the images of points in $V = E(K_c)\otimes\mathbb{C}$, which should not cause confusion.

The hypotheses imply that for each nontrivial character χ, the point $y_{c,\chi}$ has infinite order. Lemma 5 asserts that the $y_{c,\chi}$ are mutually orthogonal, so there is a lattice Λ in $W\otimes\mathbb{C}$ with basis the $y_{c,\chi}$, which has rank $h_c - 1$ (the number of nontrivial characters χ). Because the $y_{c,\chi}$ are all nonzero and orthogonal, we have

$$\mathrm{Reg}_{K_c}(\Lambda) = \prod_{\chi\neq\chi_1} \hat{h}_{K_c}(y_{c,\chi}).$$

By Proposition 10, the elements $(y_c^\sigma)_{1\neq\sigma\in G}$ are independent and nonzero, so they form a basis for their $\mathbb{Z}$-span $W_{/\mathrm{tor}}$ in V. Let M be the $(h_c-1)\times(h_c-1)$ change of basis matrix with respect to these two bases. More precisely, if for any fixed basis of V, we let B_Λ be the matrix with rows our chosen basis for Λ and B_W the matrix with rows our basis for W, then $B_\Lambda = M\cdot B_W$. We have $\mathrm{Reg}_{K_c}(\Lambda) = \det(M)^2\cdot\mathrm{Reg}_{K_c}(W)$, so to compute $\mathrm{Reg}_{K_c}(W)$, it suffices to compute $\det(M)^2$. By definition of e_χ and using that $\mathrm{Tr}_{K_c/K}(y_c) = 0$ (in V) we have

$$y_{c,\chi} = \frac{1}{h_c}\sum_{\sigma\in G}\chi^{-1}(\sigma)y_c^\sigma = \frac{1}{h_c}\sum_{1\neq\sigma\in G}(\chi^{-1}(\sigma)-1)y_c^\sigma,$$

from which we read off the rows of the matrix M. For any two rows M_{χ_i}, M_{χ_j} of M,

$$\begin{aligned} M_{\chi_i} \cdot M_{\chi_j} &= \frac{1}{h_c^2} \sum_{1 \neq \sigma \in G} (\chi_i^{-1}(\sigma) - 1)(\chi_j^{-1}(\sigma) - 1) \\ &= \frac{1}{h_c^2} \sum_{\sigma \in G} (\chi_i^{-1}(\sigma) - 1)(\chi_j^{-1}(\sigma) - 1) \\ &= \frac{1}{h_c^2} \sum_{\sigma \in G} (\chi_i \chi_j)^{-1}(\sigma) - \chi_i^{-1}(\sigma) - \chi_j^{-1}(\sigma) + 1 = \begin{cases} \frac{2}{h_c} & \text{if } \chi_i = \chi_j^{-1}, \\ \frac{1}{h_c} & \text{otherwise.} \end{cases} \end{aligned}$$

Thus

$$(\det M)^2 = \det MM^T = \det(M_{\chi_i} \cdot M_{\chi_j})_{i,j} = \pm \begin{vmatrix} \frac{2}{h_c} & \frac{1}{h_c} & \cdots & \frac{1}{h_c} \\ \frac{1}{h_c} & \frac{2}{h_c} & & \vdots \\ \vdots & & \ddots & \frac{1}{h_c} \\ \frac{1}{h_c} & \cdots & \frac{1}{h_c} & \frac{2}{h_c} \end{vmatrix},$$

where the columns in the final matrix have been permuted so we have $2/h_c$ down the diagonal and $1/h_c$ everywhere else, which only affects the determinant up to sign. To evaluate this determinant we use Lemma 18 with $a = b = 1/h_c$ and $m = h_c - 1$ and obtain

$$\det(M)^2 = \left(\frac{1}{h_c} + (h_c - 1) \cdot \frac{1}{h_c} \right) \cdot \left(\frac{1}{h_c} \right)^{h_c - 2} = 1/h_c^{h_c - 2}.$$

Thus

$$\mathrm{Reg}_{K_c}(W) = (\det M)^{-2} \cdot \mathrm{Reg}_{K_c}(\Lambda) = h_c^{h_c - 2} \cdot \prod_{\chi \neq \chi_1} \hat{h}_{K_c}(y_{c,\chi}).$$

□

Proof of Theorem 13. Apply Conjecture 12 to the left hand side of Equation (7), and to the first factor on the right hand side, and Conjecture 6 to the remaining factors on the right hand side, to get

$$\frac{\|\omega_f\|^{2h_c} \cdot \mathrm{Reg}_{K_c}(E(K_c)) \cdot \#\text{Ш}(E/K_c) \cdot \prod c_{w,K_c}}{\sqrt{|D_{K_c}|} \cdot \#E(K_c)_{\mathrm{tor}}^2}$$

$$= \frac{\|\omega_f\|^2 \cdot \mathrm{Reg}_K(E(K)) \cdot \#Ш(E/K) \cdot \prod c_{v,K}}{\sqrt{|D_K|} \cdot \#E(K)_{\mathrm{tor}}^2} \cdot \prod_{\chi \neq \chi_1} \frac{h_c \cdot \|\omega_f\|^2}{\mathrm{cond}(\chi) \cdot u^2 \cdot \sqrt{|D_K|}} \cdot \hat{h}_{K_c}(y_{c,\chi}).$$

Cancelling $\|\omega_f\|^{2h_c}$ from both sides, and rearranging factors gives

$$u^{2h_c} \cdot \frac{\sqrt{|D_K|^{h_c}} \cdot \prod_{\chi \neq \chi_1} \mathrm{cond}(\chi)}{\sqrt{|D_{K_c}|}} \cdot \frac{\prod c_{w,K_c}}{\prod c_{v,K}} \cdot \frac{\#Ш(E/K_c)}{\#Ш(E/K)}$$

$$= \frac{\mathrm{Reg}_K(E(K)) \cdot h_c^{h_c-1} \cdot \prod_{\chi \neq \chi_1} \hat{h}_{K_c}(y_{c,\chi})}{\mathrm{Reg}_{K_c}(E(K_c))} \cdot \frac{\#E(K_c)_{\mathrm{tor}}^2}{\#E(K)_{\mathrm{tor}}^2}. \tag{11}$$

We have $r = \mathrm{rank}(E(K))$, because we are assuming Conjecture 1 for E/K, and Proposition 11 implies that W and $E(K)$ are orthogonal, so

$$\mathrm{Reg}_{K_c}(E(K)+W) = \mathrm{Reg}_{K_c}(E(K)) \cdot \mathrm{Reg}_{K_c}(W) = h_c^r \cdot \mathrm{Reg}_K(E(K)) \cdot \mathrm{Reg}_{K_c}(W). \tag{12}$$

Combining Equation (12) with Proposition 19 yields

$$\mathrm{Reg}_K(E(K)) \cdot h_c^{h_c-1} \cdot \prod_{\chi \neq \chi_1} \hat{h}_{K_c}(y_{c,\chi}) = \mathrm{Reg}_K(E(K)) \cdot h_c \cdot \mathrm{Reg}_{K_c}(W)$$

$$= h_c^{1-r} \cdot \mathrm{Reg}_{K_c}(E(K) + W).$$

Taking square roots of the absolute value of both sides of the formula in Lemma 17 and simplify Equation (11) using the above, we obtain

$$u^{2h_c} \cdot \frac{\prod c_{w,K_c}}{\prod c_{v,K}} \cdot \frac{\#Ш(E/K_c)}{\#Ш(E/K)} = h_c^{1-r} \cdot \frac{\mathrm{Reg}_{K_c}(E(K)+W)}{\mathrm{Reg}_{K_c}(E(K_c))} \cdot \frac{\#E(K_c)_{\mathrm{tor}}^2}{\#E(K)_{\mathrm{tor}}^2}$$

$$= h_c^{1-r} \cdot [E(K_c)_{/\mathrm{tor}} : (E(K)+W)_{/\mathrm{tor}}]^2 \cdot \frac{\#E(K_c)_{\mathrm{tor}}^2}{\#E(K)_{\mathrm{tor}}^2}.$$

Solving for $[E(K_c)_{/\mathrm{tor}} : (E(K)+W)_{/\mathrm{tor}}]^2$ then yields the claimed formula in Theorem 13. □

If we remove the cond(χ) factor from Conjecture 6, then rederive Theorem 13 as in the proof above, the one change is that in Equation (11), instead of having

$$\frac{\sqrt{|D_K|^{h_c}} \cdot \prod_{\chi \neq \chi_1} \mathrm{cond}(\chi)}{\sqrt{|D_{K_c}|}} = 1$$

we get an extra factor of

$$\frac{\sqrt{|D_K|^{h_c}}}{\sqrt{|D_{K_c}|}}$$

next to u^{2h_c}. According to Lemma 16, we have

$$\frac{\sqrt{|D_{K_c}|}}{\sqrt{|D_K|^{h_c}}} = \prod_{p|c} p^{\frac{ph_c}{p+1}}.$$

In the special case when $c = p$ is an odd prime and K has class number 1, this simplifies to

$$\frac{\sqrt{|D_{K_c}|}}{\sqrt{|D_K|^{h_c}}} = p^{\frac{p(p+1)}{p+1}} = p^p,$$

which is never a perfect square, which leads to a contradiction (see Proposition 14).

5. An Example

Suppose E is the elliptic curve 389a given by $y^2 + y = x^3 + x^2 - 2x$, which has rank 2 and conductor 389. The field $K = \mathbb{Q}(\sqrt{-7})$ satisfies the Heegner hypothesis, $c = 5$ is inert in K, and $u = 1$. Since K has class number 1, we have $h_c = c + 1 = 6$. According to [JLS09], the field K_c is obtained by adjoining a root of

$$z^6 + 1750z^5 - 26551875z^4 - 570237500z^3 + 202540106562500z^2$$
$$- 2921132756718750000z + 1345371129783105468 75$$

to K, and we find by computer calculation (or Lemma 16) that

$$D_{K_c} = 5^{10} \cdot 7^6 = (-7)^6 5^{(2\cdot 5\cdot 6)/(5+1)}.$$

All of the p-adic Galois representations associated to E are surjective, so $E(K_c)_{\mathrm{tor}} = 0$. The BSD conjecture and a computation using [S$^+$11] implies that $\text{Ш}(E/K) = 1$, and we find by computation that $r = r_{\mathrm{an}}(E/K) = 3$. The Tamagawa numbers of E at 389 is 1. Assuming the hypothesis of Theorem 13 are satisfied, we have

$$[E(K_5) : E(K) + W]^2 = \#\text{Ш}(E/K_5) \cdot 6^2. \tag{13}$$

Let σ be a choice of generator for $G = \mathrm{Gal}(K_5/K)$. As explained in [JLS09, Ste10a], the Kolyvagin class $\tau \in \mathrm{H}^1(K, E[3])$ associated to y_5 is nonzero and $\text{Ш}(E/K)[3] = 0$, so there is some nonzero $P \in E(K)/3E(K)$ such that $[P] \mapsto [P_5] \in E(K_5)/3E(K_5)$, where $P_5 = \sum i\sigma^i(y_5) \in W$. Thus $P - P_5 = 3Q \in 3E(K_5)$, where $Q \in E(K_5)$ but $Q \notin E(K) + W$. Hence $3 \mid [E(K_5) : E(K) + W]$, as predicted by Equation (13).

6. Ideas for Future Work

It would be of interest to compute the relevant L-functions in this paper for several specific examples, using the methods of Dokchitser [Dok04] or Rubinstein. In addition, one could explicitly compute the Mordell-Weil group $E(K_c)$ in some examples. It would also be of interest to find explicit examples that illustrate the situation discussed in Remark 9, in which $\mathrm{ord}_{s=1} L(E, \chi, s) \geq 3$, since we are currently not aware of any such examples.

Regarding generalizations, it would be natural to fully treat the case when $r = 1$, so that W has finite index in $E(K_c)$. It would also be good to extend the results of this paper to modular abelian varieties A_f attached to newforms in $S_2(\Gamma_0(N))$. Another possible generalization would be to quadratic imaginary fields that do not satisfy the Heegner hypothesis, so the modular curve $X_0(N)$ is replaced by a Shimura curve (see, e.g., the extensive work of Bertolini and Darmon). In another direction, one could likely generalize our results to elliptic curves (or abelian varieties) over totally real fields, following the program initiated by Zhang in [Zha01b].

Assume that for all nontrivial χ we have $\mathrm{ord}_{s=1} L(E, \chi, s) = 1$. Under this hypothesis, it would be of great interest to prove the divisibility

$$\frac{\#\text{Ш}(E/K_c)}{\#\text{Ш}(E/K)} \;\Big|\; [E(K_c) : E(K) + W]^2,$$

at least away from an explicit finite list of primes. This might make it possible to compute $\text{Ш}(E/K_c)/\text{Ш}(E/K)$ for a specific elliptic curve. This would be a generalization of the explicit upper bounds on $\#\text{Ш}(E/K)$ from [GJP$^+$09, Thm. 3.4]. The cryptic [Ber10, Remark 5.23(1)] is relevant, because it claims one can prove at least finiteness of $\text{Ш}(E/K_c)(\chi)$, in the Shimura curve case, though warns "The original methods of Kolyvagin, based on the Gross-Zagier formula, allow to prove a similar statement only when χ is quadratic." This should be contrasted with [YZZ10, §1.6, Thm. C], where it is claimed that under our hypothesis Tian-Zhang have in fact proved that $\text{Ш}(E/K_c)(\chi)$ is finite, using the original method of Kolyvagin based on their generalization of the Gross-Zagier formula.

41 Kolyvagin's Conjecture for Some Specific Higher Rank Elliptic Curves

Kolyvagin's Conjecture for Specific Higher Rank Elliptic Curves

William Stein*

March 26, 2011

Abstract

We study Heegner points and Kolyvagin classes for elliptic curves over $\mathbb{Q}$, with special focus on curves that have analytic rank at least 2. We reinterpret Kolyvagin's "derived classes" construction in the context of divisors on modular curves directly in characteristic ℓ, and prove compatibility and multiplicity one results. We use these results to give the first complete algorithm for explicitly computing (certain) Kolyvagin classes, and thus verify a conjecture of Kolyvagin for some specific elliptic curves.

1 Introduction

A *higher rank* elliptic curve is an elliptic curve E over $\mathbb{Q}$ of analytic rank at least 2. Let K be a quadratic imaginary field such that each prime dividing the conductor of E splits in K. This paper is about the Galois cohomology classes $\tau_{c,p^n} \in \mathrm{H}^1(K, E[p^n])$ defined by Kolyvagin (see, e.g., [Kol88a, Gro91, McC91]). Our main motivation is the explicit study of these classes on higher rank elliptic curves, inspired by the results of [Ste10, BS11] and open conjectures of Kolyvagin (see [Kol91, ÇW08]). In particular, consider Conjecture A of [Kol91, pg. 255]:

Conjecture 1.1 (Kolyvagin)**.** *For each prime p, there is some n and squarefree product $c = \prod p_i$ of primes that are inert in K with $p^n \mid \gcd(a_{p_i}, p_i + 1)$ such that $\tau_{c,p^n} \neq 0$.*

For elliptic curves with analytic rank ≤ 1 over K, this conjecture with $c = 1$ follows from [GZ86], but for higher rank curves the conjecture is wide open, and we have only computational data.

The goal of this paper is to shed some light on Conjecture 1.1 by making it more explicit and computing many examples, as follows. Let p^n and c be as in Conjecture 1.1 We adapt Kolyvagin's construction to define elements in $E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z})$, then give an algorithm to compute these elements in many cases. When one of these elements is nonzero, the corresponding Kolyvagin cohomology class τ_{c,p^n} is also nonzero, which allows us to verify, in several specific examples, Conjecture 1.1. This is significant because until now this conjecture had not been verified in even a single case. In particular, we present a powerful and fairly general approach to explicitly computing information about particular classes $\tau_{c,p^n} \in \mathrm{H}^1(K, A_f[p^n])$ for a modular abelian varieties A_f, squarefree integer c and prime power p^n. Thus, our results provide further motivation and much needed tools for studying Heegner points in the context of higher rank elliptic curves

*The work was supported by NSF grant 0555776 and the Clay Mathematics Institute.

and modular abelian varieties. Moreover, we provide new algorithms for computing with Selmer groups of elliptic curves, which exploit different methods than explicit n-descent for small n (see [Cre97, §3.5] and [CFO$^+$08]) or explicit Iwasawa theory as in [SW11].

Our approach is inspired by groundbreaking work of Cornut, Vatsal, Gross, Jetchev-Kane, and Mazur (see [JK10, Cor02, Vat02]), in which they establish nontriviality results about Heegner points. Our new idea is simple: *use rational quaternion algebras to give an explicit description of the Kolyvagin derived classes construction modulo an auxiliary prime ℓ that is inert in the quadratic imaginary field K* (see Section 6). Many of the objects we use play a central role in the work of Cornut mentioned above. We hope that some of our techniques may also be useful for exploring and refining other ideas related to extra structure on higher rank elliptic curves arising from Heegner points.

The Birch and Swinnerton-Dyer conjectural rank formula (see Conjecture 3.1 below) asserts that $\mathrm{ord}_{s=1} L(E,s) = \mathrm{rank}(E(\mathbb{Q}))$. This conjecture is a theorem when E is an elliptic curve over $\mathbb{Q}$ of analytic rank ≤ 1 (see [BCDT01, GZ86, Kol88b] and Theorem 3.2 below). In sharp contrast, when E is a higher rank curve, the BSD conjecture remains shrouded in mystery, as do potential generalizations of the Gross-Zagier formula (see, e.g., [Ste10]). Unfortunately, the many exciting generalizations of the Gross-Zagier formula to other settings (see [BY09, Zha01, Zha04, YZZ11]) so far seem to yield little new insight in the higher rank case. As explained in [Ste10], Kolyvagin classes are potentially relevant to a search for a generalization of the Gross-Zagier formula that treats higher derivatives. Such a generalization is an incredibly difficult open problem and anything that might shed light on it is worth investigating. So far, finding a plausibly-provable conjecture has remained elusive.

The explicit examples in Section 8 involve rank 2 curves (instead of curves of rank ≥ 3), since the notation and computations are substantially simpler when the rank is 2. The theory and algorithms we develop apply to elliptic curves of any rank, and also to modular abelian varieties. It is thus possible to study many more general situations using our approach (see Section 9).

This paper is structured as follows. In Section 2 we give an outline of our main algorithm. Next in Section 3 we recall the BSD conjecture and give some examples, which motivate our paper. In Section 4 we recall the definition of Heegner points. In Section 5 we introduce Kolyvagin classes, make some observations, and discuss reduction of Heegner points modulo a prime over ℓ. In Section 6 we make the action of Galois on certain objects in characteristic ℓ more explicit and prove a compatibility result. In Section 7 we explain in more detail how our algorithm for computing reductions of Kolyvagin classes works. We combine our above results to obtain an algorithm to compute Kolyvagin classes, which we apply in Section 8, in which we discuss the implementation of our algorithm, tables we obtained by running it, and state some results inspired by this data. Finally, Section 9 discusses a range of related future projects.

Acknowledgement: The author would like to thank Jennifer Balakrishnan, Ralph Greenberg, Benedict Gross, Ben Howard, David Kohel, Dimitar Jetchev, Barry Mazur, Ken Ribet, Karl Rubin, Justin Walker, and Jared Weinstein for helpful discussions.

1.1 Notation and terminology

We use $\cong$ to denote a canonical isomorphism and $\approx$ to denote a noncanonical one. Unless otherwise stated, all tensor products are over $\mathbb{Z}$. We always let p, q, ℓ denote *odd* prime numbers, E an elliptic curve over $\mathbb{Q}$, and K a quadratic imaginary field such that each prime dividing the conductor N of E splits in K. Let a_n denote the nth Dirichlet series coefficient of the L-series $L(E/\mathbb{Q}, s)$ associated to E.

2 Reducing Kolyvagin Classes

As above, let E be an elliptic curve over $\mathbb{Q}$, let K be a quadratic imaginary field such that each prime dividing the conductor N of E splits in K, let p^n be an odd prime power. Let c be a squarefree product of primes that are inert in K such that for each prime $q \mid c$ we have $p^n \mid \gcd(a_q, q+1)$, where $a_q = q + 1 - \#E(\mathbb{F}_q)$. Let K_c be the ring (not ray!) class extension of K associated to c, and let σ_i be a choice of generator of $\mathrm{Gal}(K_c/K_{c/p_i})$ for each prime divisor $p_i \mid c$, and let $\sigma = (\ldots, \sigma_i, \ldots)$. As explained in Section 5 below, Kolyvagin uses Heegner points to construct a point $P_{c,\sigma} \in E(K_c)$ such that $[P_{c,\sigma}] \in (E(K_c) \otimes \mathbb{Z}/p^n\mathbb{Z})^{\mathrm{Gal}(K_c/K)}$. Under suitable hypothesis on p (e.g., the p-adic representation $\rho_{E,p}$ is surjective), Kolyvagin then uses $P_{c,\sigma}$ to define a cohomology class $\tau_{c,p^n} \in \mathrm{H}^1(K, E[p^n])$ characterized by

$$\delta([P_{c,\sigma}]) = \mathrm{res}_{K,K_c}(\tau_{c,p^n}) \in H^1(K_c, E[p^n])^{\mathrm{Gal}(K_c/K)},$$

where δ is the connecting homomorphism of Galois cohomology. (The class τ_{c,p^n} also depends on the choice of σ, but we surpress this in our notation.)

We introduce yet another prime ℓ that is also inert in K and fix a prime λ of K_c over ℓ. Reduction modulo λ induces a homomorphism $E(K_c) \otimes \mathbb{Z}/p^n\mathbb{Z} \to E(\mathbb{F}_{\ell^2}) \otimes \mathbb{Z}/p^n\mathbb{Z}$. Using Algorithm 2.1 below when $n = 1$, we compute the image z of $[P_{c,\sigma}]$ under the reduction map. When $z \neq 0$, we conclude that $\tau_{c,p}$ is also nonzero.

Algorithm 2.1.

- INPUT: *E, K, p, ℓ, c, σ, as above.*
- OUTPUT: *The (well-defined) image of $[P_{c,\sigma}]$ in $E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p\mathbb{Z})$, via reduction modulo any prime over ℓ (it does not matter which), up to some fixed nonzero scalar that is independent of c. We can compute the image of many different $P_{c,\sigma}$ with respect to a consistent choice of map.*

1. Use rational quaternion algebras and theta series of quadratic forms to directly compute a supersingular point $\overline{x}_1 \in X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}$ that is the reduction modulo λ of a choice of Heegner point $x_1 \in X_0(N)(K_1)$. (See Section 7.1.)
2. Apply a mod ℓ analogue of Kolyvagin's construction to directly obtain the reduction $\overline{Q}_{c,\sigma}$ of the "Kolyvagin derived divisor" attached to x_c as an element of $\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}})$. (See Sections 6 and 7.2.) Computing $\overline{Q}_{c,\sigma}$ closely resembles computing the image $T_c(\overline{x}_1)$ of $\overline{x}_1$ under the Hecke operator T_c using Equation (6.1), but with an appropriate choice of weighting of each summand.
3. Use linear algebra combined with refinements of results of Cornut, Ihara and Ribet (see Section 7.4) and a multiplicity one theorem (see Theorem 7.14 below) to compute a fixed nonzero scalar multiple of the image of $\overline{Q}_{c,\sigma}$, hence of $P_{c,\sigma}$, under the homomorphism of Hecke modules

$$\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}) \otimes (\mathbb{Z}/p\mathbb{Z}) \to E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p\mathbb{Z}). \qquad (2.1)$$

Remark 2.2. We emphasize that the steps of Algorithm 2.1 can all be done purely algebraically, without recourse to any numerical approximations. This contrasts with the approach of [JLS09], which provides numerical *evidence* for Kolyvagin's conjecture in one case, *without* proof. In theory the approach of [JLS09] can likely be made rigorous, but this has not been done in practice in any case, though see [Bra10] which is a step in that direction. The approach of [JLS09] can be faster for an elliptic curve with large conductor (with c *very small*); it is much worse for large c than Algorithm 2.1 (e.g., $c > 100$ would be incredibly hard).

Remark 2.3. Suppose we are only interested in verifying that the image under (2.1) of $\overline{Q}_{c,\sigma}$ is *nonzero.* Instead of the linear algebra of Step 3, we might be able to use that (2.1) is a $\mathbb{T}$-module homomorphism, where $\mathbb{T}$ is the Hecke algebra; if $\mathbb{T}\overline{Q}_{c,\sigma}$ has sufficiently large dimension, so that it cannot be contained in the nontrivial kernel, then we are done. If we take this approach and it works, we do not need to compute (2.1) at all. However, in some cases this approach cannot work, e.g., we could run into trouble if there are other elliptic curves of larger rank also of level N.

Remark 2.4. Algorithm 2.1 only computes the reduction of $P_{c,\sigma}$ up to a fixed nonzero scalar, which is enough to show that $\delta(P_{c,\sigma}) \neq 0$. The point $P_{c,\sigma}$ could in principle be normalized by finding $P_{c,\sigma}$ exactly via a numerical computation, using [JLS09] for one choice of c for which the image of $P_{c,\sigma}$ in $E(\mathbb{F}_\ell) \otimes (\mathbb{Z}/p\mathbb{Z})$ is nonzero.

To make the steps of Algorithm 2.1 explicit and machine computable, we view $\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}})$ noncanonically as the set of right ideal classes in an Eichler order R of level N in the (unique up to isomorphism) rational quaternion algebra ramified at ℓ and ∞, which we compute as explained in [Piz80, Koh01, Koh97, Ste09]. By computing representation numbers of ternary quadratic forms associated to left orders, we find the right R-ideals I whose left order admits an optimal embedding of the ring of integers $\mathcal{O}_K$ of K; this is the trick we use to compute the reduction $\overline{x}_1 \in X_0(N)(\mathbb{F}_{\ell^2})$ of x_1 modulo a prime over ℓ without ever computing x_1 itself. Then we use $\overline{x}_1$ and a parametrization of the right ideals $J \subset I$ such that $I/J \cong (\mathbb{Z}/c\mathbb{Z})^2$ to directly compute the reduction $\overline{Q}_{c,\sigma}$ (see Theorem 7.8 below). An implementation of the algorithm is included in Sage [S$^+$11].

3 The Birch and Swinnerton-Dyer Conjecture

The BSD conjecture is the main motivation for this paper, so we spend a page recalling it and emphasizing our ignorance. First we state the conjecture, then state the main theorem about it, and finish with some remarks about a curve of rank 4 and another of rank 2.

Let E be an elliptic curve over $\mathbb{Q}$. By [BCDT01, Wil95] the L-series

$$L(E, s) = \sum_{n=1}^{\infty} \frac{a_n}{n^s}$$

attached to E extends to a holomorphic function on all of $\mathbb{C}$, hence the nonnegative integer

$$r_{\mathrm{an}}(E/\mathbb{Q}) = \mathrm{ord}_{s=1} L(E, s) \geq 0$$

is defined. The BSD conjecture was first introduced by Birch and Swinnerton-Dyer in the 1960s motivated by computer computations, and was later formulated for abelian varieties over number fields (see [Bir65, Bir71, Mil72, Tat66, Wil00]).

Conjecture 3.1 (Birch and Swinnerton-Dyer)**.** *For any elliptic curve E defined over $\mathbb{Q}$ we have*

$$\operatorname{rank} E(\mathbb{Q}) = r_{\mathrm{an}}(E/\mathbb{Q}).$$

There is also a conjectural formula of Birch and Swinnerton-Dyer for the leading coefficient of the series expansion of $L(E,s)$ about $s = 1$ (see [Lan91, III, §5] for a general formulation). This formula has now been computationally verified in many cases; see [GJP$^+$09, Mil10] where the formula is fully proved for all curves with rank ≤ 1 and conductor ≤ 5000.

Results of Kolyvagin, Gross-Zagier, and Bump-Friedberg-Hoffstein (see, e.g., [BFH90, GZ86, Kol88b]) imply the following theorem.

Theorem 3.2. *Conjecture 3.1 is true for elliptic curves E with* $\operatorname{ord}_{s=1} L(E,s) \leq 1$.

As mentioned in the introduction, Conjecture 3.1 remains completely open when $\operatorname{ord}_{s=1} L(E,s) \geq 2$. As evidence for Conjecture 3.1, we have tables of specific rank 2 and 3 curves for which the conjecture is known (see, e.g., [Crea, SW02]), and assurances that many curves have analytic rank ≤ 1 (see [BS10]). There is not a single example of a curve of rank ≥ 4 for which the conjecture has been verified. Rank 4 is difficult not because of the complexity of doing computations, but because there is, as of now, no known *algorithm* (no matter how slow) that can be used to show that $r_{\mathrm{an}}(E/\mathbb{Q}) \geq 4$.

Example 3.3. Let E be the elliptic curve $y^2 + xy = x^3 - x^2 - 79x + 289$. A 2-descent (using [Creb, S$^+$11]) and point search proves that E has algebraic rank 4, with generators $(-9,19), (-8,23), (-7,25), (4,-7)$. Applying the methods of [Cre97, Dok04] and the Gross-Zagier formula, we see that $L(E,1) = L'(E,1) = 0$, $L''(E,1)$ is *very close* to 0, and $L^{(4)}(E,1) = 214.65233\ldots$. But showing that $L''(E,1) = 0$ (which would imply Conjecture 3.1 for E) is an unsolved problem.

Assume that E is an elliptic curve with $\operatorname{ord}_{s=1} L(E,s) = 2$. Then Conjecture 3.1 asserts that $\operatorname{rank} E(\mathbb{Q}) = 2$. In the explicit examples Section 8, the Birch and Swinnerton-Dyer formula predicts that $\#\text{Ш}(E/\mathbb{Q}) = 1$, though in fact $\text{Ш}(E/\mathbb{Q})$ is not known to be finite for any of these curves (or indeed, for any curve of rank ≥ 2). The best that has been done at present for a general rank 2 curve is to verify that $\text{Ш}(E/\mathbb{Q})[p] = 0$ for (finitely) many specific p, e.g., using the algorithm of [SW11]. See the recent work of [CLS09, CLS10] on CM elliptic curves of rank 2. Also, for the rank 2 elliptic curve of conductor 389, the author used modular symbols, p-adic L-series, p-adic heights, Iwasawa theory, and results of Kato and Schneider to show that $\text{Ш}(E/\mathbb{Q})[p] = 0$ for all primes $p < 2466$, except possibly the supersingular primes $p = 107$, 599, and 1049, for which the approach of [SW11] should work, but take much longer.

4 Quadratic Imaginary Fields and Heegner Points

In this section we recall the definition of Heegner points over ring class fields, and explain how they behave under taking traces. We will use these points in the next section to construct derived Galois equivariant classes.

Let E be an elliptic curve over $\mathbb{Q}$ of conductor N, and let $\pi_E : X_0(N) \to E$ be a fixed choice of minimal modular parametrization. The main theorem of [BFH90] implies that there exists infinitely many quadratic imaginary fields $K = \mathbb{Q}(\sqrt{D})$ of discriminant $D \leq -5$ such that each prime dividing N splits in K. Fix any such K.

Fix an odd prime power p^n with $n \geq 1$. Let $c = \prod p_i$ be any product of prime numbers p_i that are each inert in K, coprime to ND, and such that

$$p^n \mid \gcd(a_{p_i},\, p_i + 1),$$

for each i. Let K_c be the ring class field associated to the conductor c. As explained in [Gro91, pg. 238], the field K_c is an abelian extension of the Hilbert class field K_1 of K, is unramified outside c, and is contained in the ray class field associated to c. Moreover, the reciprocity map of class field theory induces a canonical isomorphism

$$\mathrm{Gal}(K_c/K_1) \cong (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times, \tag{4.1}$$

where $\mathcal{O}_K$ is the ring of integer of K (see Proposition 6.2 below). Let $\mathcal{O}_c = \mathbb{Z} + c\mathcal{O}_K$ be the order in $\mathcal{O}_K$ of conductor c. Each prime dividing N splits in K, so we can fix a *choice* $\mathfrak{n}$ of ideal in $\mathcal{O}_K$ with $\mathcal{O}_K/\mathfrak{n} \cong \mathbb{Z}/N\mathbb{Z}$.

The Heegner point associated to c is

$$x_c = \left[\Big(\mathbb{C}/\mathcal{O}_c,\;\; (\mathfrak{n} \cap \mathcal{O}_c)^{-1}/\mathcal{O}_c\Big)\right] \in X_0(N)(K_c),$$

which has image

$$y_c = \pi_E(x_c) \in E(K_c).$$

Remark 4.1. There are many possible choices of $\mathfrak{n}$ in the definition above, which are parametrized by the different choices of prime ideals of $\mathcal{O}_K$ over the prime divisors of N. These different choices are permuted by the action of the Atkin-Lehner operators. The Atkin-Lehner operators act as ± 1 on E, so y_c is well-defined up to sign, independent of the choice of $\mathfrak{n}$. See [Wat06] or [Coh07, Thm. 8.7.7] for an explicit description of the Atkin-Lehner action on Heegner points.

Motivated by the problem of constructing elements of $E(\mathbb{Q})$, it is natural to apply a trace map to y_c.

Proposition 4.2 (The Distribution Relation)**.** *We have* $\mathrm{Tr}_{K_c/K_1}(y_c) = a_c \cdot y_1 \in E(K_1)$. *More generally for each prime $q \mid c$, we have* $\mathrm{Tr}_{K_c/K_{c/q}}(y_c) = a_q \cdot y_{c/q} \in E(K_{c/q})$.

Proof. See [Gro84, §6] or [JK10, Lem. 5.2]. The key idea is that if T_c is the cth Hecke operator, then we have the following equality of divisors on $X_0(N)$:

$$T_c(x_1) = \sum_{\sigma \in \mathrm{Gal}(K_c/K_1)} \sigma(x_c).$$

To complete the proof, take the image of both sides in E and use that the Hecke operator T_c acts as a_c on E. □

Suppose E is a higher rank curve. The Gross-Zagier theorem [GZ86, §5.2] implies that the height of $\mathrm{Tr}_{K_1/K}(y_1) \in E(K)$ is a nonzero multiple of $L'(E/K, 1)$. However, $L(E/K, s) = L(E/\mathbb{Q}, s) \cdot L(E^D/\mathbb{Q}, s)$, and we assumed that $\mathrm{ord}_{s=1} L(E/\mathbb{Q}, s) \geq 2$, so $L'(E/K, 1) = 0$. Thus for all c,

$$\mathrm{Tr}_{K_c/K}(y_c) = \mathrm{Tr}_{K_1/K}(a_c y_1) \in E(K)_{\mathrm{tor}}. \tag{4.2}$$

Thus the traces of y_c are never non-torsion elements of the higher rank Mordell-group $E(\mathbb{Q})$.

5 Derived Points and Cohomology Classes, and their Reduction Modulo ℓ

In this section, we assume that p is an odd prime such that the p-adic representation $\rho_{E,p}$ is surjective.

In Section 5.1 we construct Kolyvagin's derived classes associated to Heegner points, then use these in Section 5.2 to construct Galois invariant classes. In Section 5.3 we explain how to reduce these classes modulo ℓ, and note that if the reduction is ever nonzero, then so is the class. Section 5.4 contains some consequences of nontriviality in the special case when E has analytic rank 2.

5.1 Derived points

Let p^n be a power of p, and let $c = p_1 \cdots p_t$ be a squarefree product of inert primes p_i such that $p^n \mid \gcd(a_{p_i}, p_i + 1)$. We recall the construction of Kolyvagin classes here, since it is important to emphasize the precise dependence on choice of generator of the Galois group, which impacts our algorithm. Also, we will make some remarks about this construction that appear to not be in the literature.

Let $[y_c]$ denote the image of y_c in $E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z})$. Let q be a prime divisor of c. The Galois group $\mathrm{Gal}(K_c/K_{c/q})$ is cyclic of order $q+1$. Fix a choice of generator $\sigma = \sigma_q \in \mathrm{Gal}(K_c/K_{c/q})$, let

$$P = \sum_{i=1}^{q} i\sigma^i(y_c) \in E(K_c),$$

and let $[P]$ denote the image of P in $E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z})$, so

$$[P] = \sum_{i \,\in\, \mathbb{Z}/(q+1)\mathbb{Z}} i\sigma^i([y_c]). \tag{5.1}$$

Proposition 5.1. *As above, assume that $p^n \mid \gcd(a_q, q+1)$. Then*

$$[P] \in (E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K_{c/q})}.$$

Proof. Applying our choice of generator σ of $\mathrm{Gal}(K_c/K_{c/q})$ to P, we have

$$\sigma([P]) = \sum_{i \,\in\, \mathbb{Z}/(c+1)\mathbb{Z}} \sigma i\sigma^i([y_c]) = \sum_{i \,\in\, \mathbb{Z}/(c+1)\mathbb{Z}} i\sigma^{i+1}([y_c]) \tag{5.2}$$

$$= \sum_{i \,\in\, \mathbb{Z}/(c+1)\mathbb{Z}} (i-1)\sigma^i([y_c]) = [P] - \mathrm{Tr}_{K_c/K_{c/q}}([y_c]) = [P]. \tag{5.3}$$

The first equality in (5.3) is because $p^n \mid q+1$, so we can enumerate the elements of $\mathbb{Z}/(q+1)\mathbb{Z}$ in any way we want (in fact, the notation we are using above only makes sense because $p^n \mid q+1$). The final equality in (5.3) holds since $p^n \mid a_q$ and $\mathrm{Tr}_{K_c/K_{c/q}}(y_c) = a_q y_{c/q}$, by Proposition 4.2. □

For each prime $p_i \mid c$, make a choice σ_i of generator for $\mathrm{Gal}(K_c/K_{c/p_i})$, and let $\sigma = (\sigma_1, \ldots, \sigma_t)$ be the tuple of those choices. Let

$$D_{c,\sigma} = \prod_{j=1}^{t} \sum_{i=1}^{p_j} i\sigma_j^i \in \mathbb{Z}[\mathrm{Gal}(K_c/K_1)],$$

and let

$$[P_{c,\sigma}] = \mathrm{Tr}_{K_1/K}(D_{c,\sigma}([y_c])) \in (E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K)}. \tag{5.4}$$

Remark 5.2. If we replace the hypothesis that $p^n \mid \gcd(a_q, q+1)$ with the hypothesis that $p^n \mid q+1$ and E has analytic rank ≥ 2, then we still have that $[P_{c,\sigma}] \in (E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K)}$. This is because $\mathrm{Tr}_{K_1/K}(y_1)$ is torsion and p is coprime to torsion, so the proof of Proposition 5.1 still goes through, but with an "obstruction" of $a_c y_1$, which vanishes upon taking a trace because of Equation (4.2).

Remark 5.3. The construction also generalizes if we replace the prime power p^n by the ideal I in $\mathbb{Z}$ generated by all a_q and $q+1$ for primes $q \mid c$, and we obtain

$$[P_{c,\sigma}] \in (E(K_c) \otimes (\mathbb{Z}/I))^{\mathrm{Gal}(K_c/K)}.$$

More generally, consider the modular Jacobian $J = J_0(N)$, and let I be the ideal of the Hecke algebra $\mathbb{T}$ generated by all T_q and $q+1$, for prime $q \mid c$. Then the above construction with x_c (instead of y_c) defines a class

$$[R_{c,\sigma}] = \mathrm{Tr}_{K_1/K}(D_{c,\sigma}([x_c])) \in (J(K_c) \otimes_{\mathbb{T}} (\mathbb{T}/I))^{\mathrm{Gal}(K_c/K)}$$

that maps to $[P_{c,\sigma}]$ under the natural map.

The next lemma explains how replacing σ_i by a different generator of $\mathrm{Gal}(K_c/K_{c/p_i})$ changes $[P_{c,\sigma}]$ by multiplication by an element of $(\mathbb{Z}/p^n\mathbb{Z})^\times$.

Lemma 5.4. *For every $j \in (\mathbb{Z}/(p_i+1)\mathbb{Z})^\times$, we have $[P_{c,(\ldots,\sigma_i^j,\ldots)}] = \frac{1}{j}[P_{c,\sigma}]$.*

Proof. Writing $q = p_i$ and $s = \sigma_i$, we have in $(\mathbb{Z}/(q+1)\mathbb{Z})[\mathrm{Gal}(K_c/K)]$ that

$$\sum_{i\,\in\,\mathbb{Z}/(q+1)\mathbb{Z}} is^{ji} = \sum_{i\,\in\,\mathbb{Z}/(q+1)\mathbb{Z}} \frac{i}{j}s^i = \frac{1}{j}\cdot \sum_{i\,\in\,\mathbb{Z}/(q+1)\mathbb{Z}} is^i.$$

□

Lemma 5.5. *If E has analytic rank r over $\mathbb{Q}$ and c is a product of t primes, then $\tau([P_{c,\sigma}]) = (-1)^{r+t+1}[P_{c,\sigma}]$. In particular, if $r+t$ is odd, then*

$$[P_{c,\sigma}] \in (E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/\mathbb{Q})}.$$

Proof. This is just [Gro91, Prop. 5.4(1)], which is proved by noting ([Gro91, Prop. 5.3]) that if $\tau \in \mathrm{Gal}(K_c/\mathbb{Q})$ is complex conjugation on K_c, then $\tau\sigma^i\tau = \sigma^{-i}$ for all i and we have that $\tau(y_c) = (-1)^{r+1}\sigma'(y_c) + (\text{torsion})$ for some $\sigma' \in \mathrm{Gal}(K_c/K)$. Thus $\tau([y_c]) = (-1)^{r+1}\sigma'([y_c])$, since p is coprime to any torsion. When $c = p_1 \cdots p_t$ is a product of t distinct primes, we have (using Lemma 5.4) that $\tau([P_{c,\sigma}]) = (-1)^{r+1}(-1)^t[P_{c,\sigma}]$. □

Remark 5.6. Following [How04, §1.2], we could alternatively encode the dependence on the choice of σ in a tensor product. Suppose for simplicity that c is prime. Consider the element

$$\sigma \otimes [P_{c,\sigma}] \in \mathrm{Gal}(K_c/K_1) \otimes (E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K)}.$$

This element does not depend on the choice of generator σ because for any $j \in (\mathbb{Z}/(c+1)\mathbb{Z})^\times$, if we define the element instead using the generator σ^j, by Lemma 5.4, we obtain

$$\sigma^j \otimes [P_{c,\sigma^j}] = \sigma^j \otimes \frac{1}{j}[P_{c,\sigma}] = (\sigma^j)^{1/j} \otimes [P_{c,\sigma}] = \sigma \otimes [P_{c,\sigma}],$$

where by $1/j$ we mean that element $j' \in \mathbb{Z}/p^n\mathbb{Z}$ such that $j'j = 1$. This generalizes to composite c by replacing $\mathrm{Gal}(K_c/K_1)$ by the tensor product $\bigotimes_{p_i \mid c} \mathrm{Gal}(K_c/K_{c/p_i})$.

Remark 5.7. We can define $[P_{c,\sigma}]$ without the hypothesis that each σ_i is a generator of $\mathrm{Gal}(K_c/K_{c/p_i})$. If we try to use exactly the definition given above, then the resulting $[P_{c,\sigma}]$ need not be $\mathrm{Gal}(K_c/K)$-equivariant, so we must modify the definition slightly. Let K' be the biggest subfield of K_c that is fixed by all σ_i, and let k_i (which divides p_i+1) be the order of σ_i. Let $[P] = \prod_{i=1}^{t} \sum_{j=1}^{k_i} j\sigma_i^j(y_c)$. Then the same argument as in Proposition 5.1 shows that $[P] \in (E(K_c)\otimes(\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K')}$, and we let

$$[P_{c,\sigma}] = \mathrm{Tr}_{K'/K}([P]) \in (E(K_c)\otimes(\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/K)}.$$

For example, if $c \neq 1$ and all $\sigma_i = 1$, then $[P_{c,\sigma}] = [a_c \cdot y_K] = 0$, since $p^n \mid a_c$.

For any multiple k of p^n, we have the following identity of polynomials:

$$\sum_{j=1}^{k-1} jX^j = \sum_{i=0}^{\frac{k}{p^n}-1} X^{p^n\cdot i}\cdot\left(\sum_{j=1}^{p^n-1} jX^j\right) \in (\mathbb{Z}/p^n\mathbb{Z})[X]. \tag{5.5}$$

Thus in the above construction, if we choose each σ_i to be of order exactly p^n, then we get (up to scaling by a unit) the same element $[P_{c,\sigma}]$ as if each σ_i is a generator of $\mathrm{Gal}(K_c/K_{c/p_i})$. The factorization (5.5) thus means we can alternatively view the Kolyvagin derived point construction as follows. Let K_c' be the compositum of the degree p^n subfields of each K_{p_i} for the primes $p_i \mid c$. If

$$D = \prod_{p_i\mid c}\sum_{j=1}^{p^n-1} j\sigma_i^j \in \mathbb{Z}[\mathrm{Gal}(K_c'/K_1)],$$

then

$$[P_{c,\sigma}] = \mathrm{Tr}_{K_1/K}([D(\mathrm{Tr}_{K_c/K_c'}(y_c))]).$$

5.2 Derived cohomology classes

As explained in [Gro91, §4], under our hypothesis that $\rho_{E,p}$ is surjective, the map

$$\mathrm{H}^1(K, E[p^n]) \to \mathrm{H}^1(K_c, E[p^n])^{\mathrm{Gal}(K_c/K)}$$

is an isomorphism, so $[P_{c,\sigma}]$ uniquely determines a cohomology class

$$\tau_{c,p^n} \in \mathrm{H}^1(K, E[p^n]).$$

In the rest of this short section, we make an additional observation in the special case when $r_{\mathrm{an}}(E/\mathbb{Q}) = 2$ and c is prime, since this is the situation for our data in Section 8.

Let $\mathrm{res} : \mathrm{H}^1(\mathbb{Q}, E[p^n]) \to \mathrm{H}^1(K_c, E[p^n])$ be the restriction map and δ the connecting homomorphism. Restricting res to Selmer groups, we obtain a commutative diagram:

$$\begin{tikzcd}
(E(K_c)\otimes(\mathbb{Z}/p^n\mathbb{Z}))^{\mathrm{Gal}(K_c/\mathbb{Q})} \arrow[r, hook, "\delta"] & \mathrm{Sel}^{(p^n)}(E/K_c)^{\mathrm{Gal}(K_c/\mathbb{Q})} \arrow[r] & Ш(E/K_c)[p^n]^{\mathrm{Gal}(K_c/\mathbb{Q})} \\
E(\mathbb{Q})\otimes(\mathbb{Z}/p^n\mathbb{Z}) \arrow[r, hook, "\delta"] \arrow[u, hook] & \mathrm{Sel}^{(p^n)}(E/\mathbb{Q}) \arrow[r, two heads] \arrow[u, hook, "\mathrm{res}"] & Ш(E/\mathbb{Q})[p^n] \arrow[u]
\end{tikzcd}$$

The following proposition *defines* an element τ_{c,p^n} in the Selmer group $\mathrm{Sel}^{(p^n)}(E/\mathbb{Q})$, not just in $\mathrm{H}^1(K, E[p^n])$ as above.

Proposition 5.8. *If c is prime and $r_{\mathrm{an}}(E/\mathbb{Q}) = 2$, then $\tau_{c,p^n} \in \mathrm{Sel}^{(p^n)}(E/\mathbb{Q})$.*

Proof. Since $r_{\mathrm{an}}(E/\mathbb{Q})$ is even and c is prime, Lemma 5.5 implies that $\delta([P_{c,\sigma}]) \in \mathrm{H}^1(K_c, E[p^n])^{\mathrm{Gal}(K_c/\mathbb{Q})}$. That the image of τ_{c,p^n} in $\mathrm{H}^1(\mathbb{Q}, E)[p^n]$ is locally trivially (hence in $\mathrm{Sel}^{(p^n)}(E/\mathbb{Q})$) follows from [Gro91, Prop. 6.2] with $n = c$ and $m = 1$, since $L'(E/K, 1) = 0$ hence y_K is torsion. □

5.3 Reduction modulo ℓ

The following lemma will be helpful when reducing the computation of τ_{c,p^n} to linear algebra (see Section 7.4). Below we will consider $M = E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z})$ as a module for the action of the nontrivial element $\mathrm{Frob}_\ell \in \mathrm{Gal}(\mathbb{F}_{\ell^2}/\mathbb{F}_\ell)$; we write M^- for the eigenspace of M on which Frob_ℓ acts by -1.

Lemma 5.9. *Let $p^n > 1$ be an odd prime power and let ℓ be a prime such that $p^n \mid \gcd(a_\ell, \ell+1)$. Then the groups $E(\mathbb{F}_\ell) \otimes (\mathbb{Z}/p^n\mathbb{Z})$ and $(E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^-$ are each cyclic of order p^n.*

Proof. (See [Ste10, Lem. 5.1].) We have

$$p^n \mid \gcd(a_\ell, \ell+1) \mid \ell + 1 - a_\ell = \#E(\mathbb{F}_\ell).$$

If $E(\mathbb{F}_\ell)[p]$ is noncyclic, then nondegeneracy of the Weil pairing implies that $\mu_p \subset \mathbb{F}_\ell^\times$, so $p \mid \ell - 1$, hence $p \mid \gcd(\ell - 1, \ell + 1) = 2$, which contradicts that p is odd. Thus $E(\mathbb{F}_\ell)[p]$ is cyclic, so the p-primary part of $E(\mathbb{F}_\ell)$ is cyclic of order divisible by p^n. For the second group, apply the above argument to the quadratic twist of E with trace of Frobenius $-a_\ell$, and note that p^n also divides $\gcd(-a_\ell, \ell+1)$. □

For any prime $\ell \nmid c$ that is inert in K, let λ be a prime ideal over ℓ in the ring of integers of the ring class field K_c. Define

$$z_{c,\sigma,\ell} \;=\; [P_{c,\sigma}] \pmod{\lambda} \in E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z}), \tag{5.6}$$

which is well defined, independent of the choice of λ. See [Ste10, Prop. 5.4] for the proof that $z_{c,\sigma,\ell}$ is well defined; the reason is that changing λ corresponds to acting on $[P_{c,\sigma}]$ by an automorphism, which does nothing since $[P_{c,\sigma}]$ is $\mathrm{Gal}(K_c/K)$-equivariant. Also, note that by Lemma 5.5, if $r_{\mathrm{an}}(E/\mathbb{Q}) + t$ is odd, then $z_{c,\sigma,\ell} \in E(\mathbb{F}_\ell) \otimes (\mathbb{Z}/p^n\mathbb{Z})$; if it is even, then $z_{c,\sigma,\ell} \in (E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z}))^-$, where the $-$ is for the action of the involution Frob_ℓ.

5.4 Consequences of nontriviality of the elements

We continue with the same notation and running assumptions as above. The first lemma below links verifying that $z_{c,\sigma,\ell} \neq 0$ to verifying Kolyvagin's Conjecture A [Kol91, pg. 255] (see Conjecture 1.1 above).

Lemma 5.10. *Suppose c is a squarefree product of inert primes q with $p^n \mid \gcd(a_q, q+1)$. If $z_{c,\sigma,\ell} \neq 0$, then $\tau_{c,p^n} \neq 0$.*

Proof. The nonzero element $z_{c,\sigma,\ell}$ is the image of $[P_{c,\sigma}]$ under the homomorphism

$$E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}) \longrightarrow E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z})$$

induced by reduction modulo a choice of prime ideal λ over ℓ. Thus if $z_{c,\sigma,\ell} \neq 0$, then $[P_{c,\sigma}] \neq 0$, so $\tau_{c,p^n} = \delta([P_{c,\sigma}]) \neq 0$, since δ is injective. □

Theorem 5.11. *Suppose $r_{\mathrm{an}}(E/\mathbb{Q}) = 2$ and that there exists inert primes c, ℓ (as above) such that $z_{c,\sigma,\ell} \neq 0$. Then*

$$\operatorname{rank} E(\mathbb{Q}) \leq 2$$

with equality if and only if $Ш(E/\mathbb{Q})(p)$ is finite. If $\operatorname{rank} E(\mathbb{Q}) = 2$, then $Ш(E/\mathbb{Q})[p] = 0$.

Proof. If $z_{c,\sigma,\ell} \neq 0$ then by Lemma 5.10, the Kolyvagin cohomology class $\tau_{c,p} \in \mathrm{H}^1(K, E[p])$ is nonzero, so Kolyvagin's Conjecture A [Kol91, pg. 255] is true. The desired conclusion then follows from [Ste10, Thm 4.2] (which is mainly a restatement of the main theorem of [Kol91]). □

For example, suppose E is a curve with $r_{\mathrm{an}}(E) = \operatorname{rank}(E(\mathbb{Q})) = 2$, that $Ш(E/\mathbb{Q})[2] = 0$ and that $\rho_{E,p}$ is surjective for all odd primes p. If we could somehow prove that for every prime p, there is a c with $z_{c,\sigma,\ell} \neq 0$, then Theorem 5.11 would imply that $Ш(E/\mathbb{Q}) = 0$. This would be an extremely deep result, since at present it is an open problem to prove unconditionally that the set of all pairs

$$\{(E,p) : Ш(E/\mathbb{Q})(p) \text{ is finite and } \operatorname{rank}(E) \geq 2\}$$

is infinite!

6 The Action of Galois and Reduction of Heegner Points Modulo ℓ

In this section, we prove a result (Theorem 6.6) that is crucial to giving a variant of Kolyvagin's derived points construction directly in characteristic ℓ, which is the main input to Algorithm 2.1. Note that the results in this section are on the level of the modular curve $X_0(N)$, and make no reference to a specific choice of elliptic curve over $\mathbb{Q}$ of conductor N, so they are equally useful in studying modular abelian varieties.

Theorem 6.6 below asserts that there is a compatible action of $\mathrm{Gal}(K_c/K_1)$ on two objects. Everything in the current paragraph will be made precise in Section 6.1 below. Let N be a positive integer and K a quadratic imaginary field such that each prime dividing N splits in K. Fix a choice of Heegner point $x_1 \in X_0(N)(K_1)$. For any square-free product c of primes that are inert in K, consider the support S of the divisor $T_c(x_1) \in \mathrm{Div}(X_0(N))$, where T_c is the cth Hecke operator. The Galois group $\mathrm{Gal}(K_c/K_1)$ acts transitively on S. Fix an inert prime $\ell \nmid c$ and a choice of prime λ of $\overline{\mathbb{Z}}$ over ℓ. Let $\mathbf{E}_1$ be the reduction mod λ of the enhanced elliptic curve corresponding to x_1, and consider the Eichler order $R = \mathrm{End}(\mathbf{E}_1)$. Also, as explained in Proposition 6.2, use class field theory to identify $\mathrm{Gal}(K_c/K_1)$ with $(\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$. For $x \in S$, represent $x \pmod{\lambda}$ by a right ideal class in R. Then Theorem 6.6 below asserts that *the action of $\mathrm{Gal}(K_c/K_1)$ on S is compatible with the action of $(\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ on the set of right ideals of R/cR of index c^2.* This result is somewhat complicated to state and prove, but we are amply compensated with an alternative interpretation of Kolyvagin's derived points construction.

In Section 6.1 we state our main result, then in Section 6.2 we prove it by deriving certain transformation rules for right ideals. We emphasize that in the arguments below, c is an arbitrary squarefree product of inert primes, and K is allowed to have arbitrary class number.

Remark 6.1. Reduction and the Galois action is also considered in [Cor02, §3.3], but via an adelic formulation that is less explicit and amenable to computation.

6.1 Notation and statement of theorem

In Section 6.1.1 we explain how Galois and Hecke operators act on higher Heegner points. In order to see the reduction of these points modulo ℓ, in Section 6.1.2 we introduce enhanced supersingular elliptic curves, and describe how they relate to points on modular curves. In Section 6.1.3, we explain how the Hecke operators act on divisors on enhanced curves, which will be used later in the proof of our main theorem. Finally, in Section 6.1.4 we precisely state the main theorem of this section, which is critical in reinterpreting Kolyvagin's derived classes operator in characteristic ℓ.

6.1.1 Galois and Hecke actions on Heegner points

Let N, K, c, and K_c be as above, and let $D = \mathrm{disc}(\mathcal{O}_K)$. Let $\mathcal{O}_c = \mathbb{Z}+c\mathcal{O}_K$ be the order of conductor c. Let $\mathfrak{n}$ be a choice of ideal in $\mathcal{O}_K$ with $\mathcal{O}_K/\mathfrak{n} \cong \mathbb{Z}/N\mathbb{Z}$, and let $\mathfrak{n}_c = \mathfrak{n}\cap\mathcal{O}_c$. As in [Gro84], for any order $\mathcal{O}$ (of conductor coprime to N) and any fractional $\mathcal{O}$-ideals $\mathfrak{m}$ and $\mathfrak{a}$, let $(\mathcal{O}, \mathfrak{m}, [\mathfrak{a}])$ denote the Heegner point $(\mathbb{C}/\mathfrak{a}, \mathfrak{m}^{-1}\mathfrak{a}/\mathfrak{a}) \in X_0(N)$, with endomorphism ring the order $\mathcal{O}$. In particular, let

$$x_c = (\mathcal{O}_c, \mathfrak{n}_c, [\mathcal{O}_c]) \in X_0(N)(K_c).$$

The elements of $(\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ are in bijection with the lines through the origin in the plane $\mathcal{O}_K/c\mathcal{O}_K \approx (\mathbb{Z}/c\mathbb{Z})^2$. These lines are in bijection with the sublattices of $\mathcal{O}_K$ of index c. The aforementioned sublattices are fractional $\mathcal{O}_c = \mathbb{Z} + c\mathcal{O}_K$ ideals, and each one represents an element of the kernel of the natural map $\mathrm{Cl}(\mathcal{O}_c) \to \mathrm{Cl}(\mathcal{O}_K)$.

Proposition 6.2. *We have a commutative diagram of abelian groups:*

$$\begin{tikzcd}
1 \arrow[r] & \mathrm{Gal}(K_c/K_1) \arrow[r] \arrow[d, "\cong"] & \mathrm{Gal}(K_c/K) \arrow[r] \arrow[d, "\theta"', "\cong"] & \mathrm{Gal}(K_1/K) \arrow[r] \arrow[d, "\cong"] & 1 \\
1 \arrow[r] & (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times \arrow[r] & \mathrm{Cl}(\mathcal{O}_c) \arrow[r] & \mathrm{Cl}(\mathcal{O}_K) \arrow[r] & 1,
\end{tikzcd}$$

where the rightmost two vertical isomorphisms are induced by the Artin reciprocity map of class field theory, and the bottom row involves the bijections mentioned above.

Proof. This is standard; see, e.g., [Gro91, §3]. □

As explained in [Gro84, §4, (4.2)], for $[\mathfrak{b}] \in \mathrm{Cl}(\mathcal{O}_c)$, we have

$$(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{a})^{\theta(\mathfrak{b})} = (\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{a}\mathfrak{b}^{-1}).$$

Also [Gro84, §6], we have

$$T_c(x_1) = T_c((\mathcal{O}_K, \mathfrak{n}, \mathcal{O}_K)) = \sum_{\mathfrak{b}\subset\mathcal{O}_K} (\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b}) \in \mathrm{Div}(X_0(N)), \tag{6.1}$$

where the sum is over *sublattices* $\mathfrak{b} \subset \mathcal{O}_K$ of index c.

Remark 6.3. We emphasize: the $\mathfrak{b}$ are not *ideals* of $\mathcal{O}_K$, but merely ideals of $\mathcal{O}_c$! If they were ideals of $\mathcal{O}_K$, they would have norm $c = \#(\mathcal{O}_K/\mathfrak{b})$, but c is a product of distinct inert primes, so there are no ideals of $\mathcal{O}_K$ of norm c.

6.1.2 Enhanced supersingular elliptic curves in characteristic ℓ

We consider enhanced elliptic curves $\mathbf{E} = (E, C)$, where E is an elliptic curve and $C \subset E$ is a cyclic subgroup of order N. The terminology *enhanced elliptic curves* is used in [Rib90a, §3].

Recall that we fixed above an inert prime $\ell \nmid c$ and a prime λ of $\overline{\mathbb{Z}}$ over ℓ. The set $X_0(N)(\mathbb{F}_{\ell^2})^{\rm ss}$ of supersingular points on the mod λ reduction of $X_0(N)$ is the set of isomorphism classes of enhanced elliptic curves $\mathbf{E} = (E, C)$, where E is a supersingular elliptic curve over $\mathbb{F}_{\ell^2}$ and $C \subset E$ is a cyclic subgroup of order N.

Let $[\mathbf{E}_1] = x_1 \in X_0(N)(K_1)$, so $\mathbf{E}_1$ is a representative enhanced elliptic curve corresponding to the Heegner point x_1. Since $\mathfrak{n}$ is an $\mathcal{O}_K$-ideal, we have $\mathcal{O}_K = \mathrm{End}(\mathbf{E}_1)$, so we obtain an inclusion

$$\mathcal{O}_K = \mathrm{End}(\mathbf{E}_1) \hookrightarrow \mathrm{End}(\overline{\mathbf{E}}_1). \tag{6.2}$$

Remark 6.4. To see that Equation (6.2) is injective, note that by [ST68, Lem. 2], reduction modulo the prime λ of $\overline{\mathbb{Z}}$ induces an isomorphism $E_1[p^n] \xrightarrow{\cong} \overline{E}_1[p^n]$ for any prime power p^n with $p \neq \ell$ and p a prime of good reduction for E_1 (the lemma only asserts the map is surjective, but it is a map between finite groups of the same order, hence is an isomorphism). If $\varphi \in \mathrm{End}(\mathbf{E}_1)$ acts as 0 on $\overline{\mathbf{E}}_1$, then it acts as 0 on $\overline{E}_1[p^\infty]$, hence acts as 0 on $E_1[p^\infty]$, hence is 0 (since endomorphisms have finite degree).

The following lemma implies that

$$[\overline{\mathbf{E}}_1] \in X_0(N)(\mathbb{F}_{\ell^2})^{\rm ss}.$$

Lemma 6.5. *Suppose F is an elliptic curve defined over an extension M of K and that F has CM by an order $\mathcal{O}$ of K. Suppose that $\ell \in \mathbb{Z}$ is a prime that is inert in K such that $\ell \nmid [\mathcal{O}_K : \mathcal{O}]$. Let λ be a prime of M lying over ℓ and assume F has good reduction at λ, and let k be residue field modulo λ. Then the reduction F_k of F modulo λ is a supersingular elliptic curve.*

Proof. This is well known (see [Lan87, Ch. 10, §4, Thm. 10, Case 1] and [Sil94, Exercise 2.30]), but for the convenience of the reader we give a more conceptual proof than the ones cited above. It follows from the definition of F_k in terms of Néron models that $\mathcal{O}$ acts (functorially) on F_k. Moreover, because $\ell \nmid [\mathcal{O}_K : \mathcal{O}]$, the ℓ-torsion subgroup $F_k[\ell] = F_k(\overline{\mathbb{F}}_\ell)[\ell]$ is a vector space over the finite field $\mathcal{O}_K/(\ell) \approx \mathbb{F}_{\ell^2}$. Thus $d = \dim_{\mathbb{F}_\ell} F_k[\ell]$ is even. Since F_k is an elliptic curve over a finite field of characteristic ℓ, we have $d \leq 1$, so $d = 0$, hence F_k is supersingular. □

We view $X_0(N)(\mathbb{F}_{\ell^2})^{\rm ss}$ as explained in [Rib90a, §3], especially [Rib90a, Rmk. 3.5, pg 441], which builds on work of Deuring and Shimura. The endomorphism ring $R = \mathrm{End}(\overline{\mathbf{E}}_1)$ is an Eichler order of level N in the (unique up to isomorphism) rational quaternion algebra B ramified at ℓ and ∞. We have a bijection

$$X_0(N)(\mathbb{F}_{\ell^2})^{\rm ss} \xrightarrow{\quad\cong\quad} \{\text{ right fractional ideal classes in } R\ \}, \tag{6.3}$$

where two (nonzero) fractional right R-ideals $I, J \subset B$ are equivalent if there exists $\alpha \in B$ such that $\alpha I = J$. For any enhanced elliptic curve $\mathbf{F}$, endow $\mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F})$ with the structure of right R-module as follows: for $\varphi \in \mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F})$ and $r \in R$ we put $\varphi.r = \varphi \circ r$. This bijection sends $[\mathbf{F}]$ to the class of a right R-ideal that is isomorphic as a right R-module to the right R-module $\mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F})$. Also, we see that the right R-module $\mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F})$ is isomorphic to *some* right R-ideal I as follows. By [Mes86,

§2.4, pg. 223] or [Rib90a, Lem. 3.17], there exists an isogeny $\psi : \mathbf{F} \to \overline{\mathbf{E}}_1$. Using such an isogeny, we obtain an embedding

$$\mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F}) \hookrightarrow \mathrm{End}(\overline{\mathbf{E}}_1) = R$$

given by $\varphi \mapsto \psi \circ \varphi$, and the right ideal I is the image of $\mathrm{Hom}(\overline{\mathbf{E}}_1, \mathbf{F})$ under this embedding. Making a different choice of isogeny ψ replaces I by an equivalent right ideal.

6.1.3 Action of Hecke operators on supersingular divisors

The Hecke operators T_n act on $\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}})$, as explained in [Rib90a, pg. 443–445], and this action translates to an action on the free abelian group on the right R-ideal classes via the bijection (6.3) above, as explained in, e.g., [Koh01, §3.2]. For n any integer coprime to ℓN, we have

$$T_n([I]) = \sum_{J \subset I} [J], \tag{6.4}$$

where the sum is over right R ideals $J \subset I$ with $I/J \approx (\mathbb{Z}/n\mathbb{Z})^2$. We apply (6.4) to obtain a more explicit description of the image of the unit ideal (which corresponds to the reduction of x_1) under the Hecke operator T_c. Let

$$\overline{R} = R \otimes (\mathbb{Z}/c\mathbb{Z}) \cong R/cR.$$

Since c is coprime to N and coprime to the unique finite prime ℓ that ramifies in B, we have $R \otimes \mathbb{Z}_c \approx M_2(\mathbb{Z}_c)$, hence

$$\overline{R} \approx M_2(\mathbb{Z}/c\mathbb{Z}) \cong \bigoplus_{\text{primes } p|c} M_2(\mathbb{F}_p).$$

For any right ideal $I \subset \overline{R}$, let $\tilde{I}$ denote the inverse image of I in R under the natural surjection $R \to \overline{R}$. The right ideals of $\overline{R}$ correspond to the right ideals of R that contain cR, so the Hecke operator T_c acts on the unit ideal R via

$$T_c([R]) = \sum_{\substack{\text{right ideals } I \subset \overline{R} \\ \text{with } \overline{R}/I \approx (\mathbb{Z}/c\mathbb{Z})^2}} [\tilde{I}]. \tag{6.5}$$

More generally, for any right R-ideal J with $[R : J]$ coprime to c, we have

$$T_c([J]) = \sum_{\substack{\text{right ideals } I \subset \overline{R} \\ \text{with } \overline{R}/I \approx (\mathbb{Z}/c\mathbb{Z})^2}} [\tilde{I} \cap J].$$

6.1.4 Statement of the main theorem

As in the diagram of Proposition 6.2 above, let $[\mathfrak{a}] \in \ker(\mathrm{Cl}(\mathcal{O}_c) \to \mathrm{Cl}(\mathcal{O}_K))$ be an ideal class, and let $[\alpha] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ be the corresponding element, so $\alpha \in \mathcal{O}_K$. By replacing $\mathfrak{a}$ by an equivalent ideal, we may assume that $\mathfrak{a} = \mathbb{Z}\alpha + c\mathcal{O}_K$. Suppose $[\mathfrak{b}] \in \ker(\mathrm{Cl}(\mathcal{O}_c) \to \mathrm{Cl}(\mathcal{O}_K))$ is another ideal class, with corresponding element $[\beta]$, and let $\theta_{[\mathfrak{b}]} \in \mathrm{Gal}(K_c/K_1)$ be the corresponding automorphism. Let $I_{\mathfrak{b}} \subset \overline{R}$ be a right ideal such that

$$(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b}) \mapsto [\tilde{I}_{\mathfrak{b}}] \tag{6.6}$$

under composition of reduction modulo λ with the equivalence (6.3) above. There is such a right ideal $I_{\mathfrak{b}}$ because $(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b})$ is in the support of $T_c(x_1)$, and $[\tilde{I}_{\mathfrak{b}}]$ is in the support of $T_c(x_1 \pmod{\lambda})$ (see Equation (6.1)).

The group $\mathrm{Gal}(K_c/K_1)$ does *not* act naturally on

$$X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}} = X_0(N)(\mathcal{O}_{K_c}/\lambda)^{\mathrm{ss}},$$

since $\ell\mathcal{O}_K$ splits as a product of many primes (of which λ is one of them); of course, the "useless" decomposition subgroup of $\mathrm{Gal}(K_c/K_1)$ associated to λ (which has order 1!) does naturally act. However, as we will now see, $\mathrm{Gal}(K_c/K_1)$ acts naturally on a subset of the right ideals of $\overline{R}$. The challenge is that we need to compute what happens if we take $x_c \in X_0(N)(K_c)$, act by Galois, then map the result to $X_0(N)(\mathbb{F}_{\ell^2})$, and we can do this explicitly by instead considering the action of $\mathrm{Gal}(K_c/K_1)$ on index c^2 ideals in $\overline{R}$.

Equation (6.2) asserts that given our choice of λ there is an inclusion $\mathcal{O}_K \hookrightarrow R$, which we fix and use to define a right action of $\mathrm{Gal}(K_c/K_1)$ on certain right ideals in $\overline{R}$. For $\alpha \in \mathcal{O}_K$, let $\overline{\alpha}$ denote the image of α in $\overline{R}$. If $\sigma \in \mathrm{Gal}(K_c/K_1)$ corresponds to $[\alpha] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$, make σ act on the right on the set of right ideals I of $\overline{R}$ with $\overline{R}/I \approx (\mathbb{Z}/c\mathbb{Z})^2$ by $I^\sigma = \overline{\alpha}^{-1}I$. Finally, we state the main result of this section, which asserts that the natural right action of $\mathrm{Gal}(K_c/K_1)$ on the support of $T_c(x_1)$ in $\mathrm{Div}(X_0(N)/K_c)$ is compatible with the right action of $\mathrm{Gal}(K_c/K_1)$ that we just defined. We will prove this theorem in Section 6.2 below.

Theorem 6.6. *Let $\sigma \in \mathrm{Gal}(K_c/K_1)$, $[\mathfrak{b}] \in \ker(\mathrm{Cl}(\mathcal{O}_c) \to \mathrm{Cl}(\mathcal{O}_K))$, and let $[\tilde{I}_{\mathfrak{b}}]$ correspond to $(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b}) \pmod{\lambda}$ as in Equation 6.6 above. Then*

$$(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b})^\sigma \pmod{\lambda} \quad = \quad [\widetilde{I_{\mathfrak{b}}^\sigma}].$$

6.2 Proof of Theorem 6.6

This section is devoted to giving a proof of Theorem 6.6. When $c = 1$ the relevant objects all have cardinality 1 and the statement is trivial, so for the rest of this section we assume that $c > 1$. The strategy of the proof is to reinterpret the ideal $I_{\mathfrak{b}}$ as the right annihilator of a certain left ideal, and observe that this left ideal behaves sensibly under the action of Galois. (The proof is long because we are not sneaking any important details under the rug.)

We may assume that the representative fractional ideal $\mathfrak{b}$ is a sublattice of $\mathcal{O}_K$ of index c. Let $\mathbf{E}_1$ be the enhanced elliptic curve corresponding to the triple $(\mathcal{O}_K, \mathfrak{n}, [\mathcal{O}_K])$ and let $\mathbf{E}_{\mathfrak{b}}$ be the enhanced elliptic curve corresponding to the triple $(\mathcal{O}_c, \mathfrak{n}_c, [\mathfrak{b}])$. Let $\psi_{\mathfrak{b}} : \mathbf{E}_{\mathfrak{b}} \to \mathbf{E}_1$ be the isogeny of degree c given by the map $\mathbb{C}/\mathfrak{b} \to \mathbb{C}/\mathcal{O}_K$ that is multiplication by 1 on tangent spaces. The complementary (or dual) isogeny $\hat{\psi}_{\mathfrak{b}} : \mathbf{E}_1 \to \mathbf{E}_{\mathfrak{b}}$ is then given by the map $\mathbb{C}/\mathcal{O}_K \to \mathbb{C}/\mathfrak{b}$ induced by multiplication by c on $\mathbb{C}$. As in Section 6.1.2, we use $\psi_{\mathfrak{b}} \pmod{\lambda}$ to define a specific R-ideal $I_{\mathfrak{b}} \subset R = \mathrm{End}(\overline{\mathbf{E}}_1)$ that corresponds to $[\overline{\mathbf{E}}_{\mathfrak{b}}] \in X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}$. More precisely, the ideal $I_{\mathfrak{b}}$ is the image of $\mathrm{Hom}(\overline{\mathbf{E}}_1, \overline{\mathbf{E}}_{\mathfrak{b}})$ in R via the map $\vartheta \mapsto \overline{\psi}_{\mathfrak{b}} \circ \vartheta$, i.e.,

$$I_{\mathfrak{b}} = \{\overline{\psi}_{\mathfrak{b}} \circ \vartheta \;\; : \;\; \vartheta : \overline{\mathbf{E}}_1 \to \overline{\mathbf{E}}_{\mathfrak{b}}\} \subset R = \mathrm{End}(\overline{\mathbf{E}}_1).$$

The following lemma follows immediately from the definitions given in Section 6.1:

Lemma 6.7. *Under our fixed choices of maps and prime λ, we have*

$$[\mathbf{E}_{\mathfrak{b}}] \pmod{\lambda} \quad \longleftrightarrow \quad [I_{\mathfrak{b}}],$$

where $I_{\mathfrak{b}}$ is defined as above.

Proposition 6.10 below characterizes $I_{\mathfrak{b}}$ as an annihilator of a left R-ideal, which will be easier to work with. Let

$$J_{\mathfrak{b}} = \{\varphi \in R : \varphi(\ker(\overline{\hat{\psi}}_{\mathfrak{b}})) = 0\},$$

which is a left R-ideal. Thus $J_{\mathfrak{b}}$ is the left ideal of all endomorphisms of $\overline{\mathbf{E}}_1$ that factor through the homomorphism $\overline{\hat{\psi}}_{\mathfrak{b}} : \overline{\mathbf{E}}_1 \to \overline{\mathbf{E}}_{\mathfrak{b}}$:

$$\begin{tikzcd}
 & \overline{\mathbf{E}}_{\mathfrak{b}} \arrow[dr, dotted] & \\
\overline{\mathbf{E}}_1 \arrow[ur, "\overline{\hat{\psi}}_{\mathfrak{b}}"] \arrow[rr, "\varphi\in J_{\mathfrak{b}}"'] & & \overline{\mathbf{E}}_1
\end{tikzcd}$$

We will use the following lemma to compute the quotient abelian group $R/J_{\mathfrak{b}}$.

Lemma 6.8. *The natural map $R \to \mathrm{End}(\overline{E}_1[c])$ is surjective.*

Proof. It suffices to prove that for each prime $p \mid c$, the map

$$\varphi : R \otimes \mathbb{F}_p \to \mathrm{End}(\overline{E}_1[p]) \tag{6.7}$$

is surjective. Since R is an Eichler order of level N, N is coprime to c and $p \mid c$, we have $R \otimes \mathbb{F}_p = \mathrm{End}(\overline{E}_1) \otimes \mathbb{F}_p$. Also, since $p \neq \ell$, we have $\mathrm{End}(\overline{E}_1[p]) \approx \mathrm{End}(\mathbb{F}_p \oplus \mathbb{F}_p) \cong M_2(\mathbb{F}_p)$, and since $\overline{E}_1$ is a supersingular elliptic curve, $\dim_{\mathbb{F}_p}(R \otimes \mathbb{F}_p) = \mathrm{rank}_{\mathbb{Z}} R = 4$, so by a dimension count it suffices to prove that φ is injective. Suppose $\overline{f} = f \otimes 1 \in R \otimes \mathbb{F}_p$ is a nonzero element of $\ker(\varphi)$, with $f \in \mathrm{End}(\overline{E}_1)$. Then f acts as 0 on $\overline{E}_1[p]$, so f factors through multiplication by p, which means that there exists $g \in \mathrm{End}(\overline{E}_1)$ with $f = pg$. But then $\overline{f} = pg \otimes 1 = g \otimes p = g \otimes 0 = 0$, a contradiction. We conclude that φ is injective, hence surjective. □

Lemma 6.9. *We have $R/J_{\mathfrak{b}} \approx (\mathbb{Z}/c\mathbb{Z})^2$, where we view both sides as quotients of additive abelian groups.*

Proof. We prove this lemma by using Lemma 6.8 to reinterpret the assertion as a statement in $M_2(\mathbb{Z}/c\mathbb{Z})$, then use linear algebra modulo prime divisors of c to count dimensions. The kernel $D = \ker(\overline{\hat{\psi}}_{\mathfrak{b}}) \subset \overline{E}_1[c]$ is a cyclic group of order c. Let $\overline{J}$ be the left annihilator in $\mathrm{End}(\overline{E}_1[c]) \approx M_2(\mathbb{Z}/c\mathbb{Z})$ of D. For each prime $p \mid c$, we have $\mathrm{End}(\overline{E}_1[p]) \approx M_2(\mathbb{F}_p)$, and the factor of D in $\overline{E}_1[p]$ is of order p. The left annihilator in $M_2(\mathbb{F}_p)$ of a 1-dimensional subspace of $(\mathbb{F}_p)^2$ has $\mathbb{F}_p$-dimension 2, since it is the 2-dimensional $\mathbb{F}_p$-vector space of matrices whose rows are both a multiple of v, where v has dot product 0 with a basis for our 1-dimensional subspace. Putting these factors for each p together, we see that $\overline{J}$ is free of rank 2 over $\mathbb{Z}/c\mathbb{Z}$.

Since c kills $\ker(\overline{\hat{\psi}}_{\mathfrak{b}})$, we see that $cR \subset J_{\mathfrak{b}}$. We thus have an isomorphism of abelian groups

$$R/J_{\mathfrak{b}} \to M_2(\mathbb{Z}/c\mathbb{Z})/\overline{J}.$$

It is surjective because of Lemma 6.8. It is injective because $J_{\mathfrak{b}}$ is defined to be those endomorphisms that kill the subgroup D of $\overline{E}_1[c]$, which is a condition we can check in $\mathrm{End}(\overline{E}_1[c])$. The lemma thus follows. □

Next we use the left R-ideal $J_{\mathfrak{b}}$ to define a right R-ideal:

$$I'_{\mathfrak{b}} = \{\varphi \in R \;:\; J_{\mathfrak{b}}\varphi \subset cR\}.$$

Proposition 6.10. *We have*

$$I_{\mathfrak{b}} = I'_{\mathfrak{b}}$$

Proof. The strategy of the proof is to show that $I_{\mathfrak{b}} \subset I'_{\mathfrak{b}}$, then observe that both $I_{\mathfrak{b}}$ and $I'_{\mathfrak{b}}$ have the same index in R, so they must be equal.

To see that the inclusion $I_{\mathfrak{b}} \subset I'_{\mathfrak{b}}$ hold is a straightforward calculation using the definitions, as follows. An element $\varphi \in I_{\mathfrak{b}}$ is by definition of the form $\varphi = \overline{\psi}_{\mathfrak{b}} \circ \vartheta$, where $\vartheta : \overline{\mathbf{E}}_1 \to \overline{\mathbf{E}}_{\mathfrak{b}}$ and $\overline{\psi}_{\mathfrak{b}} : \overline{\mathbf{E}}_{\mathfrak{b}} \to \overline{\mathbf{E}}_1$, as above. Suppose $\delta \in J_{\mathfrak{b}}$, so $\delta \in \mathrm{End}(\overline{\mathbf{E}}_1)$ and $\delta(\ker(\overline{\hat{\psi}}_{\mathfrak{b}})) = 0$, hence $\delta = \delta' \circ \overline{\hat{\psi}}_{\mathfrak{b}}$ for some $\delta' : \overline{\mathbf{E}}_{\mathfrak{b}} \to \overline{\mathbf{E}}_1$. Thus

$$\delta \circ \varphi = (\delta' \circ \overline{\hat{\psi}}_{\mathfrak{b}}) \circ (\overline{\psi}_{\mathfrak{b}} \circ \vartheta) = \delta' \circ [c] \circ \vartheta \in cR,$$

which proves that $I_{\mathfrak{b}} \subset I'_{\mathfrak{b}}$.

We next prove that $[R : I'_{\mathfrak{b}}] = c^2$, as an application of Lemma 6.9. We have $c \in I'_{\mathfrak{b}}$, so $cR \subset I'_{\mathfrak{b}} \subset R$, hence $I'_{\mathfrak{b}}$ is completely determined by an ideal $\overline{I}'_{\mathfrak{b}} \subset \overline{R} = R \otimes (\mathbb{Z}/c\mathbb{Z}) \approx M_2(\mathbb{Z}/c\mathbb{Z})$. The ideal $\overline{I}'_{\mathfrak{b}}$ is the right annihilator of the left ideal $\overline{J}_{\mathfrak{b}} \subset \overline{R}$. For each prime $p \mid c$, Lemma 6.9 implies that the right annihilator mod p of $J_{\mathfrak{b}}$, i.e., the image of $I'_{\mathfrak{b}}$ in $R \otimes \mathbb{F}_p \cong M_2(\mathbb{F}_p)$, is proper and nontrivial. We conclude that $[R : I'_{\mathfrak{b}}] = c^2$.

Finally we observe that $[R : I_b] = c^2$. In light of Equation (6.5), the ideal $I_{\mathfrak{b}}$ is one of the ideals that appears in the sum in the definition of the Hecke operator T_c, so $[R : I_{\mathfrak{b}}] = c^2$. Since $[R : I'_{\mathfrak{b}}] = c^2$ and $I_{\mathfrak{b}} \subset I'_{\mathfrak{b}}$, it follows that $I_{\mathfrak{b}} = I'_{\mathfrak{b}}$, which proves the proposition. □

Suppose $[\alpha] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ with $\alpha \in \mathcal{O}_K$, and let $\mathfrak{a} \subset \mathcal{O}_K$ be the corresponding fractional $\mathcal{O}_c$-ideal (as in Section 6.1.4). Let $J_\alpha = J_{\mathfrak{a}}$. Proposition 6.12 below asserts that the natural right action of $(\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ on the left ideals in $\overline{R}$ is compatible with the natural right action of $(\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ on sublattices $\mathfrak{a} \subset \mathcal{O}_K$ of index c. Note the inverse that appears, which makes a left action into a right action (the group acting is abelian, so we are being slightly pedantic in emphasizing this). First we prove a lemma about an action on certain kernels.

Lemma 6.11. *Suppose* $[\alpha], [\beta] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ *with* $\alpha, \beta \in \mathcal{O}_K$. *Then*

$$\ker(\hat{\psi}_{\alpha\beta}) = \alpha \ker(\hat{\psi}_\beta).$$

Proof. As above, let $\mathfrak{a} \subset \mathcal{O}_K$ be the lattice of index c corresponding to $[\alpha]$. Also, recall from page 15 that the map $\hat{\psi}_\alpha : E_1 \to E_{\mathfrak{a}}$ is given over the complex numbers by the map $\mathbb{C}/\mathcal{O}_K \to \mathbb{C}/\mathfrak{a}$ induced by multiplication by the integer c on $\mathbb{C}$. We have

$$E_1[c] = \left(\frac{1}{c}\mathcal{O}_K\right)/\mathcal{O}_K \cong \mathcal{O}_K/c\mathcal{O}_K \tag{6.8}$$

and the lattice $\mathfrak{a}$ defines a rank 1 subspace of $\mathcal{O}_K/c\mathcal{O}_K$. The isomorphism (6.8) identifies $\ker(\hat{\psi}_\alpha) \subset E_1[c]$ with the image of $\mathfrak{a}$ in $\mathcal{O}_K/c\mathcal{O}_K$. If $\mathfrak{b}$ corresponds to $[\beta]$, then $\alpha\mathfrak{b} = [\alpha\beta]$, so in terms of this presentation of $E_1[c]$, the claimed equality of the lemma follows. □

Note that since $[\alpha] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$, the image $\overline{\alpha} \in \overline{R} = R \otimes (\mathbb{Z}/c\mathbb{Z})$ of α is invertible.

Proposition 6.12. *Let* α, β *be as above, let* J *be a left* R*-ideal, and let* $\overline{J}$ *denote its image in* $\overline{R}$. *Then*

$$\overline{J}_{\alpha\beta} = \overline{J}_\beta \cdot \overline{\alpha}^{-1},$$

where $\overline{\alpha}$ *is the image of* α *in* $\overline{R}$.

Proof. The reduction modulo λ map $E_1[c]$ to $\overline{E}_1[c]$ is an isomorphism since $\ell \nmid cN$ (see Remark 6.4), so reducing both sides of Lemma 6.11 modulo λ, we see that $\ker(\overline{\hat{\psi}}_{\alpha\beta}) = \alpha \ker(\overline{\hat{\psi}}_{\beta})$. Thus

$$\begin{aligned} J_{\alpha\beta} =& \{\varphi \in R : \varphi(\ker(\overline{\hat{\psi}}_{\alpha\beta})) = 0\} \\ =& \{\varphi \in R : \varphi(\alpha(\ker(\overline{\hat{\psi}}_{\beta}))) = 0\} \\ =& \{\varphi \in R : (\varphi\alpha)(\ker(\overline{\hat{\psi}}_{\beta})) = 0\} \\ =& \{\varphi \in R : \varphi\alpha \in J_\beta\} = R \cap (J_\beta \cdot \alpha^{-1}) \subset J_\beta \cdot \alpha^{-1}. \end{aligned}$$

We thus have an inclusion of (equivalent) fractional left R-ideals

$$J_{\alpha\beta} \subset J_\beta \cdot \alpha^{-1}.$$

Taking the image of both ideals in $\overline{R}$ gives an inclusion

$$\overline{J}_{\alpha\beta} \subset \overline{J}_\beta \cdot \overline{\alpha}^{-1} \subset \overline{R}.$$

Right multiplication by an invertible element in $\overline{R}$ is a bijection, so $[\overline{R} : \overline{J}_\beta \cdot \overline{\alpha}^{-1}] = [\overline{R} : \overline{J}_\beta] = c^2$, by Lemma 6.9. Since $[\overline{R} : \overline{J}_{\alpha\beta}] = c^2$, again by Lemma 6.9, it follows that $\overline{J}_{\alpha\beta} = \overline{J}_\beta \cdot \overline{\alpha}^{-1}$, as claimed.

□

Proof of Theorem 6.6. We have $\mathfrak{a}, \mathfrak{b} \subset \mathcal{O}_K$ two lattices of index c and corresponding classes

$$[\alpha], [\beta] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times.$$

Let $\sigma \in \mathrm{Gal}(K_c/K_1)$ be the automorphism corresponding to $\mathfrak{a} \in \mathrm{Cl}(\mathcal{O}_c)$. Let $\mathfrak{g} \subset \mathcal{O}_K$ be the lattice of index c corresponding to the class $[\alpha^{-1}\beta] = [\alpha]^{-1}[\beta] \in (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$, so $I_{\alpha^{-1}\beta} = I_{\mathfrak{g}}$. Then, under reduction modulo λ, we have

$$(\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{b})^\sigma = (\mathcal{O}_c, \mathfrak{n}_c, \mathfrak{a}^{-1}\mathfrak{b}) \longmapsto [I_{\alpha^{-1}\beta}].$$

For any left or right ideal I of R, let $\overline{I}$ be the image of I in $\overline{R} = R \otimes (\mathbb{Z}/c\mathbb{Z})$. By Proposition 6.10 the right ideal $\overline{I}_{\mathfrak{b}}$ is the right annihilator of the left ideal $\overline{J}_{\mathfrak{b}}$, and this is true for any $\mathfrak{b}$. By Proposition 6.12, we have that $\overline{I}_{\alpha^{-1}\beta}$ is the right annihilator of the left ideal $\overline{J}_{\alpha^{-1}\beta} = \overline{J}_\beta \cdot \overline{\alpha}$. We thus have

$$\begin{aligned} \overline{\alpha}^{-1} \cdot \overline{I}_\beta &= \overline{\alpha}^{-1} \cdot \{\varphi \in \overline{R} \ : \ \overline{J}_\beta \cdot \varphi = 0\} \\ &= \{\overline{\alpha}^{-1} \cdot \varphi \in \overline{R} \ : \ \overline{J}_\beta \cdot \varphi = 0\} \\ &= \{\varphi \in \overline{R} \ : \ \overline{J}_\beta \cdot \overline{\alpha}\varphi = 0\} \\ &= \{\varphi \in \overline{R} \ : \ \overline{J}_{\alpha^{-1}\beta} \cdot \varphi = 0\} = \overline{I}_{\alpha^{-1}\beta}, \end{aligned}$$

where in the third equality we replace φ by $\overline{\alpha}\varphi$, using that multiplication by $\overline{\alpha}$ defines a bijection $\overline{R} \to \overline{R}$. The displayed equality proves the theorem.

□

7 Reduction of Derived Classes

Let E be an elliptic curve over $\mathbb{Q}$, and let $P_{c,\sigma}$ be as in Equation (5.4) of Section 5. In this section, we apply the general results of Section 6 to give an algorithm to compute the reduction $z_{c,\sigma,\ell} \in E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p\mathbb{Z})$ (see Equation 5.6) when p is an odd prime and $E[p]$ is absolutely irreducible. We will apply this algorithm in Section 8 to verify that $[P_{c,\sigma}] \neq 0$, in specific examples. It is of interest to verify that $[P_{c,\sigma}] \neq 0$ in specific examples since, as was mentioned in Section 1, this was until now not known in even a single case for a curve E of rank ≥ 2.

We continue to assume that E and K satisfy the Heegner hypothesis. The goal of this section is to give an algorithm that we can use (in some specific examples) to verify that $[P_{c,\sigma}] \neq 0$ for some c. To do this, we consider the reduction map

$$r_\ell : E(K_c) \otimes (\mathbb{Z}/p^n\mathbb{Z}) \to E(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z}), \tag{7.1}$$

given by reducing points modulo a fixed choice of prime λ over ℓ, where $\ell \nmid c$ is a prime that is inert in K, just as at the end of Section 5. If we find one prime ℓ such that $z_{c,\sigma,\ell} = r_\ell([P_{c,\sigma}]) \neq 0$, we conclude that $[P_{c,\sigma}] \neq 0$, as desired. We will thus be concerned primarily with computing whether or not $z_{c,\sigma,\ell}$ is 0 in the case when $n = 1$.

Remark 7.1. Assume that $\text{Ш}(E/\mathbb{Q})[p] = 0$, that $r_{\text{an}}(E/\mathbb{Q}) = \text{rank}(E(\mathbb{Q})) = 2$, and that we have shown that $[P_{c,\sigma}] \neq 0$ for some prime c. Then there is an alternative approach to compute the line spanned by $P_{c',\sigma'}$ for *any* inert prime c'. Jared Weinstein and the author learned about this idea from Karl Rubin after we implemented and ran the main algorithm of this paper, and wanted to better understand the data we obtained. The algorithm builds on [How04] and the Mazur-Rubin theory of Kolyvagin systems [MR04]. This is the subject of the forthcoming paper [SW10], and we have also used this algorithm as a double check on the calculations in Section 8. Quick summary: an easy calculation shows that the line has to be in the kernel of r_c; moreover, and this is deeper, r_c fails to have maximal rank if and only if $[P_c] = 0$.

In Section 7.1 we explain how to compute the reduction map from Heegner points in characteristic 0 to supersingular points in characteristic ℓ as an application of Deuring's lifting theorem and explicit computation with ternary quadratic forms. Section 7.2 contains the promised reinterpretation of Kolyvagin's derived classes construction directly on the divisor group of supersingular points, and Section 7.3 explicitly links this construction with reduction of derived classes from characteristic 0. Section 7.4 refines a crucial surjectivity result that Cornut used in proving Mazur's conjecture, which is also extremely important to our algorithm. Finally, Section 7.5 proves a multiplicity one theorem, which ensures that we have a general algorithm, rather than just a procedure that happens to work in every case we try.

7.1 Explicit computation of the reduction map using quaternion algebras

Let ℓ be a prime that is inert in K, as above. Following [Ste09, Piz80], let $B = B_{\ell,\infty}$ be the unique (up to isomorphism) quaternion algebra ramified at ℓ and ∞, and fix an Eichler order R of level N in B.

The group of Atkin-Lehner operators of level N has order 2^ν, where ν is the number of prime divisors of N. As discussed in Remark 4.1 above, the Heegner point x_1 is only well defined up to the choice of an ideal $\mathfrak{n}$ of $\mathcal{O}_K$ with $\mathcal{O}_K/\mathfrak{n} \cong \mathbb{Z}/N\mathbb{Z}$, and there are 2^ν

choices for $\mathfrak{n}$. We temporarily write $x_{1,\mathfrak{n}}$ for the choice of Heegner point x_1 associated to the ideal $\mathfrak{n}$.

The prime ℓ is inert in K, so by Lemma 6.5, each of the points $x_{1,\mathfrak{n}}$ defines a point on $X_0(N)(K_1)$ that reduces to a supersingular point in $X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}$. Moreover, we have the bijection of Equation 6.3 between $X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}$ and a certain set of right R-ideal classes. In terms of this bijection, we compute some $\overline{x}_1 \in X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}}$ corresponding to a choice of $\mathfrak{n}$ as follows. First, we enumerate all right ideal classes $[I]$ using standard algorithms, e.g., if N is odd by applying the Hecke operator T_2 repeatedly, starting with the unit ideal, and using theta series to check equivalence (see, e.g., [Piz80, Prop. 1.18]). Then we apply Theorem 7.2 below to find an I such that $\mathcal{O}_K$ embeds in R_I.

Let I be a fractional right R-ideal, and consider the left order

$$R_I = \{x \in B : xI \subset I\}$$

associated to I. We use the Deuring lifting theorem to give an algorithm to compute $\overline{x}_1$.

Theorem 7.2 (Deuring)**.** *The bijection of Equation* (6.3) *induces a bijection*

$$\{\overline{x}_{1,\mathfrak{n}} \in X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}} : \text{ ideals } \mathfrak{n} \text{ with } \mathcal{O}_K/\mathfrak{n} \cong \mathbb{Z}/N\mathbb{Z}\} \xrightarrow{\cong} \{[I] : \mathcal{O}_K \text{ embeds in } R_I\}.$$

Proof. See [GZ85, Prop. 2.7] (see also [JK10, §2] for a generalization in which $\mathcal{O}_K$ is replaced by $\mathcal{O}_c$). □

To compute a choice of $\overline{x}_1$ thus reduces to giving an algorithm to decide whether or not $\mathcal{O}_K$ embeds in R_I. As in [Gro87, pg. 172], let $G_I \approx \mathbb{Z}^3$ be the trace zero elements in $2R_I + \mathbb{Z}$, and let $q_I : G_I \to \mathbb{Q}$ be the normalized *ternary* quadratic form got by restricting the reduced norm on B to G_I.

Lemma 7.3. *There is an embedding of $\mathcal{O}_K$ into R_I if and only if the quadratic form q_I represents the absolute value $|D_K|$ of the discriminant of $\mathcal{O}_K$.*

Proof. This follows from [Gro87, Prop. 12.9] (see also [JK10, Lem. 4.1]). □

To compute $\overline{x}_1$ we compute the quadratic form q_I for a representative I for each right ideal class in turn, and decide whether or not it represents $|D_K|$. When we find one that does, we declare that our representative element is $\overline{x}_1 = \overline{x}_{1,\mathfrak{n}}$, which is well defined up to the choice of ideal $\mathfrak{n}$. In general (e.g., when the class number of K is bigger than 1), our current formula unfortunately requires computing all $x_{1,\mathfrak{n}}$ for all $\mathfrak{n}$ (see Theorem 7.8).

7.2 Kolyvagin's derived classes construction in terms of quaternion algebras

Let I be a right ideal in our fixed choice of Eichler order R of level N such that I corresponds to $\overline{x}_{1,\mathfrak{n}}$, computed as above.

Lemma 7.4. *By replacing I by an equivalent ideal, we can arrange that $I \otimes (\mathbb{Z}/c\mathbb{Z}) = R \otimes (\mathbb{Z}/c\mathbb{Z})$.*

Proof. For any prime $r \nmid N\ell$, the graph of the Hecke operator T_r is connected (see [Mes86, §2.4, pg. 223] or [Rib90a, Lem. 3.17]). If we choose r also coprime to c, then enumerate the right ideals of R by computing the action of T_r, starting with the unit ideal, we will cover all the right ideal classes of R; in particular, there is an ideal I' equivalent to I obtained via this procedure. From the formula of Equation (6.4) for the action of Hecke operators, we see that $[R : I']$ is a power of r. Thus $I' \otimes (\mathbb{Z}/c\mathbb{Z}) = R \otimes (\mathbb{Z}/c\mathbb{Z})$, as claimed. □

Next we compute a choice of homomorphism

$$s : R \twoheadrightarrow M_2(\mathbb{Z}/c\mathbb{Z}). \tag{7.2}$$

This can be done individually for each prime divisor of c, and the maps assembled together to give s. For example, for each prime divisor $q \mid c$, one could consider the algebra $R \otimes (\mathbb{Z}/q\mathbb{Z})$ and apply [Voi, §4] to find an explicit isomorphism $R \otimes (\mathbb{Z}/q\mathbb{Z}) \to M_2(\mathbb{Z}/q\mathbb{Z})$.

Let q be any prime that is inert in K. Suppose the image of $\alpha \in \mathcal{O}_K$ generates the cyclic group

$$(\mathcal{O}_K/q\mathcal{O}_K)^\times/(\mathbb{Z}/q\mathbb{Z})^\times$$

of order $q + 1$. Using a fixed choice of embedding of $\mathcal{O}_K$ into the left order of I from above (which exists by Theorem 7.2), we view α as an element of B. Let $\overline{\alpha}$ be the canonical image of α in $M_2(\mathbb{Z}/q\mathbb{Z}) = \overline{R}/q\overline{R}$ using the splitting s of (7.2).

For each $i = 0, \ldots, q$, let

$$\overline{J}_i = \{B \in M_2(\mathbb{Z}/q\mathbb{Z}) : (1, 0)\overline{\alpha}^i B = 0\} \subset \overline{R}/q\overline{R}.$$

Suppose $[M]$ is a right ideal class of R, and (as in Lemma 7.4) choose a representative right ideal $M \subset R$ such that $q \nmid [R : M]$, so s defines a map $M \twoheadrightarrow \overline{R}$. For each i, let J_i be the inverse image of $\overline{J}_i$ in M. Define

$$D_{q,\alpha}([M]) = \sum_{i=1}^{q} i[J_i].$$

Extending linearly, we define an endomorphism

$$D_{q,\alpha} \in \mathrm{End}(\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}})).$$

Remark 7.5. We make two remarks about the above operator:

1. The map $D_{q,\alpha}$ is explicitly computable; it is closely related to computing the Hecke operator T_q, since $T_q([M]) = \sum_{i=0}^{q}[J_i]$ is almost the same as $D_{q,\alpha}([M])$, except without the coefficient in the enumeration of the J_i's.
2. The maps $D_{q,\alpha}$ typically do not commute with the Hecke operators or with each other.

Next write $c = p_1 \cdots p_t$, let $\sigma = (\sigma_1, \ldots, \sigma_t)$ with $\sigma_i \in \mathrm{Gal}(K_c/K_{c/p_i})$ be choices of generators, and let $\alpha = (\alpha_1, \ldots, \alpha_t)$ with $\alpha_i \in \mathcal{O}_K$ be the corresponding elements via the map of Equation 4.1 above. Define

$$D_{c,\alpha} = \prod_{i=1}^{t} D_{p_i,\alpha_i} \in \mathrm{End}(\mathrm{Div}(X_0(N)(\mathbb{F}_{\ell^2})^{\mathrm{ss}})).$$

7.3 Reduction of Kolyvagin's derived points

Let $f \in S_2(\Gamma_0(N))$ be a newform, let $I_f \subset \mathbb{T}$ be the annihilator of f in the Hecke algebra associated to $J_0(N)$, let $A_f = J_0(N)/I_f J_0(N)$ be the corresponding modular abelian variety with modular parametrization $\pi_f : J_0(N) \to A_f$ and let

$$\psi_f : \mathrm{Div}(X_0(N)^{\mathrm{ss}}_{\mathbb{F}_{\ell^2}}) \to A_f(\mathbb{F}_{\ell^2})$$

be the homomorphism that sends each supersingular point x to $\overline{\pi}_f(x - \infty)$, where $\overline{\pi}_f$ is the reduction modulo λ of π_f. By [BCDT01], our elliptic curve E is isogeneous to some A_f for a newform $f \in S_2(\Gamma_0(N))$ where N is the conductor of E.

Theorem 7.6. *We have the following in $A_f(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z})$:*

$$[\overline{\pi}_f(D_{c,\sigma}(y_c))] = [\psi_f\left(D_{c,\alpha}([I])\right)].$$

Proof. This follows from Theorem 6.6. □

Let

$$\mathcal{I} = \{[I] : \mathcal{O}_K \hookrightarrow R_I\}$$

be the set of all right ideal classes of R whose left order admits an embedding of $\mathcal{O}_K$. For each such $[I]$, let n_I be half the number of primitive representatives of $|D_K|$ by the ternary quadratic form q_I. Let $\mathcal{H}$ be the $\mathrm{Gal}(\overline{\mathbb{Q}}/K)$-orbit of the set of all Heegner points $x_{1,\mathfrak{n}} \in X_0(N)(K_1)$ for all ideals $\mathfrak{n} \subset \mathcal{O}_K$ with $\mathcal{O}_K/\mathfrak{n} \cong \mathbb{Z}/N\mathbb{Z}$.

Lemma 7.7. *For each $[I] \in \mathcal{I}$, the number of elements of $\mathcal{H}$ reducing to the point of $X_0(N)(\mathbb{F}_{\ell^2})$ corresponding to $[I]$ is equal to n_I.*

Proof. By [JK10, §2] there is a one-to-one correspondence between the Heegner points $x_{1,\mathfrak{n}}$ reducing to $[I]$ and $R_I^\times$ conjugacy classes of embeddings $O_K \hookrightarrow R_I$. By [JK10, Prop. 4.2] there is a $(\#R_I^\times/2)$-to-1 correspondence between embeddings $\mathcal{O}_K \hookrightarrow R_I$ and primitive representations of $|D|$ by q_I. Thus every pair of primitive representations of $|D|$ by q_I corresponds to $\#R_I^\times$ embeddings, so half the number of primitive representatives is the number of $R_I^\times$ conjugacy classes of embeddings. □

Theorem 7.8. *Let ν be the number of distinct prime divisors of N. We have the following in $A_f(\mathbb{F}_{\ell^2}) \otimes (\mathbb{Z}/p^n\mathbb{Z})$:*

$$\overline{\pi}_f([P_{c,\sigma}]) = 2^{-\nu} \cdot \sum_{[I]\in\mathcal{I}} n_I \cdot [\psi_f\left(D_{c,\alpha}([I])\right)] \tag{7.3}$$

Proof. This follows by combining Lemma 7.7 and Theorem 7.6, and noting that $\mathcal{H}$ is a disjoint union of $[K_1 : K]$ Atkin-Lehner orbits, each of size 2^ν. Thus in computing the sum on the right of (7.3) we are computing $\mathrm{Tr}_{K_1/K}(D_{c,\sigma}(y_c))$ separately 2^ν times, hence we divide out this extra factor of 2^ν, which is harmless since p is odd. □

We still have not explained how to explicitly compute the map ψ_f, so Theorem 7.8 does not yet yield an algorithm. In Section 7.4 we will establish that ψ_f is surjective after tensoring with $\mathbb{Z}/p\mathbb{Z}$, and in Section 7.5 we give conditions under which ψ_f is uniquely determined up to scalars by being Hecke equivariant ("multiplicity one"), which means we can compute ψ_f up to a scalar. Alternatively, as mentioned in Remark 2.3, we can sometimes instead avoid computing ψ_f at all if we know ψ_f is surjective by instead verifying that the $\mathbb{T}$-span of $\sum n_I D_{c,\alpha}([I])$ is all of $X \otimes \mathbb{F}_p$.

7.4 Map from the supersingular module to an optimal abelian variety quotient

Let ℓ be an inert prime that does not divide the level N, and let $k = \mathbb{F}_{\ell^2} \approx \mathcal{O}_K/\ell\mathcal{O}_K$, which is a finite field of order ℓ^2. The Hecke algebra $\mathbb{T}$ acts via correspondences on many objects attached to the modular curves $X_0(N)$ and $X_1(N)$, e.g., via endomorphisms on the Jacobian $J_0(N)$ and also on

$$X = \mathrm{Div}(X_0(N)(k)^{\mathrm{ss}}) \qquad \text{and} \qquad X^0 = \mathrm{Div}^0(X_0(N)(k)^{\mathrm{ss}}). \tag{7.4}$$

Also, $\mathbb{T}$ acts on the *Shimura subgroup* $\Sigma = \ker(J_0(N) \to J_1(N))$. We say that a $\mathbb{T}$-module M is *Eisenstein* (in the sense of [Maz77]) if for any prime $p \nmid N$, the operator $T_p - (1+p)$ annihilates M. For example, [Rib88, Thm. 1] asserts that Σ is Eisenstein.

Let $J = J_0(N)_k$, and consider the natural $\mathbb{T}$-module homomorphism

$$X \to J(k) \tag{7.5}$$

that sends a divisor $D \in X$ to the equivalence class of the degree zero divisor $D - \deg(D)\infty$ in the Jacobian.

Proposition 7.9 (Ribet). *The cokernel S of the induced map*

$$X^0 \to J(k) \tag{7.6}$$

is the Cartier dual $\Sigma^\vee$ of Σ, and the $\mathbb{T}$-module $\Sigma^\vee$ is Eisenstein.

Proof. The following argument is due to Ribet (see [Rib10]). Let F be the ℓth power Frobenius endomorphism of J and let V be its dual. We have $J(k) = J[1-F^2]$. This kernel is Cartier dual to $J[1-V^2]$, since it is obtained by dualizing the following exact sequence (see [Mum70, §15, pg. 143] and [Mil86, §11]):

$$0 \to J[1-F^2] \to J \xrightarrow{1-F^2} J \to 0.$$

Ribet proved in 1983 (see [Pra95, Prop. 3.6]) that the subgroup $J[1-V^2]$ contains the reduction modulo ℓ of the Shimura subgroup Σ of J, and S is the annihilator of Σ in the natural perfect pairing between $J[1-F^2]$ and $J[1-V^2]$. The content of [Pra95, Prop. 3.6] is that the supersingular group is "as large as possible" in the sense that it is the full annihilator.

In the pairing between $J[1-F^2]$ and $J[1-V^2]$, there is the standard formula $\langle Tx, y\rangle = \langle x, T^\dagger y\rangle$, where the dagger refers to the Rosati involution of $\mathrm{End}(J)$ and T is a Hecke operator. The Hecke operators T_n with n coprime to N are self dual with respect to the Rosati involution.

To see that the group $J[1-F^2]/S$ is Eisenstein in the sense that $T_p = 1+p$ on this quotient for p prime to N, let η be the difference $T_p - (1+p)$, which is self dual with respect to the Rosati involution, since T_p is self dual and multiplication by the integer $(1+p)$ is also self dual. For $x \in J[1-F^2]$, we want to show that $\eta(x)$ is in the supersingular divisor class group; by [Pra95, Prop. 3.6], as mentioned above, this is the same as showing that $\langle \eta(x), y\rangle = 0$ for all $y \in \Sigma$. However, η annihilates Σ (see [Rib88, Thm. 1]), so

$$\langle \eta(x), y\rangle = \langle x, \eta(y)\rangle = 0.$$

□

The following proposition is a refinement of [Cor02, Prop. 4.4]. An *optimal quotient* A of $J_0(N)$ is any quotient of $J_0(N)$ by an abelian subvarieties (see [CS01, §3] for the basic properties of optimal quotients). For example, the abelian varieties A_f of Section 7.3 above are, up to isogeny, the simple optimal quotients of $J_0(N)$ that satisfy the hypothesis of Proposition 7.10 below.

Proposition 7.10. *Let A be any abelian variety optimal quotient of $J_0(N)$ such that $\ker(J_0(N) \to A)$ is Hecke stable, let $\mathfrak{m}$ be a non-Eisenstein maximal ideal of $\mathbb{T}$, and let X^0 be as in Equation (7.6). Then the natural map*

$$X^0 \to A(k) \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) \tag{7.7}$$

is surjective. In particular, if $A[\mathfrak{m}]$ is irreducible, then (7.7) is surjective.

Proof. As above, let S be the image of X^0 in $J(k)$, and let S_A be the image of S in $A(k)$. Also, let $Q = A(k)/S_A$. In light of Proposition 7.9, we have a commutative diagram of $\mathbb{T}$-modules with exact rows

$$\begin{tikzcd}
0 \arrow[r] & S \arrow[r] \arrow[d] & J(k) \arrow[r] \arrow[d] & \Sigma^\vee \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & S_A \arrow[r] & A(k) \arrow[r] & Q \arrow[r] & 0.
\end{tikzcd}$$

Since A is an optimal quotient of $J_0(N)$, there is an abelian variety B such that we have an exact sequence $0 \to B \to J_0(N) \to A \to 0$ of abelian varieties over $\mathbb{Q}$ with good reduction at ℓ (since $\ell \nmid N$). This sequences reduces to an exact sequence $0 \to B_k \to J \to A_k \to 0$ over k by [BLR90, §7.5, Thm. 4] (we have "$e < p-1$", since $p = \ell$ is odd and $e = 1$). Lang's theorem (see [Lan56] or [Ser88, §VI.4]) implies that $\mathrm{H}^1(k, B_k) = 0$, so $J(k) \to A(k)$ is surjective. The snake lemma then implies that the vertical map $\Sigma^\vee \to Q$ is surjective.

If $\Sigma^\vee \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) \cong \Sigma^\vee/\mathfrak{m}\Sigma^\vee$ is nonzero then $I = \mathrm{Ann}_{\mathbb{T}}(\Sigma^\vee/\mathfrak{m}\Sigma^\vee)$ equals $\mathfrak{m}$ since $\mathfrak{m}$ is maximal. Every $\eta_q = T_q - (q+1)$ for $q \nmid N$ is in I, since $\Sigma^\vee$ is Eisenstein by Proposition 7.9. But some $\eta_q \notin \mathfrak{m}$, since $\mathfrak{m}$ is non-Eisenstein, a contradiction. Thus $\Sigma^\vee \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) = 0$, so upon tensoring the rightmost vertical surjection of the above diagram with $\mathbb{T}/\mathfrak{m}$, we conclude that $Q \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) = 0$. Tensoring the bottom row over $\mathbb{T}$ with $\mathbb{T}/I$ and using that tensor product is right exact again then implies that (7.7) is surjective.

Since $\mathfrak{m}$ is a maximal ideal such that $A[\mathfrak{m}]$ is irreducible (which implies by definition that $A[\mathfrak{m}] \neq 0$), there is a prime $q \nmid N$ such that $\eta_q = T_q - (1+q)$ does not act as 0 on $A[\mathfrak{m}]$, since otherwise $A[\mathfrak{m}]$ would have semisimplification the reducible representation $1 \oplus \chi$, where χ is the cyclotomic character. Thus $\mathfrak{m}$ is non-Eisenstein, and the first part of the proposition proves the second claim. □

7.5 Multiplicity one theorem

The results of this section may be viewed as a partial generalization of [Rib99, Theorem. 2.3] and [Eme02, Thm. 4.2, Thm. 4.6] to more general levels. In particular, we prove under mild hypothesis that the multiplicity of a certain submodule of the $\mathbb{T}$-module $\mathrm{Div}(X_0(N)^{\mathrm{ss}}_{\mathbb{F}_{\ell^2}}) \otimes \mathbb{F}_p$ is 1. Our proof proceeds by finding a natural injective map from this submodule into $J_0(N\ell)[p]$, and observing that the image lies in a 1-dimensional subspace, as a consequence of a general multiplicity one result for $J_1(N\ell)$. For any positive integer N, let $\mathbb{T}(N)$ denote the ring of Hecke operators acting on $S_2(\Gamma_0(N))$.

Let N be a positive integer and ℓ a prime that does divide N, and let $X = \mathrm{Div}(X_0(N)^{\mathrm{ss}}_{\mathbb{F}_{\ell^2}})$, as in Equation (7.4). Let $f = \sum a_n q^n \in S_2(\Gamma_0(N))$ be a newform of level N and let $\mathfrak{m}_0$ be a maximal ideal of $\mathbb{T}(N)$ such that the following three conditions simultaneously hold:

1. $\mathfrak{m}_0$ has odd residue characteristic p,
2. $a_\ell, \ell + 1 \in \mathfrak{m}_0$, and
3. the 2-dimensional mod p Galois representation ρ attached to $\mathfrak{m}_0$ is absolutely irreducible.

By Ribet's level raising theorem (see [Rib90b]), for each choice of ± 1, there is a maximal ideal $\mathfrak{m}$ in the Hecke algebra $\mathbb{T} = \mathbb{T}(N\ell)$ such that $\rho_{\mathfrak{m}} \approx \rho$ and $T_\ell \pm 1 \in \mathfrak{m}$. Letting $J = J_0(N\ell)$, as explained in [RS01, §3.3], we have

$$J[\mathfrak{m}] \cong \bigoplus_{i=1}^{t} \rho, \tag{7.8}$$

for some integer $t \geq 1$ called the *multiplicity of* $\mathfrak{m}$. That $t \geq 1$ follows from an argument of Mazur, as explained in [RS01, §3.3].

Proposition 7.11. *We have* $\dim_{\mathbb{T}/\mathfrak{m}} \mathrm{Hom}(X, \mu_p)[\mathfrak{m}] \leq t$.

Proof. The proof is inspired by [Rib94, Prop. 7.7], though that argument takes place in the midst of a proof by contradiction.

Let $G_\ell \approx \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ be the decomposition subgroup of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ associated to our fixed choice of prime λ of $\overline{\mathbb{Z}}$ over ℓ, and let $I_\ell \subset G_\ell$ be the inertia subgroup. Let $k = \mathbb{F}_\ell$, and let J_k be the special fiber of the Néron model of J at k. By [ST68, Lem. 2], we have $J_k[\mathfrak{m}] \cong J[\mathfrak{m}]^{I_\ell}$, and because ρ is unramified at ℓ, we have $J[\mathfrak{m}]^{I_\ell} = J[\mathfrak{m}]$, so $J_k[\mathfrak{m}] \cong J[\mathfrak{m}]$.

Let Φ be the component group of J_k. As explained in [CS01, §4], we have a diagram with an exact row and exact column, where T is the toric part of J_k^0 and B is an abelian variety:

$$\begin{tikzcd}
 & 0 \arrow[d] & & & \\
 & T \arrow[d] & & & \\
0 \arrow[r] & J_k^0 \arrow[r] \arrow[d] & J_k \arrow[r] & \Phi \arrow[r] & 0 \\
 & B \arrow[d] & & & \\
 & 0 & & &
\end{tikzcd}$$

Moreover, $X^0 \cong \mathrm{Hom}(T, \mathbb{G}_m)$, so $T \cong \mathrm{Hom}(X^0, \mathbb{G}_m)$ and $T[p] = \mathrm{Hom}(X^0, \mu_p)$. Hence

$$\mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}] = T[\mathfrak{m}] \hookrightarrow J_k^0[\mathfrak{m}] \subset J_k[\mathfrak{m}] \cong J[\mathfrak{m}]. \tag{7.9}$$

The representation ρ arises from level N, so is unramified at ℓ. The characteristic polynomial of $\rho(\mathrm{Frob}_\ell)$ is $x^2 - a_\ell x + \ell$. Our hypothesis 2 on a_ℓ and $\ell + 1$ imply that

$$x^2 - a_\ell x + \ell = x^2 - 1 \in \mathbb{F}_p[x].$$

Since $x^2 - 1 = (x-1)(x+1)$ and p is odd, we have a decomposition of $\mathbb{T}[D]$-modules $J[\mathfrak{m}] \cong J[\mathfrak{m}]^+ \oplus J[\mathfrak{m}]^-$ and (7.8) implies that the two summands have dimension t. Here we are using that $J[\mathfrak{m}] = \oplus\rho$; if V is the space underlying ρ, then V has dimension 2 and the characteristic polynomial of Frob_ℓ on V is $(x-1)(x+1)$, so V^+ and V^- each have dimension 1.

By [Rib90a, Prop. 3.7–3.8], the action of Frob_ℓ on X^0 is via $-T_\ell$. Since $T_\ell \pm 1 \in \mathfrak{m}$ (for some choice of sign), the action of Frob_ℓ on the $\mathbb{T}[D]$-module $\mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}]$ is by $\pm\ell$ (because Frob_ℓ acts on μ_p by ℓth powering). Since $\ell + 1 \in \mathfrak{m}_0$, we have $\ell \equiv \pm 1 \pmod{p}$, so we conclude that Frob_ℓ acts on $\mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}]$ as either $+1$ or -1. Thus the sequence of inclusions of Equation (7.9) sends $\mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}]$ to a submodule of $J[\mathfrak{m}]^\pm$ for one choice of sign, from which we conclude that

$$\dim_{\mathbb{T}/\mathfrak{m}} \mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}] \leq \dim_{\mathbb{T}/\mathfrak{m}} J[\mathfrak{m}]^\pm = t.$$

□

Lemma 7.12. *We have $X/\mathfrak{m}X \cong X^0/\mathfrak{m}X^0$. (In fact, this lemma is true for any non-Eisenstein maximal ideal $\mathfrak{m}$.)*

Proof. It follows from the explicit description of Hecke operators (see Section 6.1.3) that we have an exact sequence $0 \to X^0 \to X \xrightarrow{\deg} \mathbb{Z} \to 0$, where $\mathbb{T}$ acts on $\mathbb{Z}$ by $T_r = r + 1$ for r a prime coprime to $N\ell$. Tensoring this exact sequence over $\mathbb{T}$ with $\mathbb{T}/\mathfrak{m}$ yields an exact sequence

$$\mathrm{Tor}_1^{\mathbb{T}}(\mathbb{Z}, \mathbb{T}/\mathfrak{m}) \to X/\mathfrak{m}X \to X^0/\mathfrak{m}X^0 \to \mathbb{Z} \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) \to 0.$$

Since $\mathfrak{m}$ is non-Eisenstein, $\mathbb{Z} \otimes_{\mathbb{T}} (\mathbb{T}/\mathfrak{m}) = 0$ and

$$\mathrm{Tor}_1^{\mathbb{T}}(\mathbb{Z}, \mathbb{T}/\mathfrak{m}) = \mathrm{Tor}_1^{\mathbb{T}}(\mathbb{T}/\mathfrak{m}, \mathbb{Z}) = \mathbb{Z}[\mathfrak{m}] = 0.$$

□

Recall that $\mathfrak{m}$ is any maximal ideal of level $N\ell$ arising from level raising, as explained above (7.8) at the beginning of this section.

Proposition 7.13. *We have $\dim_{\mathbb{T}/\mathfrak{m}} \mathrm{Hom}(X, \mu_p)[\mathfrak{m}] \geq 1$.*

Proof. Let $A = A_f$ be the optimal quotient of $J_0(N)$ attached to f, let $k = \mathbb{F}_{\ell^2}$, and let $\mathbb{T} = \mathbb{T}(N)$. Consider the $\mathbb{T}[\mathrm{Frob}_\ell]$-module $M = A(k) \otimes \mathbb{T}/\mathfrak{m}_0$. Proposition 7.10 implies that the $\mathbb{T}$-module homomorphism

$$X^0 \to M \cong M^+ \oplus M^-$$

is surjective. Projection onto a one-dimensional $\mathbb{T}/\mathfrak{m}_0$-subspace of each of M^+ and M^- defines a nonzero element of $\mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}]$ for each of the two possible choices of $\mathfrak{m}$. Note that $\mathrm{Frob}_\ell^2 = 1$ on $A[\mathfrak{m}]$ by hypothesis, so $A[\mathfrak{m}](\overline{k}) = A[\mathfrak{m}](k)$. Here we also use that $\dim_{\mathbb{T}/\mathfrak{m}} A[\mathfrak{m}] \geq 1$ (see [RS01, §3.3]).

It is elementary that every element of $\mathrm{Hom}(X, \mu_p)[\mathfrak{m}]$ factors through $X/\mathfrak{m}X$ and likewise for X^0, so by Lemma 7.12 we have

$$\mathrm{Hom}(X, \mu_p)[\mathfrak{m}] \cong \mathrm{Hom}(X/\mathfrak{m}X, \mu_p)[\mathfrak{m}] \cong \mathrm{Hom}(X^0/\mathfrak{m}X^0, \mu_p)[\mathfrak{m}] \cong \mathrm{Hom}(X^0, \mu_p)[\mathfrak{m}].$$

□

Theorem 7.14. *If $p \nmid N$, then* $\dim_{\mathbb{T}/\mathfrak{m}} \mathrm{Hom}(X, \mu_p)[\mathfrak{m}] = 1$.

Proof. In light of the above two propositions, it suffices to show that $t = 1$, where t is the multiplicity in Equation (7.8). Let f be a cuspidal eigenform in $S_2(\Gamma_0(N\ell))$ such that $\mathrm{Ann}_{\mathbb{T}}(f) \subset \mathfrak{m}$, and view f as an element of $S_2(\Gamma_1(N\ell))$. Let $\mathfrak{m}_1$ be the inverse image of $\mathfrak{m}$ in $\mathbb{T}_1 = \mathbb{T}_1(N\ell)$ under the natural map $\mathbb{T}_1 \to \mathbb{T}$. Since $p > 2$ and $p \nmid N\ell$, [Edi92, Th. 9.2, part 1] implies that $\dim_{\mathbb{T}_1/\mathfrak{m}_1} J_1(N\ell)[\mathfrak{m}_1] = 2$. The inclusion $J_0(N\ell) \to J_1(N\ell)$ has kernel the Shimura subgroup, which is Eisenstein (by [Rib88, Thm. 1]), so $J_0(N\ell)[\mathfrak{m}] \hookrightarrow J_1(N\ell)[\mathfrak{m}_1]$. Since $t \geq 1$, this inclusion implies that $t = 1$. □

8 Implementation and Data

We implemented in Sage[1] algorithms based on the above results, and used them to compute $z_{c,\sigma,\ell}$ for 10 different rank 2 curves, and various primes ℓ, primes $q = 3, 5, 7$, discriminants D of class number 1, and primes c, as in Table 8.1. Let r_ℓ be the reduction map from Equation (7.1). We choose the pairs (E, ℓ) so that r_ℓ is surjective and if ℓ_1 and ℓ_2 are the first two primes for a given elliptic curve E, then $\ker(r_{\ell_1}) \cap \ker(r_{\ell_2}) = 0$. For each pair (E, ℓ) in the table, we considered all fundamental discriminants $D \leq -5$ such that $K = \mathbb{Q}(\sqrt{D})$ has class number 1, satisfies the Heegner hypothesis for E, has $\mathrm{ord}_{s=1} L(E^D, s) \leq 1$, and for which ℓ is inert. The restriction to class number 1 is not essential.

[1] All computations in this section can be done in Version 4.6.1 using the free open source software Sage [S$^+$11]. Our implementation was peer reviewed by John Cremona for inclusion in Sage. Some relevant output files from running the computation can be found at `http://wstein.org/home/wstein/db/kolyconj/`. All computations were done under Linux (Ubuntu and Redhat) on several NSF-funded Sun Fire X4450 servers with 24 2.6Ghz cores and 128GB RAM each, at University of Washington and University of Georgia, and the computations took a few weeks CPU time.

We refer to elliptic curves using Cremona's notation (see [Crea]). Table 8.1 has columns E, D, p, ℓ. Each row has the property that E has rank 2, ℓ is inert in the field $K = \mathbb{Q}(\sqrt{D})$, and K satisfies the Heegner hypothesis for E. Also, we have $p \mid \gcd(\ell+1, a_\ell(E))$. We selected these examples because the $\mathbb{Z}$-rank of $\mathrm{Div}(X_0(N)^{\mathrm{ss}}_{\mathbb{F}_{\ell^2}})$ is relatively small (the dimensions are in Table 8.2).

The Tamagawa numbers of all of our curves are 1 or 2, and in all cases $\rho_{E,p}$ is surjective (see Proposition 8.1).

Table 8.2 contains data about the points $z_{c,\sigma,\ell}$. The columns labeled E, D, p, and ℓ correspond exactly to the entries in Table 8.2. The column labeled dim gives the dimension of $\mathrm{Div}(X_0(N)^{\mathrm{ss}}_{\mathbb{F}_{\ell^2}})$; this dimension directly impacts the runtime of our implementation. The column labeled $\max c$ contains the largest c such that we managed to compute $z_{c,\sigma,\ell}$. The columns labeled "$= 0$" and "$\neq 0$" are a count of how many $z_{c,\sigma,\ell}$ are 0 and not 0 among those we computed; note that for each c, ℓ we compute $z_{c,\sigma,\ell}$ for only one choice of generator σ (see below for how we chose σ), since other choices of σ would yield a nonzero scalar multiple, hence we often just write $z_{c,\ell}$. The columns labeled $z_{c,\ell} = 0$ and $z_{c,\ell} \neq 0$ give the first few c such that $z_{c,\ell}$ is zero or nonzero, respectively.

A consistency check on Table 8.2 comes from the rows labeled (**389a1**, $-7, 3, 17$) and (**389a1**, $-7, 3, 41$), since the reduction maps

$$E(\mathbb{Q}) \to E(\mathbb{F}_\ell) \otimes (\mathbb{Z}/3\mathbb{Z})$$

have the same kernel for $\ell = 17$ and 41. Hence the $z_{c,17} \neq$ if and only if $z_{c,41} \neq 0$, which was indeed the case in the range of our computations.

In every single case in Table 8.2 we find at least one c such that $z_{c,\ell} \neq 0$, so Conjecture 1.1 is true in these cases.

One initially surprising numerical observation we made is that the classes $\tau_{c,p}$ appear to *not* be equidistributed in the most naive possible sense. For example, in our computations with $p = 3$, the 0 subspace occurs about twice as much as any other subspace. Once we know that one class is nonzero, the exact asymptotic distribution of *all* classes can then be determined as an application of work of Mazur-Rubin, B. Howard [How04], and the Chebotarev density theorem. See the forthcoming paper [SW10]. As mentioned in Remark 7.1 above, this also leads to an alternate way to compute $\tau_{c,p}$ up to scaling. This provided an convincing double check on the correctness of our tables.

Tables 8.3–8.4 provide further details about the distribution of elements of

$$\mathrm{Sel}^{(p)}(E/\mathbb{Q}) \cong (\mathbb{Z}/p\mathbb{Z})^2$$

coming from this construction. The first 5 columns labeled E, D, p, ℓ_1 and ℓ_2 specify an elliptic curve, fundamental discriminant D, a prime p and two primes ℓ_1 and ℓ_2, chosen from the data summarized in Table 8.2. As mentioned above, the primes ℓ_1 and ℓ_2 are chosen so that the intersection of the two reduction maps to $E(\mathbb{F}_{\ell_i}) \otimes (\mathbb{Z}/p\mathbb{Z})$ is 0. Since the Selmer group has dimension 2 and in our implementation we chose the generator $\sigma \in \mathrm{Gal}(K_c/K_1) \cong (\mathcal{O}_K/c\mathcal{O}_K)^\times/(\mathbb{Z}/c\mathbb{Z})^\times$ to be $\sqrt{D} + n$ with $n \geq 1$ minimal, where $D = \mathrm{disc}(K)$. This allows us to deduce the subspace spanned by $\tau_{c,p}$ in $\mathrm{Sel}^{(p)}(E/\mathbb{Q})$ with respect to some unknown basis for $\mathrm{Sel}^{(p)}(E/\mathbb{Q})$. The column labeled $\tau_{c,p}$ gives the normalized generator for this subspace. The next column, labeled # gives the number of c such that $\tau_{c,p}$ spans the given subspace, and the last column gives the first few such primes c.

8.2 Appendix: remarks about surjectivity of Galois representations

In order to pass from $[P_{c,\sigma}]$ to $\tau_{c,p^n} \in \mathrm{H}^1(K, E[p^n])$ in Section 5.2, we assumed that p is an odd prime such that

$$\rho_{E,p} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{GL}_2(\mathbb{Z}_p)$$

is surjective. If we assume that E does not have CM (as will be the case for our examples), the p-adic representation $\rho_{E,p} : G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_p)$ is surjective for all but finitely many p. Moreover, we can compute all primes p such that $\rho_{E,p}$ is not surjective, as explained in [GJP$^+$09, §2.1] and implemented in Sage (see also forthcoming work of A. Sutherland [Sut09]). For example, we have the following proposition:

Proposition 8.1. *If E is a rank 2 elliptic curve with conductor < 1058, then $\rho_{E,p}$ is surjective for all odd primes p.*

Proof. Using the algorithm of [GJP$^+$09, §2.1] as implemented in [S$^+$11] shows that the mod-p representations $\overline{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{F}_p)$ are surjective for all rank 2 curves E of conductor < 1058 and all primes p. As explained in [GJP$^+$09, §2.1], this implies that the p-adic representation $\rho_{E,p}$ is surjective for $p \geq 5$.

It remains to deal with $p = 3$. For $p = 3$ we use the method of [Elk06], namely that it is enough to check that $j(E) - f(x)$ has no rational zero, where $f(x)$ is the function

$$f(x) = \frac{3^7 \cdot (x^2-1)^3 \cdot (x^6+3x^5+6x^4+x^3-3x^2+12x+16)^3 \cdot (2x^3+3x^2-3x-5)}{(x^3-3x-1)^9}$$

of degree 27 from [Elk06, pg. 5]. Elkies remarks (see [Elk10]) that there is a minus sign in the formula in [Elk06, pg. 5] that does not belong, as we verify by trying the integral specializations tabulated on [Elk06, pg. 7], and also by factoring $f - 1728$. Doing this computation for our curves yields the claimed result.

□

Remark 8.2. Andrew Sutherland used the techniques of [Sut09] to show [Sut10] that "the rank 2 elliptic curves with conductor less than 1058 all have surjective Galois images in $\mathrm{GL}_2(\mathbb{Z}/16\mathbb{Z})$." We thus also expect that $\rho_{E,2}$ is surjective for all rank 2 curves with conductor less than 1058.

Remark 8.3. The rank 2 curve 1058c1 has a rational 3 isogeny.

9 Related Projects

There are several future projects that are suggested by this paper, and we briefly sketch some of the most promising ones here.

We can do the same computations as we do here, but for modular abelian varieties A_f attached to newforms with $\mathrm{ord}_{s=1} L(f,s) \geq 2$. There is a table of such abelian varieties in [AS05]. For example, we carried out this computation for the modular abelian variety **1061b** of dimension 2 and indeed verified the natural higher dimensional analogue of Kolyvagin's conjecture for this abelian variety (for $p = 3$). Note that Kolyvagin appears to have never explicitly made such a conjecture, though of course he considers modular abelian varieties in [KL89]. We could also use our method to show that $Ш(A_f/\mathbb{Q})[p] = 0$ for a particular A_f, even when $\operatorname{ord} L(f,s) \leq 1$. This may require extending Kolyvagin's structure theorem to abelian varieties, or otherwise making results of [KL89] more explicit.

We could verify Conjecture 1.1 for the rank 3 elliptic curve of conductor 5077, and possibly some other rank 3 curves. Indeed, Jennifer Balakrishnan and the author have verified Conjecture 1.1 at least for **5077a** for $p = 3$.

It would be of interest to generalize Algorithm 2.1 to treat the case p^n with $n > 1$ or the case when $\rho_{E,p}$ is reducible. We could also consider an example such as the rank 2 curve **916c1** and $p = 3$ in which p divides a Tamagawa number.

Since we are doing explicit computation, it would also be interesting to closely investigate the case $p = 2$; this is particularly exciting when $r_{\mathrm{an}}(E/\mathbb{Q}) = 2$, since, after a harmless trace (as in Remark 5.7), we find that the points y_c, for c prime, are defined over **real quadratic** extensions of $\mathbb{Q}$, and define explicit elements of $\mathrm{Sel}^{(2)}(E/\mathbb{Q})$ that define globally trivial [2]-coverings $X \to E$. For example, if we take E to be **389a**, $K = \mathbb{Q}(\sqrt{-7})$ and $c = 3$, then y_3 is defined over a cyclic degree 4 extension K_3 of K; the trace z_3 of y_3 to the quadratic subfield of K_3 is defined over the real quadratic field $\mathbb{Q}(\sqrt{21})$; it is the point

$$z_3 = \left(-\frac{131}{84}, \frac{1091}{3528}\sqrt{21} - \frac{1}{2}\right).$$

Also, we find that $0 \neq \tau_{3,2} = \delta((0,0)) \in \mathrm{Sel}^{(2)}(E/\mathbb{Q})$. Is there any connection between these Heegner points over real quadratic fields and Stark-Heegner points?

Much of the work of Kolyvagin and Gross-Zagier has been generalized to totally real fields by Zhang and his students. Likewise, it would be of interest to see to what extent the results of this paper generalize to totally real fields.

It would also be of interest to investigate rank 2 curves E for which E^D exhibits some unusual behavior, e.g., nontrivial odd Ш or rank ≥ 3. For example, for E the curve **389a** of rank 2, and $K = \mathbb{Q}(\sqrt{-264})$, which has class number 8, the twist E^D has rank 3, so Kolyvagin's structure theorem implies that $[P_{c,\sigma}] = 0$ for all prime c, and it would be interesting to (a) computationally observe this, and (b) find a c that is a product of primes for which $[P_{c,\sigma}] \neq 0$. Similarly, if we take $K = \mathbb{Q}(\sqrt{-667})$, then K has class number 4 and $5 \mid \#Ш(E^D/\mathbb{Q})$; thus we expect that $[P_{c,5}] = 0$ for all prime c. Again it would beinteresting to observe this computationally, and find a prime c such that $[P_{c,5^2}] \neq 0$.

As a challenge, we could attempt to verify Conjecture 1.1 for the rank 4 elliptic curve of conductor 234446 given by the equation $y^2 + xy = x^3 - x^2 - 79x + 289$. This computation is at the edge of feasible, so it will require very sophisticated linear algebra or some other new idea.

ALGORITHMS FOR THE ARITHMETIC OF ELLIPTIC CURVES USING IWASAWA THEORY

WILLIAM STEIN AND CHRISTIAN WUTHRICH

Abstract. We explain how to use results from Iwasawa theory to obtain information about p-parts of Tate-Shafarevich groups of specific elliptic curves over $\mathbb{Q}$. Our method provides a practical way to compute $\#Ш(E/\mathbb{Q})(p)$ in many cases when traditional p-descent methods are completely impractical and also in situations where results of Kolyvagin do not apply, e.g., when the rank of the Mordell-Weil group is greater than 1. We apply our results along with a computer calculation to show that $Ш(E/\mathbb{Q})[p] = 0$ for the 1,534,422 pairs (E, p) consisting of a non-CM elliptic curve E over $\mathbb{Q}$ with conductor $\leq$ 30,000, rank ≥ 2, and good ordinary primes p with $5 \leq p < 1000$ and surjective mod-p representation.

1. Introduction

The papers [GJP$^+$09, Mil10] describe verification of the Birch and Swinnerton-Dyer conjecture for elliptic curves of conductor ≤ 5000 with rank ≤ 1 by a computational application of Euler system results of Kato and Kolyvagin combined with explicit descent. The main motivation for the present paper is to develop algorithms using Iwasawa theory, in order to enable verification of the conjecture in new directions, e.g., large-scale verification of assertions about $Ш(E/\mathbb{Q})$, when E has rank at least 2. The present paper naturally complements related projects by Perrin-Riou [PR03] and Coates [CLS09, Coa11]. Moreover, we fill small gaps in the literature (e.g., precision bounds in Section 3) and take the opportunity to correct errors in the literature (e.g., Lemma 4.2) that we found in the course of implementing algorithms.

In Sections 2–7 we recall the main objects and theorems involved in the classical and p-adic Birch and Swinnerton-Dyer conjectures (BSD conjectures), correct some minor errors in the literature, and state a tight error bound that is essential for rigorous computation with p-adic L-series. These sections gather together disparate results and provide unified notation and fill minor gaps. In Section 3, we define p-adic L-functions and explain how to compute them. Next we define the p-adic regulator, treating separately the cases of split multiplicative and supersingular reduction, and recall p-adic analogues of the BSD conjecture. In Section 6, we recall the basic definitions and results for the algebraic p-adic L-functions defined using Iwasawa theory. This leads to the statement of the main conjecture and Kato's theorem.

In Section 8 we discuss using p-adic results to bound $Ш(E)(p)$ when E has analytic rank 0, and Section 9 covers the case when the analytic rank is 1. In Section 10 we describe a conditional algorithm for computing the rank of an elliptic curve that uses p-adic methods and hence differs in key ways from the standard n-descent approach. Similarly, Section 11 contains an algorithm that applies to curves of any rank, and either computes $Ш(E/\mathbb{Q})(p)$ or explicitly disproves some standard conjecture. In Section 12 we give examples that illustrate the algorithms described above in numerous cases, including verifying for a rank 2 curve E that $Ш(E/\mathbb{Q})(p) = 0$ for a large number of p, as predicted by the BSD conjecture. In particular, we prove the following theorem via a computation of p-adic regulators and p-adic L-functions, which provides evidence for the BSD conjecture for curves of rank at least 2:

Theorem 1.1. *Let X be the set of 1,534,422 pairs (E,p), where E is a non-CM elliptic curve over $\mathbb{Q}$ with rank at least 2 and conductor $\leq$30,000, and $p \geq 5$ is a good ordinary prime for E with $p < 1000$ such that the mod p representation is surjective. Then $Ш(E/\mathbb{Q})[p] = 0$ for each of the pairs in X.*

1.1. **Background.** Let E be an elliptic curve defined over $\mathbb{Q}$ and let

$$y^2 + a_1 x y + a_3 y = x^3 + a_2 x^2 + a_4 x + a_6 \tag{1.1}$$

be the unique global minimal Weierstrass equation for E with $a_1, a_3 \in \{0,1\}$ and $a_2 \in \{-1,0,1\}$. Mordell proved that the set of rational points $E(\mathbb{Q})$ is an abelian group of finite rank $r = \operatorname{rank}(E(\mathbb{Q}))$. Birch and Swinnerton-Dyer conjectured that $r = \operatorname{ord}_{s=1} L(E,s)$, where $L(E,s)$ is the Hasse-Weil L-function of E (see Conjecture 2.1 below). We call $r_{\mathrm{an}} = \operatorname{ord}_{s=1} L(E,s)$ the analytic rank of E, which is defined since $L(E,s)$ can be analytically continuted to all $\mathbb{C}$ (see [BCDT01]).

There is no known algorithm (procedure that has been proved to terminate) that computes r in all cases. We can computationally obtain upper and lower bounds in any particular case. One way to give a lower bound on r is to search for linearly independent points of small height via the method of descent. We can also use constructions of complex and p-adic Heegner points in some cases to bound the rank from below. To compute an upper bound on the rank r, in the case of analytic ranks 0 and 1, we can use Kolyvagin's work on Euler systems of Heegner points; for general rank, the only known method is to do an n-descent for some integer $n > 1$. The 2-descents implemented by Cremona [Cre97], by Simon [Sim02] in Pari [PAR11] (and SAGE [S$^+$11b]), and the $2,3,4$, etc., descents in Magma [BCP97] (see also [CFO$^+$08, CFO$^+$09, CFO$^+$11]), are particularly powerful. But they may fail in practice to compute the exact rank due to the presence of 2 or 3-torsion elements in the Tate-Shafarevich group.

The Tate-Shafarevich group $Ш(E/\mathbb{Q})$ is a torsion abelian group associated to $E/\mathbb{Q}$. It is the kernel of the localization map loc in the exact sequence

$$0 \longrightarrow Ш(E/\mathbb{Q}) \longrightarrow \mathrm{H}^1(\mathbb{Q},E) \xrightarrow{\mathrm{loc}} \bigoplus_v \mathrm{H}^1(\mathbb{Q}_v,E),$$

where the sum runs over all places v in $\mathbb{Q}$. The arithmetic importance of this group lies in its geometric interpretation. There is a bijection from $Ш(E/\mathbb{Q})$ to the $\mathbb{Q}$-isomorphism classes of principal homogeneous spaces $C/\mathbb{Q}$ of E which have points everywhere locally. In particular, such a C is a curve of genus 1 defined over $\mathbb{Q}$ whose Jacobian is isomorphic to E. Nontrivial elements in $Ш(E/\mathbb{Q})$ correspond to curves C that defy the Hasse principle, i.e., have a point over every completion of $\mathbb{Q}$, but have no points over $\mathbb{Q}$.

Conjecture 1.2. *Shafarevich and Tate The group* $\text{Ш}(E/\mathbb{Q})$ *is finite.*

The rank r and the Tate-Shafarevich group $\text{Ш}(E/\mathbb{Q})$ are encoded in the Selmer groups of E. Fix a prime p, and let $E(p)$ denote the $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$-module of all torsion points of E whose orders are powers of p. The Selmer group $\mathcal{S}\rceil\updownarrow_p(E/\mathbb{Q})$ is defined by the following exact sequence:

$$0 \longrightarrow \mathcal{S}\rceil\updownarrow_p(E/\mathbb{Q}) \longrightarrow \mathrm{H}^1(\mathbb{Q}, E(p)) \longrightarrow \bigoplus_v \mathrm{H}^1(\mathbb{Q}_v, E)\,.$$

Likewise, for any positive integer m, the m-Selmer group is defined by the exact sequence

$$0 \to \mathcal{S}\rceil\updownarrow^{(m)}(E/\mathbb{Q}) \to \mathrm{H}^1(\mathbb{Q}, E[m]) \longrightarrow \bigoplus_v \mathrm{H}^1(\mathbb{Q}_v, E)$$

where $E[m]$ is the subgroup of elements of order dividing m in E.

It follows from the Kummer sequence that there are short exact sequences

$$0 \longrightarrow E(\mathbb{Q})/mE(\mathbb{Q}) \longrightarrow \mathcal{S}\rceil\updownarrow^{(m)}(E/\mathbb{Q}) \longrightarrow \text{Ш}(E/\mathbb{Q})[m] \longrightarrow 0$$

and

$$0 \longrightarrow E(\mathbb{Q}) \otimes \mathbb{Q}_p/\mathbb{Z}_p \longrightarrow \mathcal{S}\rceil\updownarrow_p(E/\mathbb{Q}) \longrightarrow \text{Ш}(E/\mathbb{Q})(p) \longrightarrow 0\,.$$

If the Tate-Shafarevich group is finite, then the $\mathbb{Z}_p$-corank of $\mathcal{S}\rceil\updownarrow_p(E/\mathbb{Q})$ is equal to the rank r of $E(\mathbb{Q})$.

The finiteness of $\text{Ш}(E/\mathbb{Q})$ is only known for curves of analytic rank 0 and 1, in which case computation of Heegner points and Kolyvagin's work on Euler systems gives an explicit computable multiple of its order [GJP$^+$09]. The group $\text{Ш}(E/\mathbb{Q})$ is not known to be finite for even a single elliptic curve with $r_{\mathrm{an}} \geq 2$. In such cases, the best we can do using current techniques is hope to bound the p-part $\text{Ш}(E/\mathbb{Q})(p)$ of $\text{Ш}(E/\mathbb{Q})$, for specific primes p. Even this might not a priori be possible, since it is not known that $\text{Ш}(E/\mathbb{Q})(p)$ is finite. However, if it were the case that $\text{Ш}(E/\mathbb{Q})(p)$ is finite (as Conjecture 1.2 asserts), then this could be verified by computing Selmer groups $\mathcal{S}\rceil\updownarrow^{(p^n)}(E/\mathbb{Q})$ for sufficiently many n (see, e.g., [SS04]). Note that practical unconditional computation of $\mathcal{S}\rceil\updownarrow^{(p^n)}(E/\mathbb{Q})$ via the method of descent is prohibitively difficult for all but a few very small p^n.

We present in this paper two algorithms using p-adic L-functions $\mathcal{L}_p(E,T)$, which are p-adic analogs of the complex function $L(E,s)$ (see Section 3 for the definition). Both algorithms rely heavily on the work of Kato [Kat04], which is a major breakthrough in the direction of a proof of the p-adic version of the BSD conjecture (see Section 5). The possibility of using these results to compute information about the Tate-Shafarevich group is well known to specialists and was for instance mentioned in [Col04] which gives a nice overview of the p-adic BSD conjecture. For supersingular primes such methods were used by Perrin-Riou in [PR03] to calculate $\text{Ш}(E/\mathbb{Q})(p)$ in many interesting cases when p is a prime of supersingular reduction.

Our first algorithm, which we describe in Section 10, finds a provable upper bound for the rank r of $E(\mathbb{Q})$ by computing approximations to the p-adic L-series for various small primes p. Any upper bound on the vanishing of $\mathcal{L}_p(E,T)$ at $T=0$ is also an upper bound on the rank r.

The second algorithm, which we discuss in Section 11, gives a new method for computing bounds on the order of $\text{Ш}(E/\mathbb{Q})(p)$, for specific primes p. We will exclude $p = 2$, since traditional descent methods work well at $p = 2$, and Iwasawa theory is not as well developed for $p = 2$. We also exclude some primes p, e.g., those for which E has additive reduction, since much of the theory we rely on has not yet been developed in this case.

Our second algorithm uses again the p-adic L-functions $\mathcal{L}_p(E, T)$, but also requires that the full Mordell-Weil group $E(\mathbb{Q})$ is known. Its output, if it yields any information, is a proven upper bound on the order of $\text{Ш}(E/\mathbb{Q})(p)$; in particular, we expect it to often prove the finiteness of the p-primary part of the Tate-Shafarevich group. But it will not in general be able to give any information about the structure of $\text{Ш}(E/\mathbb{Q})(p)$ as an abelian group or any information on its elements. For such finer results on the Tate-Shafarevich group, one general method is to use p^n-descents as described above. In some cases, we can also use visibility [AS02] to relate $\text{Ш}(E/\mathbb{Q})(p)$ to Mordell-Weil groups of other elliptic curves or abelian varieties. Assuming Kolyvagin's conjecture, it may also be possible to compute the structure of $\text{Ш}(E/\mathbb{Q})(p)$, for E of any rank, by making Kolyvagin's Euler system explicit in some cases (see forthcoming work of the first author and Jared Weinstein that builds on [Kol91b], and the remarks at the end of [Kol91a]). The computability of our upper bound on $\#\text{Ш}(E/\mathbb{Q})(p)$ relies on several conjectures, such as the finiteness of $\text{Ш}(E/\mathbb{Q})(p)$ and Conjectures 4.1 and 4.4 on the nondegeneracy of the p-adic height on E.

Under the assumption of the main conjecture (see Section 7), the number output by our algorithm equals the order of $\text{Ш}(E/\mathbb{Q})(p)$. There are several cases when this conjecture is known to hold by Greenberg and Vatsal in [GV00], by Grigorov in [Gri05], and in a forthcoming paper by Skinner and Urban [SU10]. In particular, under appropriate hypotheses, [SU10] prove the main conjecture for elliptic curves with good ordinary reduction (see Theorem 7.5 below). Thus in some cases, the upper bound on $\text{Ш}(E/\mathbb{Q})(p)$ that we obtain is actually a lower bound too, if all the computations go through, e.g. the p-adic height is nondegenerate and we find enough points to verify that the rank is equal to the order of vanishing.

Note that our algorithms can in principle be extended to give bounds in some cases on the rank of $E(K)$ and $\#\text{Ш}(E/K)(p)$ for number fields K which are abelian extensions of $\mathbb{Q}$ (here we still assume E is defined over $\mathbb{Q}$).

Acknowledgments. It is a pleasure to thank John Coates, Henri Darmon, Jerôme Grand'maison, Ralph Greenberg and Dimitar Jetchev for helpful discussions and comments. We are also greatly indebted to Robert Pollack who shared his code for computing p-adic L-functions and helped with the error estimates in Section 3. We also thank Mark Watkins, who independently implemented in Magma some of the algorithms of this paper, and in so doing found bugs in our implementation and discovered mistakes in an early draft of this manuscript.

2. The Birch and Swinnerton-Dyer conjecture

Let E be an elliptic curve defined over $\mathbb{Q}$. If the BSD conjecture (Conjecture 2.1 below) were true, it would yield an algorithm to compute both the rank r and the order of $\text{Ш}(E/\mathbb{Q})$.

Let E be an elliptic curve over $\mathbb{Q}$, and let $L(E, s)$ be the Hasse-Weil L-function associated to the $\mathbb{Q}$-isogeny class of E. According to [BCDT01] (which completes work initiated in [Wil95]), the function $L(E, s)$ is holomorphic on the whole complex plane. Let ω_E be the invariant differential $dx/(2y + a_1x + a_3)$ of the minimal

Weierstrass equation (1.1) of E. We write $\Omega_E = \int_{E(\mathbb{R})} \omega_E \in \mathbb{R}_{>0}$ for the Néron period of E.

Conjecture 2.1. *Birch and Swinnerton-Dyer*

(1) *The order of vanishing of the Hasse-Weil function $L(E,s)$ at $s=1$ is equal to the rank $r = \operatorname{rank}(E(\mathbb{Q}))$.*

(2) *The leading coefficient $L^*(E,1)$ of the Taylor expansion of $L(E,s)$ at $s=1$ satisfies*

$$\frac{L^*(E,1)}{\Omega_E} = \frac{\prod_v c_v \cdot \#\text{Ш}(E/\mathbb{Q})}{(\#E(\mathbb{Q})_{\mathrm{tor}})^2} \cdot \operatorname{Reg}(E/\mathbb{Q}) \tag{2.1}$$

where the Tamagawa numbers are denoted by c_v and $\operatorname{Reg}(E/\mathbb{Q})$ is the regulator of E, i.e., the discriminant of the Néron-Tate canonical height pairing on $E(\mathbb{Q})$.

Below we write $\#\text{Ш}(E/\mathbb{Q})_{\mathrm{an}}$ for the order of $\text{Ш}(E/\mathbb{Q})$ that is predicted by Conjecture 2.1.

Cassels proved in [Cas65] that if Conjecture 2.1 is true for an elliptic curve E over $\mathbb{Q}$, then it is true for all curves that are $\mathbb{Q}$-isogenous to E.

Proposition 2.2 (Manin)**.** *If Conjecture 2.1 is true, then there is an algorithm to compute r and $\#\text{Ш}(E/\mathbb{Q})$.*

Proof. Manin proved this result in [Man71, §11], but we recall the essential ideas here. By searching for points in $E(\mathbb{Q})$ we obtain a lower bound on r, which gets closer to the true rank r the longer we run the search. At some point this lower bound will equal r, but without using further information we have no way to know if that has occurred. As explained, e.g., in [Cre97, Coh07, Dok04], we can for any k compute $L^{(k)}(E,1)$ to any precision. Such computations yield upper bounds on r_{an}. In particular, if we compute $L^{(k)}(E,1)$ and it is nonzero (to the precision of our computation), then $r_{\mathrm{an}} \leq k$. Eventually this method will also converge to give the correct value of r_{an}, though again without further information we do not know when this will occur. However, if we know Conjecture 2.1, we know that $r = r_{\mathrm{an}}$, hence at some point the lower bound on r computed using point searches will equal the upper bound on r_{an} computed using the L-series. At this point, by Conjecture 2.1 we know the true value of both r and r_{an}.

Once r is known, we can compute $E(\mathbb{Q})$ via a point search (as explained in [Cre97, §3.5] or [Ste07a, §1.2]), hence we can approximate $\operatorname{Reg}(E/\mathbb{Q})$ to any desired precision. All quantities in (2.1) except $\#\text{Ш}(E/\mathbb{Q})$ can then be approximated to any desired precision. Solving for $\#\text{Ш}(E/\mathbb{Q})$ in (2.1) and computing all other quantities to large enough precision to determine the integer $\#\text{Ш}(E/\mathbb{Q})_{\mathrm{an}}$ then determines $\#\text{Ш}(E/\mathbb{Q})$, as claimed. □

The above algorithm would only produce the order of $\text{Ш}(E/\mathbb{Q})$ but no information about its structure as an abelian group. We could compute the structure of $\text{Ш}(E/\mathbb{Q})$ by computing the group $\mathcal{S}\rceil\updownarrow^{(n)}(E/\mathbb{Q})$ where $n^2 = \#\text{Ш}(E/\mathbb{Q})$, which is possible since $\mathcal{S}\rceil\updownarrow^{(m)}(E/\mathbb{Q})$ is computable for all m. The algorithms in Section 10 and 11 mimic the ideas of the proof of Proposition 2.2, but they replace the complex L-function by a p-adic L-series and use that much is known unconditionally about p-adic analogues of the BSD conjecture.

3. The p-adic L-function

We will assume for the rest of this article that E does not admit complex multiplication, though curves with complex multiplication are an area of active research for these methods (see e.g., [Rub99, PR04, CLS09, CLS10]).

Formulating a p-adic analogue of the BSD conjecture requires a p-adic analogue of the analytic function $L(E,s)$, as introduced by Mazur and Swinnerton-Dyer [MSD74, MTT86]. In this section, we recall the definition of this p-adic L-function, and fill a gap in the literature by giving a *complete recipe* for how to compute it in all cases, including proven error bounds on each coefficient.

Let $\pi\colon X_0(N) \longrightarrow E$ be the modular parametrization and let c_π be the Manin constant, i.e., the positive integer satisfying $c_\pi \cdot \pi^*\omega_E = 2\pi i f(\tau)d\tau$ with f the newform associated to E. When E is an optimal quotient (so the dual map $E \to \mathrm{Jac}(X_0(N))$ is injective), Manin conjectured that $c_\pi = 1$, and much work has been done toward this conjecture (see [Edi91, ARS06]).

Given a rational number r, define

$$\lambda^+(r) = -\pi i \cdot \left(\int_r^{i\infty} f(\tau)\, d\tau + \int_{-r}^{i\infty} f(\tau)\, d\tau \right) \in \mathbb{R}.$$

There is a basis $\{\gamma_+, \gamma_-\}$ of $H_1(E,\mathbb{Z})$ such that $\int_{\gamma_+} \omega_E$ is equal to Ω_E if $E(\mathbb{R})$ is connected and to $\frac{1}{2}\,\Omega_E$ otherwise. By a theorem of Manin [Man72], we know that $\lambda^+(r)$ belongs to $\mathbb{Q}\cdot\Omega_E$. For all $r \in \mathbb{Q}$, the *modular symbol* $[r]^+ \in \mathbb{Q}$ is

$$[r]^+ = \frac{\lambda^+(r)}{\Omega_E}.$$

In particular, we have $[0]^+ = L(E,1)\cdot\Omega_E^{-1}$. The quantity $[r]^+$ can be computed algebraically using modular symbols and linear algebra (see [Cre97] and [Ste07b]).

Let p be a prime of semistable reduction. We write[1] a_p for the trace of Frobenius. Suppose first that E has good reduction at p, and let $\tilde{E}$ denote the reduction of a minimal model of E modulo p. Then $N_p = p + 1 - a_p$ is the number of points on $\tilde{E}(\mathbb{F}_p)$. Let $X^2 - a_p \cdot X + p$ be the characteristic polynomial of Frobenius and let $\alpha \in \bar{\mathbb{Q}}_p$ be a root of this polynomial such that $\mathrm{ord}_p(\alpha) < 1$. There are two choices of α if E has supersingular reduction at p and there is a single possibility for α when E has good ordinary reduction at p. Next suppose E has bad multiplicative reduction at p. Then a_p is 1 if the reduction is split multiplicative and a_p is -1 if it is nonsplit multiplicative reduction. In either multiplicative case, we define $\alpha = a_p$.

As in [MTT86, §I.10], define a measure on $\mathbb{Z}_p^\times$ with values in $\mathbb{Q}(\alpha)$ by

$$\mu_\alpha(a + p^k\mathbb{Z}_p) = \begin{cases} \frac{1}{\alpha^k}\cdot\left[\frac{a}{p^k}\right]^+ - \frac{1}{\alpha^{k+1}}\cdot\left[\frac{a}{p^{k-1}}\right]^+ & \text{if } E \text{ has good reduction,} \\ \frac{1}{\alpha^k}\cdot\left[\frac{a}{p^k}\right]^+ & \text{otherwise.} \end{cases}$$

for any $k \geq 1$ and $a \in \mathbb{Z}_p^\times$ (by $\left[\frac{a}{p^k}\right]^+$ we mean $\left[\frac{a'}{p^k}\right]^+$ where $a' \in \mathbb{Z}$ is equivalent to a modulo p^k, which is well defined because of the modular symbols relations). Given a continuous character χ on $\mathbb{Z}_p^\times$ with values in the completion $\mathbb{C}_p$ of the algebraic closure of $\mathbb{Q}_p$, we may integrate χ against μ_α.

[1] The context should make it clear if we mean traces a_p of Frobenius, coefficients a_i as in (1.1), or series coefficients as in Proposition 3.1.

We assume henceforth that p is odd.[2] As in [MTT86, §I.13], any invertible element x of $\mathbb{Z}_p^\times$ can be written as $\omega(x) \cdot \langle x \rangle$ where $\omega(x)$ is a $(p-1)$-st root of unity and $\langle x \rangle$ belongs to $1 + p\mathbb{Z}_p$. We call ω the Teichmüller character. We define the analytic p-adic L-function by

$$L_\alpha(E, s) = \int_{\mathbb{Z}_p^\times} \langle x \rangle^{s-1} \, d\mu_\alpha(x) \quad \text{ for all } s \in \mathbb{Z}_p.$$

where by $\langle x \rangle^{s-1}$ we mean $\exp_p((s-1) \cdot \log_p(\langle x \rangle))$, and $\exp_p$ and $\log_p$ are the p-adic exponential and logarithm. The function $L_\alpha(E, s)$ extends to a locally analytic function in s on the disc defined by $|s-1| < 1$ (see the first proposition of [MTT86, §I.13]).

Let ${}_\infty G$ be the Galois group of the cyclotomic extension $\mathbb{Q}(\mu_{p^\infty})$ obtained by adjoining to $\mathbb{Q}$ all p-power roots of unity. By κ we denote the cyclotomic character ${}_\infty G \longrightarrow \mathbb{Z}_p^\times$. Because the cyclotomic character is an isomorphism, choosing a topological generator γ in $\Gamma = {}_\infty G^{(p-1)}$ amounts to picking a generator $\kappa(\gamma)$ of $1 + p\mathbb{Z}_p^\times$. With this choice, we may convert the function $L_\alpha(E, s)$ into a p-adic power series in $T = \kappa(\gamma)^{s-1} - 1$. We write $\mathcal{L}_\alpha(E, T)$ for this series in $\mathbb{Q}_p(\alpha)[\![T]\!]$. We have

$$\mathcal{L}_\alpha(E, T) = \int_{\mathbb{Z}_p^\times} (1+T)^{\frac{\log_p(\langle x \rangle)}{\log_p(\kappa(\gamma))}} d\mu_\alpha(x)\,. \tag{3.1}$$

For each integer $n \geq 1$, define a polynomial

$$P_n(T) = \sum_{a=1}^{p-1} \left(\sum_{j=0}^{p^{n-1}-1} \mu_\alpha\left(\omega(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot (1+T)^j \right) \in \mathbb{Q}_p(\alpha)[T].$$

Note that $P_n(T)$ depends on the choice of α, but for simplicity we do not include α in the notation.

Proposition 3.1. *We have*

$$\lim_{n \to \infty} P_n(T) = \mathcal{L}_\alpha(E, T),$$

where the convergence is coefficient-by-coefficient, in the sense that if $P_n(T) = \sum_j a_{n,j} T^j$ *and* $\mathcal{L}_\alpha(E, T) = \sum_j a_j T^j$*, then* $\lim_{n \to \infty} a_{n,j} = a_j$*.*

We now give a proof of this convergence and in doing so obtain an explicit upper bound for $|a_j - a_{n,j}|$, which is critical to making the computation of $\mathcal{L}_\alpha(E, T)$ algorithmic, and which appears to not be explicitly stated in the literature.

For any choice ζ_r of p^r-th root of unity in $\mathbb{C}_p$, let χ_r be the $\mathbb{C}_p$-valued character of $\mathbb{Z}_p^\times$ of order p^r obtained by composing the map $\langle\ \rangle : \mathbb{Z}_p^\times \to 1 + p\mathbb{Z}_p$ defined above with the map $1 + p\mathbb{Z}_p \to \mathbb{C}_p^*$ that sends $1 + p$ to ζ_r. Note that the conductor of χ_r is p^{r+1}.

Lemma 3.2. *Let* ζ_r *be a* p^r*-th root of unity with* $1 \leq r \leq n-1$*, and let* χ_r *be the corresponding character of order* p^r*, as above. Then*

$$P_n(\zeta_r - 1) = \int_{\mathbb{Z}_p^\times} \chi_r \ d\mu_\alpha.$$

In particular, note that the right hand side does not depend on n*.*

[2] Everything in this section can be done for $p = 2$ with $1 + p$ replaced by an integer that is congruent to 5 modulo 8, and various other slight modifications.

Proof. Writing $\chi = \chi_r$, we have

$$\begin{aligned} P_n(\zeta_r - 1) &= \sum_{a=1}^{p-1} \sum_{j=0}^{p^{n-1}-1} \mu_\alpha \left(\omega(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot \zeta_r^j \\ &= \sum_{a=1}^{p-1} \sum_{j=0}^{p^{n-1}-1} \mu_\alpha \left(\omega(a)(1+p)^j + p^n\mathbb{Z}_p\right) \cdot \chi\left((1+p)^j\right) \\ &= \sum_{b\in(\mathbb{Z}/p^n\mathbb{Z})^\times} \mu_\alpha\left(b + p^n\mathbb{Z}_p\right) \cdot \chi(b) = \int_{\mathbb{Z}_p^\times} \chi \; d\mu_\alpha. \end{aligned}$$

In the second to the last equality, we use that

$$(\mathbb{Z}/p^n\mathbb{Z})^\times \cong (\mathbb{Z}/p\mathbb{Z})^\times \times (1 + p(\mathbb{Z}/p^n\mathbb{Z}))$$

to sum over lifts of $b \in (\mathbb{Z}/p^n\mathbb{Z})^\times$ of the form $\omega(a)(1+p)^j$, i.e., a Teichmüller lift times a power of $(1+p)^j$. In the last equality, we use that χ has conductor dividing p^n, so is constant on the residue classes modulo p^n, and use the Riemann sums definition of the given integral. □

For each positive integer n, let $w_n(T) = (1+T)^{p^n} - 1$.

Corollary 3.3. *We have in $\mathbb{Q}_p(\alpha)[T]$ that*

$$w_{n-1}(T) \textit{ divides } P_{n+1}(T) - P_n(T).$$

Proof. By Lemma 3.2, $P_{n+1}(T)$ and $P_n(T)$ agree on $\zeta_j - 1$ for $0 \le j \le n-1$ and any choice ζ_j of p^j-th root of unity, so their difference vanishes on every root of the polynomial $w_{n-1}(T) = (1+T)^{p^{n-1}} - 1$. The claimed divisibility follows, since $w_{n-1}(T)$ has distinct roots. □

Lemma 3.4. *Let $f(T) = \sum_j b_j T^j$ and $g(T) = \sum_j c_j T^j$ be in $\mathcal{O}[T]$ with $\mathcal{O}$ the ring of integers of a finite field extension of $\mathbb{Q}_p$. If $f(T)$ divides $g(T)$, then*

$$\mathrm{ord}_p(c_j) \ge \min_{0\le i\le j} \mathrm{ord}_p(b_i).$$

Proof. We have $f(T)k(T) = g(T)$ with $k(T) \in \mathcal{O}[T]$. The lemma follows by using the definition of polynomial multiplication and the nonarchimedean property of ord_p. □

As above, let $a_{n,j}$ be the j-th coefficient of the polynomial $P_n(T)$. Let

$$c_n = \max(0, -\min_j \mathrm{ord}_p(a_{n,j}))$$

so that $p^{c_n} P_n(T) \in (\mathbb{Z}_p[\alpha])[T]$. For any $j > 0$, let

$$e_{n,j} = \min_{1\le i\le j} \mathrm{ord}_p \binom{p^n}{i}.$$

Proposition 3.5. *For all $n \ge 0$, we have $a_{n+1,0} = a_{n,0}$, and for $j > 0$,*

$$\mathrm{ord}_p(a_{n+1,j} - a_{n,j}) \ge e_{n-1,j} - \max(c_n, c_{n+1}).$$

Proof. Corollary 3.3 implies that there is a polynomial $h(T) \in \mathbb{Q}_p(\alpha)[T]$ with $w_{n-1}(T) \cdot h(T) = P_{n+1}(T) - P_n(T)$. Let $c \leq \max(c_n, c_{n+1})$ be the integer such that $p^c \cdot (P_{n+1}(T) - P_n(T)) \in \mathbb{Z}_p[\alpha][T]$ is primitive. Multiply both sides of the above equation by p^c, to get

$$w_{n-1}(T) \cdot p^c h(T) = p^c P_{n+1}(T) - p^c P_n(T) \in \mathbb{Z}_p[\alpha][T].$$

The right hand side is primitive and integral, so it is reducible in $\mathbb{Z}_p[\alpha][T]$. Since $w_{n-1}(T)$ is integral, we must have $p^c h(T) \in \mathbb{Z}_p[\alpha][T]$. Applying Lemma 3.4 and renormalizing by p^c gives $c + \mathrm{ord}_p(a_{n+1,j} - a_{n,j}) \geq e_{n-1,j}$, so

$$\mathrm{ord}_p(a_{n+1,j} - a_{n,j}) \geq e_{n-1,j} - c \geq e_{n-1,j} - \max(c_n, c_{n+1}).$$

□

Lemma 3.6. *The c_k are uniformly bounded above.*

Proof. Tracing through the definitions and using that $\mathrm{ord}_p(1/\alpha) > 1$, we see that the lemma is equivalent to showing that the modular symbol $[x]^+$ appearing in the definition of μ_α has bounded denominator. By the Abel-Jacobi theorem, the quotient of the image of the modular symbol map $[x]$ modulo $\mathbb{Z}^2 \approx H_1(E, \mathbb{Z})$ is equal to the image of the cuspidal subgroup C of $J_0(N)$. In particular, a bound on the denominator of $[x]^+$ is the largest power of p that divides the exponent of the image of C in $E(\bar{\mathbb{Q}})$. The claim follows since C is finite, since it is generated by finitely many "Manin symbols" as explained in [Man72, Thm. 2.7] or [Cre97, Ch. 2], and C is torsion as noted on the footnote of [Man72, pg. 35]. □

For j fixed, $e_{n-1,j} - \max(c_{n+1}, c_n)$ goes to infinity as n grows since the c_k are uniformly bounded above, by Lemma 3.6. Thus, $\{a_{n,j}\}$ is a Cauchy sequence and Proposition 3.5 implies that

$$\mathrm{ord}_p(a_j - a_{n,j}) \geq e_{n-1,j} - \max(c_n, c_{n+1}).$$

3.1. **The p-adic multiplier.** In this section we specialize the definition of p-adic multiplier from [MTT86, §I.14] to the case of an elliptic curve. For a prime p of good reduction, we define the p-adic multiplier by

$$\epsilon_p = \left(1 - \tfrac{1}{\alpha}\right)^2 . \tag{3.2}$$

Note that $\mathrm{ord}_p(\epsilon_p)$ is equal to 2 $\mathrm{ord}_p(N_p)$ where $N_p = p + 1 - a_p$ is the number of points in $\tilde{E}(\mathbb{F}_p)$.

For a prime of bad multiplicative reduction, we put

$$\epsilon_p = 1 - \tfrac{1}{\alpha} = \begin{cases} 0 & \text{if } p \text{ is split multiplicative,} \\ 2 & \text{if } p \text{ is nonsplit.} \end{cases}$$

3.2. **Interpolation property.** The p-adic L-function constructed above satisfies an interpolation property with respect to the complex L-function (see [MTT86, §I.14]). For instance, we have that

$$\mathcal{L}_\alpha(E, 0) = L_\alpha(E, 1) = \int_{\mathbb{Z}_p^\times} d\mu_\alpha = \epsilon_p \cdot \frac{L(E, 1)}{\Omega_E} .$$

A similar formula holds when integrating nontrivial characters of $\mathbb{Z}_p^\times$ against $d\mu_\alpha$. If χ is the character on ${}_\infty G$ sending γ to a root of unity ζ of exact order p^n, then

$$\mathcal{L}_\alpha(E,\zeta-1)=\frac{1}{\alpha^{n+1}}\cdot\frac{p^{n+1}}{G(\chi^{-1})}\cdot\frac{L(E,\chi^{-1},1)}{\Omega_E}\,.$$

Here $G(\chi^{-1})$ is the Gauss sum and $L(E,\chi^{-1},1)$ is the Hasse-Weil L-function of E twisted by χ^{-1}.

3.3. **The good ordinary case.** Suppose that the reduction of the elliptic curve at the prime p is good and ordinary, so a_p is not divisible by p. As mentioned before, in this case there is a unique choice of root α of the characteristic polynomial x^2-a_px+p that satisfies $\mathrm{ord}_p(\alpha)<1$. Since α is an algebraic integer, this implies that $\mathrm{ord}_p(\alpha)=0$, so α is a unit in $\mathbb{Z}_p$. We get therefore a unique p-adic L-function that we will denote simply by $\mathcal{L}_p(E,T)=\mathcal{L}_\alpha(E,T)$.

Proposition 3.7. *Let E be an elliptic curve with good ordinary reduction at a prime $p>2$ such that $E[p]$ is irreducible. Then the series $\mathcal{L}_p(E,T)$ belongs to $\mathbb{Z}_p[\![T]\!]$.*

Proof. See [GV00, Prop. 3.7] with $\chi=1$. □

We next illustrate the above material with a few numerical examples, one for each type of reduction. Let $E_0/\mathbb{Q}$ be the curve

$$E_0\colon\quad y^2+xy=x^3-x^2-4x+4 \tag{3.3}$$

which is labeled 446d1 in Cremona's tables [Cre]. The Mordell-Weil group $E_0(\mathbb{Q})$ is isomorphic to $\mathbb{Z}^2$ generated by the points $(2,0)$ and $(1,-1)$. We consider the prime $p=5$ where E_0 has good and ordinary reduction. As the number of points $N_p=10$ is divisible by p, this is an anomalous prime in the terminology of [Maz72]. Using [S$^+$11b], we compute an approximation to the p-adic L-series as explained above with $n=5$ to find

$$\begin{aligned}\mathcal{L}_5(E_0,T)\ &=\mathbf{O}(5^4)\cdot T+(5+5^2+3\cdot5^3+\mathbf{O}(5^4))\cdot T^2\\&\quad+(2\cdot5+3\cdot5^2+3\cdot5^3+\mathbf{O}(5^4))\cdot T^3+(4\cdot5^2+4\cdot5^3+\mathbf{O}(5^4))\cdot T^4\\&\quad+(4\cdot5+4\cdot5^2+\mathbf{O}(5^3))\cdot T^5\\&\quad+(1+2\cdot5+5^2+4\cdot5^3+\mathbf{O}(5^4))\cdot T^6+\mathbf{O}(T^7)\,.\end{aligned}$$

We see that the order of vanishing is at least 1 as follows. The interpolation formula implies that $\mathcal{L}_5(E_0,0)=0$ since $[0]^+=0$. We will give an explanation for the vanishing of the coefficient of T^1 later in the comments right after Theorem 6.1. We remark that the coefficient of T^2 has valuation 1, but the coefficient of T^6 is a unit.

3.4. **Multiplicative case.** We separate the cases of split and nonsplit multiplicative reduction. In fact, if the reduction is nonsplit, then the description of the good ordinary case applies just the same. But if the reduction is split multiplicative (the "exceptional case" in [MTT86]), then the p-adic L-series must have a trivial zero, i.e., $\mathcal{L}_p(E,0)=0$ because $\epsilon_p=0$. By a result of Greenberg and Stevens [GS93] (see also [Kob06] for a proof using Kato's Euler system), we know that

$$\left.\frac{d\,\mathcal{L}_p(E,T)}{d\,T}\right|_{T=0}=\frac{1}{\log_p\kappa(\gamma)}\cdot\frac{\log_p(q_E)}{\mathrm{ord}_p(q_E)}\cdot\frac{L(E,1)}{\Omega_E}$$

where q_E denotes the Tate period of E over $\mathbb{Q}_p$. It is now known thanks to [BDGP96] that $\log_p(q_E)$ is nonzero. Hence we define the p-adic $\mathscr{L}$-invariant as

$$\mathscr{L}_p = \frac{\log_p(q_E)}{\operatorname{ord}_p(q_E)} \neq 0\,. \tag{3.4}$$

We refer to [Col10] for a detailed discussion of the different $\mathscr{L}$-invariants and their connections.

3.5. **The supersingular case.** In the supersingular case, that is when $a_p \equiv 0 \pmod{p}$, we have two roots α and β both of valuation $\frac{1}{2}$. An analysis of the functions $\mathcal{L}_\alpha$ and $\mathcal{L}_\beta$ is in [Pol03]. The series $\mathcal{L}_\alpha(E,T)$ might not have integral coefficients in $\mathbb{Q}_p(\alpha)$. Nevertheless we can still extract two integral series $\mathcal{L}_p^{\pm}(E,T)$. We will not need this description.

There is a way of rewriting the p-adic L-series which relates more easily to the p-adic height defined in the next section. We follow Perrin-Riou's description in [PR03].

As before, ω_E denotes the chosen invariant differential on E. Let $\eta_E = x \cdot \omega_E$. The pair $\{\omega_E, \eta_E\}$ forms a basis of the Dieudonné module

$$D_p(E) = \mathbb{Q}_p \otimes \mathrm{H}^1_{\mathrm{dR}}(E/\mathbb{Q}).$$

This $\mathbb{Q}_p$-vector space comes equipped with a canonical Frobenius endomorphism φ that acts on it linearly. We normalize it in the following way, which makes it equal to $\frac{1}{p}\cdot F$ with F being the Frobenius as used in [MST06] and [Ked01, Ked03, Ked04]. Let t be any uniformizer at the point O_E at infinity on E, e.g., take $t = -\frac{x}{y}$. Let ν be a class in $D_p(E)$ represented by the differential $\sum c_n \cdot t^{n-1}\, dt$ with $c_n \in \mathbb{Q}_p$. Then $\varphi(\nu)$ can be represented by the differential $\sum c_n \cdot t^{pn-1}\, dt$. In particular $\varphi(dt) = t^{p-1}\, dt$. The characteristic polynomial of φ is equal to $X^2 - p^{-1}\, a_p\, X + p^{-1}$.

Write $\mathcal{L}_\alpha(E,T)$ as $G(T) + \alpha \cdot H(T)$ with $G(T)$ and $H(T)$ in $\mathbb{Q}_p[\![T]\!]$. Then we define

$$\mathcal{L}_p(E,T) = G(T)\cdot\omega_E \;+\; a_p \cdot H(T)\cdot\omega_E \;-\; p\cdot H(T)\cdot\varphi(\omega_E)\,,$$

which we view as a formal power series with coefficients in $D_p(E)\otimes\mathbb{Q}_p[\![T]\!]$, which contains exactly the same information as $\mathcal{L}_\alpha(E,T)$. See [PR03, §1] for a direct definition. Since the invariant differential ω_E depends on the choice of the Weierstrass equation (1.1), the expression $\mathcal{L}_p(E,T)$ is also dependent on this choice. However, if we write the series in the basis $\{\omega_E, \varphi(\omega_E)\}$ rather than in $\{\omega_E, \eta_E\}$, then the coordinates as above are independent. The D_p-valued L-series satisfies again certain interpolation properties,[3] e.g.,

$$(1-\varphi)^{-2}\,\mathcal{L}_p(E,0) = \frac{L(E,1)}{\Omega_E}\cdot\omega_E \,\in\, D_p(E)\,.$$

See Section 12.2 for an example.

3.6. **Additive case.** The case of additive reduction is much harder to treat, though we are optimistic that such a treatment is possible. We have not tried to include the possibility of additive reduction in our algorithm, especially because the existence of the p-adic L-function is not yet guaranteed in general. Note that there are two interesting papers [Del98] and [Del02] of Delbourgo on this subject.

[3] Perrin-Riou writes in [PR03] the multiplier as $(1-\varphi)^{-1}\cdot(1-p^{-1}\varphi^{-1})$ and she multiplies the right hand side with $L(E/\mathbb{Q}_p,1)^{-1} = N_p\cdot p^{-1}$. It is easy to see that $(1-\varphi)\cdot(1-p^{-1}\varphi^{-1}) = 1-\varphi+(\varphi - a_p\cdot p^{-1}) + p^{-1} = N_p\cdot p^{-1}$.

3.7. **Quadratic twists.** When the curve E is not semistable, we can try to use the modular symbols of a quadratic twist $E^\dagger$ of E in the computation of the p-adic L-function for E. This leads to dramatic speedups when the quadratic twist has lower conductor than E.

Suppose that there exists a fundamental discriminant D of a quadratic field satisfying the following conditions:

- p does not divide D,
- D^2 divides N,
- $M = N/D^2$ is coprime to D, and
- the conductor $N^\dagger$ of the quadratic twist $E^\dagger$ of E by D is of the form $M \cdot Q$ with Q dividing D.

Then $\psi = (\frac{D}{\cdot})$ is the Dirichlet character associated to the quadratic field $\mathbb{Q}(\sqrt{D})$ over which E and $E^\dagger$ become isomorphic. Let $f_{\scriptscriptstyle E}^\dagger$ be the newform of level $N^\dagger$ associated to the isogeny class of $E^\dagger$. As explained in [MTT86, §II.11], the twist of $f_{\scriptscriptstyle E}^\dagger$ by ψ is equal to $f_{\scriptscriptstyle E}$ and we can use their formula (I.8.3)

$$f_{\scriptscriptstyle E}(\tau) = \frac{1}{G(\psi)} \sum_{u \bmod |D|} \psi(u) \cdot f_{\scriptscriptstyle E}^\dagger\Bigl(\tau + \frac{u}{|D|}\Bigr). \tag{3.5}$$

Here $G(\psi)$ is as before the Gauss sum of ψ, whose value we know to be the square root $\sqrt{D}$ of D in $\mathbb{R}_{>0}$ or in $i\cdot\mathbb{R}_{>0}$. Let $c_{\mathbb{R}}$ be the number of connected components of $E(\mathbb{R})$, which is also the number of connected components of $E^\dagger(\mathbb{R})$. We write $\Omega_{E^\dagger}^-$ for $c_{\mathbb{R}} \cdot \int_{\gamma^-} \omega_{E^\dagger}$, similar to $\Omega_{E^\dagger} = \Omega_{E^\dagger}^+ = c_{\mathbb{R}} \cdot \int_{\gamma^+} \omega_{E^\dagger}$ with the notations from (3.1). We also put

$$\lambda^-(r) = \pi i \cdot \left(\int_r^{i\infty} - \int_{-r}^{i\infty} \right) f(\tau)\, d\tau$$

and $[r]^- = \lambda^-(r)/\Omega_{\scriptscriptstyle E}^-$. As for the modular symbol $[r]^+$, we have $[r]^- \in \mathbb{Q}$. Following [MTT86], we define the quantity η such that

$$\sqrt{D} \cdot \Omega_E^+ = \eta \cdot \Omega_{E^\dagger}^{\operatorname{sign}(D)}\,.$$

It is known that η is either 1 or 2.

Now we can compute the modular symbol $[r]^+$ for the curve E in terms of modular symbols for $E^\dagger$. Suppose first that $D > 0$.

$$\begin{aligned}
\lambda_E^+(r) &= \pi i \cdot \left(\int_r^{i\infty} + \int_{-r}^{i\infty} \right) \frac{1}{\sqrt{D}} \sum_{u=1}^{D-1} \psi(u) f_{\scriptscriptstyle E}^\dagger\Bigl(\tau + \frac{u}{D}\Bigr) d\tau \\
&= \frac{\pi i}{\sqrt{D}} \sum_{u=1}^{D-1} \psi(u) \int_{r+u/D}^{i\infty} f_{\scriptscriptstyle E}^\dagger(\tau) d\tau \\
&\qquad + \frac{\pi i}{\sqrt{D}} \sum_{v=1}^{D-1} \psi(D-v) \int_{-r}^{i\infty} f_{\scriptscriptstyle E}^\dagger\Bigl(\tau + 1 - \frac{v}{D}\Bigr) d\tau \\
&= \frac{\pi i}{\sqrt{D}} \sum_{u=1}^{D-1} \psi(u) \left(\int_{r+u/D}^{i\infty} + \int_{-r-u/D}^{i\infty} \right) f_{\scriptscriptstyle E}^\dagger(\tau) d\tau \\
&= \frac{1}{\sqrt{D}} \sum_{u=1}^{D-1} \psi(u)\, \lambda_{E^\dagger}^+\Bigl(r + \frac{u}{D}\Bigr).
\end{aligned}$$

We used that $\psi(u) = \operatorname{sign}(D)\,\psi(D-u)$, that $f_E^\dagger(\tau+1) = f_E^\dagger(\tau)$ and Equation (3.5). Similarly for $D<0$, we find

$$\lambda_E^+(r) = \frac{-1}{\sqrt{D}} \sum_{u=1}^{|D|-1} \psi(u)\,\lambda_{E^\dagger}^-\Bigl(r + \frac{u}{D}\Bigr).$$

Therefore, we have for any fundamental discriminant D

$$[r]_E^+ = \frac{\operatorname{sign}(D)}{\eta} \sum_{u=1}^{|D|-1} \Bigl(\frac{D}{u}\Bigr) \cdot \Bigl[r + \frac{u}{D}\Bigr]_{E^\dagger}^{\operatorname{sign}(D)}.$$

We can also express the unit eigenvalue α of Frobenius in terms of the corresponding $\alpha^\dagger$ unit eigenvalue for $E^\dagger$ as

$$\alpha = \psi(p) \cdot \alpha^\dagger.$$

In summary, we can evaluate the approximations to the p-adic L-function of E using only modular symbols of the curve $E^\dagger$ with smaller conductor. The estimations for the error of these approximations remain exactly the same.

We recalled that the computation of the modular symbols $[r]^\pm$ can be done purely algebraically. Unfortunately, the algebraic computation determines them only up to one single fixed choice of sign. If $[0]^+$ is nonzero, we can simply compare the value of the modular symbol at 0 with $L(E,1)/\Omega_E$ and adjust the sign when needed. If $L(E,1)=0$, we can use the above formula to compute $[0]_{E^\dagger}^+$ for some quadratic twist $E^\dagger$ with nonvanishing L-value. So we can easily adjust the unknown sign. Also, if we only know the modular symbols up to a rational multiple, we can use these formulae to scale them.

We should also add here that we can not possibly do a similar thing with quartic or sextic twists when they exist. This is due to the fact that the extension over which the twists become isomorphic is no longer an abelian extension. So we would have to twist the modular symbols with a Galois representation of dimension at least 2. Nevertheless there is a way of using these twists for computing the p-adic L-function as explained in [CLS09], using the fact that these curves have complex multiplication.

4. p-adic heights

The second term that we will generalize in the BSD formula is the real-valued regulator. In p-adic analogues of the conjecture we replace it by a p-adic regulator, which we define using a p-adic analogue of the height pairing. We follow here the generalized version [BPR93] and [PR03].

Let ν be an element of the Dieudonné module $D_p(E)$ (see Section 3.5). We will define a p-adic height function $h_\nu\colon E(\mathbb{Q}) \longrightarrow \mathbb{Q}_p$ which depends linearly on the vector ν. Hence it is sufficient to define it on the basis $\omega = \omega_E$ and $\eta = \eta_E$.

If $\nu = \omega$, then we define

$$h_\omega(P) = \log_E(P)^2$$

where $\log_E$ is the linear extension of the p-adic elliptic logarithm

$$\log_{\hat{E}}\colon \hat{E}(p\mathbb{Z}_p) \longrightarrow p\mathbb{Z}_p$$

defined on the formal group $\hat{E}$, by integrating our fixed differential ω_E.

For $\nu = \eta$, we define the p-adic sigma function of Bernardi as in [Ber81] to be the solution σ of the differential equation

$$-x = \frac{d}{\omega_{E}}\left(\frac{1}{\sigma}\cdot\frac{d\sigma}{\omega_{E}}\right)$$

such that $\sigma(O_{E}) = 0$, $\frac{d\sigma}{\omega_E}(O_{E}) = 1$, and $\sigma(-P) = -\sigma(P)$. If we denote by $t = -\frac{x}{y}$ the uniformizer at O_{E}, we may develop the sigma function as a series in t:

$$\sigma(t) = t + \frac{a_1}{2}\,t^2 + \frac{a_1^2 + a_2}{3}\,t^3 + \frac{a_1^3 + 2a_1a_2 + 3a_3}{4}\,t^4 + \cdots \in \mathbb{Q}(\!(t)\!),$$

where the a_i are the coefficients of the Weierstrass equation (1.1). As a function on the formal group $\hat{E}(p\mathbb{Z}_p)$, it converges for all t with $\operatorname{ord}_p(t) > \frac{1}{p-1}$.

We say that a point P in $E(\mathbb{Q})$ has good reduction at a prime p if P reduces to the identity component of the special fiber of the Néron model of E at p. Given a point P in $E(\mathbb{Q})$ there exists a multiple $m\cdot P$ such that $\sigma(m\cdot P)$ converges and such that $m\cdot P$ has good reduction at all primes. Denote by $e(m\cdot P)\in\mathbb{Z}$ the square root of the denominator of the x-coordinate of $m\cdot P$. Define

$$h_\eta(P) = \frac{2}{m^2}\cdot\log_p\left(\frac{e(m\cdot P)}{\sigma(m\cdot P)}\right).$$

Bernardi [Ber81] proves that this function is quadratic and satisfies the parallelogram law.

Finally, if $\nu = a\,\omega + b\,\eta$ then put

$$h_\nu(P) = a\,h_\omega(P) + b\,h_\eta(P)\,.$$

Since this function is quadratic and satisfies the parallelogram law, it induces a bilinear symmetric pairing $\langle\cdot,\cdot\rangle_\nu$ with values in $\mathbb{Q}_p$ defined by

$$\langle P, Q\rangle_\nu = \frac{1}{2}\cdot\big(h_\nu(P+Q) - h_\nu(P) - h_\nu(Q)\big)\,.$$

Note that all these definitions are dependent on the choice of the Weierstrass equation. It is easy to verify that the pairing is zero if one of the points is a torsion point.

4.1. **The good ordinary case.** Since we have only a single p-adic L-function in the case that the reduction is good ordinary, we have also to pin down a canonical choice of a p-adic height function. This was first done by Schneider [Sch82] and Perrin-Riou [PR82]. We refer to [MT91] and [MST06] for more details.

Let $\nu_\alpha = a\,\omega + b\,\eta$ be an eigenvector of φ on $D_p(E)$ associated to the eigenvalue $\frac{1}{\alpha}$. The value $e_2 = \mathbf{E}_2(E,\omega_{E}) = -12\cdot\frac{a}{b}$ is the value of the Katz p-adic Eisenstein series of weight 2 at (E,ω_{E}). If a point P has good reduction at all primes and lies in the range of convergence of $\sigma(t)$, we define the canonical p-adic height of P to be

$$\begin{aligned}\hat{h}_p(P) &= \frac{1}{b}\cdot h_{\nu_\alpha}(P)\\ &= -\frac{a}{b}\cdot\log_{E}(P)^2 + 2\,\log\left(\frac{e(P)}{\sigma(P)}\right)\\ &= 2\,\log_p\left(\frac{e(P)}{\exp(\frac{e_2}{24}\log_{E}(P)^2)\cdot\sigma(P)}\right) = 2\,\log_p\left(\frac{e(P)}{\sigma_p(P)}\right). \qquad (4.1)\end{aligned}$$

The function σ_p, defined by the last line, is called the canonical sigma-function, see [MT91]; it is known to lie in $\mathbb{Z}_p[\![t]\!]$. The p-adic height defined here is up to a factor of 2 the same as in [MST06].[4] It is also important to note that the function $\hat{h}_p$ is independent of the Weierstrass equation.

We write $\langle\cdot,\cdot\rangle_p$ for the canonical p-adic height pairing on $E(\mathbb{Q})$ associated to $\hat{h}_p$, and $\mathrm{Reg}_p(E/\mathbb{Q})$ for the discriminant of the height pairing on $E(\mathbb{Q})/E(\mathbb{Q})_{\mathrm{tor}}$.

Conjecture 4.1. *Schneider* [Sch82] *The canonical p-adic height is nondegenerate on $E(\mathbb{Q})/E(\mathbb{Q})_{\mathrm{tor}}$. In other words, the canonical p-adic regulator* $\mathrm{Reg}_p(E/\mathbb{Q})$ *is nonzero.*

Apart from the special case treated in [Ber82] of curves with complex multiplication of rank 1, there are hardly any results on this conjecture. See also [Wut04].

We return to our running example curve E_0 from Section 3.3. The methods of [MST06, Har08] permit us to quickly compute to relatively high precision the p-adic regulator of E_0. We have

$$\mathbf{E}_2(E_0,\omega_{E}) = 3\cdot 5 + 4\cdot 5^2 + 5^3 + 5^4 + 5^5 + 2\cdot 5^6 + 4\cdot 5^7 + 3\cdot 5^9 + \mathbf{O}(5^{10}),$$

and the regulator associated to the canonical p-adic height is

$$\mathrm{Reg}_p(E_0/\mathbb{Q}) = 2\cdot 5 + 2\cdot 5^2 + 5^4 + 4\cdot 5^5 + 2\cdot 5^7 + 4\cdot 5^8 + 2\cdot 5^9 + \mathbf{O}(5^{10}). \tag{4.2}$$

4.2. **The multiplicative case.** When E has multiplicative reduction at p, if we want to have the same closed formula in the p-adic version of the BSD conjecture for multiplicative primes as for other ordinary primes, the p-adic height has to be changed slightly. We use the description of the p-adic regulator given in [MTT86, §II.6]. Alas, their formula is not correct, as explained in [Wer98], so we use the corrected version.

If the reduction is nonsplit multiplicative, we use the same formula (4.1) to define the p-adic height as for the good ordinary case.

We assume for the rest of this section that the reduction is split multiplicative. We use Tate's p-adic uniformization (see for instance in [Sil94, Ch. V]). We have an explicit description of the height pairing in [Sch82]. Let q_E be the Tate parameter of the elliptic curve E over $\mathbb{Q}_p$, so we have an analytic homomorphism $\psi\colon \bar{\mathbb{Q}}_p^\times \longrightarrow E(\bar{\mathbb{Q}}_p)$ whose kernel is precisely $q_E^{\mathbb{Z}}$. The image of $\mathbb{Z}_p^\times$ under ψ is equal to the subgroup of points of $E(\mathbb{Q}_p)$ lying on the connected component of the reduction modulo p of the Néron model of E. Let C be the constant such that $\psi^*(\omega_E) = C\cdot\frac{du}{u}$ where u is a uniformizer of $\mathbb{Q}_p^\times$ at 1. The value of the p-adic Eisenstein series of weight 2 is

$$e_2 = \mathbf{E}_2(E,\omega_E) = C^2\cdot\left(1 - 24\cdot\sum_{n\geq 1}\sum_{d\mid n} d\cdot q_E^n\right).$$

Then we use the formula as in the good ordinary case to define the canonical sigma function $\sigma_p(t(P)) = \exp(\frac{e_2}{24}\log_E(P)^2)\cdot\sigma(t(P))$. We could also have used directly the formula

$$\sigma_p(u) = \frac{u-1}{u^{1/2}}\cdot\prod_{n\geq 1}\frac{(1-q_E^n\cdot u)(1-q_E^n/u)}{(1-q_E^n)^2}$$

[4] This factor is needed if we do not want to modify the p-adic version of the BSD conjecture (Conjecture 5.1).

where $u \in 1+p\mathbb{Z}_p$ is the unique preimage of $P \in \widehat{E}(p\mathbb{Z}_p)$ under the Tate parametrization ψ, where $\widehat{E}$ is the formal group of E at p.

Let P be a point in $E(\mathbb{Q})$ having good reduction at all finite places and with trivial reduction at p. Then we define

$$\hat{h}_p(P) = 2\log_p\left(\frac{e(P)}{\sigma_p(t(P))}\right) - \frac{\log_p(u)^2}{\log_p(q_{E})}$$

with u as above. The p-adic regulator is formed as before but with this modified p-adic height $\hat{h}_p$.

4.3. **The supersingular case.** In the supersingular case, we do not find a canonical p-adic height with values in $\mathbb{Q}_p$. Instead, the height has values in the Dieudonné module $D_p(E)$, as explained in [BPR93] and [PR03].

First, if the rank of the curve is 0, we define the p-adic regulator of $E/\mathbb{Q}$ to be $\omega = \omega_{E} \in D_p(E)$. Thus assume for the rest of this section that the rank r of $E(\mathbb{Q})$ is positive. Let $\nu = a\,\omega + b\,\eta$ be any element of $D_p(E)$ not lying in $\mathbb{Q}_p\,\omega$, (so $b \neq 0$). It can be easily checked that the value of

$$H_p(P) = \frac{1}{b}\cdot\left(h_\nu(P)\cdot\omega - h_\omega(P)\cdot\nu\right) \in D_p(E)$$

is independent of the choice of ν. We will call this the D_p-valued height on $E(\mathbb{Q})$. But note that it depends on the choice of the Weierstrass equation of E: if we change coordinates by putting

$$x' = u^2\cdot x + r \qquad \text{and} \qquad y' = u^3\cdot y + s\cdot x + t, \tag{4.3}$$

then the D_p-valued height $H_p'(P)$ computed in the new coordinates x', y' will satisfy $H_p'(P) = \frac{1}{u}\cdot H_p(P)$ for all points $P \in E(\mathbb{Q})$.

On $D_p(E)$ there is a canonical alternating bilinear form $[\cdot,\cdot]$ characterized by the property that $[\omega_{E}, \eta_{E}] = 1$. Write $\mathrm{Reg}_\nu \in \mathbb{Q}_p$ for the regulator of h_ν on $E(\mathbb{Q})/E(\mathbb{Q})_{\mathrm{tor}}$. Then we have the following lemma which is a corrected version[5] of [PR03, Lem. 2.6].

Lemma 4.2. *Suppose that the rank r of $E(\mathbb{Q})$ is positive. There exists a unique element $\mathrm{Reg}_p(E/\mathbb{Q})$ in $D_p(E)$ such that for all $\nu \in D_p(E)$ not in $\mathbb{Q}_p\omega$, we have*

$$[\mathrm{Reg}_p(E/\mathbb{Q}), \nu] = \frac{\mathrm{Reg}_\nu}{[\omega,\nu]^{r-1}}. \tag{4.4}$$

Furthermore, if the rank r is 1, then $\mathrm{Reg}_p(E/\mathbb{Q}) = H_p(P)$ for a generator P. If the Weierstrass equation is changed as in (4.3), the regulator $\mathrm{Reg}_p'(E/\mathbb{Q})$ computed in the new equation satisfies $\mathrm{Reg}_p'(E/\mathbb{Q}) = \frac{1}{u}\cdot\mathrm{Reg}_p(E/\mathbb{Q})$.

We call $\mathrm{Reg}_p(E/\mathbb{Q}) \in D_p(E)$ the *D_p-valued regulator* of $E/\mathbb{Q}$, or better, of the chosen Weierstrass equation.

Proof. Since h_ω is made out of the square of the linear function $\log_{E}$, the matrix of the associated pairing on a basis $\{P_i\}$ of $E(\mathbb{Q})$ modulo torsion has entries of

[5] The wrong normalization in [PR03] only influences the computations for curves of rank greater than 1. It seems that, by chance, the computations in [PR03] were done with a ν in $D_p(E)$ such that $[\omega,\nu] = 1$, so that the normalization did not enter into the end results.

the form $\log_{E}(P_i)\cdot\log_{E}(P_j)$ and hence has rank 1. Therefore the regulator of the pairing associated to $\nu = a\cdot\omega + b\cdot\eta$ is equal to

$$\operatorname{Reg}_{a\omega+b\eta} = a\cdot b^{r-1}\cdot X + b^{r}\cdot Y$$

for some constants X and Y. In fact, we must have $X = \operatorname{Reg}_{\omega+\eta} - \operatorname{Reg}_{\eta}$ and $Y = \operatorname{Reg}_{\eta}$. Therefore the expression on the right hand side of (4.4) is linear in ν. More explicitly, we may define

$$\operatorname{Reg}_p(E/\mathbb{Q}) = Y\cdot\omega - X\cdot\eta.$$

The formula for the case of rank 1 is then also immediate. The variance of the regulator with the change of the equation can be checked just as for H_p. □

We continue to assume that the rank r of $E/\mathbb{Q}$ is positive, as in Lemma 4.2. Define the *fine Mordell-Weil group* as in [Wut07] to be the kernel

$$\mathfrak{M}(E/\mathbb{Q}) = \ker\left(E(\mathbb{Q})\otimes\mathbb{Z}_p \longrightarrow E(\mathbb{Q}_p)^{p\text{-adic completion}}\right),$$

which is a free $\mathbb{Z}_p$-module of rank $r-1$. The bilinear form associated to the normalized p-adic height

$$\frac{h_\nu(P)}{[\omega,\nu]},$$

can be restricted to obtain a pairing

$$\langle\cdot,\cdot\rangle_0\colon \mathfrak{M}(E/\mathbb{Q})\times(E(\mathbb{Q})\otimes\mathbb{Z}_p)\longrightarrow\mathbb{Q}_p\,.$$

It is then independent of the choice of $\nu\notin\mathbb{Q}_p\omega$. We call the regulator of this bilinear form $\langle\cdot,\cdot\rangle_0$ on a basis of $\mathfrak{M}(E/\mathbb{Q})$ the *fine regulator* $\operatorname{Reg}_0(E/\mathbb{Q})\in\mathbb{Q}_p$, which is an element of $\mathbb{Q}_p$ defined up to multiplication by a unit in $\mathbb{Z}_p$.

Lemma 4.3. *Suppose there exists a point Q in $E(\mathbb{Q})\otimes\mathbb{Z}_p$ such that $\mathfrak{M}(E/\mathbb{Q}) + \mathbb{Z}_pQ = E(\mathbb{Q})\otimes\mathbb{Z}_p$. Then*

$$[\operatorname{Reg}_p(E/\mathbb{Q}_p),\omega] \equiv \log_{E}(Q)^2\cdot\operatorname{Reg}_0(E/\mathbb{Q}) \pmod{\mathbb{Z}_p^\times}.$$

Proof. From the proof of the Lemma 4.2, we only have to show that

$$X = \operatorname{Reg}_{\omega+\eta} - \operatorname{Reg}_{\eta} \equiv h_\omega(Q)\operatorname{Reg}_0(E/\mathbb{Q}).$$

By hypothesis, there is a basis of $\mathfrak{M}(E/\mathbb{Q})$ that we can complete to a basis of $E(\mathbb{Q})\otimes\mathbb{Z}_p$ by adding Q to it. If M is the matrix of the pairing for η in this basis, then the matrix for $\omega+\eta$ is obtained by changing the entry for $\langle Q,Q\rangle$ by adding $h_\omega(Q)$ to it. Since X is the difference of the two determinants, it is $h_\omega(Q)$ times the determinant of $\langle\cdot,\cdot\rangle_\eta$ on the basis of $\mathfrak{M}(E/\mathbb{Q})$, which equals $\operatorname{Reg}_0(E/\mathbb{Q})$ by definition. □

This lemma proves the last equality in [PR03, §2]. We should mention that the formula just above it, linking $\operatorname{Reg}_p(E/\mathbb{Q})$ to $H_p(Q)\cdot\operatorname{Reg}_0(E/\mathbb{Q})$, is not known to hold as it can not be assumed in general that we can find a point Q as in the lemma above which is orthogonal to $\mathfrak{M}(E/\mathbb{Q})$. In particular, the D_p-valued regulator $\operatorname{Reg}_p(E/\mathbb{Q})$ is nonzero provided the fine regulator does not vanish, because $\log_{E}(Q)\neq 0$.

Conjecture 4.4. *Perrin-Riou* [PR93, Conjecture 3.3.7.i] *The fine regulator of $E/\mathbb{Q}$ is nonzero for all primes p. In particular, $\operatorname{Reg}_p(E/\mathbb{Q})\neq 0$ for all primes where E has supersingular reduction.*

Conjecture 3.3.7.ii' in [PR93], which asserts that Reg_ν is nonzero for at least one ν, is implied by the above conjecture. This is explained in remark iii) following the conjecture there, if we use the fact that the weak Leopoldt conjecture is now known for E and p.

We have presented here how to compute the p-adic regulator in the basis $\{\omega, \eta\}$, but in order to compare it later to the leading term of the p-adic L-function, it is better to write it in terms of the basis $\{\omega, \varphi(\omega)\}$. In particular, we would then have a vector whose coordinates are independent of the chosen Weierstrass equation.

In [BPR93, pg. 232], there is an algorithm for computing the action of φ by successive approximation using the expansion of ω in terms of a uniformizer t. It is dramatically more efficient to replace this by the computation of φ using Monsky-Washnitzer cohomology as explained in [Ked01, Ked03, Ked04, Har08].

4.4. **Normalization.** In view of Iwasawa theory, it is natural to normalize the heights and the regulators depending on the choice of the generator γ. In this way the heights depend on the choice of an isomorphism $\Gamma \longrightarrow \mathbb{Z}_p$ rather than on the $\mathbb{Z}_p$-extension only. This normalization can be achieved by simply dividing $\hat{h}_p(P)$ and $h_\nu(P)$ by $\kappa(\gamma)$. The regulators will be divided by $\log_p \kappa(\gamma)^r$ where r is the rank of $E(\mathbb{Q})$. Hence we write

$$\mathrm{Reg}_\gamma(E/\mathbb{Q}) = \frac{\mathrm{Reg}_p(E/\mathbb{Q})}{\log(\kappa(\gamma))^r}.$$

5. The p-adic Birch and Swinnerton-Dyer conjecture

5.1. **The ordinary case.** The following conjecture is due to Mazur, Tate and Teitelbaum [MTT86]. Rather than formulating it for the function $L_\alpha(E, s)$, we state it directly for the series $\mathcal{L}_p(E, T)$. It is then a statement about the expansion of this function at $T = 0$ rather than at $s = 1$.

Conjecture 5.1. *Mazur, Tate and Teitelbaum* [MTT86] *Let E be an elliptic curve with good ordinary reduction or with multiplicative reduction at a prime p.*

- *The order of vanishing of the p-adic L-function $\mathcal{L}_p(E, T)$ at $T = 0$ is equal to the rank $r = \mathrm{rank}(E(\mathbb{Q}))$, unless E has split multiplicative reduction at p in which case the order of vanishing is equal to $r + 1$.*
- *The leading term $\mathcal{L}_p^*(E, 0)$ satisfies*

$$\mathcal{L}_p^*(E,0) = \epsilon_p \cdot \frac{\prod_v c_v \cdot \#\text{Ш}(E/\mathbb{Q})}{(\#E(\mathbb{Q})_{\mathrm{tor}})^2} \cdot \mathrm{Reg}_\gamma(E/\mathbb{Q}) \tag{5.1}$$

unless the reduction is split multiplicative in which case the leading term is

$$\mathcal{L}_p^*(E,0) = \frac{\mathscr{L}_p}{\log(\kappa(\gamma))} \cdot \frac{\prod_v c_v \cdot \#\text{Ш}(E/\mathbb{Q})}{(\#E(\mathbb{Q})_{\mathrm{tor}})^2} \cdot \mathrm{Reg}_\gamma(E/\mathbb{Q}), \tag{5.2}$$

where $\mathscr{L}_p$ is as in Equation (3.4).

The conjecture asserts exact equality, not just equality up to a p-adic unit. However, the current approaches to the conjecture, which involve the main conjecture of Iwasawa theory, prove results up to a p-adic unit, since the characteristic power series is only defined up to a unit, as we will see in Section 7.

Again, we consider the curve E_0 (see Equation (3.3)) for an example in the good ordinary case. For this curve, we have $\prod c_v = 2$ and $E_0(\mathbb{Q})_{\mathrm{tor}} = 0$, so all the terms in the expression above can be computed except for the unknown size of $Ш(E_0/\mathbb{Q})$. The p-adic BSD conjecture predicts that

$$\#Ш(E_0/\mathbb{Q}) = 1 + \mathbf{O}(5^3)$$

which is consistent with the complex BSD conjecture, which predicts that $Ш(E_0/\mathbb{Q})$ is trivial.

5.2. **The supersingular case.** The conjecture in the case of supersingular reduction is given in [BPR93] and [PR03]. The conjecture relates an algebraic and an analytic value in the $\mathbb{Q}_p$-vector space $D_p(E)$ of dimension 2. (The fact that we have two coordinates was used by Kurihara and Pollack in [KP07] to construct global points via a p-adic analytic computation.)

Conjecture 5.2. *Bernardi and Perrin-Riou* [BPR93] *Let E be an elliptic curve with supersingular reduction at a prime p.*

- *The order of vanishing of the D_p-valued L-series $\mathcal{L}_p(E,T)$ at $T=0$ is equal to the rank r of $E(\mathbb{Q})$.*
- *The leading term $\mathcal{L}_p^*(E,0)$ satisfies*

$$(1-\varphi)^{-2}\cdot\mathcal{L}_p^*(E,0) = \frac{\prod_v c_v\cdot\#Ш(E/\mathbb{Q})}{(\#E(\mathbb{Q})_{\mathrm{tor}})^2}\cdot\mathrm{Reg}_\gamma(E/\mathbb{Q}) \quad \in D_p(E)\,. \tag{5.3}$$

We emphasize that both sides of (5.3) are dependent on the Weierstrass equation. But under a change of the form $x' = u^2\cdot x + r$, they both get multiplied by $\frac{1}{u}$ and hence the conjecture is independent of this choice.

6. Iwasawa theory of elliptic curves

We suppose from now on that $p>2$. Let ${}_\infty\mathbb{Q}$ be the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$, which is a Galois extension of $\mathbb{Q}$ whose Galois group is Γ. Let Λ be the completed group algebra $\mathbb{Z}_p[\![\Gamma]\!]$. We use a fixed topological generator γ of Γ to identify Λ with $\mathbb{Z}_p[\![T]\!]$ by sending γ to $1+T$. Any finitely generated Λ-module admits a decomposition up to quasi-isomorphism as a direct sum of elementary Λ-modules. Denote by ${}_n\mathbb{Q}$ the n-th layer of the $\mathbb{Z}_p$-extension, so ${}_n\mathbb{Q}$ is a subfield of ${}_\infty\mathbb{Q}$ and $\mathrm{Gal}({}_n\mathbb{Q}/\mathbb{Q})\approx\mathbb{Z}/p^n\mathbb{Z}$. As in Section 1.1, we define the p-Selmer group of E over ${}_n\mathbb{Q}$ by the exact sequence

$$0\longrightarrow\mathcal{S}\rceil\updownarrow_p(E/{}_n\mathbb{Q})\longrightarrow\mathrm{H}^1({}_n\mathbb{Q},E(p))\longrightarrow\bigoplus_v\mathrm{H}^1({}_n\mathbb{Q}_v,E)$$

with the product running over all places v of ${}_n\mathbb{Q}$. Over the full $\mathbb{Z}_p$-extension, we define $\mathcal{S}\rceil\updownarrow_p(E/{}_\infty\mathbb{Q})$ to be the direct limit $\varinjlim\mathcal{S}\rceil\updownarrow_p(E/{}_n\mathbb{Q})$ with respect to the maps induced by the restriction maps $\mathrm{H}^1({}_n\mathbb{Q},E(p))\longrightarrow\mathrm{H}^1({}_{n+1}\mathbb{Q},E(p))$. The group $\mathcal{S}\rceil\updownarrow_p(E/{}_\infty\mathbb{Q})$ encodes information about the growth of the rank of $E({}_n\mathbb{Q})$ and of the size of $Ш(E/{}_n\mathbb{Q})(p)$ as n tends to infinity. We will consider the Pontryagin dual

$$X(E/{}_\infty\mathbb{Q}) = \mathrm{Hom}\Big(\mathcal{S}\rceil\updownarrow_p(E/{}_\infty\mathbb{Q}),\mathbb{Q}_p/\mathbb{Z}_p\Big)\,,$$

which is a finitely generated Λ-module (see [CS00]). For further introduction to these objects, see [Gre01].

6.1. **The ordinary case.** Assume that the reduction at p is either good ordinary or of multiplicative type. Kato's theorem (see [Kat04, Thm. 17.4]), which uses the work of Rohrlich [Roh84], states that $X(E/_{\infty}\mathbb{Q})$ is a torsion Λ-module, so we may associate to it a characteristic series

$$f_{E}(T) \in \mathbb{Z}_p[\![T]\!] \tag{6.1}$$

that is well-defined up to multiplication by a unit in $\mathbb{Z}_p[\![T]\!]^{\times}$.

The following result is due to Schneider [Sch85] and Perrin-Riou [PR82], and the multiplicative case is due to Jones [Jon89]. Note that it uses the analytic and algebraic p-adic height defined by Schneider in [Sch82]; taking into account the mentioned correction by Werner, these heights agree with the height in Section 4.2.

Theorem 6.1 (Schneider, Perrin-Riou, Jones)**.** *The order of vanishing of $f_{E}(T)$ at $T = 0$ is at least equal to the rank r. It is equal to r if and only if the p-adic height pairing is nondegenerate (Conjecture 4.1) and the p-primary part of the Tate-Shafarevich group $Ш(E/\mathbb{Q})(p)$ is finite (Conjecture 1.2). In this case the leading term of the series $f_{E}(T)$ has the same valuation as*

$$\epsilon_p \cdot \frac{\prod_v c_v \cdot \#Ш(E/\mathbb{Q})(p)}{(\#E(\mathbb{Q})(p))^2} \cdot \mathrm{Reg}_{\gamma}(E/\mathbb{Q}),$$

unless the reduction is split multiplicative in which case the same formula holds with ϵ_p replaced by $\mathscr{L}_p/\log(\kappa(\gamma))$.

Let us consider again our running example curve E_0. We have computed the 5-adic regulator and found that it is nonzero. The above theorem shows that the order of vanishing of $f_{E_0}(T)$ is at least equal to the rank. The finiteness of $Ш(E_0/\mathbb{Q})(5)$ is now equivalent to the statement that the order of vanishing of $f_{E_0}(T)$ is equal to the rank 2 of E_0. If this is the case, then the leading coefficient has valuation equal to

$$\mathrm{ord}_5(f^*_{E_0}(0)) = \mathrm{ord}_5(\#Ш(E_0/\mathbb{Q})(5)) + 1,$$

since $\mathrm{ord}_5(\mathrm{Reg}_5(E_0/\mathbb{Q})) = 1$ by Equation (4.2) and c_v, ϵ_5 and torsion are coprime to 5.

For general E, if the valuation of the leading term of $f_E(T)$ is positive we call p an *irregular*[6] prime for E. For irregular primes either the Mordell-Weil rank of E over $_{\infty}\mathbb{Q}$ is larger than the rank of $E(\mathbb{Q})$ or the Tate-Shafarevich group $Ш(E/_{\infty}\mathbb{Q})$ is no longer finite or both. We will determine exactly what happens for E_0 with $p = 5$ in Section 7.1 below.

6.2. **The supersingular case.** The supersingular case is more complicated, since the Λ-module $X(E/_{\infty}\mathbb{Q})$ is not torsion. A beautiful approach to the supersingular case has been found by Pollack [Pol03] and Kobayashi [Kob03]. As mentioned above (in Section 3.5), there are two p-adic series $\mathcal{L}_p^{\pm}(E,T)$ to which will correspond two new Selmer groups $X^{\pm}(E/_{\infty}\mathbb{Q})$, which are Λ-torsion. Despite the advantages of this ±-theory, we use the approach of Perrin-Riou here (see [PR03, §3]).

Let T_pE be the Tate module and define $\mathbb{H}^1_{\mathrm{loc}}$ to be the projective limit of the cohomology groups $\mathrm{H}^1({}_n\mathbb{Q}_{\mathfrak{p}}, T_pE)$ with respect to the corestriction maps. Here ${}_n\mathbb{Q}_{\mathfrak{p}}$ is the localization of ${}_n\mathbb{Q}$ at the unique prime $\mathfrak{p}$ above p. Perrin-Riou [PR94]

[6] For a good introduction to such terminology and the basics of Iwasawa theory of elliptic curves, we refer the reader to [Gre99].

constructed a Λ-linear Coleman map Col from $\mathbb{H}^1_{\text{loc}}$ to a submodule of $\mathbb{Q}_p[\![T]\!] \otimes D_p(E)$.

Define the fine Selmer group to be the kernel

$$\mathcal{R}(E/_n\mathbb{Q}) = \ker\left(\mathcal{S}\rceil\updownarrow(E/_n\mathbb{Q}) \longrightarrow E(_n\mathbb{Q}_\mathfrak{p}) \otimes \mathbb{Q}_p/\mathbb{Z}_p\right) .$$

It is again a consequence of the work of Kato, namely [Kat04, Thm. 12.4], that the Pontryagin dual $Y(E/_\infty\mathbb{Q})$ of $\mathcal{R}(E/_\infty\mathbb{Q})$ is a Λ-torsion module. Denote by $g_{E}(T)$ its characteristic series.

Let Σ be any finite set of places in $\mathbb{Q}$ containing the places of bad reduction for E and the places ∞ and p. Let $G_\Sigma(_n\mathbb{Q})$ denote the Galois group of the maximal extension of $_n\mathbb{Q}$ unramified at all places which do not lie above Σ. Next we define $\mathbb{H}^1_{\text{glob}}$ as the projective limit of $\mathrm{H}^1(G_\Sigma(_n\mathbb{Q}), T_pE)$. It is a Λ-module of rank 1 and it is independent of the choice of Σ.

By Kato again, the Λ-module $\mathbb{H}^1_{\text{glob}}$ is torsion-free and $\mathbb{H}^1_{\text{glob}} \otimes \mathbb{Q}_p$ has $\Lambda \otimes \mathbb{Q}_p$-rank 1. Choose now any element $_\infty c$ in $\mathbb{H}^1_{\text{glob}}$ such that $Z_c = \mathbb{H}^1_{\text{glob}}/(\Lambda \cdot {_\infty c})$ is Λ-torsion. Typically such a choice could be the "zeta element" of Kato, i.e., the image of his Euler system in $\mathbb{H}^1_{\text{glob}}$. Write $h_c(T)$ for the characteristic series of Z_c. Then we define an algebraic equivalent of the $D_p(E)$-valued L-series by

$$f_{E}(T) = \mathrm{Col}(_\infty c) \cdot g_{E}(T) \cdot h_c(T)^{-1} \in \mathbb{Q}_p[\![T]\!] \otimes D_p(E)$$

where by $\mathrm{Col}(_\infty c)$ we mean the image under the Coleman map Col of the localization of $_\infty c$ to $\mathbb{H}^1_{\text{loc}}$. The resulting series $f_{E}(T)$ is independent of the choice of $_\infty c$. Of course, $f_{E}(T)$ is again only defined up to multiplication by a unit in $\Lambda^\times$.

Again we have a result due to Perrin-Riou [PR93]:

Theorem 6.2 (Perrin-Riou). *The order of vanishing of $f_{E}(T)$ at $T = 0$ is at least equal to the rank r. It is equal to r if and only if the $D_p(E)$-valued regulator $\mathrm{Reg}_p(E/\mathbb{Q})$ is nonzero (Conjecture 4.4) and the p-primary part of the Tate-Shafarevich group $\text{Ш}(E/\mathbb{Q})(p)$ is finite (Conjecture 1.2). In this case the leading term of the series $(1-\varphi)^{-2}\, f_{E}(T)$ has the same valuation as*

$$\prod_{\upsilon} c_\upsilon \cdot \#\text{Ш}(E/\mathbb{Q})(p) \cdot \mathrm{Reg}_p(E/\mathbb{Q}) \, .$$

Note that the proof of this theorem in the appendix of [PR03] for the supersingular case uses the formula in Lemma 4.3 rather than the wrong definition of the regulator. Also we simplified the right hand term in comparison to (5.3), because the reduction at p is supersingular, so $N_p \equiv 1 \pmod{p}$, hence $\#E(\mathbb{Q})_{\text{tor}}$ must be a p-adic unit.

7. The Main Conjecture

The main conjecture links the two p-adic power series (3.1) and (6.1) of the previous sections. We formulate everything simultaneously for the ordinary and the supersingular case, even though they are of a quite different nature. We still assume that $p \neq 2$.

Conjecture 7.1. *Main conjecture of Iwasawa theory for elliptic curves If E has good or nonsplit multiplicative reduction at p, then there exists an element $u(T)$ in $\Lambda^\times$ such that $\mathcal{L}_p(E,T) = f_{E}(T) \cdot u(T)$. If the reduction of E at p is split multiplicative, then there exists such a $u(T)$ in $T \cdot \Lambda^\times$.*

Our statement above of the main conjecture for supersingular primes is equivalent to Kato's formulation in [Kat04, Conj. 12.10] and to Kobayashi's version in [Kob03]. In the notation of Section 6.2, it asserts that $g_{E}(T) = h_c(T)$, where c is Kato's zeta element.

Much is now known about this conjecture. To the elliptic curve E we attach the p-adic representation

$$\rho_p : \mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(T_p(E)) \approx \mathrm{GL}_2(\mathbb{Z}_p)$$

and its reduction

$$\bar{\rho}_p : \mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(E[p]) \approx \mathrm{GL}_2(\mathbb{F}_p).$$

Serre [Ser72] proved that $\bar{\rho}_p$ is almost always surjective (note our running hypothesis that E does not have complex multiplication) and that for curves with multiplicative reduction at p, surjectivity can only fail when there is an isogeny of degree p defined over $\mathbb{Q}$ (see [Ser96] and [RS01, Prop. 1.1] for the case $p = 2$ of this statement, though the theorem below has the hypothesis that p is odd).

Proposition 7.2. *If $p \geq 5$ then $\bar{\rho}_p$ is surjective if and only if ρ_p is surjective.*

Proof. See [GJP$^+$09, §2.1] for references for this and related results. □

Kato's Theorem 7.3. *Suppose that E has semistable reduction at p and that ρ_p is surjective. Then there exists a series $d(T)$ in Λ such that $\mathcal{L}_p(E,T) = f_{E}(T) \cdot d(T)$. If the reduction is split multiplicative then T divides $d(T)$.*

The main ingredient for this theorem is in [Kat04, Thm. 17.4], which addresses the good ordinary case when $\bar{\rho}_p$ is surjective. For the exceptional case we refer to [Kob06], which treats the case of split multiplicative reduction (i.e., where exceptional zeroes appear).

For the remaining cases, we obtain only a weaker statement:

Kato's Theorem 7.4. *Suppose that $\bar{\rho}_p$ is not surjective. Then there is an integer $m \geq 0$ such that $f_{E}(T)$ divides $p^m \cdot \mathcal{L}_p(E,T)$.*

Greenberg and Vatsal [GV00] have shown that in certain cases the main conjecture holds when $E[p]$ is reducible. Recently, Skinner-Urban have proved the main conjecture in many more cases. The following is a slightly weaker form of [SU10, Thm. 1]:

Theorem 7.5 (Skinner-Urban)**.** *Suppose that E has good ordinary reduction at p, that ρ_p is surjective and that there exists a prime q of multiplicative reduction such that $\bar{\rho}_p$ is ramified at q. Then the main conjecture holds, i.e., $\mathcal{L}_p(E,T)$ is equal to $f_{E}(T)$, up to a unit in Λ.*

The condition on the extra prime q is satisfied if E has split multiplicative reduction at q and p does not divide the Tamagawa number c_q. If E has non-split multiplicative reduction, one has to check that p does not divide the Tamagawa number over the unramified quadratic extension of $\mathbb{Q}_q$. Equivalently, in both cases of multiplicative reduction, the representation $\bar{\rho}_p$ is ramified at q if $p \nmid \mathrm{ord}_q(\Delta_E)$, as explained in [RS01, §2.4].

7.1. **The Example.** Consider again the curve E_0 (see Equation (3.3)) and the good ordinary prime $p = 5$. Kato's theorem implies that $f_{E_0}(T)$ divides $\mathcal{L}_p(E_0, T)$. Since we have found two linearly independent points of infinite order in $E_0(\mathbb{Q})$, we know that the rank of $E_0(\mathbb{Q})$ is at least 2. Hence the order of vanishing of $f_{E_0}(T)$ at $T = 0$ is at least 2 and, by Theorem 7.3, so is the order of vanishing of $\mathcal{L}_p(E_0, T)$. By explicitly computing an approximation to $\mathcal{L}_p(E_0, T)$ we see that the order of vanishing cannot be larger than 2. Therefore the rank of $E_0(\mathbb{Q})$ is equal to the order of vanishing of the p-adic L-series.

But we know more now. The fact that the order of vanishing of $f_{E_0}(T)$ is equal to 2 shows that the 5-primary part of $Ш(E_0/\mathbb{Q})$ cannot be infinite. We compute the p-adic valuation of the leading term of $f_{E_0}(T)$ by approximating $\mathrm{Reg}_p(E)$ and using Theorem 6.1. Comparing the leading term of $\mathcal{L}_p(E_0, T)$, which has valuation 1, and the leading term of $f_{E_0}(T)$, which has valuation $1 + \mathrm{ord}_5(\#Ш(E_0/\mathbb{Q})(5))$, shows that *the* 5*-primary part of* $Ш(E_0/\mathbb{Q})$ *is trivial*.

Moreover, the series $f_{E_0}(T)$ and $\mathcal{L}_p(E_0, T)$ have the same leading term, which implies that the main conjecture holds, i.e., $f_{E_0}(T) \in \mathcal{L}_p(E_0, T) \cdot \Lambda^\times$. By analyzing the series $\mathcal{L}_p(E_0, T)$, one can show that

$$f_{E_0}(T) = T \cdot ((T + 1)^5 - 1) \cdot u(T)$$

for a unit $u(T) \in \Lambda^\times$. Let ${}_1\mathbb{Q}$ be the first layer of the $\mathbb{Z}_5$-extension of $\mathbb{Q}$. Unless the Tate-Shafarevich group $Ш(E/{}_1\mathbb{Q})(5)$ is infinite, Iwasawa theory predicts that the rank of the Mordell-Weil group $E_0({}_1\mathbb{Q})$ is 6. Doing a quick search it is easy to find points of infinite order in $E_0({}_1\mathbb{Q})$ which are not defined over $\mathbb{Q}$. Therefore, we know that the rank of $E_0({}_1\mathbb{Q})$ and of $E_0({}_\infty\mathbb{Q})$ is 6 and that $Ш(E_0/{}_1\mathbb{Q})(5)$ and $Ш(E_0/{}_\infty\mathbb{Q})(5)$ are finite. For more examples of such factorizations of p-adic L-series we refer to [Pol].

8. If the L-series does not vanish

Suppose the Hasse-Weil L-function $L(E, s)$ does not vanish at $s = 1$. In this case, Kolyvagin proved that $E(\mathbb{Q})$ and $Ш(E/\mathbb{Q})$ are finite. In particular, Conjecture 1.2 is valid; also, Conjectures 4.1 and 4.4 are trivially true in this case.

Let $p > 2$ be a prime of semistable reduction such that the representation $\bar{\rho}_p$ is surjective. By the interpolation property, we know that $\mathcal{L}_p(E, 0)$ is nonzero, unless E has split multiplicative reduction.

8.1. **The good ordinary case.** In the ordinary case we have

$$\epsilon_p^{-1} \cdot \mathcal{L}_p(E, 0) = \frac{L(E, 1)}{\Omega_E} = [0]^+,$$

which is a nonzero rational number by [Man72]. In the following inequality, we use Theorem[7] 6.1 of Perrin-Riou and Schneider for the first equality and Kato's

[7] In the case of analytic rank 0, the theorem is actually relatively easy and well explained in [CS00, Ch. 3].

Theorem 7.3 on the main conjecture for the inequality in the second line.

$$\begin{aligned}\operatorname{ord}_p\left(\epsilon_p\cdot\frac{\prod_v c_v\cdot\#\text{Ш}(E/\mathbb{Q})(p)}{(\#E(\mathbb{Q})(p))^2}\right) &= \operatorname{ord}_p(f_E(0))\\ &\le \operatorname{ord}_p(\mathcal{L}_p(E,0))\\ &= \operatorname{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right)+\operatorname{ord}_p(\epsilon_p)\end{aligned}$$

Hence, we have the following upper bound on the p-primary part of the Tate-Shafarevich group

$$\begin{aligned}\operatorname{ord}_p\left(\#\text{Ш}(E/\mathbb{Q})(p)\right) &\le \operatorname{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right)-\operatorname{ord}_p\left(\frac{\prod c_v}{(\#E(\mathbb{Q})_{\text{tor}})^2}\right)\\ &= \operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})_{\text{an}}).\end{aligned}\tag{8.1}$$

Under the assumption of the main conjecture, this is sharp. In particular, if the conditions of Theorem 7.5 are satified for p, then we have the equality

$$\operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)) = \operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})_{\text{an}}).$$

This is Theorem 2.a in [SU10].

8.2. **The multiplicative case.** If the reduction is nonsplit, then the above holds just the same, because in all the theorems involved the nonsplit case never differs from the good ordinary case (only the split multiplicative case is exceptional). If instead the reduction is split multiplicative, we have that $\mathcal{L}_p(E,0)=0$ and

$$\mathcal{L}_p'(E,0)=\frac{\mathscr{L}_p}{\log\kappa(\gamma)}\cdot\frac{L(E,1)}{\Omega_E}=\frac{\mathscr{L}_p}{\log\kappa(\gamma)}\cdot[0]^+\neq 0\,.$$

Since the p-adic multiplier is the same on the algebraic as on the analytic side, we can once again compute as above to obtain the same bound (8.1).

8.3. **The supersingular case.** For the supersingular $D_p(E)$-valued series, we have

$$(1-\varphi)^{-2}\cdot\mathcal{L}_p(E,0)=\frac{L(E,1)}{\Omega_E}\cdot\omega_E=[0]^+\cdot\omega_E,$$

which is a nonzero element of $D_p(E)$. The $D_p(E)$-valued regulator $\operatorname{Reg}_p(E/\mathbb{Q})$ is equal to ω_E. We may therefore concentrate solely on the coordinate in ω_E. Write $\operatorname{ord}_p(f_E(0))$ for the p-adic valuation of the leading coefficient of the ω_E-coordinate of $f_E(T)$. Again we obtain an inequality by using Theorem 6.2:

$$\begin{aligned}\operatorname{ord}_p\left(\prod_v c_v\cdot\#\text{Ш}(E/\mathbb{Q})(p)\right) &= \operatorname{ord}_p((1-\varphi)^{-2}\,f_E(0))\\ &\le \operatorname{ord}_p((1-\varphi)^{-2}\,\mathcal{L}_p(E,0))\\ &= \operatorname{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right).\end{aligned}$$

So we have once again that $\#\text{Ш}(E/\mathbb{Q})(p)$ is bounded from above by the highest power of p dividing $\#\text{Ш}(E/\mathbb{Q})_{\text{an}}$.

8.4. **Conclusion.** Summarizing the above computations, we have

Theorem 8.1 (Kato, Perrin-Riou, Schneider)**.** *Let E be an elliptic curve such that $L(E,1) \neq 0$. Then $\text{Ш}(E/\mathbb{Q})$ is finite and*

$$\#\text{Ш}(E/\mathbb{Q}) \;\Big|\; C \cdot \frac{L(E,1)}{\Omega_E} \cdot \frac{(\#E(\mathbb{Q})_{\text{tor}})^2}{\prod c_v}$$

where C is a product of a power of 2 and of powers of primes of additive reduction and of powers of primes for which the representation $\bar{\rho}_p$ is not surjective.

This improves [Rub00, Cor. 3.5.19].

9. If the L-series vanishes to the first order

We suppose for this section that E has good ordinary reduction at p and that the complex L-series $L(E,s)$ has a zero of order 1 at $s = 1$. Kolyvagin's theorem implies that $\text{Ш}(E/\mathbb{Q})$ is finite and that the rank of $E(\mathbb{Q})$ is equal to 1. Let P be a choice of generator of the Mordell-Weil group modulo torsion. Suppose that the p-adic height $\hat{h}_p(P)$ is nonzero. A theorem of Perrin-Riou in [PR87] asserts the following equality of rational numbers:

$$\frac{1}{\text{Reg}(E/\mathbb{Q})} \cdot \frac{L'(E,1)}{\Omega_E} = \frac{1}{\text{Reg}_p(E/\mathbb{Q})} \cdot \frac{\mathcal{L}_p'(E,0)}{(1-\frac{1}{\alpha})^2 \cdot \log(\kappa(\gamma))},$$

where, on the left hand side, the canonical real-valued regulator $\text{Reg}(E/\mathbb{Q}) = \hat{h}(P)$ appears along with the leading coefficient of $L(E,s)$, while, on the right hand side, we have the p-adic regulator $\text{Reg}_p(E/\mathbb{Q}) = \hat{h}_p(P)$ and the leading term of the p-adic L-series. By the BSD conjecture (or its p-adic analogue), this rational number should be equal to $\prod c_v \cdot \#\text{Ш}(E/\mathbb{Q}) \cdot (\#E(\mathbb{Q})_{\text{tor}})^{-2}$. By Kato's theorem, we know that the characteristic series $f_E(T)$ of the Selmer group divides $\mathcal{L}_p(E,T)$, at least up to a power of p. Hence the series $f_E(T)$ has a zero of order 1 at $T = 0$ and its leading term divides the above rational number in $\mathbb{Q}_p$ (here we use that $E(\mathbb{Q})$ has rank 1 so $T \mid f_E(T)$). Imposing the additional hypothesis that ρ_p is surjective, Theorem 7.3 implies the above divisibility over $\mathbb{Z}_p$ (rather than just up to a power of p), and we thus arrive at the following theorem.

Theorem 9.1 (Kato, Perrin-Riou)**.** *Let $E/\mathbb{Q}$ be an elliptic curve with good ordinary reduction at the odd prime p. Assume that the p-adic regulator of E is nonzero. Suppose that the representation ρ_p is surjective. If $L(E,s)$ has a simple zero at $s = 1$, then*

$$\begin{aligned}\text{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)) &\leq \text{ord}_p\left(\frac{(\#E(\mathbb{Q})_{\text{tor}})^2}{\prod c_v} \cdot \frac{1}{\text{Reg}(E/\mathbb{Q})} \cdot \frac{L'(E,1)}{\Omega_E}\right) \\ &= \text{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)_{\text{an}}).\end{aligned}$$

In other words the upper bound asserted by the BSD conjecture is true up to a factor involving only bad and supersingular primes, and primes p for which $\bar{\rho}_p$ is not surjective or the p-adic regulator is 0.

The above theorem has as a hypothesis that the reduction is good ordinary, because this is the only case when we know a proof of the p-adic Gross-Zagier formula. It would be interesting to obtain a generalization of the p-adic Gross-Zagier formula to the supersingular case.

10. Algorithm for an upper bound on the rank

Let $E/\mathbb{Q}$ be an elliptic curve. In this section we explain how to compute upper bounds on the rank r of the Mordell-Weil group $E(\mathbb{Q})$. For this purpose, we choose a prime p satisfying the following conditions:

- $p > 2$,
- E has good reduction at p.

By computing the analytic p-adic L-function $\mathcal{L}_p(E,T)$ to a certain precision, we find an upper bound, say b, on the order of vanishing of $\mathcal{L}_p(E,T)$ at $T=0$. Note that a theorem of Rohrlich [Roh84] guarantees that $\mathcal{L}_p(E,T)$ is not zero. Then

$$b \;\geq\; \operatorname{ord}_{T=0} \mathcal{L}_p(E,T) \;\geq\; \operatorname{ord}_{T=0} f_E(T) \;\geq\; r$$

by Kato's Theorems 7.3 and 7.4 and by Theorems 6.1 and 6.2. Hence we have an upper bound on the rank r.

Proposition 10.1. *The computation of an approximation of the p-adic L-series of E for an odd prime p of good reduction produces an upper bound on the rank r of the Mordell-Weil group $E(\mathbb{Q})$.*

By searching for points of small height on E, we also obtain a lower bound on the rank r. Simultaneously, we can increase the precision of the computation of the p-adic L-function in order to try to lower the bound b. Eventually, the lower bound is equal to the upper bound, unless the p-adic BSD Conjecture 5.1 or 5.2 is false. This is similar to the conditional algorithm described in Proposition 2.2, except that we do know here that our upper bounds are unconditional. We do not know unconditionally that this procedure terminates after finitely many steps. Summarizing we can claim the following.

Proposition 10.2. *Let E be an elliptic curve, and assume that there is a prime p of good reduction such that the p-adic BSD conjecture is true. Then there is an algorithm that computes the rank r of E using p-adic L-functions.*

Of course, the procedure for computing bounds on the rank r using m-descents has the same properties: it tries to determine the rank by searching for points and by bounding r from above by the rank of the various m-Selmer groups. Unless all the p-primary parts of the Tate-Shafarevich group are infinite, this procedure returns the rank r after a finite number of steps.

But the two algorithms are fundamentally different, since the m-descent algorithm is fast and there are optimized implementations for small m, but it would be prohibitively time-consuming for larger m (e.g., $m \geq 13$). In contrast, computing the p-adic L-series even for p around 1000 is reasonably efficient, assuming one can compute the relevant modular symbols spaces.

10.1. **Technical remarks.**

The second condition above (good reduction) on the prime p is too strict. We may actually allow primes of multiplicative reduction, too. Of course in the exceptional case, when E has split multiplicative reduction, the upper bound b on the order of vanishing of the p-adic L-function $\mathcal{L}_p(E,T)$ at $T=0$ satisfies $b \geq r+1$.

Note that, assuming that the p-adic BSD conjecture holds, it is easy to predict the needed precision in the computation of the p-adic L-series. So we can compute immediately with the precision that should be sufficient and concentrate on the search for points of small heights.

For practical purposes, we take p as small as possible. The computation of the leading term of $\mathcal{L}_p(E,T)$ using the algorithm of Section 3 for curves of higher rank r is time-consuming for large p. Also we should avoid primes p with supersingular or split multiplicative reduction as there the needed precision is much higher and the computation of b is much slower.

Also the speed of the computation of $\mathcal{L}_p(E,T)$ using modular symbols depends on the size of the conductor. As the conductor grows, the determination of the rank, when it is larger than 1, using the descent method becomes much more efficient than the use of p-adic L-series computed using modular symbols following the linear algebra algorithm of [Cre97]. However, using p-adic L-series may provide an advantage when considering families of quadratic twists.

An advantage to the descent method is that the determination of the m-Selmer group for some $m>1$ can be used for the search of points of infinite order. If the elements of the Selmer group can be expressed as coverings, it is more efficient to search for rational points on the coverings rather than on the elliptic curve itself.

11. The algorithm for the Tate-Shafarevich group

The second algorithm takes as input an elliptic curve E and a prime p and tries to compute an upper bound on the p-primary part of $Ш(E/\mathbb{Q})$. To apply the results above, we impose the following conditions on (E,p):

- $p>2$,
- E does not have additive reduction at p,
- the image of $\bar{\rho}_p$ is the full group $\mathrm{GL}_2(\mathbb{F}_p)$.

As mentioned above, these conditions apply to all but finitely many primes p.

Algorithm 11.1. Given an elliptic curve $E/\mathbb{Q}$ and a prime p satisfying the above conditions, this procedure either gives an upper bound for $\#Ш(E/\mathbb{Q})(p)$ or terminates with an error.

(1) Attempt to determine the rank r and the full Mordell-Weil group $E(\mathbb{Q})$. Exit with an error if we fail to do this.

(2) Compute higher and higher approximations to the p-adic regulator of E over $\mathbb{Q}$ using the algorithm in [MST06, Har08]. Exit with an error if after a predetermined number of steps, the p-adic height pairing is not shown to be nondegenerate.

(3) Using modular symbols, compute an approximation of the coefficient $\mathcal{L}_p^*(E,0)$ of the leading term of the p-adic L-series $\mathcal{L}_p(E,T)$. If the order of vanishing
$$\mathrm{ord}_{T=0}\,\mathcal{L}_p(E,T)$$
is equal to r (or $r+1$ if E has split multiplicative reduction at p), then we print that $Ш(E/\mathbb{Q})(p)$ is finite, otherwise we increase the precision of the computation of $\mathcal{L}_p(E,T)$. If, after some prespecified cutoff, this fails to prove that $\mathrm{ord}_{T=0}\,\mathcal{L}_p(E,T)=r$ (or $r+1$), then exit with an error.

(4) Compute the remaining information, including the Tamagawa numbers c_v and the p-adic multiplier ϵ_p. If p is a good ordinary prime or a prime at which E has nonsplit multiplicative reduction, let
$$\begin{aligned} b_p = &\,\mathrm{ord}_p(\mathcal{L}_p^*(E,0)) - \mathrm{ord}_p(\epsilon_p) \\ &- \sum_v \mathrm{ord}_p(c_v) - \mathrm{ord}_p(\mathrm{Reg}_\gamma(E/\mathbb{Q})). \end{aligned}$$

If p is supersingular, let

$$b_p = \operatorname{ord}_p((1-\varphi)^{-2}\,\mathcal{L}_p^*(E,0)) - \operatorname{ord}_p(\operatorname{Reg}_p(E/\mathbb{Q})) - \sum_v \operatorname{ord}_p(c_v).$$

Finally, if E has split multiplicative reduction at p, let

$$\begin{aligned} b_p &= \operatorname{ord}_p(\mathcal{L}_p^*(E,0)) - \operatorname{ord}_p(\mathscr{L}_p) \\ &\quad - \sum_v \operatorname{ord}_p(c_v) - \operatorname{ord}_p(\operatorname{Reg}_\gamma(E/\mathbb{Q}))\,. \end{aligned}$$

(5) Output that $\#\text{Ш}(E/\mathbb{Q})(p)$ is bounded by p^{b_p}.

Proof. At Step 4, we have shown that Conjecture 4.1 (or Conjecture 4.4 in the supersingular case) on the nondegeneracy of the p-adic regulator holds and that $\text{Ш}(E/\mathbb{Q})(p)$ is indeed finite by Theorem 6.1 (or Theorem 6.2 in the supersingular case). Moreover this theorem shows that

$$\operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)) = \operatorname{ord}_p(f_E^*(0)) + \operatorname{ord}_p\left(\frac{(\#E(\mathbb{Q})(p))^2}{\epsilon_p\cdot\prod_v c_v}\cdot\frac{1}{\operatorname{Reg}_\gamma(E/\mathbb{Q})}\right)$$

in the ordinary case (or the same formula where ϵ_p is replaced by $\mathscr{L}_p$ in the split multiplicative case) and

$$\operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p)) = \operatorname{ord}_p((1-\varphi)^{-2}\,f_E^*(0)) - \operatorname{ord}_p(\operatorname{Reg}_p(E/\mathbb{Q})) - \sum_v \operatorname{ord}_p(c_v)$$

in the supersingular case. Note that $\#E(\mathbb{Q})(p) = 1$ since we assumed that $\bar\rho_p$ is surjective. Finally, we use Kato's Theorem 7.3 that

$$\operatorname{ord}_p(f_E^*(0)) \le \operatorname{ord}_p(\mathcal{L}_p^*(E,0))$$

to prove that b_p is indeed an upper bound on $\operatorname{ord}_p(\#\text{Ш}(E/\mathbb{Q})(p))$. □

In the next proposition we summarize the discussion of this section.

Proposition 11.2. *Let E be an elliptic curve and $p>2$ a prime for which E has semistable reduction. If Conjectures 4.1 and 4.4 hold and if we are able to determine the Mordell-Weil group of E, then there is a algorithm to verify that the p-primary part of $\text{Ш}(E/\mathbb{Q})$ is finite. If moreover the representation $\bar\rho_p$ is surjective, then the algorithm produces an upper bound on $\#\text{Ш}(E/\mathbb{Q})(p)$. If Conjecture 7.1 holds then the result of the algorithm is equal to the order of $\text{Ш}(E/\mathbb{Q})(p)$.*

11.1. **Technical remarks.** In Step 1 of Algorithm 11.1 we may use several ways to determine the rank and the Mordell-Weil group. E.g., first compute the modular symbol $[0]^+$. If it is not zero, we have that $L(E,1)\neq 0$ and the rank has to be 0. If the order of vanishing of $L(E,s)$ at $s=1$ is 1, we may use Heegner points to find the full Mordell-Weil group, which then is of rank 1. Otherwise we use descent methods or the algorithm in the previous section to bound the rank from above and search for points to find a lower bound. When enough points are found to generate a group of finite index, we saturate the group using infinite descent in order to find the full group $E(\mathbb{Q})$. In practice this step does not create any problems as Step 3 is usually computationally more difficult.

In Step 3, it is easy to determine the precision that will be needed to compute the p-adic valuation of the leading term $\mathcal{L}_p^*(E,0)$ if we assume the complex and the p-adic version of the BSD conjecture. Hence it is easy to decide when to exit at this step.

The algorithm exits with an error only if the Mordell-Weil group could not be determined (in Step 1), if Conjecture 4.1 or 4.4 is wrong (in Step 2), if the p-primary part of $\text{Ш}(E/\mathbb{Q})$ is infinite or if the main conjecture is false (both in Step 3). Hence only weaker variants of the p-adic Birch and Swinnerton-Dyer conjecture are needed.

Another application of the algorithm is the following remark. If, for a given elliptic curve E and a prime p, the algorithm yields as output that the p-primary part of $\text{Ш}(E/\mathbb{Q})$ is trivial, then the algorithm has actually also proved the main conjecture for E and p. Because we know by then that $\mathcal{L}_p(E,T)$ and the characteristic series $f_{E}(T)$ of the Selmer group have the same order of vanishing at $T=0$ and the leading terms have the same valuation. Since, by Kato's theorem $f_{E}(T)$ divides $\mathcal{L}_p(E,T)$, we know then that the quotient is a unit in $\mathbb{Z}_p[\![T]\!]$. Such calculations and especially this remark on how to verify the main conjecture in special cases are already contained in [PR03] for supersingular primes p.

12. Numerical results

The algorithms described above were implemented by the authors in Sage (see [S$^+$11b]) and all of the calculations given below can be carried out using Sage and PSage [S$^+$11a].

12.1. **A split multiplicative example.**

To give an example of a curve with split multiplicative reduction, we use the same curve as before (see Equation (3.3))

$$E_0\colon \quad y^2 + x\,y = x^3 - x^2 - 4\,x + 4$$

but with the prime $p=223$. Of course, there is no hope in practice that an explicit 223-descent could be used to compute the order of $\text{Ш}(E_0/\mathbb{Q})(223)$. However, we can compute the p-adic regulator and the $\mathscr{L}$-invariant to high precision quickly using Tate's parametrization of E_0:

$$\begin{aligned}\operatorname{Reg}_p(E_0/\mathbb{Q}) &= 153\cdot 223^2 + 125\cdot 223^3 + 124\cdot 223^4 + \mathbf{O}(223^5),\\ \mathscr{L} &= 179\cdot 223 + 85\cdot 223^2 + 30\cdot 223^3 + \mathbf{O}(223^4).\end{aligned}$$

The computation of the p-adic L-series is more time consuming[8]. But as we only need the first p-adic digit to prove the triviality of $\text{Ш}(E_0/\mathbb{Q})(223)$, we only need to sum over $222\cdot 223$ modular symbols. This yields

$$\mathcal{L}_p(E_0,T) = \mathbf{O}(223^4) + \mathbf{O}(223^1)\cdot T + \mathbf{O}(223^1)\cdot T^2 + (139 + \mathbf{O}(223))\cdot T^3 + \mathbf{O}(T^4).$$

In fact, we know that the first three coefficients vanish as we are in the exceptional case, so the leading term has valuation 0. From these computations, we see that the p-adic BSD conjecture predicts that

$$\#\text{Ш}(E_0/\mathbb{Q}) \equiv 1 \pmod{223};$$

in particular, we may conclude that $\text{Ш}(E_0/\mathbb{Q})(223) = 0$.

[8] The optimized implementation mentioned in Section 12.4 does this entire computation in less than one second total time, including the modular symbols space computation.

12.2. **A supersingular example.** Let E be the elliptic curve

$$E\colon\quad y^2 + x = x^3 + x^2 + 2x + 2$$

listed as curve 1483a1 in Cremona's tables. The curve has rank 2 generated by $(-1,0)$ and $(0,1)$. The reduction of E at $p=5$ is supersingular. The p-adic L-series is

$$\begin{aligned}\mathcal{L}_p(E,T) =& \big((1+\mathbf{O}(5))\cdot T^2 + (1+\mathbf{O}(5))\cdot T^3 + \mathbf{O}(T^4)\big)\cdot \omega_{E}\\ &+ \big((4\cdot 5+\mathbf{O}(5^2))\cdot T^2 + (4\cdot 5+\mathbf{O}(5^2))\cdot T^3 + \mathbf{O}(T^4)\big)\cdot \varphi(\omega_E)\end{aligned}$$

where we have already taken in account that the first two terms vanish. We compute the normalized D_p-valued regulator

$$\begin{aligned}\mathrm{Reg}_\gamma(E/\mathbb{Q}) =& \big(1+2\cdot 5+3\cdot 5^2+5^3+\mathbf{O}(5^5)\big)\cdot \omega_{E}\\ &+ \big(4\cdot 5+4\cdot 5^2+4\cdot 5^3+5^4+2\cdot 5^5+\mathbf{O}(5^6)\big)\cdot \varphi(\omega_{E})\,.\end{aligned}$$

Hence the p-adic BSD conjecture predicts that

$$\begin{aligned}&\big(1+\mathbf{O}(5)\big)\,\omega_{E} + \big(4\cdot 5+\mathbf{O}(5^2)\big)\,\varphi(\omega_{E}) =\\ &\qquad \#Ш(E/\mathbb{Q})\cdot\Big(\big(1+\mathbf{O}(5)\big)\,\omega_{E} + \big(4\cdot 5+\mathbf{O}(5^2)\big)\,\varphi(\omega_{E})\Big).\end{aligned}$$

In particular, we have shown that $Ш(E/\mathbb{Q})(5)$ is trivial. It follows from Iwasawa-theoretic consideration as in [PR03] that, if $\#Ш(E/_n\mathbb{Q})(5) = 5^{e_n}$ then

$$e_n = \frac{p}{p^2-1}\cdot p^n + \mathbf{O}(1)\,.$$

12.3. **An example whose Tate-Shafarevich group is nontrivial.** Let E be the elliptic curve given by

$$E\colon\quad y^2 + x\,y = x^3 + 16353089\,x - 335543012233$$

which is labeled 858k2 in [Cre]. The curve has rank 0 and is semistable, and the full BSD conjecture predicts that the Tate-Shafarevich group $Ш(E/\mathbb{Q})$ consists of two copies of $\mathbb{Z}/7\mathbb{Z}$.

We may compute the 7-adic L-series, which yields

$$\begin{aligned}\mathcal{L}_7(E,T) =& 7^2\cdot(2\cdot 7^2+7^3+7^4+3\cdot 7^5+\mathbf{O}(7^6) + (5\cdot 7^2+\mathbf{O}(7^3))\cdot T\\ &+ (3+4\cdot 7+5\cdot 7^2+\mathbf{O}(7^3))\cdot T^2 + \mathbf{O}(T^3))\end{aligned}$$

On the algebraic side, we find that the constant term of the characteristic series of E has valuation $2+\mathrm{ord}_7(\#Ш(E/\mathbb{Q}))$. So our algorithm yields the correct upper bound, that $\#Ш(E/\mathbb{Q})(7) \le 7^2$. We can change to the curve 858k1 with a 7-isogeny and prove there directly that the upper bound on the 7-primary part of the Tate-Shafarevich group is 1, so by isogeny invariance of the Birch and Swinnerton-Dyer conjecture it follows that $\#Ш(E/\mathbb{Q})(7) = 7^2$. (Of course, this can be shown with other methods for this curve of rank 0, e.g., by using Heegner points.) Since we know the exact order of $Ш(E/\mathbb{Q})$, we deduce that the main conjecture holds. (Also, this can be deduced from Theorem 7.5 taking $q = 11$.)

Once again we learn even more from the computation of the p-adic L-series. Iwasawa theory tells us that the order of the Tate-Shafarevich group grows quickly (for an ordinary prime) in the $\mathbb{Z}_7$-extension. Namely if $\#Ш(E/_n\mathbb{Q}) = 7^{e_n}$ then $e_n = 2\cdot 7^n + 2\cdot n + \mathbf{O}(1)$.

12.4. **Tate-Shafarevich Groups of Elliptic Curves of Rank at Least 2.** According to [Cre], for every elliptic curve with rank ≥ 2 and conductor up to 130,000, the BSD conjecture predicts that $Ш(E/\mathbb{Q}) = 0$. In this section, we describe the computation we did to verify Theorem 1.1, which gives evidence for this observation, at least up to conductor 30,000.

Consider a pair (E, p) consisting of

(1) an optimal elliptic curve E defined over $\mathbb{Q}$ with rank $r \geq 2$ and conductor $\leq$ 30,000, and
(2) a good ordinary prime p with $5 \leq p <$ 1,000 such that $\bar{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(E[p])$ is surjective.

There are 9,679 such curves E and 1,534,422 such pairs (E, p). For each pair, we do the following:

(1) Show that $r = \mathrm{ord}_T\, \mathcal{L}_p(E, T)$.
(2) Compute the conjectural order of $Ш(E/\mathbb{Q})$ according to Conjecture 5.1 mod p, and check that it is $1 + O(p)$.

As explained in the proof of Algorithm 11.1, our hypotheses on p then imply that $Ш(E/\mathbb{Q})[p] = 0$. As evidence for Conjecture 5.1 and as a double check on our implementation, we also verify the conjecture to precision $O(p)$ for each pair (E, p).

(1) We compute[9] approximations to $\mathcal{L}_p(E, T)$ that are sufficient to show that $\mathrm{ord}_T(\mathcal{L}_p(E, T)) = r$. For 1,523,413 of our 1,534,422 pairs (E, p), we did this by computing $P_2 \equiv \mathcal{L}_p(E, T) \pmod{(p, T^5)}$; for the remaining 11,009 pairs, we computed to higher precision.
(2) For all of our pairs (E, p), we computed the p-adic regulator $\mathrm{Reg}_p(E) \in \mathbb{Q}_p$ to precision at least $O(p^{12})$. In all cases this computation confirmed that $\mathrm{Reg}_p(E) \neq 0$.
(3) With the above data for our pairs (E, p), it was then straightforward to compute the conjectural order of $Ш(E/\mathbb{Q})$ according to Conjecture 5.1, and in all cases we got $1 + O(p)$, so $Ш(E/\mathbb{Q})[p] = 0$.

Remark 12.1. In fact, we carried out the regulator calculation mentioned above for all pairs (E, p) with $5 \leq p < 1000$ good ordinary for which the conductor of E is $\leq$ 130,000 and the rank is ≥ 2. A selection of large $\mathrm{ord}_p(\mathrm{Reg}_p(E))$ is given in Table 1. For example, for the first curve 53770a1 with $p = 7$, the conductor factors as $53770 = 2 \cdot 5 \cdot 19 \cdot 283$, the Tamagawa numbers are $12, 2, 6, 1$, which are all coprime to 7, we have $Ш(E/\mathbb{Q})_{\mathrm{an}} = 1$, and $N_7 = 9$, which is coprime to 7, but

$$\mathrm{Reg}_7(E) = 7^7 \cdot 419257219506 + O(7^{21})$$

is divisible by a rather large power of 7. The leading coefficient of the 7-adic L-series vanishes to order $7 - \mathrm{rank}(E)$, as expected, so $Ш(E/\mathbb{Q})(7) = 0$:

$$\begin{aligned}\mathcal{L}_7(E, T) = O(7^9) + O(7^6)T + \left(6 \cdot 7^5 + O(7^6)\right) T^2 + \left(3 \cdot 7^5 + O(7^6)\right) T^3 \\ + \left(5 + 5 \cdot 7 + 2 \cdot 7^4 + 7^5 + O(7^6)\right) T^4 + O(T^5)\end{aligned}$$

Remark 12.2. A very hard case is $(E, p) = (17856j1, 757)$, in which E has rank 2 and

$$\mathrm{Reg}_p(E) = 261 \cdot 757^4 + 531 \cdot 757^5 + 293 \cdot 757^6 + 309 \cdot 757^7 + \cdots$$

[9] The computation of the approximate p-adic L-series for all of our pairs (E, p) took *several months of CPU time* using an optimized implementation of the algorithm of Section 3.

The leading coefficient of the 757-adic L-series must be divisible by 757^2, so we must compute $\mathcal{L}_7(E,T) \pmod{757^3}$, which is enormously time consuming, even with our highly optimized implementation, since each power of p increases the complexity by a factor of p (and, in addition, we use slower arbitrary precision arithmetic to avoid overflow). The computation took over two months of CPU time, and yielded

$$\mathcal{L}_{757}(T) = O(757^3) + O(757^3)T + \left(399 \cdot 757^2 + O(757^3)\right) T^2 + \cdots$$

Thus the p-adic BSD conjecture predicts that $\#\text{Ш}(E/\mathbb{Q})(757) \equiv 1 \pmod{757}$, hence $\text{Ш}(E/\mathbb{Q})[757] = 0$.

TABLE 1. Various examples in which $\mathrm{ord}_p(\mathrm{Reg}_p(E))$ is large

Curve	Rank	p	$\mathrm{Reg}_p(E)$
53770a1	2	7	$7^7 \cdot 419257219506 + O(7^{21})$
60237b1	2	7	$7^7 \cdot 195984223121 + O(7^{21})$
65088bm1	2	5	$5^7 \cdot 3628814228 + O(5^{21})$
71236b1	2	5	$5^7 \cdot 2905505203 + O(5^{21})$
74220b1	2	7	$7^7 \cdot 411568240919 + O(7^{21})$
82096e1	2	11	$11^7 \cdot 163096174634581 + O(11^{21})$
91143f1	2	17	$17^7 \cdot 32722747582988964 + O(17^{21})$
101552a1	2	5	$5^7 \cdot 1575344534 + O(5^{21})$
116634k1	2	5	$5^7 \cdot 1877361868 + O(5^{21})$
121212q1	2	5	$5^7 \cdot 5806958402 + O(5^{21})$
123888bm1	2	7	$7^7 \cdot 537125029809 + O(7^{21})$
127368d1	2	13	$13^7 \cdot 485242111874635 + O(13^{21})$
27448d1	3	5	$5^6 \cdot 115188708423 + O(5^{22})$
53122a1	3	5	$5^6 \cdot 31988633 + O(5^{22})$
90953a1	3	7	$7^6 \cdot 28674298268349 + O(7^{22})$

Let E be the elliptic curve 389a of rank 2. We verified for a large number of primes p that $\text{Ш}(E/\mathbb{Q})[p] = 0$.

Theorem 12.3. *Let E be the rank 2 elliptic curve of conductor 389. Then for* 2 *and all 5,005 good ordinary primes $p <$ 48,859 except $p =$ 16,231 we have $\text{Ш}(E/\mathbb{Q})[p] = 0$. For each such p, the p-adic BSD conjectural order of* Ш *is congruent to* 1 *modulo p. This only excludes the following bad or supersingular primes and the good ordinary prime 16,231:*

$$\begin{aligned} p =& 107, 389, 599, 1049, 2957, 6661, 8263, 9397, 9551, 14633, 15101, 28591, \\ & 30671, 30869, 31799, 34781, 36263, 45161. \end{aligned}$$

Proof. This is a computation similar to the one described above that takes several weeks CPU time. □

Remark 12.4. For the prime $p =$ 16,231, we have $\mathrm{ord}_p(\mathrm{Reg}_p) = 3$ instead of $2 = \mathrm{rank}(E)$. Thus the computation is roughly 16,231 times as difficult as it is for nearby primes using our algorithm, so we estimate it would take several CPU years to finish. It should be possible to instead deal with this exceptional case efficiently using the overconvergent modular symbols approach of Pollack-Stevens [PS11], when a suitable implementation is available.

Remark 12.5. We have excluded supersingular primes from this section not because our algorithms do not apply (they do apply), but because our implementations are significantly slower in this case. We hope to address this shortcoming in future work.

43 Sage: Creating a Viable Free Open Source Alternative to Magma, Maple, Mathematica, and MATLAB

1

Sage: Creating a Viable Free Open Source Alternative to Magma, Maple, Mathematica, and MATLAB

William Stein[1]

[1] The work was supported by NSF grant DUE-1022574.

1.1 Introduction

The goal of the Sage project (`http://www.sagemath.org`) is to create a viable free open source alternative to Magma, Maple$^{\text{TM}}$, Mathematica®, and MATLAB®, which are the most popular non-free closed source mathematical software systems.[1] Magma is (by far) the most advanced non-free system for structured abstract algebraic computation, Mathematica and Maple are popular and highly developed systems that shine at symbolic manipulation, and MATLAB is the most popular system for applied numerical mathematics. Together there are over 3,000 employees working at the companies that produce the four Ma's listed above, which take in over a hundred million dollars of revenue annually.

By a viable free alternative to the Ma's, we mean a system that will have the important mathematical features of each Ma, with comparable speed. It will have 2d and 3d graphics, an interactive graphical user interface, and documentation, including books, papers, school and college curriculum materials, etc. A single alternative to all of the Ma's is not necessarily a drop-in replacement for any of the Ma's; in particular, it need not run programs written in the custom languages of those systems. Thus an alternative may be philosophically different than the open source system Octave, which understands the MATLAB source language and attempts to implement the entire MATLAB library. Development could instead focus on implementing functions that users demand, rather than systematically trying to implement every single function of the Ma's. The culture, architecture, and general look and feel of such a system would be very different than that of the Ma's.

In Section 1.2 we explain some of the motivation for starting the Sage project, in Section 1.3 we describe the basic architecture of Sage, and in Section 1.4 we sketch aspects of the history of the project.

1.2 Motivation for Starting Sage

Each of the Ma's cost substantial money, and is hence expensive for me, my collaborators, and students. The Ma's are not *owned by the community* like Sage is, or Wikipedia is, for that matter.

The Ma's are closed, which means that the implementation of some

[1] Maple is a trademark of Waterloo Maple Inc. Mathematica is a registered trademark of Wolfram Research Incorporated. MATLAB is a registered trademark of MathWorks. I will refer to the four systems together as "the Ma's" in the rest of this article.

algorithms are secret, in which case you are not allowed to modify or extend them.

> "You should realize at the outset that while knowing about the internals of Mathematica may be of intellectual interest, it is usually much less important in practice than you might at first suppose. Indeed, in almost all practical uses of Mathematica, issues about how Mathematica works inside turn out to be largely irrelevant. Particularly in more advanced applications of Mathematica, it may sometimes seem worthwhile to try to analyze internal algorithms in order to predict which way of doing a given computation will be the most efficient. [...] But most often the analyses will not be worthwhile. For the internals of Mathematica are quite complicated.."
> – The Mathematica Documentation

The philosophy espoused in Sage, and indeed by the vast open source software community, is exactly the opposite. We want you to know about the internals, and when they are quite complicated, we want you to help make them more understandable. Indeed, Sage's growth depends on *you* analyzing how Sage works, improving it, and contributing your improvements back.

```
sage: crt(2, 1, 3, 5)  # Chinese Remainder Theorem
11
sage: crt?         # ? = documentation and examples
Returns a solution to a Chinese Remainder Theorem...
...
sage: crt??        # ?? = source code
def crt(...):
...
    g, alpha, beta = XGCD(m, n)
    q, r = (b - a).quo_rem(g)
    if r != 0:
        raise ValueError("No solution ...")
    return (a + q*alpha*m) % lcm(m, n)
```

Moreover, by browsing `http://hg.sagemath.org/sage-main/`, you can see exactly who wrote or modified any particular line of code in the Sage library, when they did it, and why. Everything included in Sage is free and open source, and it will forever remain that way.

> "I see open source as Science. If you don't spread your ideas in the open, if you don't allow other people to look at how your ideas work and verify that they work, you are not doing Science, you are doing Witchcraft. Traditional software development models, where you keep things inside a company and hide what you are doing, are basically Witchcraft. Open source is all about the fact that it is open; people can actually look at what you are doing, and they can improve it, and they can build on top of it. [...] One of my favorite quotes from history is Newton: 'If I had seen further, it has been by standing on the shoulders of giants.'"

– Linus Torvalds.

The design decisions of the Ma's are not made openly by the community. In contrast, important decisions about Sage development are made via open public discussions and voting that is archived on public mailing lists with thousands of subscribers.

Every one of the Ma's uses a special mathematics-oriented interpreted programming language, which locks you into their product, makes writing some code outside mathematics unnecessarily difficult, and impacts the number of software engineers that are experts at programming in that language. In contrast, the user language of Sage is primarily the mainstream free open source language Python `http://python.org`, which is one of the world's most popular interpreted programming languages. The Sage project neither invented nor maintains the underlying Python language, but gains immediate access to the IPython shell, Python scientific libraries (such as NumPy, SciPy, CVXopt and MatPlotLib), and a large Python community with major support from big companies such as Google. In comparison to Python, the Ma's are small players in terms of language development. Thus for Sage most of the problems of language development are handled by someone else.

The bug tracking done for three of four of the Ma's is currently secret[2], which means that there is no published accounting of all known bugs, the status of work on them, and how bugs are resolved. But the Ma's do have many bugs; see the release notes of each new version, which lists bugs that were fixed[3]. Sage also has bugs, which are all publicly tracked at `http://trac.sagemath.org`, and there are numerous "Bug Days" workshops devoted entirely to fixing bugs in Sage. Moreover, all discussion about resolving a given bug, including peer review of solutions, is publicly archived. We note that sadly even some prize winning[4] free open source systems, such as GAP `http://www.gap-system.org/`, do not have an open bug tracking system, resulting in people reporting the same bugs over and over again.

Each of the Ma's is a combination of secret unchangeable compiled code and less secret interpreted code. Users with experience programming in compiled languages such as Fortran or C++ may find the loss of a compiler to be frustrating. None of the Ma's has an optimizing compiler that converts programs written in their custom interpreted language to a

[2] MATLAB has an open bug tracker, though it requires free registration to view.

[3] See also `http://cybertester.com/` and `http://maple.bug-list.org/`.

[4] Jenks Prize, 2008

fast executable binary format that is not interpreted at runtime.[5] In contrast, Sage is tightly integrated with Cython[6] `http://www.cython.org`, which is a ython-to-C/C++ compiler that speeds up code execution and has support for statically declaring data types (for potentially enormous speedups) and natively calling existing C/C++/Fortran code. For example, enter the following in a cell of the Sage notebook (e.g., `http://sagenb.org`):

```
def python_sum2(n):
    s = int(0)
    for i in xrange(1, n+1):
        s += i*i
    return s
```

Then enter the following in another cell:

```
%cython
def cython_sum2(long n):
    cdef long i, s = 0
    for i in range(1, n+1):
        s += i*i
    return s
```

The second implementation, despite looking nearly identical, is nearly a hundred times faster than the first one (your timings may vary).

```
sage: timeit('python_sum2(2*10^6)')
5 loops, best of 3: 154 ms per loop
sage: timeit('cython_sum2(2*10^6)')
125 loops, best of 3: 1.76 ms per loop
sage: 154/1.76
87.5
```

Of course, it is better to choose a different algorithm. In case you don't remember a closed form expression for the sum of the first n squares, Sage can deduce it:

```
sage: var('k, n')
sage: factor(sum(k^2, k, 1, n))
```

[5] MATLAB has a compiler, but "the source code is still interpreted at run-time, and performance of code should be the same whether run in standalone mode or in MATLAB." Mathematica also has a `Compile` function, but simply compiles expressions to a different internal format that is interpreted, much like Sage's `fast_callable` function.

[6] The Cython project has received extensive contributions from Sage developers, and is very popular in the world of Python-based scientific computing.

```
1/6*(n + 1)*(2*n + 1)*n
```

And now our simpler fast implementation is:

```
def sum2(n):
    return n*(2*n+1)*(n+1)/6
```

Just as above, we can also use the Cython compiler:

```
%cython
def c_sum2(long n):
    return n*(2*n+1)*(n+1)/6
```

Comparing times, we see that Cython is 10 times faster:

```
sage: n = 2*10^6
sage: timeit('sum2(n)')
625 loops, best of 3: 1.41 microseconds per loop
sage: timeit('c_sum2(n)')
625 loops, best of 3: 0.145 microseconds per loop
sage: 1.41/.145
9.72413793103448
```

In this case, the enhanced speed comes at a cost, in that the answer is *wrong* when the input is large enough to cause an overflow:

```
sage: c_sum2(2*10^6)   # WARNING: overflow
-407788678951258603
```

Cython is very powerful, but to fully benefit from it, one must understand machine level arithmetic data types, such as long, int, float, etc. With Sage you have that option.

1.3 What is Sage?

The goal of Sage is to compete with the Ma's, and the intellectual property at our disposal is the complete range of GPL-compatibly licensed open source software.

Sage is a self-contained free open source *distribution* of about 100 open source software packages and libraries[7] that aims to address all

[7] See the list of packages in Sage at `http://sagemath.org/packages/standard/`. The list includes R, Pari, Singular, GAP, Maxima, GSL, Numpy, Scipy, ATLAS, Matplotlib, and many other popular programs.

computational areas of pure and applied mathematics. The download of Sage contains all dependencies required for the normal functioning of Sage, including Python itself. Sage includes a substantial amount of code that provides a unified Python-based *interface* to these other packages. Sage also includes a library of new code written in Python, Cython and C/C++, which implements a huge range of algorithms.

1.4 History

I made the first release of Sage in February 2005, and at the time called it "**S**oftware for **A**rithmetic **G**eometry **E**xperimentation." I was a serious user of, and contributor to, Magma at the time, and was motivated to start Sage for many of the reasons discussed above. In particular, I was personally frustrated with the top-down closed development model of Magma, the fact that *several million lines* of the source code of Magma are closed source, and the fees that my colleagues had to pay in order to use the substantial amount of code that I contributed to Magma. Despite my early naive hope that Magma would be open sourced, it never was. So I started Sage motivated by the dream that someday the single most important item of software I use on a daily basis would be free and open. David Joyner, David Kohel, Joe Wetherell, and Martin Albrecht were also involved in the development of Sage during the first year.

In February 2006, the National Science Foundation funded a 2-day workshop called "Sage Days 2006" at UC San Diego, which had about 40 participants and speakers from several open and closed source mathematical software projects. After doing a year of fulltime mostly solitary work on Sage, I was surprised by the positive reception of Sage by members of the mathematical research community. What Sage promised was something many mathematicians wanted. Whether or not Sage would someday deliver on that promise was (and for many still is) an open question.

I had decided when I started Sage that I would make it powerful enough for my research, with or without the help of anybody else, and was pleasantly surprised at this workshop to find that many other people were interested in helping, and understood the shortcomings of existing open source software, such as GAP and PARI, and the longterm need to move beyond Magma. Six months later, I ran another Sage Days workshop, which resulted in numerous talented young graduate students, including David Harvey, David Roe, Robert Bradshaw, and Robert Miller, getting involved in Sage development. I used startup money from University of Washington to hire Alex Clemesha as a fulltime employee to implement 2d graphics and help create a notebook interface to Sage. I also learned that there was much broader interest in such a system, and stopped referring to Sage as being exclusively for "arithmetic geometry"; instead, Sage became "**S**oftware for **A**lgebra and **G**eometry **E**xperimentation." Today the acronym is deprecated.

The year 2007 was a major turning point for Sage. Far more people got involved with development, we had four Sage Days workshops, and prompted by Craig Citro, we instituted a requirement that all new code must have tests for 100% of the functions touched by that code, and every modification to Sage must be peer reviewed. Our peer review process is much more open than in mathematical research journals; everything that happens is publicly archived at `http://trac.sagemath.org`. During 2007, I also secured some funding for Sage development from Microsoft Research, Google, and NSF. Also, a German graduate student studying cryptography, Martin Albrecht presented Sage at the Trophées du Libre competition in France, and Sage won first place in "Scientific Software", which led to a huge amount of good publicity, including articles in many languages around the world and appearances[8] on the front page of `http://slashdot.org`.

In 2008, I organized 7 Sage Days workshops at places such as IPAM (at UCLA) and the Clay Mathematics Institute, and for the first time, several people besides me made releases of Sage. In 2009, we had 8 more Sage Days workshops, and the underlying foundations of Sage improved, including development of a powerful coercion architecture. This *coercion model* systematically determines what happens when performing operations such as `a + b`, when `a` and `b` are elements of potentially different rings (or groups, or modules, etc.).

```
sage: R.<x> = PolynomialRing(ZZ)
sage: f = x + 1/2; f
x + 1/2
sage: parent(f)
Univariate Polynomial Ring in x over Rational Field
```

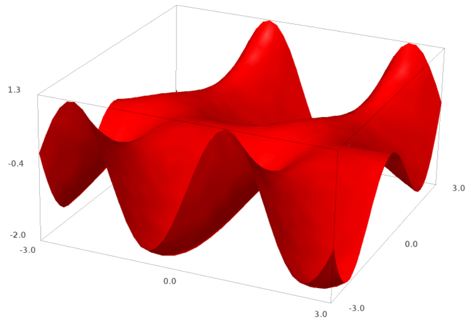
We compare this with Magma (V2.17-4), which has a more ad hoc coercion system:

[8] For example, `http://science.slashdot.org/story/07/12/08/1350258/Open-Source-Sage-Takes-Aim-at-High-End-Math-Software`

```
> R<x> := PolynomialRing(IntegerRing());
> x + 1/2
    ^
Runtime error in '+': Bad argument types
Argument types given: RngUPolElt[RngInt], FldRatElt
```

Robert Bradshaw and I also added support for beautiful browser-based 3D graphics to Sage, which involved writing a 3D graphics library, and adapting the free open source JMOL Java library (see `http://jmol.sourceforge.net/`) for rendering molecules to instead plot mathematical objects.

```
sage: f(x,y) = sin(x - y) * y * cos(x)
sage: plot3d(f, (x,-3,3), (y,-3,3), color='red')
```



In 2009, following a huge amount of porting work by Mike Hansen, development of algebraic combinatorics in Sage picked up substantial momentum, with the switch of the entire MuPAD-combinat group to Sage (forming sage-combinat `http://wiki.sagemath.org/combinat`), only months before the formerly free system MuPAD®[9] was bought out by Mathworks (makers of MATLAB). In addition to work on Lie theory by Dan Bump, this also led to a massive amount of work on a category theoretic framework for Sage by Nicolas Thiery.

In 2010, there were 13 Sage Days workshops in many parts of the world, and grant funding for Sage significantly improved, including new NSF funding for undergraduate curriculum development. I also spent much of my programming time during 2010–2011 developing a number theory library called psage `http://code.google.com/p/purplesage/`, which is currently not included in Sage, but can be easily installed.

[9] MuPAD is a registered trademark of SciFace Software GmbH & Co.

Many aspects of Sage make it an ideal tool for teaching mathematics, so there's a steadily growing group of teachers using it: for example, there have been MAA PREP workshops on Sage for the last two years, and a third is likely to run next summer, there are regular posts on the Sage lists about setting up classroom servers, and there is an NSF-funded project called UTMOST (see `http://utmost.aimath.org/`) devoted to creating undergraduate curriculum materials for Sage.

The page `http://sagemath.org/library-publications.html` lists 101 accepted publications that use Sage, 47 preprints, 22 theses, and 16 books, and there are surely many more "in the wild" that we are not aware of. According to Google Analytics, the main Sage website gets about 2,500 absolute unique visitors per day, and the website `http://sagenb.org`, which allows anybody to easily use Sage through their web browser, has around 700 absolute unique visitors per day.

For many mathematicians and students, Sage is today the mature, open source, and free foundation on which they can build their research program.

44 Numerical computation of Chow-Heegner points associated to pairs of elliptic curves

Numerical computation of Chow-Heegner points associated to pairs of elliptic curves[*][†]

William Stein

February 5, 2012

Abstract

In this paper, we consider a special case of Chow-Heegner points that has a simple concrete description due to Shouwu Zhang. Given a pair E, F of nonisogenous elliptic curves, and surjective morphisms $\varphi_E : X_0(N) \to E$ and $\varphi_F : X_0(N) \to F$ of curves over $\mathbb{Q}$, we associate a rational point $P \in E(\mathbb{Q})$. We describe a numerical approach to computing P, state some motivating results of Zhang et al. about the height of P, and present a table of data.

1 Introduction: Zhang's Construction

Consider a pair E, F of nonisogenous elliptic curves over $\mathbb{Q}$ and fix surjective morphisms from $X_0(N)$ to each curve. We do *not* assume that N is the conductor of either E or F, though N is necessarily a multiple of the conductor.

$$\begin{tikzcd} & X_0(N) \arrow[dl, "\varphi_E"'] \arrow[dr, "\varphi_F"] & \\ E & & F \end{tikzcd}$$

Let $(\varphi_E)_* : \mathrm{Div}(X_0(N)) \to \mathrm{Div}(E)$ and $\varphi_F^* : \mathrm{Div}(F) \to \mathrm{Div}(X_0(N))$ be the pushforward and pullback maps on divisors on algebraic curves. Let $Q \in F(\mathbb{C})$ be any point, and let

$$P_{\varphi_E,\varphi_F,Q} = \sum (\varphi_E)_* \varphi_F^*(Q) \in E(\mathbb{C}),$$

where $\sum$ means the sum of the points in the divisor using the group law on E, i.e., given a divisor $D = \sum n_i P_i \in \mathrm{Div}(E)$, we have $(\sum D) - \infty \sim D - \deg(D)\infty$, which uniquely determines $\sum D$.

[*] Work on this paper was partly supported by National Science Foundation Grant No. DMS-0821725.

[†] A modified version of this paper will be published as an appendix to [DDLR11].

Proposition 1.1. *The point $P_{\varphi_E,\varphi_F,Q}$ does not depend on the choice of Q.*

Proof. The composition $(\varphi_E)_* \circ \varphi_F^*$ induces a homomorphism of elliptic curves

$$\psi : \mathrm{Pic}^0(F) = \mathrm{Jac}(F) \to \mathrm{Jac}(E) = \mathrm{Pic}^0(E).$$

Our hypothesis that E and F are nonisogenous implies that $\psi = 0$. We denote by $[D]$ the linear equivalence class of a divisor in the Picard group. If $Q' \in F(\mathbb{C})$ is another point, then under the above composition of maps,

$$[Q - Q'] \mapsto [(\varphi_E)_*\varphi_F^*(Q) - (\varphi_E)_*\varphi_F^*(Q')] = [P_Q - P_{Q'}].$$

Thus the divisor $P_Q - P_{Q'}$ is linearly equivalent to 0. But F has genus 1, so there is no rational function on F of degree 1, hence $P_Q = P_{Q'}$, as claimed. □

We let $P_{\varphi_E,\varphi_F} = P_{\varphi_E,\varphi_F,Q} \in E(\mathbb{C})$, for any choice of Q.

Corollary 1.2. *We have $P_{\varphi_E,\varphi_F} \in E(\mathbb{Q})$.*

Proof. Taking $Q = \mathcal{O} \in F(\mathbb{Q})$, we see that the divisor $(\varphi_E)_* \circ \varphi_F^*(Q)$ is rational, so its sum is also rational. □

In the rest of this paper, we write $P_{E,F} = P_{\varphi_E,\varphi_F}$ when E and F are both optimal curves of the same conductor N, and φ_E and φ_F are as in Section 5.

1.1 Outline

In Section 2 we discuss an example in which E and F both have conductor 37. Section 3 is about a formula of Yuan-Zhang-Zhang for the height of $P_{E,F}$ in terms of the derivative of an L-function, in some cases. In Section 4, we discuss the connection between this paper and the paper [DDLR11] about computing Chow-Heegner points using iterated integrals. The heart of the paper is Section 5, which describes our numerical approach to approximating $P_{E,F}$. Finally, Section 5.2 presents a table of points $P_{E,F}$.

Acknowledgements: We would like to thank Ralph Greenberg, Ken Ribet, Barry Mazur, Karl Rubin, Shouwu Zhang, and Jon Bober for helpful conversations related to this paper, and especially thank Xinyi Yuan for introducing us to this topic, Henri Darmon for encouraging us to flesh out the details and write it up for publication, and Victor Rotger for clarifying some issues in Section 3. We would also like to thank John Cremona for refereeing the corresponding Sage [S$^+$11] code and Cremona, Bas Edixhoven and Samit Dasgupta for contributions to Section 5.1.

2 Example: $N = 37$

The smallest conductor curve of rank 1 is the curve E with Cremona label 37a (see [Cre]). The paper [MSD74] discusses the modular curve $X_0(37)$ in detail.

It gives the affine equation $y^2 = -x^6 - 9x^4 - 11x^2 + 37$ for $X_0(37)$, and describes how $X_0(37)$ is equipped with three independent involutions w, T and S. The quotient of $X_0(37)$ by w is E, the quotient by T is an elliptic curve F with $F(\mathbb{Q}) \approx \mathbb{Z}/3\mathbb{Z}$ and Cremona label 37b, and the quotient by S is the projective line $\mathbb{P}^1$.

$$\begin{tikzcd}
 & X_0(37) \arrow[dl, "\varphi_E"'] \arrow[d, "\varphi_F"] \arrow[dr] & \\
E = X/w & F = X/T & \mathbb{P}^1 = X/S
\end{tikzcd}$$

The maps φ_E and φ_F have degree 2, by virtue of being induced by an involution. As explained in [MSD74], the fiber over $Q = 0 \in F(\mathbb{Q})$ contains 2 points:

1. the cusp $[\infty] \in X_0(37)(\mathbb{Q})$, and
2. the noncuspidal affine rational point $(-1, -4) = T(\infty) \in X_0(37)(\mathbb{Q})$.

We have $\varphi_E([\infty]) = 0 \in E(\mathbb{Q})$, and [MSD74, Prop. 3, pg. 30] implies that

$$\varphi_F((-1, -4)) = (6, 14) = -6(0, -1),$$

where $(0, -1)$ generates $E(\mathbb{Q})$. We conclude that

$$P_{E,F} = (6, 14) \qquad \text{and} \qquad [E(\mathbb{Q}) : \mathbb{Z}P_{E,F}] = 6.$$

On [MSD74, pg. 31], they remark: "It would be of the utmost interest to link this index to something else in the theory."

This remark motivates our desire to compute more examples. Unfortunately, it is very difficult to generalize the above approach directly, since it involves computations with $X_0(37)$ and its quotients that rely on explicit defining equations. Just as there are multiple approaches to computing Heegner points, there are several approaches to computing $P_{E,F}$:

- a Gross-Zagier style formula for the height of $P_{E,F}$ (see Section 3),
- explicit evaluation of iterated integrals (see Section 4), and
- numerical approximation of the fiber in the upper half plane over a point on F using a polynomial approximation to φ_F (see Section 5).

This paper is mainly about the last approach listed above.

3 The Formula of Yuan-Zhang-Zhang

Consider a special case of the triple product L-function of [GK92]

$$L(E, F, F, s) = L(E, s) \cdot L(E, \mathrm{Sym}^2(F), s), \tag{1}$$

where E and F are elliptic curves of the same conductor N, and all L-functions are normalized so that $1/2$ is the center of the critical strip. The following theorem is proved in [YZZ11]:

Theorem 3.1 (Yuan-Zhang-Zhang). *Assume that the local root number of $L(E, F, F, s)$ at every prime of bad reduction is $+1$ and that the root number at infinity is -1. Then $\hat{h}(P_{E,F}) = (*) \cdot L'(E, F, F, \frac{1}{2})$, where $(*)$ is nonzero.*

Remark 3.2. The above formula resembles the Gross-Zagier formula

$$\hat{h}(P_K) = (*) \cdot (L(E/\mathbb{Q}, s) \cdot L(E^K/\mathbb{Q}, s))'|_{s=\frac{1}{2}},$$

where K is a quadratic imaginary field satisfying certain hypotheses.

If one could evaluate $L'(E, F, F, \frac{1}{2})$, e.g., by applying the algorithm of [Dok04], along with the factor $(*)$ in the theorem, this would yield an algorithm to compute $\pm P_{E,F} \pmod{E(\mathbb{Q})_{\mathrm{tor}}}$ when the root number hypothesis is satisfied. Unfortunately, it appears that nobody has numerically evaluated the formula of Theorem 3.1 in any interesting cases.

When E and F have the same squarefree conductor N, [GK92, §1] implies that the local root number of $L(E, F, F, s)$ at p is the same as the local root number of E at p; computing the local root number when the level is not square free is more complicated.

Proposition 3.3. *Assume that E and F have the same squarefree conductor N, that the local root numbers of E at primes $p \mid N$ are all $+1$ (equivalently, that we have $a_p(E) = -1$) and that $r_{\mathrm{an}}(E/\mathbb{Q}) = 1$. Then $L(E, \mathrm{Sym}^2 F, \frac{1}{2}) \neq 0$ if and only if $\hat{h}(P_{E,F}) \neq 0$.*

Proof. By hypothesis, we have $L(E, \frac{1}{2}) = 0$ and $L'(E, \frac{1}{2}) \neq 0$. Theorem 3.1 and the factorization (1) imply that

$$\hat{h}(P_{E,F}) = (*) \cdot L'(E, \frac{1}{2}) \cdot L(E, \mathrm{Sym}^2 F, \frac{1}{2}),$$

from which the result follows. □

Section 5.2 contains numerous examples in which E has rank 1, F has rank 0, and yet $P_{E,F}$ is a torsion point. The first example is when E is 91b and F is 91a. Then $P_{E,F} = (1, 0)$ is a torsion point (of order 3). In this case, we cannot apply Proposition 3.3 since $\varepsilon_7 = \varepsilon_{13} = -1$ for E. Another example is when E is 99a and F is 99c, where we have $P_{E,F} = 0$, and $\varepsilon_3 = \varepsilon_{11} = +1$, but Proposition 3.3 does not apply since the level is not square free. Fortunately, we found an example with squarefree level $158 = 2 \cdot 79$: here E is 158b, F is 158d, we have $P_{E,F} = 0$ and $\varepsilon_2 = \varepsilon_{79} = +1$, so Proposition 3.3 implies that $L(E, \mathrm{Sym}^2 F, \frac{1}{2}) = 0$.

4 Iterated Complex Path Integrals

The paper [DDLR11] contains a general approach using iterated path integrals to compute certain Chow-Heegner points, of which $P_{E,F}$ is a specific instance. Comparing our data (Section 5.2) with theirs, we find that if E and F are optimal elliptic curves over $\mathbb{Q}$ of the same conductor $N \leq 100$, if $e, f \in S_2(\Gamma_0(N))$

are the corresponding newforms, and if $P_{f,e,1} \in E(\mathbb{Q}) \otimes_{\mathbb{Q}} \mathbb{Q}$ the associated Chow-Heegner point in the sense of [DDLR11], then $2P_{E,F} = P_{f,e,1}$. This is (presumably) a consequence of [DRS11].

5 A Numerical Approach to Computing $P_{E,F}$

The numerical approach to computing P that we describe in this section uses relatively little abstract theory. It is inspired by work of Delaunay (see [Del02]) on computing the fiber of the map $X_0(389) \to E$ over rational points on the rank 2 curve E of conductor 389. We make no guarantee about how many digits of our approximation to $P_{E,F}$ are correct, instead viewing this as an algorithm to produce something that is useful for experimental mathematics only.

Let $\mathfrak{h}$ be the upper half plane, and let $Y_0(N) = \Gamma_0(N)\backslash\mathfrak{h} \subset X_0(N)$ be the affine modular curve. Let E and F be nonisogenous optimal elliptic curve quotients of $X_0(N)$, with modular parametrization maps φ_E and φ_F, and assume both Manin constants are 1. Let Λ_E and Λ_F be the period lattices of E and F, so $E \cong \mathbb{C}/\Lambda_E$ and $F \cong \mathbb{C}/\Lambda_F$. Viewed as a map $[\tau] \mapsto \mathbb{C}/\Lambda_E$, we have, using square brackets to denote equivalence classes, that

$$\varphi_E([\tau]) = \left[\sum_{n=1}^{\infty} \frac{a_n}{n} e^{2\pi i n\tau}\right],$$

and similarly for φ_F, where $a_n = a_n(E)$ are the L-series coefficients of E (see [Cre97, §2.10], which uses the oppositive sign convention). For any positive integer B, define the polynomial

$$\varphi_{E,B} = \sum_{n=1}^{B} \frac{a_n}{n} T^n \in \mathbb{Q}[T],$$

and similarly for $\varphi_{F,B}$.

To approximate $P_{E,F}$, we proceed as follows. First we make some choices, and after making these choices we run the algorithm, which will either find a "probable" numerical approximation to $P_{E,F}$ or fail.

- $y \in \mathbb{R}_{>0}$ – minimum imaginary part of points in fiber,
- $d \in \mathbb{Z}_{>0}$ – degree of the first approximation to φ_F in Step 1 below,
- $r \in \mathbb{R}_{\neq 0}$ – real number specified to b bits of precision that defines $Q \in \mathbb{C}/\Lambda$,
- b' – bits of precision when dividing points into $\Gamma_0(N)$ orbits, and
- n – number of trials before we give up and output FAIL.

We compute $P_{E,F,Q}$ using an approach that will always fail if Q is a ramification point. Our algorithm will also fail if any points in the fiber over Q are cusps. This is why we do not allow $r = 0$. One can modify the algorithm to work when Q is an unramified torsion point by using modular symbols and keeping track of images of cusps.

To increase our confidence that we have computed the right point $P_{E,F}$, we often carry out the complete computation with more than one choice of r.

1. **Low precision roots:** Compute all complex double precision roots of the polynomial $\varphi_{F,d} - r$. One way to do this is to use "balanced QR reduction of the companion matrix", as implemented in GSL.[1] Record the roots that correspond to $\tau \in \mathfrak{h}$ with $\mathrm{Im}(\tau) \geq y$.

2. **High precision roots:** Compute B such that if $\mathrm{Im}(\tau) \geq y$, then

$$\left| \sum_{n=B+1}^{\infty} \frac{a_n(F)}{n} \tau^n \right| < 2^{-b},$$

   where b is the number of bits of precision of r. Summing the tail end of the series and using that $|a_n| \leq n$ (see [GJP+09, Lem. 2.9]), we find that

$$B = \left\lceil \frac{\log(2^{-(b+1)} \cdot (1 - e^{-2\pi y_1}))}{-2\pi y} \right\rceil$$

   works. Next, compute the polynomial $\varphi_{F,B} \in \mathbb{Q}[T]$, and use Newton iteration to refine all roots saved in Step 1 to roots α of $f = \varphi_{F,B} - r \in \mathbb{R}[T]$ such that $|f(\alpha)| < 2^{-b}$. Save those roots that correspond to $\tau \in \mathfrak{h}$ with $\mathrm{Im}(\tau) \geq y$.

3. $\Gamma_0(N)$**-orbits:** Divide the τ's from Step 2 into $\Gamma_0(N)$-equivalence classes, testing equivalence to the chosen bit precision $b' \leq b$, as explained in Section 5.1. It is easy to efficiently compute the modular degree $m_F = \deg(\varphi_F)$ (see [Wat02]). If we find m_F distinct $\Gamma_0(N)$ classes of points, we suspect that we have found the fiber over $[r]$, so we map each element of the fiber to E using φ_E and sum, then apply the elliptic exponential to obtain $P_{E,F}$ to some precision, then output this approximation and terminate. If we find more than m_F distinct classes, there was an error in the choices of precision in our computation, so we output FAIL (and suggest either increasing b or decreasing b').

4. **Try again:** We did not find enough points in the fiber. Systematically replace r by $r + m\Omega_F$, for $m = 1, -1, 2, -2, \ldots$, where Ω_F is the least real period of F, then try again going to Step 1 and including the new points found. If upon trying n choices $r + m\Omega_F$ in a row we find no new points, we output FAIL and terminate the algorithm.

5.1 Determining $\Gamma_0(N)$ equivalency

The field of meromorphic functions invariant under $\Gamma_0(N)$ is generated by $j(z)$ and $j(Nz)$, so if two points z_1 and z_2 in the upper half plane are equivalent under $\Gamma_0(N)$, then z_1 and z_2 are equivalent under $\mathrm{SL}_2(\mathbb{Z})$ and Nz_1 and Nz_2 are also equivalent under $\mathrm{SL}_2(\mathbb{Z})$. Because of singularities in the affine curve defined

[1] GSL is the the GNU scientific library, which is part of Sage [S+11]. Rough timings of GSL for this computation: it takes less than a half second for degree 500, about 5 seconds for degree 1000, about 45 seconds for degree 2000, and several minutes for degree 3000.

by $j(z)$ and $j(Nz)$, the converse is *not* true: for example, $z_1 = (-2+i)/5$ and $z_2 = (2+i)/5$ are equivalent under $\mathrm{SL}_2(\mathbb{Z})$ as are $5z_1$ and $5z_2$, but z_1 and z_2 are not equivalent under $\Gamma_0(5)$. This is why the algorithm we give below must take into account singularities.

Suppose we are given arbitrary z_1 and z_2 in the upper half plane. We first find $g_1, g_2 \in \mathrm{SL}_2(\mathbb{Z})$ such that $w_i = g_i(z_i)$ is the canonical representative for z_i in the standard fundamental domain for $\mathrm{SL}_2(\mathbb{Z})$, as explained in [Cre97, §2.14] but using interval arithmetic to avoid rounding errors. If $w_1 \neq w_2$, then z_1 and z_2 are not equivalent under $\mathrm{SL}_2(\mathbb{Z})$, so they cannot be equivalent under $\Gamma_0(N)$. Thus let $w = g_1(z_1) = g_2(z_2)$. The elements of $\mathrm{PSL}_2(\mathbb{Z})$ that send z_1 to z_2 are the finitely many elements $g_2^{-1}Ag_1$, for $A \in \mathrm{Stab}(w)$, so we check whether any $g_2^{-1}Ag_1$ is in $\Gamma_0(N)$. The only elements of the standard fundamental domain for $\mathrm{SL}_2(\mathbb{Z})$ with nontrivial stabilizers are $w = i$, with stabilizer generated by $S \in \mathrm{PSL}_2(\mathbb{Z})$ of order 2, and $w = e^{2\pi i/3}$ with stabilizer generated by ST, where T corresponds to $z \mapsto z+1$.

5.2 Data

We implemented the above algorithm in Sage [S$^+$11][2]. The columns of the tables below are as follows. The columns labeled E and F contain Cremona labels for elliptic curves, and those labeled r_E and r_F contain the corresponding ranks. The column labeled $E(\mathbb{Q})$ gives a choice of generators $P_1, P_2, \ldots$ for the Mordell-Weil group, with r_E points of infinite order listed first, then 0, 1 or 2 torsion points listed with a subscript of their order. The column labeled $P_{E,F}$ contains a rational point close to the numerically computed Chow-Heegner point, represented in terms of the generators P_i from the column labeled $E(\mathbb{Q})$, where P_1 is the first generator, P_2 the second, and so on. The columns labeled m_E and m_F give the modular degrees of E and F. The column labeled ε's contains the local root numbers of $L(E,s)$ at each bad prime. The notes column refers to the notes after the table, which give information about the input parameters needed to compute $P_{E,F}$.

We believe that the values of $P_{E,F}$ are "likely" to be correct, but we emphasize again that *they are not proven correct.* In the table we give an exact point, but the algorithm computes a numerical approximation $\tilde{P}_{E,F}$ to $P_{E,F} \in E(\mathbb{Q})$. We find what we call $P_{E,F}$ in the table by running through several hundred low height points in $E(\mathbb{Q})$ and find the one closest to $\tilde{P}_{E,F}$; in all cases, the coordinates of the point we list are within 10^{-5} of the coordinates of $\tilde{P}_{E,F}$.

The table contains *every* pair E, F of nonisogenous optimal elliptic curves of the same conductor $N \leq 184$ with $r_E = 1$, and *most* (but not all) with $N \leq 250$. It also contains a few additional miscellaneous examples, e.g., with $r_E = 0$ and some of larger conductor with $r_F = 2$. Most rows took only a few seconds to compute, though ones with m_F large in some cases took much longer; the total CPU time to compute the entire table was about 8 hours. Unless otherwise noted, we used $y = 10^{-4}$, $d = 500$, $b' = 20$, and $r = 0.1$ with 53 bits of precision,

[2] See `http://trac.sagemath.org/sage_trac/ticket/11975`.

as in Section 5. We also repeated all computations with at least one additional value of $r \neq 0.1$, and in every case got the same result (usually we used $r = 0.2$).

5.3 Discussion

In the table we always have $2 \mid [E(\mathbb{Q})_{/\,\mathrm{tor}} : \mathbb{Z}P_{E,F}]$. In may be possible to prove this in some cases by using that when $r_{\mathrm{an}}(E) = 1$ then the sign in the functional equation for $L(E,s)$ is -1, so at least one nontrivial Atkin-Lehner involution w_q acts as $+1$ on E, which means that the map $X_0(N) \to E$ factors through $X_0(N) \to X_0(N)/w_q$. Also, there are four cases in which the index $[E(\mathbb{Q})/_{\mathrm{tor}} : \mathbb{Z}P_{E,F}]$ is divisible by a prime $\ell \geq 5$. They are (106b, 106c, $\ell = 11$), (118a, 118d, $\ell = 7$), (121b, 121d, $\ell = 7$), and (158b, 158c, $\ell = 7$). These prime divisors do not appear to have anything to do with the invariants of E and F, individually.

45 A Database Of Elliptic Curves Over $\mathbf{Q}(\sqrt{5})$ – First Report, with J. Bober, A. Deines, A. Klages-Mundt, B. LeVeque, R. A. Ohana, A. Rabindranath, P. Sharaba

A DATABASE OF ELLIPTIC CURVES OVER $\mathbb{Q}(\sqrt{5})$—FIRST REPORT

JONATHAN BOBER, ALYSON DEINES, ARIAH KLAGES-MUNDT, BENJAMIN LEVEQUE, R. ANDREW OHANA, ASHWATH RABINDRANATH, PAUL SHARABA, WILLIAM STEIN

Abstract. We describe a tabulation of (conjecturally) modular elliptic curves over the field $\mathbb{Q}(\sqrt{5})$ up to the first curve of rank 2. Using an efficient implementation of an algorithm of Lassina Dembélé [Dem05], we computed tables of Hilbert modular forms of weight $(2, 2)$ over $\mathbb{Q}(\sqrt{5})$, and via a variety of methods we constructed corresponding elliptic curves, including (again, conjecturally) all elliptic curves over $\mathbb{Q}(\sqrt{5})$ that have conductor with norm less than or equal to 1831.

1. Introduction

1.1. **Elliptic Curves over $\mathbb{Q}$.** Tables of elliptic curves over $\mathbb{Q}$ have been of great value in mathematical research. Some of the first such tables were those in Antwerp IV [BK75], which included all elliptic curves over $\mathbb{Q}$ of conductor up to 200, and also a table of all elliptic curves with bad reduction only at 2 and 3.

Cremona's book [Cre97] gives a detailed description of algorithms that together output a list of all elliptic curves over $\mathbb{Q}$ of any given conductor, along with extensive data about each curve. The proof that his algorithm outputs *all* curves of given conductor had to wait for the proof of the full modularity theorem in [BCDT01]. Cremona has subsequently computed tables [Cre] of all elliptic curves over $\mathbb{Q}$ of conductor up to 220,000, including Mordell-Weil groups and other extensive data about each curve; he expects to soon reach his current target, conductor 234,446, which is the smallest known conductor of a rank 4 curve.

In a different direction, Stein-Watkins (see [SW02, BMSW07]) created a table of 136,832,795 elliptic curves over $\mathbb{Q}$ of conductor $\leq 10^8$, and a table of 11,378,911 elliptic curves over $\mathbb{Q}$ of prime conductor $\leq 10^{10}$. There are many curves of large discriminant missing from the Stein-Watkins tables, since these tables are made by enumerating curves with relatively small defining equations, and discarding those of large conductor, rather than systematically finding all curves of given conductor no matter how large the defining equation.

1.2. **Why $\mathbb{Q}(\sqrt{5})$?** Like $\mathbb{Q}$, the field $F = \mathbb{Q}(\sqrt{5})$ is a totally real field, and many of the theorems and ideas about elliptic curves over $\mathbb{Q}$ have been generalized to totally real fields. As is the case over $\mathbb{Q}$, there is a notion of modularity of elliptic curves over F, and work of Zhang [Zha01] has extended many results of Gross-Zagier [GZ86] and Kolyvagin [Kol91] to the context of elliptic curves over totally real fields.

This work is supported by NSF grant DMS-0757627, administered by the American Institute of Mathematics.

If we order totally real number fields K by the absolute value of their discriminant, then $F = \mathbb{Q}(\sqrt{5})$ comes next after $\mathbb{Q}$ (the Minkowski bound implies that $|D_K| \geq (n^n/n!)^2$, where $n = [K : \mathbb{Q}]$, so if $n \geq 3$ then $|D_K| > 20$). That 5 divides $\mathrm{disc}(F) = 5$ thwarts attempts to easily generalize the method of Taylor-Wiles to elliptic curves over F, which makes $\mathbb{Q}(\sqrt{5})$ even more interesting. The field F also has 31 CM j-invariants, which is far more than any other quadratic field (see Section 5). Letting $\varphi = \frac{1+\sqrt{5}}{2}$, we have that the group of units $\{\pm 1\} \times \langle \varphi \rangle$ of the ring $R = \mathcal{O}_F = \mathbb{Z}[\varphi]$ of integers of F is infinite, leading to additional complications. Finally, F has even degree, which makes certain computations more difficult, as the cohomological techniques of [GV11] are not available.

1.3. **Modularity conjecture.**

The following conjecture is open:

Conjecture 1.1 (Modularity)**.** *The set of L-functions of elliptic curves over F equals the set of L-functions associated to cuspidal Hilbert modular newforms over F of weight $(2,2)$ with rational Hecke eigenvalues.*

Given the progress on modularity theorems initiated by [Wil95], we are optimistic that Conjecture 1.1 will be proved. *We officially assume Conjecture 1.1 for the rest of this paper.*

In Section 2 we sketch how to compute Hilbert modular forms using arithmetic in quaternion algebras. Section 3 gives numerous methods for finding an elliptic curve corresponding to a Hilbert modular form. Section 4 addresses how to find all curves that are isogenous to a given curve. In Section 5 we enumerate the CM j-invariants in F. We discuss some projects for future work in Section 6. Finally, Section 7 contains tables that summarize various information about our dataset [BDKM$^+$12].

Acknowledgements. We would like to thank John Cremona, Tom Fisher, Noam Elkies, Richard Taylor, and John Voight for helpful conversations. We would especially like to thank Joanna Gaski for providing (via the method of Section 3.1) the explicit table of elliptic curves that kickstarted this project. We used `Sage` [S$^+$12] extensively throughout this project.

2. Computing Hilbert modular forms over F

In Section 2.1 we sketch Dembélé's approach to computing Hilbert modular forms over F, then in Section 2.2 we make some remarks about our fast implementation.

2.1. **Hilbert modular forms and quaternion algebras.**

Dembélé [Dem05] introduced an algebraic approach via the Jacquet-Langlands correspondence to computing Hilbert modular forms of weight $(2,2)$ over F. The Hamiltonian quaternion algebra $F[i,j,k]$ over F is ramified exactly at the two infinite places, and contains the maximal order

$$S = R\left[\frac{1}{2}(1 - \overline{\varphi}i + \varphi j),\ \frac{1}{2}(-\overline{\varphi}i + j + \varphi k),\ \frac{1}{2}(\varphi i - \overline{\varphi}j + k),\ \frac{1}{2}(i + \varphi j - \overline{\varphi}k)\right].$$

For any nonzero ideal $\mathfrak{n}$ in $R = \mathcal{O}_F$, let $\mathbb{P}^1(R/\mathfrak{n})$ be the set of equivalence classes of column vectors with two coprime entries $a, b \in R/\mathfrak{n}$ modulo the action of $(R/\mathfrak{n})^*$. We use the notation $[a : b]$ to denote the equivalence class of $\left(\begin{smallmatrix} a \\ b \end{smallmatrix}\right)$. For each prime $\mathfrak{p} \mid \mathfrak{n}$, we fix a choice of isomorphism $F[i,j,k] \otimes F_{\mathfrak{p}} \approx M_2(F_{\mathfrak{p}})$, which induces a left action of S^* on $\mathbb{P}^1(R/\mathfrak{n})$. The Jacquet-Langlands correspondence implies that the space of Hilbert modular forms of level $\mathfrak{n}$ and weight $(2,2)$ is noncanonically isomorphic as a module over the Hecke algebra

$$\mathbb{T} = \mathbb{Z}[T_{\mathfrak{p}} : \mathfrak{p} \text{ nonzero prime ideal of } R]$$

to the finite dimensional complex vector space $V = \mathbb{C}[S^* \backslash \mathbb{P}^1(R/\mathfrak{n})]$. The action of $T_{\mathfrak{p}}$, for $p \nmid \mathfrak{n}$, is $T_{\mathfrak{p}}([x]) = \sum[\alpha x]$, where the sum is over the classes $[\alpha] \in S/S^*$ with $N_{\mathrm{red}}(\alpha) = \pi_{\mathfrak{p}}$ (reduced quaternion norm), where $\pi_{\mathfrak{p}}$ is a fixed choice of totally positive generator of $\mathfrak{p}$.

2.2. **Remarks on Computing with $\mathbb{P}^1(R/\mathfrak{n})$.** In order to implement the algorithm sketched in Section 2.1, it is critical that we can compute with $\mathbb{P}^1(R/\mathfrak{n})$ very, very quickly. For example, to apply the method of Section 3.7 below, in some cases we have to compute tens of thousands of Hecke operators. Thus in this section we make some additional remarks about this fast implementation.

When $\mathfrak{n} = \mathfrak{p}^e$ is a prime power, it is straightforward to efficiently enumerate representative elements of $\mathbb{P}^1(R/\mathfrak{p}^e)$, since each element $[x : y]$ of $\mathbb{P}^1(R/\mathfrak{p}^e)$ has a unique representative of the form $[1 : b]$ or $[a : 1]$ with a divisible by $\mathfrak{p}$, and these are all distinct. It is easy to put any $[x : y]$ in this canonical form and enumerate the elements of $\mathbb{P}^1(R/\mathfrak{p}^e)$, after choosing a way to enumerate the elements of $R/\mathfrak{p}^e$. An enumeration of $R/\mathfrak{p}^e$ is easy to give once we decide on how to represent $R/\mathfrak{p}^e$.

In general, factor $\mathfrak{n} = \prod_{i=1}^m \mathfrak{p}_i^{e_i}$. We have a bijection $\mathbb{P}^1(R/\mathfrak{n}) \cong \prod_{i=1}^m \mathbb{P}^1(R/\mathfrak{p}_i^{e_i})$, which allows us to reduce to the prime power case, at the expense of having to compute the bijection $R/\mathfrak{n} \cong \prod R/\mathfrak{p}_i^{e_i}$. To this end, we *represent elements* of $R/\mathfrak{n}$ as m-tuples in $\prod R/\mathfrak{p}_i^{e_i}$, thus making computation of the bijection trivial.

To minimize dynamic memory allocation, thus speeding up the code by an order of magnitude, in the implementation we make some arbitrary bounds; this is not a serious constraint, since the linear algebra needed to isolate eigenforms for levels beyond this bound is prohibitive. We assume $m \leq 16$ and each individual $p_i^{e_i} \leq 2^{31}$, where p_i is the residue characteristic of $\mathfrak{p}_i$. In all cases, we represent an element of $R/\mathfrak{p}_i^{e_i}$ as a pair of 64-bit integers, and represent an element of $R/\mathfrak{n}$ as an array of 16 pairs of 64-bit integers. We use this representation in all cases, even if $\mathfrak{n}$ is divisible by less than 16 primes; the gain in speed coming from avoiding dynamic memory allocation more than compensates for the wasted memory.

Let $\mathfrak{p}^e$ be one of the prime power factors of $\mathfrak{n}$, and let p be the residue characteristic of $\mathfrak{p}$. We have one of the following cases:

- $\mathfrak{p}$ splits in R; then $R/\mathfrak{p} \cong \mathbb{Z}/p\mathbb{Z}$ and we represent elements of $R/\mathfrak{p}^e$ as pairs $(a, 0)$ mod p^e with the usual addition and multiplication in the first factor.
- $\mathfrak{p}$ is inert in R; then $R/\mathfrak{p}^e \cong (\mathbb{Z}/p^e\mathbb{Z})[x]/(x^2 - x - 1)$, and we represent elements by pairs $(a, b) \in \mathbb{Z}/p^e\mathbb{Z}$ with multiplication

$$(a, b)(c, d) = (ac + bd, ad + bd + bc) \mod p^e.$$

- $\mathfrak{p}$ is ramified and $e = 2f$ is even; this is exactly the same as the case when $\mathfrak{p}$ is inert but with e replaced by f, since $R/\mathfrak{p}^e R \cong (\mathbb{Z}/p^f\mathbb{Z})[x]/(x^2 - x - 1)$.
- $\mathfrak{p}$ is ramified (so $p = 5$) and $e = 2f - 1$ is odd; the ring $A = R/\mathfrak{p}^e$ is trickier than the rest, because it is *not* of the form $\mathbb{Z}[x]/(m, g)$ where $m \in \mathbb{Z}$ and $g \in \mathbb{Z}[x]$. We have $A \approx (\mathbb{Z}/5^f\mathbb{Z})[x]/(x^2 - 5, 5^{f-1}x)$, and represent elements

of A as pairs $(a,b) \in (\mathbb{Z}/5^f) \times (\mathbb{Z}/5^{f-1}\mathbb{Z})$, with arithmetic given by

$$(a,b) + (c,d) = (a + c \mod 5^f,\ \ b + d \mod 5^{f-1})$$
$$(a,b) \cdot (c,d) = (ac + 5bd \mod 5^f,\ \ ad + bc \mod 5^{f-1}).$$

We find that $\varphi \in R \mapsto (1/2, 1/2)$.

3. Strategies for finding an elliptic curve attached to a Hilbert modular form

In this section we describe various strategies to find an elliptic curve associated to each of the Hilbert modular forms computed in Section 2. Let f be a rational cuspidal Hilbert newform of weight $(2,2)$ as in Section 2. According to Conjecture 1.1, there is some elliptic curve E_f over F such that $L(f,s) = L(E_f,s)$. (Note that E_f is only well defined up to isogeny.) Unlike the case for elliptic curves over $\mathbb{Q}$ (see [Cre97]), there seems to be no known *efficient* direct algorithm to find E_f. Nonetheless, there are several approaches coming from various directions, which are each efficient in some cases.

Everywhere below, we continue to assume that Conjecture 1.1 is true and assume that we have computed (as in Section 2) the Hecke eigenvalues $a_\mathfrak{p} \in \mathbb{Z}$ of all rational Hilbert newforms of some level $\mathfrak{n}$, for $\mathrm{Norm}(\mathfrak{p}) \leq B$ a good prime, where B is large enough to distinguish newforms. In some cases we will need far more $a_\mathfrak{p}$ in order to compute with the L-function attached to a newform. We will also need the $a_\mathfrak{p}$ for bad $\mathfrak{p}$ in a few cases, which we obtain using the functional equation for the L-function (as an application of Dokchitser's algorithm [Dok04]).

We define the *norm conductor* of an elliptic curve over F to be the absolute norm of the conductor ideal of the curve.

In Section 3.1 we give a very simple enumeration method for finding curves, then in Section 3.2 we refine it by taking into account point counts modulo primes; together, these two methods found a substantial fraction of our curves. Sections 3.3 and 3.4 describe methods for searching in certain families of curves, e.g., curves with a torsion point of given order or curves with a given irreducible mod ℓ Galois representation. Section 3.5 is about how to find all twists of a curve with bounded norm conductor. In Section 3.6 we mention the Cremona-Lingham algorithm, which relies on computing all S-integral points on many auxiliary curves. Finally, Section 3.7 explains in detail an algorithm of Dembélé that uses explicit computations with special values of L-functions to find curves.

3.1. **Extremely naive enumeration.**

The most naive strategy is to systematically enumerate elliptic curves $E : y^2 = x^3 + ax + b$, with $a, b \in R$, and for each E, to compute $a_\mathfrak{p}(E)$ for $\mathfrak{p}$ not dividing $\mathrm{Disc}(E)$ by counting points on E reduced modulo $\mathfrak{p}$. If all the $a_\mathfrak{p}(E)$ match with those of the input newform f up to the bound B, we then compute the conductor $\mathfrak{n}_E$, and if it equals $\mathfrak{n}$, we conclude from the sufficient largeness of B that E is in the isogeny class of E_f.

Under our hypotheses, this approach provides a deterministic and terminating algorithm to find all E_f. However, it can be extremely slow when $\mathfrak{n}$ is small but the simplest curve in the isogeny class of E_f has large coefficients. For example, using this search method it would be infeasible to find the curve (3.1) computed by Fisher using the visibility of Ш[7].

3.2. **Sieved enumeration.** A refinement to the approach discussed above uses the $a_{\mathfrak{p}}$ values to impose congruence conditions modulo $\mathfrak{p}$ on $\#\tilde{E}(R/\mathfrak{p})$. If f is a newform with Hecke eigenvalues $a_{\mathfrak{p}}$, then $\#\tilde{E}_f(R/\mathfrak{p}) = \mathbf{N}(\mathfrak{p}) + 1 - a_{\mathfrak{p}}$. Given $\mathfrak{p}$ not dividing the level $\mathfrak{n}$, we can find all elliptic curves modulo $\mathfrak{p}$ with the specified number of points, especially when $\mathbf{N}(\mathfrak{p}) + 1 - a_{\mathfrak{p}}$ has few prime factors. We impose these congruence conditions at multiple primes $\mathfrak{p}_i$, use the Chinese Remainder Theorem, and lift the resulting curves modulo $R/(\prod \mathfrak{p}_i)$ to non-singular curves over R.

While this method, like the previous one, will eventually terminate, it too is very ineffective if every E in the class of isogenous curves corresponding to f has large coefficients. However in practice, by optimally choosing the number of primes $\mathfrak{p}_i$, a reasonably efficient implementation of this method can be obtained.

3.3. **Torsion families.** We find elliptic curves of small conductor by specializing explicit parametrizations of families of elliptic curves over F having specified torsion subgroups. We use the parametrizations of [Kub76].

Theorem 3.1 (Kamienny-Najman, [KN12]). *The following is a complete list of torsion structures for elliptic curves over F:*

$$\begin{aligned} &\mathbb{Z}/m\mathbb{Z}, && 1 \le m \le 10, \quad m = 12,\\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, && 1 \le m \le 4,\\ &\mathbb{Z}/15\mathbb{Z}. \end{aligned}$$

Moreover, there is a unique curve with 15*-torsion.*

We use the following proposition to determine in which family to search.

Proposition 3.2. *Let ℓ be a prime and E a curve over F. Then $\ell \mid \#E'(F)_{\mathrm{tor}}$ for some curve E' in the isogeny class of E if and only if $\ell \mid \mathbf{N}(\mathfrak{p}) + 1 - a_{\mathfrak{p}}$ for all odd primes $\mathfrak{p}$ at which E has good reduction.*

Proof. If $\ell \mid \#E'(F)_{\mathrm{tor}}$, from the injectivity of the reduction map at good primes [Kat81, Appendix], we have that $\ell \mid \#\tilde{E}'(\mathbb{F}_{\mathfrak{p}}) = \mathbf{N}(\mathfrak{p}) + 1 - a_{\mathfrak{p}}$. The converse statement is one of the main results of [Kat81]. □

By applying Proposition 3.2 for all $a_{\mathfrak{p}}$ with $\mathfrak{p}$ up to some bound, we can decide whether or not it is *likely* that some curve in the isogeny class of E contains an F-rational ℓ-torsion point. If this is the case, then we search over those families of curves with rational ℓ-torsion. With a relatively small search space, we thus find many curves with large coefficients more quickly than with the algorithm of Section 3.1. For example, we first found the curve E given by

$$y^2 + \varphi y = x^3 + (27\varphi - 43)\,x + (-80\varphi + 128)$$

with norm conductor 145 by searching for curves with torsion subgroup $\mathbb{Z}/7\mathbb{Z}$.

3.4. **Congruence families.** Suppose that we are searching for a curve E and we already know another curve E' with $E[\ell] \approx E'[\ell]$, where ℓ is some prime and $E[\ell]$ is irreducible. If $\ell = 7, 11$ then we can use techniques of Fisher [Fis12] to attempt to search through the finitely many curves with mod ℓ Galois representation isomorphic to $E[\ell]$. We used this approach to find the curve E given by

$$\begin{aligned} y^2 + \varphi xy = x^3 + (\varphi - 1)\,x^2 + &\\ (-257364\varphi - 159063)\,x &+ (-75257037\varphi - 46511406) \end{aligned} \tag{3.1}$$

with conductor $-38\varphi+10$, which has norm 1476. Given just the $a_{\mathfrak{p}}$, we noticed that $E[7] \approx E'[7]$, where E' has norm conductor 369, then Fisher used a Magma [BCP97] program to find rational points on a certain quartic surface that parametrize curves with the same $E'[7]$. Fortunately, our curve E was amongst those curves. We had already found E' via a naive search, since it is given by the equation $y^2+(\varphi+1)\,y = x^3+(\varphi-1)\,x^2+(-2\varphi)\,x$.

3.5. **Twisting.** Let E be an elliptic curve F. A *twist* E' of E is a curve over F that is isomorphic to E over some extension of F. A *quadratic twist* is a twist in which the extension has degree 2. We can use twisting to find curves that may otherwise be difficult to find as follows: starting with a known elliptic curve E of some (small) conductor, we compute its twists of conductor up to some bound, and add them to our table.

More explicitly, if E is given by $y^2 = x^3+ax+b$ and $d \in F^*$, then the twist E^d of E by d is given by $dy^2 = x^3+ax+b$; in particular, we may assume that d is square free. The following is well known:

Proposition 3.3. *If $\mathfrak{n}$ is the conductor of E and $d \in F^*$ is coprime to $\mathfrak{n}$, then the conductor of E^d is divisible by $d^2\mathfrak{n}$.*

Proof. There are choices of Weierstrass equations such that $\Delta(E^d) = 2^{12}d^6\Delta(E)$, where Δ is the discriminant. Thus the curve E^d has bad reduction at each prime that divides d, because twisting introduces a 6th power of the squarefree d into the discriminant, and d is coprime to $\Delta(E)$, so no change of Weierstrass equation can remove this 6th power. Moreover, E^d is isomorphic to E over an extension of the base field, so E^d has potentially good reduction at each prime dividing d. Thus the reduction at each prime dividing d is additive. The conductor is unchanged at the primes dividing $\mathfrak{n}$ because of the formula relating the conductor, discriminant and reduction type (see [Sil92, App. C,§15]), that formation of Néron models commutes with unramified base change, and the fact that at the primes that divide $\mathfrak{n}$ the minimal discriminant of E^d is the same as that of E. □

To find all twists E^d with norm conductor at most B, we twist E by all d of the form $\pm\varphi^\delta d_0 d_1$, where $\delta \in \{0,1\}$, d_0 is a product of a fixed choice of generators for the prime divisors of $\mathfrak{n}$, d_1 is a squarefree product of a fixed choice of generators of primes not dividing $\mathfrak{n}$, and $|\mathbf{N}(d_1)| \le \sqrt{B/C}$, where C is the norm of the product of the primes that exactly divide $\mathfrak{n}$. We know from 3.3 that this search is exhaustive.

For example, let E be given by $y^2+xy+\varphi y = x^3+(-\varphi-1)\,x^2$ of conductor $5\varphi-3$ having norm 31. Following the above strategy to find twists of norm conductor $\le B := 1831$, we have $C = 31$ and square-free d_1 such that $|\mathbf{N}(d_1)| \le \sqrt{B/C} \approx 7.6\ldots$. Thus $d_1 \in \{1,2,\varphi,2\varphi\}$ and checking all possibilities for $\varphi^\delta d_0 d_1$, we find the curve $E^{-\varphi-2}$ having norm conductor 775 and the curve $E^{5\varphi-3}$ having norm conductor 961. Other twists have larger norm conductors, e.g., E^2 has norm conductor $126976 = 2^{12}\cdot 31$.

3.6. **Curves with good reduction outside S.** We use the algorithm of Cremona and Lingham from [CL07] to find all elliptic curves E having good reduction at primes outside of a finite set $\mathcal{S}$ of primes in F. This algorithm has limitations over a general number field K due to the difficulty of finding a generating set for $E(K)$ and points on E defined over $\mathcal{O}_K$. Using Cremona's Magma implementation of the algorithm, we found several curves not found by other methods, e.g., y^2+

$(\varphi+1)\,xy+y = x^3-x^2+(-19\varphi-39)\,x+(-143\varphi-4)$, which has norm conductor 1331.

3.7. **Special values of twisted L-series.** In [Dem08], Lassina Dembélé outlines some methods for finding modular elliptic curves from Hilbert modular forms over real quadratic fields. Formally, these methods are not proven to be any better than a direct search procedure, as they involve making a large number of guesses, and a priori we do not know just how many guesses we will need to make. And unlike other methods described in this paper, this method requires many Hecke eigenvalues, and computing these takes a lot of time. However, this method certainly works extremely well in many cases, and after tuning it by using large tables of curves that we had already computed, we are able to use it to find more curves that we would have had no hope of finding otherwise; we will give an example of one of these curves later.

When the level $\mathfrak{n}$ is not square, Dembélé's method relies on computing or guessing periods of the curve by using special values of L-functions of twists of the curve. In particular, the only inputs required are the level of the Hilbert modular form and its L-series. So we suppose that we know the level $\mathfrak{n}=(N)$ of the form, where N is totally positive, and that we have sufficiently many coefficients of its L-series $a_{\mathfrak{p}_1}, a_{\mathfrak{p}_2}, a_{\mathfrak{p}_3}, \ldots$.

Let σ_1 and σ_2 denote the embeddings of F into the real numbers, with $\sigma_1(\varphi)\approx 1.61803\ldots$. For an elliptic curve E over F we get two associated embeddings into the complex numbers, and hence a pair of period lattices. We let Ω_E^+ and Ω_E^-, which we refer to as the periods of E, be the least real and imaginary periods of the lattice which come from the embedding σ_1, and as the period lattices are interchanged when E is replaced with its conjugate curve, we let $\Omega_{\overline{E}}^+$ and $\Omega_{\overline{E}}^-$ denote the least real and imaginary periods of the lattice under the embedding σ_2.

For ease, we write

$$\begin{aligned} \Omega_E^{++} &= \Omega_E^+\Omega_{\overline{E}}^+ & \qquad \Omega_E^{+-} &= \Omega_E^+\Omega_{\overline{E}}^- \\ \Omega_E^{-+} &= \Omega_E^-\Omega_{\overline{E}}^+ & \qquad \Omega_E^{--} &= \Omega_E^-\Omega_{\overline{E}}^-. \end{aligned}$$

We refer to these numbers as the *mixed periods* of E.

3.7.1. *Recovering the curve from its mixed periods.* If we know these mixed periods to sufficient precision, it is not hard to recover the curve E. Without the knowledge of the discriminant of the curve, we do not know the lattice type of the curve and its conjugate, but there are only a few possibilities for what they might be. This gives us a few possibilities for the j-invariant of E. Observe that $\sigma_1(j(E))$ is either $j(\tau_1(E))$ or $j(\tau_2(E))$ and $\sigma_2(j(E))$ is either $j(\tau_1(\overline{E}))$ or $j(\tau_2(\overline{E}))$, where

$$\begin{aligned} \tau_1(E) &= \frac{\Omega_E^{-+}}{\Omega_E^{++}} = \frac{\Omega_E^-}{\Omega_E^+} & \qquad \tau_2(E) &= \frac{1}{2}\left(1+\frac{\Omega_E^{-+}}{\Omega_E^{++}}\right) = \frac{1}{2}\left(1+\frac{\Omega_E^-}{\Omega_E^+}\right) \\ \tau_1(\overline{E}) &= \frac{\Omega_E^{+-}}{\Omega_E^{++}} = \frac{\Omega_{\overline{E}}^-}{\Omega_E^+} & \qquad \tau_2(\overline{E}) &= \frac{1}{2}\left(1+\frac{\Omega_E^{+-}}{\Omega_E^{++}}\right) = \frac{1}{2}\left(1+\frac{\Omega_{\overline{E}}^-}{\Omega_{\overline{E}}^+}\right) \end{aligned}$$

and $j(\tau)$ is the familiar

$$j(\tau) = e^{-2\pi i\tau} + 744 + 196884e^{2\pi i\tau} + 21493760e^{4\pi i\tau} + \cdots .$$

We try each pair of possible embeddings for $j(E)$ in turn, and recognize possibilities for $j(E)$ as an algebraic number. We then construct curves E' corresponding to each possibility for $j(E)$. By computing a few $a_{\mathfrak{p}}(E)$, we should be able to determine whether we have chosen the correct j-invariant, in which case E' will be a twist of E. We can then recognize which twist it is in order to recover E.

In practice, of course, as we have limited precision, and as $j(E)$ will not be an algebraic integer, it may not be feasible to directly determine its exact value, especially if its denominator is large.

To get around the problem of limited precision, we suppose that we have some extra information; namely, the discriminant Δ_E of the curve we are looking for. With Δ_E in hand we can directly determine which τ to choose: if $\sigma_1(\Delta_E) > 0$ then $\sigma_1(j(E)) = j(\tau_1(E))$, and if $\sigma_1(\Delta_E) < 0$ then $\sigma_1(j(E)) = j(\tau_2(E))$, and similarly for σ_2. We then compute $\sigma_1(c_4(E)) = (j(\tau)\sigma_1(\Delta_E))^{1/3}$ and $\sigma_2(c_4(E)) = (j(\tau')\sigma_2(\Delta_E))^{1/3}$.

Using the approximations of the two embeddings of c_4, we can recognize c_4 approximately as an algebraic integer. Specifically, we compute

$$\alpha = \frac{\sigma_1(c_4) + \sigma_2(c_4)}{2} \quad \text{and} \quad \beta = \frac{\sigma_1(c_4) - \sigma_2(c_4)}{2\sqrt{5}}.$$

Then $c_4 = \alpha + \beta\sqrt{5}$, and we can find c_6.

In practice, there are two important difficulties we must overcome: we do not know Δ_E and it may be quite difficult to get high precision approximations to the mixed periods, and thus we may not be able to easily compute c_4. Thus, we actually proceed by choosing a Δ_{guess} from which we compute half-integers α and β and an integer $a + b\varphi \approx \alpha + \beta\sqrt{5}$, arbitrarily rounding either a or b if necessary. We then make some choice of search range M, and for each pair of integers m and n, bounded in absolute value by M, we try each $c_{4,\text{guess}} = (a + m) + (b + n)\varphi$.

Given $c_{4,\text{guess}}$, we attempt to solve

$$c_{6,\text{guess}} = \pm\sqrt{c_{4,\text{guess}}^3 - 1728\Delta_{\text{guess}}},$$

and, if we can, we use these to construct a curve E_{guess}. If E_{guess} has the correct conductor and the correct Hecke eigenvalues, we declare that we have found the correct curve; otherwise, we proceed to the next guess.

For a choice of Δ_{guess}, we will generally start with the conductor N_E, and then continue by trying unit multiples and by adding in powers of factors of N_E.

3.7.2. *Guessing the mixed periods.* We have thus far ignored the issue of actually finding the mixed periods of the curve that we are looking for. Finding them presents an extra difficulty as our procedure involves even more guesswork. Dembélé's idea is to use special values of twists of the L-function $L(f, s)$. Specifically, we twist by primitive quadratic Dirichlet characters over $\mathcal{O}_F$, which are homomorphisms $\chi : (\mathcal{O}_F/\mathfrak{c})^* \to \pm 1$, pulled back to $\mathcal{O}_F$.

In the case of odd prime conductor, which we will stick to here, there is just a single primitive quadratic character, which is the quadratic residue symbol. A simple way to compute it is by making a table of squares, or by choosing a primitive root of $g \in (\mathcal{O}_F/\mathfrak{c})^*$, assigning $\chi(g) = -1$, and again making a table by extending multiplicatively. Alternatively, one could use a reciprocity formula as described in [BS10]. For general conductor, one can compute with products of characters having prime conductor.

For a given f and a primitive χ, we can construct the twisted L-function

$$L(f,\chi,s) = \sum_{\mathfrak{m}\subseteq\mathcal{O}_F} \frac{\chi(m)a_{\mathfrak{m}}}{N(\mathfrak{m})^s},$$

where m is a totally positive generator of $\mathfrak{m}$. (Note that χ is not well defined on ideals, but *is* well defined on totally positive generators of ideals.) $L(f,\chi,s)$ will satisfy a functional equation similar to that of $L(f,s)$, but the conductor is multiplied by $\mathrm{Norm}(\mathfrak{c})^2$ and the sign is multiplied by $\chi(-N)$. The key to finding the mixed periods of E is contained in the following conjecture that Dembélé has distilled from [BDG04], and we have stated specifically for $\mathbb{Q}(\sqrt{5})$.

Conjecture 3.4. *If χ is a primitive quadratic character with conductor $\mathfrak{c}$ relatively prime to the conductor of E, with $\chi(\varphi) = s'$ and $\chi(1-\varphi) = s$, (where $s, s' \in \{+,-\} = \{\pm 1\}$), then*

$$\Omega_E^{s,s'} = c_\chi \tau(\overline{\chi}) L(E,\chi,1)\sqrt{5},$$

for some integer c_χ, where $\tau(\chi)$ is the Gauss sum

$$\tau(\chi) = \sum_{\alpha \bmod \mathfrak{c}} \chi(\alpha)\exp\left(2\pi i \operatorname{Tr}\left(\alpha/m\sqrt{5}\right)\right),$$

with m a totally positive generator of $\mathfrak{c}$.

Remark 3.5. The Gauss sum is more innocuous than it seems. For odd conductor $\mathfrak{c}$ it is of size $\sqrt{\mathrm{Norm}(\mathfrak{c})}$, while for an even conductor it is of size $\sqrt{2\,\mathrm{Norm}(\mathfrak{c})}$. Its sign is a 4-th root of unity, and whether it is real or imaginary can be deduced directly from the conjecture, as it matches with the sign of $\Omega_E^{s,s'}$. In particular, $\tau(\chi)$ is real when $\chi(-1) = 1$ and imaginary when $\chi(-1) = -1$, which is a condition on $\mathrm{Norm}(\mathfrak{c}) \bmod 4$, as $\chi(-1) \equiv \mathrm{Norm}(\mathfrak{c}) \pmod 4$. This can all be deduced, for example, from [BS10].

Also, note that Dembélé writes this conjecture with an additional factor of $4\pi^2$; this factor does not occur with the definition of $L(f,s)$ that we have given.

Remark 3.6. Contained in this conjecture is the obstruction to carrying out the method described here when $\mathfrak{n}$ is a square. In this case, the sign of $L(f,\chi,s)$ will be completely determined by whether or not $\chi(\varphi) = \chi(1-\varphi)$, so we can only obtain information about either Ω^{--} and Ω^{++} or Ω^{-+} and Ω^{+-}, and we need three of these values to find E.

With this conjecture in place, we can describe a method for guessing the mixed periods of E. Now, to proceed, we construct four lists of characters up to some conductor bound M (we are restricting to odd prime modulus here for simplicity, as primitivity is ensured, but this is not necessary):

$$S^{s,s'} = \{\chi \bmod \mathfrak{p} : \chi(\varphi) = s', \chi(1-\varphi) = s, (\mathfrak{p},\mathfrak{n}) = 1, \mathrm{Norm}(\mathfrak{p}) < M, \chi(-N) = \epsilon_E\}.$$

Here $s, s' \in \{+,-\} = \pm 1$ again. We will consider these lists to be ordered by the norms of the conductors of the characters in increasing order, and index their elements as $\chi_0^{s,s'}, \chi_1^{s,s'}, \chi_2^{s,s'}, \ldots$. For each character we compute the central value of the twisted L-function to get four new lists

$$\mathcal{L}^{s,s'} = \{i^{ss'}\sqrt{5\,\mathrm{Norm}(\mathfrak{p})}L(E,\chi,1), \chi \in S^{s,s'}\} = \{\mathcal{L}_0^{s,s'}, \mathcal{L}_1^{s,s'}, \ldots\}.$$

These numbers should now all be integer multiples of the mixed periods, so to get an idea of which integer multiples they might be, we compute each of the ratios

$$\frac{\mathcal{L}_0^{s,s'}}{\mathcal{L}_k^{s,s'}} = \frac{c_{\chi_0^{s,s'}}}{c_{\chi_k^{s,s'}}} \in \mathbb{Q}, \quad k = 1, 2, \ldots,$$

attempt to recognize these as rational numbers, and choose as an initial guess

$$\Omega_{E,\text{guess}}^{ss'} = \mathcal{L}_0^{s,s'} \left(\operatorname{lcm} \left\{ \text{numerator} \left(\frac{\mathcal{L}_0^{s,s'}}{\mathcal{L}_k^{s,s'}} \right), k = 1, 2, \ldots \right\} \right)^{-1}.$$

3.7.3. *An example.* We give an example of an elliptic curve that we were only able to find by using this method. At level $\mathfrak{n} = (-38\varphi + 26)$ we found a newform f, computed

$$a_{(2)}(f) = -1,\ a_{(-2\varphi+1)}(f) = 1,\ a_{(3)}(f) = -1,\\ a_{(-3\varphi+1)}(f) = -1,\ a_{(-3\varphi+2)}(f) = -6, \cdots, a_{(200\varphi-101)}(f) = 168$$

and determined, by examining the L-function, that the sign of the functional equation should be -1. (In fact, we do not really need to know the sign of the functional equation, as we would quickly determine that $+1$ is wrong when attempting to find the mixed periods.) Computing the sets of characters described above, and choosing the first 3 of each, we have

$$S^{--} = \{\chi_{(\varphi+6)}, \chi_{(7)}, \chi_{(7\varphi-4)}\}, \quad S^{-+} = \{\chi_{(-3\varphi+1)}, \chi_{(5\varphi-2)}, \chi_{(\varphi-9)}\}\\ S^{+-} = \{\chi_{(-4\varphi+3)}, \chi_{(5\varphi-3)}, \chi_{(-2\varphi+13)}\} \quad S^{++} = \{\chi_{(\varphi+9)}, \chi_{(9\varphi-5)}, \chi_{(\varphi+13)}\}.$$

By using the 5133 eigenvalues above as input to Rubinstein's `lcalc` [Rub11], we compute the lists of approximate values

$$\begin{aligned} \mathcal{L}^{--} &= \{-33.5784397862407, -3.73093775400387, -18.6546887691646\} \\ \mathcal{L}^{-+} &= \{18.2648617736017i, 32.8767511924831i, 3.65297235421633i\} \\ \mathcal{L}^{+-} &= \{41.4805656925342i, 8.29611313850694i, 41.4805677827298i\} \\ \mathcal{L}^{++} &= \{32.4909970742969, 162.454985515474, 162.454973589303\}. \end{aligned}$$

Note that `lcalc` will warn us that we do not have enough coefficients to obtain good accuracy, and we make no claim as far as the accuracy of these values is concerned. Hoping that the ends will justify the means, we proceed forward.

Dividing each list by the first entry, and recognizing the quotients as rational numbers, we get the lists

$$\begin{aligned} \{1.000, 9.00000000005519, 1.80000000009351\} &\approx \{1, 9, 9/5\} \\ \{1.000, 0.555555555555555, 5.00000000068986\} &\approx \{1, 5/9, 5\} \\ \{1.000, 4.99999999999994, 0.999999949610245\} &\approx \{1, 5, 1\} \\ \{1.000, 0.199999999822733, 0.200000014505165\} &\approx \{1, 1/5, 1/5\}, \end{aligned}$$

which may give an indication of the accuracy of our values. We now proceed with the guesses

$$\begin{aligned}
\Omega_{E,\text{guess}}^{--} &\approx -33.5784397862407/9 &&\approx -3.73093775402141\\
\Omega_{E,\text{guess}}^{-+} &\approx 18.2648617736017i/5 &&\approx 3.65297235472034i\\
\Omega_{E,\text{guess}}^{+-} &\approx 41.4805656925342i/5 &&\approx 8.29611313850683i\\
\Omega_{E,\text{guess}}^{++} &\approx 32.4909970742969 &&= 32.4909970742969.
\end{aligned}$$

These cannot possibly be all correct, as $\Omega_E^{--}\Omega_E^{++} = \Omega_E^{-+}\Omega_E^{+-}$. Still, we can choose any three and get a reasonable guess, and in fact we may choose all possible triples, dividing some of the guesses by small rational numbers, and choosing the fourth guess to be consistent with the first three; we build a list of possible embeddings of $j(E)$, which will contain the possibility $\sigma_1(j(E)) \approx 1.365554233954 \times 10^{12}$, $\sigma_2(j(E)) \approx 221270.95861123$, which is a possibility if

$$\Omega_E^{-+} = \Omega_{E,\text{guess}}^{-+},\quad \Omega_E^{+-} = \Omega_{E,\text{guess}}^{+-},\quad \Omega_E^{-+} = \frac{\Omega_{E,\text{guess}}^{-+}}{2},\quad \Omega_E^{++} = \frac{\Omega_{E,\text{guess}}^{++}}{8}.$$

Cycling through many discriminants, we eventually try

$$\Delta_{\text{guess}} = \varphi \cdot 2^5 \cdot (19\varphi - 13),$$

which leads us to the guess

$$\begin{aligned}
\sigma_1(c_{4,\text{guess}}) &= (\sigma_1(j(E))\sigma_1(\Delta_{\text{guess}}))^{1/3} \approx 107850.372979378\\
\sigma_2(c_{4,\text{guess}}) &= (\sigma_2(j(E))\sigma_2(\Delta_{\text{guess}}))^{1/3} \approx 476.625892034286.
\end{aligned}$$

We have enough precision to easily recognize this as

$$c_{4,\text{guess}} = \frac{108327 + 48019\sqrt{5}}{2} = 48019\varphi + 30154,$$

and

$$\sqrt{c_{4,\text{guess}}^3 - 1728\Delta_{\text{guess}}}$$

does in fact have two square roots: $\pm(15835084\varphi + 9796985)$. We try both of them, and the choice with the minus sign gives the curve

$$y^2 + \varphi xy + \varphi y = x^3 + (\varphi - 1)\,x^2 + (-1001\varphi - 628)\,x + (17899\varphi + 11079)\,,$$

which has the correct conductor. We compute a few values of $a_{\mathfrak{p}}$ for this curve, and it turns out to be the one that we are looking for.

4. Enumerating the curves in an isogeny class

Given an elliptic curve E/F, we wish to find representative isomorphism classes for all elliptic curves E'/F that are isogenous to E via an isogeny defined over F. The analogue of this problem over $\mathbb{Q}$ has an algorithmic solution as explained in [Cre97, §3.8]; it relies on:

(1) Mazur's theorem [Maz78] that if $\psi : E \to E'$ is a $\mathbb{Q}$-rational isogeny of prime degree, then $\deg(\psi) \leq 163$.

(2) Formulas of Vélu [Vél71] that provide a way to explicitly enumerate all p-isogenies (if any) with domain E. Vélu's formulas are valid for any number field, but so far there has not been an explicit generalization of Mazur's theorem for any number field other than $\mathbb{Q}$.

Remark 4.1. Assume the generalized Riemann hypothesis. Then work of Larson-Vaintrob from [LV] implies that there is an effectively computable constant C_F such that any prime degree isogeny over F has degree at most C_F.

Since we are interested in specific isogeny classes, we can use the algorithm described in [Bil11] that takes as input a specific non-CM elliptic curve E over a number field K, and outputs a provably finite list of primes p such that E might have a p-isogeny. The algorithm is particularly easy to implement in the case when K is a quadratic field, as explained in [Bil11, §2.3.4]. Using this algorithm combined with Vélu's formulas, we were able to enumerate *all* isomorphism classes of curves isogenous to the curves we found via the methods of Section 3, and thus divide our curves up into isogeny classes.

5. CM elliptic curves over F

In this section we make some general remarks about CM elliptic curves over F. The main surprise is that there are 31 distinct $\overline{\mathbb{Q}}$-isomorphism classes of CM elliptic curves defined over F, more than for any other quadratic field.

Proposition 5.1. *The field F has more isomorphism classes of CM elliptic curves than any other quadratic field.*

Proof. Let K be a quadratic extension of $\mathbb{Q}$. Let H_D denote the Hilbert class polynomial of the CM order $\mathcal{O}_D$ of discriminant D, so $H_D \in \mathbb{Q}[X]$ is the minimal polynomial of the j-invariant j_D of any elliptic curve $E = E_D$ with CM by $\mathcal{O}_D$. Since K is Galois, we have $j_D \in K$ if and only if H_D is either linear or quadratic with both roots in K. The D for which H_D is linear are the thirteen values $-3, -4, -7, -8, -11, -12, -16, -19, -27, -28, -43, -67, -163$. According to [Cre92], the D for which H_D is quadratic are the following 29 discriminants:

$$\begin{aligned}&-15, -20, -24, -32, -35, -36, -40, -48, -51, -52, -60,\\ &-64, -72, -75, -88, -91, -99, -100, -112, -115, -123,\\ &-147, -148, -187, -232, -235, -267, -403, -427.\end{aligned}$$

By computing discriminants of these Hilbert class polynomials, we obtain the following table:

Field	D so H_D has roots in field	Field	D so H_D has roots in field
$\mathbb{Q}(\sqrt{2})$	$-24, -32, -64, -88$	$\mathbb{Q}(\sqrt{21})$	-147
$\mathbb{Q}(\sqrt{3})$	$-36, -48$	$\mathbb{Q}(\sqrt{29})$	-232
$\mathbb{Q}(\sqrt{5})$	$-15, -20, -35, -40, -60,$	$\mathbb{Q}(\sqrt{33})$	-99
	$-75, -100, -115, -235$	$\mathbb{Q}(\sqrt{37})$	-148
$\mathbb{Q}(\sqrt{6})$	-72	$\mathbb{Q}(\sqrt{41})$	-123
$\mathbb{Q}(\sqrt{7})$	-112	$\mathbb{Q}(\sqrt{61})$	-427
$\mathbb{Q}(\sqrt{13})$	$-52, -91, -403$	$\mathbb{Q}(\sqrt{89})$	-267
$\mathbb{Q}(\sqrt{17})$	$-51, -187$		

The claim follows because the $\mathbb{Q}(\sqrt{5})$ row is largest, containing 9 entries. There are thus $31 = 2 \cdot 9 + 13$ distinct CM j-invariants in $\mathbb{Q}(\sqrt{5})$.

□

6. Related future projects

It would be natural to extend the tables to the first known curve of rank 3 over F, which may be the curve $y^2 + y = x^3 - 2x + 1$ of norm conductor $163^2 = 26569$. It would also be interesting to make a table in the style of [SW02], and compute analytic ranks of the large number of curves that we would find; this would benefit from Sutherland's `smalljac` program, which has very fast code for computing L-series coefficients. Some aspects of the tables could also be generalized to modular abelian varieties A_f attached to Hilbert modular newforms with not-necessarily-rational Hecke eigenvalues; in particular, we could enumerate the A_f up to some norm conductor, and numerically compute their analytic ranks.

7. Tables

As explained in Sections 3 and 4, assuming Conjecture 1.1, we found the complete list of elliptic curves with norm conductor up to 1831, which is the first norm conductor of a rank 2 curve over F. The complete dataset can be downloaded from [BDKM$^+$12].

In each of the following tables #isom refers to the number of curves, #isog refers to the number of classes, $\mathfrak{n}$ refers to the conductor of the given elliptic curve, and Weierstrass equations are given in the form $[a_1, a_2, a_3, a_4, a_6]$.

Table 7.1 gives the number of curves and isogeny classes we found. Note that in these counts we do not exclude conjugate curves, i.e., if σ denotes the nontrivial element of $\mathrm{Gal}(F/\mathbb{Q})$, then we count E and E^σ separately if they are not isomorphic.

Table 7.1. Curves over $\mathbb{Q}(\sqrt{5})$

rank	**#isog**	**#isom**	**smallest** Norm($\mathfrak{n}$)
0	745	2174	31
1	667	1192	199
2	2	2	1831
total	1414	3368	-

Table 7.2 gives counts of the number of isogeny classes of curves in our data of each size; note that we find some isogeny classes of cardinality 10, which is bigger than what one observes with elliptic curves over $\mathbb{Q}$.

Table 7.2. Number of Isogeny classes of a given size

	size							
bound	1	2	3	4	6	8	10	**total**
199	2	21	3	20	8	9	1	64
1831	498	530	36	243	66	38	3	1414

Table 7.3 gives the number of curves and classes up to a given norm conductor bound. Note that the first curve of rank 1 has norm conductor 199, and there are no curves of norm conductor 200.

TABLE 7.3. Counts of classes and curves with bounded norm conductors and specified ranks

Table 7.4 gives the number of curves and classes with isogenies of each degree; note that we do not see all possible isogeny degrees. For example, the elliptic curve $X_0(19)$ has rank 1 over F, so there are infinitely many curves over F with degree 19 isogenies (unlike over $\mathbb{Q}$ where $X_0(19)$ has rank 0). We also give an example curve (that need not have minimal conductor) with an isogeny of the given degree.

TABLE 7.4. Isogeny degrees

degree	**#isog**	**#isom**	**example curve**	Norm($\mathfrak{n}$)
None	498	498	$[\varphi+1, 1, 1, 0, 0]$	991
2	652	2298	$[\varphi, -\varphi+1, 0, -4, 3\varphi-5]$	99
3	289	950	$[\varphi, -\varphi, \varphi, -2\varphi-2, 2\varphi+1]$	1004
5	65	158	$[1, 0, 0, -28, 272]$	900
7	19	38	$[0, \varphi+1, \varphi+1, \varphi-1, -3\varphi-3]$	1025

Table 7.5 gives the number of curves with each torsion structure, along with an example curve (again, not necessarily with minimal conductor) with that torsion structure.

Table 7.5. Torsion subgroups

structure	**#isom**	**example curve**	Norm($\mathfrak{n}$)
1	296	$[0,-1,1,-8,-7]$	225
$\mathbb{Z}/2\mathbb{Z}$	1453	$[\varphi,-1,0,-\varphi-1,\varphi-3]$	164
$\mathbb{Z}/3\mathbb{Z}$	202	$[1,0,1,-1,-2]$	100
$\mathbb{Z}/4\mathbb{Z}$	243	$[\varphi+1,\varphi-1,\varphi,0,0]$	79

46 Non-commutative Iwasawa theory for modular forms, with J. Coates, T. Dokchitser, Z. Liang, and R. Sujatha

NON-COMMUTATIVE IWASAWA THEORY FOR MODULAR FORMS

J. COATES, T. DOKCHITSER, Z. LIANG, W. STEIN, R. SUJATHA

Abstract. The aim of the present paper is to give evidence, largely numerical, in support of the non-commutative main conjecture of Iwasawa theory for the motive of a primitive modular form of weight $k > 2$ over the Galois extension of $\mathbb{Q}$ obtained by adjoining to $\mathbb{Q}$ all p-power roots of unity, and all p-power roots of a fixed integer $m > 1$. The predictions of the main conjecture are rather intricate in this case because there is more than one critical point, and also there is no canonical choice of periods. Nevertheless, our numerical data agrees perfectly with all aspects of the main conjecture, including Kato's mysterious congruence between the cyclotomic Manin p-adic L-function, and the cyclotomic p-adic L-function of a twist of the motive by a certain non-abelian Artin character of the Galois group of this extension.

1. Introduction

Let z be a variable in the upper half complex plane, and put $q = e^{2\pi i z}$. Let

$$f(z) = \sum_{n=1}^{\infty} a_n q^n, \tag{1}$$

be a primitive cusp form of conductor N (in the sense of [18]), with trivial character, and weight $k > 2$. For simplicity, we shall always assume that the Fourier coefficients a_n $(n \geq 1)$ of f are in $\mathbb{Q}$. Let p be an odd prime number. The aim of the present paper is to provide some evidence, largely numerical, for the validity of the non-commutative main conjecture of Iwasawa theory for the motive $M(f)$ attached to f over the p-adic Lie extension

$$F_\infty = \mathbb{Q}(\mu_{p^\infty}, m^{1/p^n}, n = 1, 2, \dots),$$

which is obtained by adjoining to $\mathbb{Q}$ the group μ_{p^∞} of all p-power roots of unity, and all p-power roots of some fixed integer $m > 1$. In this case, the analytic continuation and functional equation for the complex L-function $L(f, \phi, s)$ of f twisted by any Artin character ϕ of the Galois group of F_∞ over $\mathbb{Q}$ are well-known consequences of the theory of automorphic base change. The points $s = 1, \dots, k-1$ are critical for all of the complex L-functions $L(f, \phi, s)$, and we show that essentially the same arguments as in [1] enable one to prove the expected algebraicity statement at these points. Moreover, these values

2000 *Mathematics Subject Classification.* Primary 11F67; Secondary 11F33, 11R23.

T. Dokchitser was supported by a Royal Society University Research Fellowship, Z. Liang by the National Natural Sciences Foundation of China (Grant Nos. 11001183 and 11171231), W. Stein from NSF Grant DMS-1015114, and R. Sujatha from NSERC Grant 22R65339.

are all non-zero, except perhaps for the central value $s = k/2$; in particular, there is always at least one non-zero critical value since $k > 2$.

In [2], a precise main conjecture was formulated for an elliptic curve over any p-adic Lie extension of a number field F containing the cyclotomic $\mathbb{Z}_p$-extension of F, and under the assumption that the elliptic curve is ordinary at the prime p. This was generalized to arbitrary ordinary motives in [8], and it is a special case of the main conjecture of [8] which we consider here. Thus we assume that p is an odd prime number such that $(p, a_p) = (p, N) = 1$. One of the underlying ideas of the non-commutative main conjecture is to prove the existence of a p-adic L-function, which interpolates a canonical normalization of the critical values $L(f, \phi, n)$, where $n = 1, \ldots, k-1$, and ϕ runs over all Artin representations of the Galois group

$$G = \mathrm{Gal}(F_\infty/\mathbb{Q}).$$

We denote these normalized L-values by $\mathcal{L}_p^{\mathrm{can}}(f, \phi, n)$ (for the precise definition, see formulae (68), (69) and (71) in §5). The definition of these normalized L-values requires making a choice of canonical periods for the form f, and, until such a time as the main conjectures of non-commutative Iwasawa theory are fully proven, we are only able to make an educated guess at present as to what these canonical periods should be. However, as we explain in §5, Manin's work on the construction of the p-adic L-function for our modular form f over the field $\mathbb{Q}(\mu_{p^\infty})$ gives some information about these canonical periods, which is relevant for our numerical examples.

As we explain in more detail in §5, the existence of a p-adic L-function attached to f over the non-abelian extension F_∞ of $\mathbb{Q}$, when combined with the work of Kato [14], implies the existence of the following mysterious congruence between two p-adic L-functions attached to f over certain abelian sub-extensions of $F_\infty/\mathbb{Q}$. We are very grateful to M. Kakde for explaining to us how this congruence follows from Kato's work. Let σ denote the $(p-1)$-dimensional representation of G given by the direct sum of the irreducible representations of $\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$. Let ρ be the unique irreducible representation of dimension $p-1$ of the Galois group of the field

$$F = \mathbb{Q}(\mu_p, m^{1/p})$$

over $\mathbb{Q}$, where we now assume that $m > 1$ is p-power free. Write $\mathbb{Q}^{\mathrm{cyc}}$ for the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$, and Ξ for the group of irreducible characters of finite order of $\Gamma = \mathrm{Gal}(\mathbb{Q}^{\mathrm{cyc}}/\mathbb{Q})$. Further, let χ_p denote the character giving the action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ on μ_{p^∞}. We fix a topological generator γ of Γ, and put $u = \chi_p(\gamma)$. The work of Manin [16] proves that there exists a unique power series $H(\sigma, T)$ in the ring $R = \mathbb{Z}_p[[T]]$ such that

$$H(\sigma, \psi(\gamma)u^r - 1) = \mathcal{L}_p^{\mathrm{can}}(f, \sigma\psi, k/2 + r), \tag{2}$$

for all ψ in Ξ, and all integers r with $-k/2 + 1 \leq r \leq k/2 - 1$. On the other hand, the conjectural existence of a good p-adic L-function for f over the field F_∞ would imply, in particular, the existence of a power series $H(\rho, T)$ in the ring R such that

$$H(\rho, \psi(\gamma)u^r - 1) = \mathcal{L}_p^{\mathrm{can}}(f, \rho\psi, k/2 + r), \tag{3}$$

for all ψ in Ξ, and all integers r with $-k/2+1 \leq r \leq k/2-1$. Then Kato's work [14] implies the following conjectural congruence between formal power series

$$H(\rho, T) \equiv H(\sigma, T) \mod pR. \tag{4}$$

This conjectural congruence in R has the following consequences for our critical L-values. Firstly, on evaluation of our power series at the relevant point in $p\mathbb{Z}_p$, we deduce from (2) and (3) that the congruence

$$\mathcal{L}_p^{\mathrm{can}}(f, \rho, n) \equiv \mathcal{L}_p^{\mathrm{can}}(f, \sigma, n) \bmod p\mathbb{Z}_p \tag{5}$$

should hold for $n = 1, \ldots, k-1$. Secondly, if we assume the additional property that

$$L(f, \sigma, k/2) = L(f, \rho, k/2) = 0, \tag{6}$$

then we would have that $H(\rho, T)$ and $H(\sigma, T)$ both belong to the ideal TR. It is then clear from (2), (3) and (4) that the stronger congruence

$$\mathcal{L}_p^{\mathrm{can}}(f, \rho, n) \equiv \mathcal{L}_p^{\mathrm{can}}(f, \sigma, n) \bmod p^2\mathbb{Z}_p \tag{7}$$

should hold for $n = 1, \ldots, k-1$.

Our numerical computations (see §6) verify the first congruence (5) for the prime $p = 3$ and a substantial range of cube free integers $m > 1$, for three forms f of weight 4 and conductors 5, 7, 121, and one form f of weight 6 and conductor 5, all of which are ordinary at 3. These computations require us to determine numerically the Fourier coefficients a_n of these forms f for n in the range $1 \leq n \leq 10^8$. In addition, for the two forms of weight 4 and conductors 7 and 121, we prove that (6) holds for all integers $m > 1$, and happily, our numerical results show that the sharper congruence (7) holds for these two forms and the prime $p = 3$ for a good range of cube free integers $m > 1$. When f is a complex mutliplication form, some cases of the congruence (4) have already been established theoretically by Delbourgo and Ward [3] and Kim [15]. However, when f is not a complex multiplication form, our numerical data seems to provide the first hard evidence in support of the mysterious non-abelian congruence (4) between abelian p-adic L-functions.

We warmly thank T. Bouganis, M. Kakde, and D. Kim for very helpful advice on the writing of this paper.

2. Algebraicity of L-values

As in the Introduction, let f given by (1) be a primitive cusp form of conductor $N \geq 1$ with trivial character and weight $k > 2$ (thus k is necessarily even). For simplicity, we always assume that the Fourier coefficients $a_n\,(n \geq 1)$ of f belong to $\mathbb{Q}$. The complex L-function attached to f is

$$L(f, s) = \sum_{n=1}^{\infty} a_n/n^s. \tag{8}$$

This L-function has the following Euler product. For any prime p, let

$$\tau_p : \mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}_{\mathbb{Q}_p}(V_p) \tag{9}$$

be the p-adic Galois representation attached to f; here V_p is a two dimensional vector space over the field $\mathbb{Q}_p$ of p-adic numbers. If q is any prime distinct from p, define the polynomial

$$P_q(f, X) = \det(1 - \tau_p(\mathrm{Frob}_q^{-1})X \mid V_p^{I_q}), \tag{10}$$

where I_q is the inertial subgroup of the decomposition group of any fixed prime of $\bar{\mathbb{Q}}$ above q, and Frob_q denote the Frobenius automorphism of q. Moreover, if $(q, N) = 1$, we have

$$P_q(f, X) = 1 - a_q X + q^{k-1}X^2. \tag{11}$$

Then

$$L(f, s) = \prod_q P_q(f, q^{-s})^{-1} \tag{12}$$

when $\mathrm{Re}(s) > 1 + (k-1)/2$. Defining

$$\Lambda(f, s) = N^{s/2}(2\pi)^{-s}\Gamma(s)L(f, s), \tag{13}$$

we know, since Hecke, that $\Lambda(f, s)$ is entire and satisfies the functional equation

$$\Lambda(f, s) = w(f)\Lambda(f, k - s) \tag{14}$$

where $w(f) = \pm 1$ is the sign in the functional equation. The critical values of $L(f, s)$ are at the points $s = 1, \dots, k-1$. Following Shimura [23], [24], we introduce the following naive periods for f, which we have normalized in view of our later numerical calculations. Define

$$\Omega_-(f) = iw(f)(2\pi)^{-1}L(f, 1). \tag{15}$$

Since the Euler product for $L(f, s)$ converges to a positive real number when s is real and $s > 1 + (k-1)/2$, it is clear from the functional equation (14), that $\Omega_-(f)$ is purely imaginary in the upper half plane. Motivated again by numerical calculations, we assume throughout the following simplifying hypothesis (see [7] for examples in which this hypothesis fails).

Hypothesis H1: $L(f, 2) \neq 0$ when $k = 4$.

We then define

$$\Omega_+(f) = w(f)(2\pi)^{-2}\, L(f, 2). \tag{16}$$

Again, $\Omega_+(f)$ is always a positive real number when $k > 4$, and presumably (it would, of course, be implied by the generalized Riemann Hypothesis) this remains true even when $k = 4$, although this value is outside the region of convergence of the Euler product.

Theorem 2.1. (See [23],[24]) *(i) If n is an odd integer such that $1 \leq n \leq k-1$, then*

$$(2\pi i)^{-n} L(f,n)/\Omega_-(f) \in \mathbb{Q};$$

(ii) If n is an even integer such that $1 \leq n \leq k-1$, then

$$(2\pi i)^{-n} L(f,n)/\Omega_+(f) \in \mathbb{Q}.$$

In what follows, we shall mainly be interested in the L-functions of f twisted by Artin characters. We rapidly recall the definitions of these L-functions. By an Artin representation, we mean a homomorphism

$$\phi\,:\,\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}_{\bar{\mathbb{Q}}}(W) \tag{17}$$

which factors through the Galois group of a finite extension of $\mathbb{Q}$; here W is a vector space of finite dimension over $\bar{\mathbb{Q}}$. Put

$$d(\phi) = \dim_{\bar{\mathbb{Q}}}(W).$$

For each prime p, let

$$M_p(f) = V_p \otimes_{\mathbb{Q}_p} \bar{\mathbb{Q}}_p,\;\; M_p(\phi) = W \otimes_{\bar{\mathbb{Q}}} \bar{\mathbb{Q}}_p.$$

Then

$$L(f,\phi,s) = \prod_q P_q(f,\phi,q^{-s})^{-1}, \tag{18}$$

where

$$P_q(f,\phi,X) = \det\left((1-\mathrm{Frob}_q^{-1}X) \mid (M_p(f) \otimes_{\bar{\mathbb{Q}}_p} M_p(\phi))^{I_q}\right) \;\; (q \neq p) \tag{19}$$

is the Euler product attached to the tensor product Galois representation $M_p(f) \otimes_{\bar{\mathbb{Q}}_p} M_p(\phi)$. The Euler product (18) converges in the region $\mathrm{Re}(s) > 1 + (k-1)/2$. It is one of the fundamental problems of number theory to prove the analytic continuation and the following conjectural functional equation for $L(f,\phi,s)$. Let $N(f,\phi)$ be the conductor of the family of p-adic representations $M_p(f) \otimes_{\bar{\mathbb{Q}}_p} M_p(\phi)$, and define

$$\Lambda(f,\phi,s) = N(f,\phi)^{s/2} \left((2\pi)^{-s}\Gamma(s)\right)^{d(\phi)} L(f,\phi,s). \tag{20}$$

Then conjecturally

$$\Lambda(f,\phi,s) = w(f,\phi)\Lambda(f,\hat{\phi},k-s), \tag{21}$$

where $w(f,\phi)$ is an algebraic number of complex absolute value 1, and $\hat{\phi}$ is the contragredient representation of ϕ. There is one important case in which this result is known.

Theorem 2.2. *Let K be any finite Galois extension of $\mathbb{Q}$ with Galois group* $\mathrm{Gal}(K/\mathbb{Q})$ *abelian. Let ψ be an abelian character of K and define ϕ to be the induced character of* $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$. *Then $\Lambda(f,\phi,s)$ is entire and satisfies the functional equation* (21).

Proof. Since K is an abelian extension of $\mathbb{Q}$, the base change of f to K, which we denote by $\pi_K(f)$, exists as a cuspidal automorphic representation of GL_2/K. The results of Jacquet-Langlands then establish the analytic continuation and functional equation for the automorphic L-function of $\pi_K(f)$, twisted by the abelian character ψ of K, which we view as a Hecke character of GL_1/K. We denote this automorphic L-function by $L(\pi_K(f), \psi, s)$. On the other hand, by the theory of base change, and the local Langlands correspondence for GL_2, $L(\pi_K(f), \psi, s)$ coincides with $L(f, \phi, s)$ defined by the Euler product (18). This completes the proof on noting that the functional equation (21) coincides with the automorphic functional equation. □

The following conjectural generalisation of Theorem 2.1 is folklore. Given an Artin representation ϕ as in (17), define $d^+(\phi)$ (resp. $d^-(\phi)$) to be the dimension of the subspaces of W on which complex conjugation acts like $+1$, (resp. as -1). If n is any integer, we write

$$d_n^+(\phi) = d^{(-1)^n}(\phi), \; d_n^-(\phi) = d^{(-1)^{n+1}}(\phi). \tag{22}$$

Conjecture 2.3. *For every Artin representation ϕ of* $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$, *and all integers $n = 1, \dots, k-1$, we have*

$$\frac{L(f, \phi, n)}{\left((2\pi i)^{nd(\phi)} \times \Omega_+(f)^{d_n^+(\phi)} \times \Omega_-(f)^{d_n^-(\phi)}\right)} \in \bar{\mathbb{Q}}. \tag{23}$$

Of course, when ϕ has dimension 1, this conjecture is a well known consequence of the theory of higher weight modular symbols. However, as in [1], we shall study special cases of this conjecture by using the work of Shimura [23] on the special values of Rankin products of Hilbert modular forms for totally real number fields. Let K be an arbitrary totally real field, which is Galois over $\mathbb{Q}$, with $\mathrm{Gal}(K/\mathbb{Q})$ abelian. Take $\mathfrak{g}$ to be any Hilbert modular form relative to K, which corresponds to an Artin representation θ of dimension 2 of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$. The form $\mathfrak{g}$ has parallel weight 1 and level equal to the conductor of θ. We denote the Artin L-series of θ by

$$L(\theta, s) = \sum_{\mathfrak{a}} c(\mathfrak{a})(N\mathfrak{a})^{-s},$$

where $\mathfrak{a}$ runs over all integral ideals of K. Further, let $L(f/K, s)$ be the complex L-function attached to the restriction of the Galois representation (13) to $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$, and write

$$L(f/K, s) = \sum_{\mathfrak{a}} b(\mathfrak{a})(N\mathfrak{a})^{-s},$$

for its corresponding Dirichlet series. Since we have assumed K to be an abelian extension of $\mathbb{Q}$, the base change to K of our modular form f also exists as a primitive cusp form for the Hilbert modular group of K. We denote this base change by $\mathfrak{f}_K$. It has parallel weight k, trivial character, and level dividing $N\mathcal{O}_K$, where $\mathcal{O}_K$ is the ring of integers of K. In what follows, we will be primarily interested in the complex L-series defined by the tensor product of the Artin representation θ and the Galois representation (13) of f restricted to $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$. We denote this L-series by $L(\mathfrak{f}_K, \theta, s)$, and recall that it is defined by the Euler product

$$L(\mathfrak{f}_K, \theta, s) = \prod_v P_v(\mathfrak{f}_K, \theta, (Nv)^{-s})^{-1},$$

where v runs over all finite places of K, and

$$P_v(\mathfrak{f}_K, \theta, X) = \det\left(1 - \mathrm{Frob}_v^{-1} X \mid \left(M_p(f) \otimes_{\bar{\mathbb{Q}}_p} W_\theta\right)^{I_v}\right); \tag{24}$$

here W_θ is a two dimensional $\bar{\mathbb{Q}}_p$-vector space realizing θ, and I_v is the inertial subgroup of a place of $\bar{\mathbb{Q}}$ above v. Of course, by the inductive property of L-functions, we also have

$$L(\mathfrak{f}_K, \theta, s) = L(f, \phi_\theta, s), \tag{25}$$

where ϕ_θ is the Artin representation of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ induced from the representation θ of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$.

On the other hand, the classical theory of Rankin products (see [25, §4]) considers instead the complex L-series $\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s)$ defined by

$$\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s) = L_{\mathfrak{n}}(\psi, 2s - k + 1) \times \sum_{\mathfrak{a}} c(\mathfrak{a}) b(\mathfrak{a}) N(\mathfrak{a})^{-s} \tag{26}$$

with $\mathfrak{a}$ running over all integral ideals of K; here $\mathfrak{n}$ is the least common multiple of the levels of $\mathfrak{f}_K$ and $\mathfrak{g}$, ψ is the character of $\mathfrak{g}$, and $L_{\mathfrak{n}}(\psi, s)$ is the imprimitive L-series of ψ where the Euler factors at the primes dividing $\mathfrak{n}$ have been omitted. A well-known classical argument shows that $\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s)$ has the Euler product expansion

$$\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s) = \prod_v D_v(\mathfrak{f}_K, \mathfrak{g}, (Nv)^{-s})^{-1} \tag{27}$$

where

$$D_v(\mathfrak{f}_K, \mathfrak{g}, X) = \det\left(1 - \mathrm{Frob}_v^{-1} X \mid \left(M_p(f)^{I_v} \otimes_{\bar{\mathbb{Q}}_p} W_\theta^{I_v}\right)\right). \tag{28}$$

Thus the complex L-functions $L(\mathfrak{f}_K, \theta, s)$ and $\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s)$ coincide, except for the possible finite set of Euler factors at places v for which

$$\left(M_p(f) \otimes_{\bar{\mathbb{Q}}_p} W_\theta\right)^{I_v} \neq \left(M_p(f)^{I_v} \otimes_{\bar{\mathbb{Q}}_p} W_\theta^{I_v}\right). \tag{29}$$

To avoid this technical difficulty, we impose an additional simplifying hypothesis.

Lemma 2.4. *Assume that for each prime q such that $q^2 \mid N$, that q does not divide the conductor of the representation of* $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ *induced from θ. Then for every prime number p, and every finite place v of $\mathcal{K}$ which does not lie above p, we have*

$$\left(M_p(f) \otimes_{\bar{\mathbb{Q}}_p} W_\theta)\right)^{I_v} = (M_p(f))^{I_v} \otimes_{\bar{\mathbb{Q}}_p} (W_\theta)^{I_v}, \tag{30}$$

where I_v denotes the inertial subgroup at v. In particular, $\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s) = L(\mathfrak{f}_K, \theta, s)$.

Proof. Suppose that v lies above a prime q, where $q \neq p$. Assume first that $(q, N) = 1$. Then I_q, and hence also I_v, acts trivially on $M_p(f)$, and so (30) is plain. Suppose next that q divides N but q^2 does not divide N. Then it is well known that the image of I_q, hence also that of I_v, in the automorphism group of $M_p(f)$ is infinite, and that $M_p(f)^{I_q}$ has dimension one over $\bar{\mathbb{Q}}_p$. Clearly the same assertions remain valid if we replace I_q by any open subgroup I'_q of I_q. Thus we must have $M_p(f)^{I_v} = M_p(f)^{I'_v}$ for every open subgroup I'_v of I_v. Since some open subgroup of I_v acts trivially on W_θ, (30) follows immediately. Finally, if q^2 divides N, the hypothesis of the lemma shows that I_v acts trivially on W_θ, whence (30) is again clearly true.

□

Our next result relates the automorphic period of $\mathfrak{f}_K$ to the periods $\Omega^+(f)$ and $\Omega^-(f)$. We normalize the Petersson inner product on the space of cusp forms of level dividing $N\mathcal{O}_K$ for the Hilbert modular group of K as in [25] (see formula (2.7) on p. 651).

Proposition 2.5. *Let K be a real abelian field, and write $\mathfrak{f}_K$ for the base change of f to K. Then*

$$\frac{(2\pi i)^{(1-k)\beta}\pi^{\beta k}\langle \mathfrak{f}_K, \mathfrak{f}_K\rangle_K}{(\Omega_+(f) \times \Omega_-(f))^\beta} \in \mathbb{Q}, \tag{31}$$

where $\beta = [K : \mathbb{Q}]$.

We shall use the following notation in the proof of this proposition. If ψ is any abelian character of K, write $L(f/K, \psi, s)$ for the primitive L-function attached to the tensor product of ψ with the restriction of (13) to $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$. Also, for any abelian character χ of $\mathbb{Q}$, we write χ_K for the restriction of χ to $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$.

Lemma 2.6. *Let K be any real abelian extension of $\mathbb{Q}$ and η any abelian character of $\mathbb{Q}$. Then there exists an abelian character χ of $\mathbb{Q}$ as follows. For all σ in $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$, we have*

1. $L(f/K, \chi_K^\sigma, k/2) \neq 0$ and $L(f/K, \chi_K^\sigma\eta_K, k/2) \neq 0$;
2. *$L(f/K, \chi_K^\sigma, s)$ (resp. $L(f/K, \chi_K^\sigma\eta_K, s)$) has Euler factor equal to 1 at all places of K where χ_K^σ (resp. $\chi_K^\sigma\eta_K$) is ramified.*

Proof. Let Σ be any finite set of primes of $\mathbb{Q}$ containing the primes dividing N, the primes dividing the conductor of η, and the primes which ramify in K. By an important theorem of Rohrlich [22], there exists a finite abelian extension M of $\mathbb{Q}$, unramified outside Σ, such that $L(f, \lambda, k/2) \neq 0$ for every abelian character λ of $\mathbb{Q}$ that is unramified outside Σ, and which does not factor through $\mathrm{Gal}(M/\mathbb{Q})$. By enlarging M if necessary, we can assume that $M \supset K$. Let $\mathcal{N}_K$ be the conductor of f/K, and $\Delta_{M/K}$ the relative discriminant of M over K. Also, if ξ is an abelian character of K, write $\mathcal{N}(\xi)$ for its conductor. Let χ be any abelian character of $\mathbb{Q}$ such that, for every prime v of K above Σ, we have

$$\mathrm{ord}_v(\mathcal{N}(\chi_K)) > \max\bigl\{\mathrm{ord}_v(\Delta_{M/K}), \mathrm{ord}_v(\mathcal{N}(\eta)), \mathrm{ord}_v(\mathcal{N}_K)\bigr\}. \tag{32}$$

Such a character can always be found by taking a character of $\mathrm{Gal}(\mathbb{Q}(\mu_m)/\mathbb{Q})$ for sufficiently large m. Let v be any place of K above Σ, and put

$$t_v = \max\bigl\{\mathrm{ord}_v(\Delta_{M/K}), \mathrm{ord}_v(\mathcal{N}_K)\bigr\}.$$

Thanks to (32), it is clear, that for each σ in $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$, we have

$$\operatorname{ord}_v(\mathcal{N}(\chi_K^\sigma)) = \operatorname{ord}_v(\mathcal{N}(\chi_K^\sigma\eta)) > t_v. \tag{33}$$

In particular, none of these characters can factor through $\mathrm{Gal}(M/K)$. Moreover, it is also easily seen from (33) that

$$\left(M_p(f)\otimes_{\bar{\mathbb{Q}}_p}\chi_K^\sigma\right)^{I_v} = \left(M_p(f)\otimes_{\bar{\mathbb{Q}}_p}\chi_K^\sigma\eta\right)^{I_v} = 0,$$

whence the final assertion of the lemma is clear. □

We now prove that the left hand side of (31) is an algebraic number. Take $J = K(i)$, and let η be any abelian character of $\mathbb{Q}$ such that J is the fixed field of the kernel of η_K. Now let χ be an abelian character of $\mathbb{Q}$ having the properties specified in Lemma 2.6, and write χ_J for the restriction of χ to $\mathrm{Gal}(\bar{\mathbb{Q}}/J)$. Note that the representation of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$ induced by χ_J is $\theta = \chi_K \oplus \chi_K\eta_K$. Write $\mathfrak{g}$ for the Hilbert modular form relative to K which corresponds to θ. Thus $\mathfrak{g}$ has parallel weight one, and character $\eta_K\chi_K^2$. Moreover, by the second assertion of Lemma 2.5, we have the exact equality of L-functions

$$\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s) = L(f/K, \theta, s). \tag{34}$$

On the other hand, since K is abelian over $\mathbb{Q}$, we also have the identity

$$L(f/K,\theta,s) = \prod_{j=1}^{\beta} L(f,\chi\zeta_j,s)L(f,\chi\eta\zeta_j,s), \tag{35}$$

where $\zeta_1,\dots,\zeta_d$ denote the characters of $\mathrm{Gal}(K/\mathbb{Q})$.

The desired algebraicity assertion follows by evaluating both sides of (35) at $s = k/2$, noting that this common value is non-zero by Lemma 2.6, and then applying Shimura's algebraicity results to each L-function. Indeed, Theorem 4.2 of [25] shows that

$$\frac{\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, k/2)}{(2\pi i)^\beta \pi^{\beta k}\langle \mathfrak{f}_K, \mathfrak{f}_K\rangle \tau_K(\eta_K\chi_K^2)} \in \bar{\mathbb{Q}}, \tag{36}$$

where $\tau_K(\eta_K\chi_K^2)$ denotes the Gauss sum for the character $\eta_K\chi_K^2$ of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$ (see (3.9) of [25] for the definition of this Gauss sum). On the other hand, recalling that $\chi\zeta_j(-1) \neq \chi\zeta_j\eta(-1)$ for $j = 1,\dots,\beta$, it follows from [24, Theorem 1] that

$$\frac{\prod_{j=1}^{\beta} L(f,\chi\zeta_j,k/2)\times L(f,\chi\eta\zeta_j,k/2)}{(2\pi i)^{\beta k}\times(\Omega_+(f)\Omega_-(f))^\beta\times\prod_{j=1}^{\beta}\tau_{\mathbb{Q}}(\chi\zeta_j)\tau_{\mathbb{Q}}(\chi\eta\zeta_j)} \in \bar{\mathbb{Q}}; \tag{37}$$

here $\tau_{\mathbb{Q}}(\kappa)$ denotes the usual Gauss sum of an abelian character κ of $\mathbb{Q}$. Combining (36)and (37), it follows immediately that the left hand side of (31) is an algebraic number. Moreover, a more detailed analysis, exactly as in the proof of [1, Theorem 3.4] shows that this algebraic number is invariant under the action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$, completing the proof of Proposition 2.5. □

As a first application of Proposition 2.5, we establish the following case of Conjecture 2.3.

Theorem 2.7. *Assume F is an imaginary number field with* $\mathrm{Gal}(F/\mathbb{Q})$ *abelian. Let ψ be any abelian character of* $\mathrm{Gal}(\bar{\mathbb{Q}}/F)$*, and let ϕ be the induced character of* $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$*. Assume that, for every prime q such that q^2 divides N, q does not divide the conductor of ϕ. Then Conjecture 2.3 is valid for f and ϕ.*

Proof. Let K be the maximal real subfield of F, and let θ be the representation of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$ induced from ψ. Thus θ is a two dimensional Artin representation of $\mathrm{Gal}(\bar{\mathbb{Q}}/K)$, and we let $\mathfrak{g}$ be the associated Hilbert modular form as above. Then, by Lemma 30,

$$\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, s) = L(\mathfrak{f}_K, \theta, s) = L(f, \phi, s). \tag{38}$$

But, assuming n is an integer with $1 \leq n \leq k-1$, it is shown in [25, (4.10)] that

$$\frac{(2\pi i)^{-2n\beta}\mathcal{D}(\mathfrak{f}_K, \mathfrak{g}, n)}{(2\pi i)^{\beta(1-k)}\pi^{\beta k}\langle \mathfrak{f}_K, \mathfrak{f}_k\rangle_K} \in \bar{\mathbb{Q}}. \tag{39}$$

Now making use of Lemma 2.6, and noting that

$$d(\phi) = 2\beta,\ d_n^+(\phi) = d_n^-(\phi) = \beta,$$

the algebraicity statement (23) follows on putting $s = n$ in (38). This completes the proof of Theorem 2.7. □

Again following the ideas of [1], we now prove a refined version of Conjecture 2.3 for Artin representations ϕ which factor through the Galois group over $\mathbb{Q}$ of the field

$$F_r = \mathbb{Q}(\mu_{p^r}, m^{1/p^r}); \tag{40}$$

here p is an odd prime number, $r \geq 1$ is an integer, μ_{p^r} is the group of p^r-th roots of unity, and m is an integer > 1. For simplicity, we shall always assume that m is not divisible by the p-th power of an integer > 1. In order to state the refinement of (23), we first recall the epsilon-factors of the Artin representation ϕ (for a fuller discussion, see [5, §6.2]). Fix the Haar measure μ on $\mathbb{Q}_p$ determined by $\mu(\mathbb{Z}_p) = 1$, and the additive character α of $\mathbb{Q}_p$ given by

$$\alpha(zp^{-t}) = e^{2i\pi z/p^t}, \text{ for } z \in \mathbb{Z}_p.$$

Write $\epsilon_p(\phi)$ for the local epsilon-factor of ϕ at the prime p, which is uniquely determined by this choice of μ and α. For each integer $n = 1, \ldots, k-1$, define

$$L_p^*(f, \phi, n) = \frac{L(f, \phi, n)\epsilon_p(\phi)}{\left((2\pi i)^{nd(\phi)} \times \Omega_+(f)^{d_n^+(\phi)} \times |\Omega_-(f)|^{d_n^-(\phi)}\right)} \tag{41}$$

Hypothesis H2: For all primes q such that q^2 divides N, we have $(q, mp) = 1$.

Theorem 2.8. *Assume that the Artin representation ϕ factors through* $\mathrm{Gal}(F_r/\mathbb{Q})$ *for some integer $r \geq 1$, where F_r is given by* (40)*. Suppose in addition that Hypotheses H1* *and H2 are valid. Then* $\Lambda(f, \phi, s)$ *is entire, and satisfies the functional equation* (21). *Moreover, for all integers* $n = 1, \ldots, k-1$, $L_p^*(f, \phi, n)$ *is an algebraic number satisfying*

$$L_p^*(f, \phi, n)^\sigma = L_p^*(f, \phi^\sigma, n) \tag{42}$$

for all σ *in* $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$.

Proof. As remarked above, the proof we now give follows closely that given in [1], where f was assumed to have weight $k = 2$, and therefore corresponded to an isogeny class of elliptic curves defined over $\mathbb{Q}$. For each integer $r \geq 1$, define $\mathcal{K}_r = \mathbb{Q}(\mu_{p^r})$ and write K_r for its maximal real subfield. Note that $\mathrm{Gal}(F_r/\mathcal{K}_r)$ is cyclic of order p^r, since m is assumed to be p-power free. Put

$$F_\infty = \bigcup_{r \geq 1} F_r, \ \mathcal{K}_\infty = \bigcup_{r \geq 1} \mathcal{K}_r, \ G = \mathrm{Gal}(F_\infty/\mathbb{Q}). \tag{43}$$

For this proof, define ρ to be the representation of $\mathrm{Gal}(F_r/\mathbb{Q})$ induced by any character of exact order p^r of $\mathrm{Gal}(F_r/\mathcal{K}_r)$. It is then easy to see that ρ is irreducible, and that every irreducible Artin representation ϕ of G is of the form λ or $\rho\lambda$ for some integer $r \geq 1$,where λ is a one dimensional character of $\mathrm{Gal}(\mathcal{K}_\infty/\mathbb{Q})$. For the proof of Theorem 2.8, we may assume that ϕ is irreducible. Now it is clear from these remarks that every irreducible Artin representation ϕ of G is induced from an abelian character of $\mathcal{K}_r$ for some integer $r \geq 1$. Thus Theorem 2.2 implies that $\Lambda(f, \phi, s)$ is entire and satisfies the functional equation (21). Also, noting that $F_\infty/\mathbb{Q}$ is unramified outside of the primes dividing mp, we conclude from Theorem 2.7 that $L_p^*(f, \phi, n)$ is an algebraic number for all Artin characters ϕ of G and all integers $n = 1, \ldots, k-1$. Thus it remains to establish (42) for irreducible ϕ.

If $d(\phi) = 1$, one can easily deduce (42) from [23, Theorem 1]. Assuming $d(\phi) > 1$, it follows that for some integer $r \geq 1$, ϕ is induced by an abelian character of $\mathcal{K}_r$ of the form $\psi\lambda_{\mathcal{K}_r}$, where ψ is a character of $\mathrm{Gal}(F_r/\mathcal{K}_r)$ of exact order p^r, and $\lambda_{\mathcal{K}_r}$ is the restriction to $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathcal{K}_r)$ of a one dimensional character λ of $\mathrm{Gal}(\mathcal{K}_\infty/\mathbb{Q})$. We define θ to be the two dimensional Artin representation of $\mathrm{Gal}(\bar{\mathbb{Q}}/K_r)$ induced by $\psi\lambda_{\mathcal{K}_r}$, and take $\mathfrak{g}$ to be the corresponding Hilbert modular form relative to K_r of parallel weight one. Let ν be the abelian character of K_r defining the quadratic extension $\mathcal{K}_r/K_r$, and let λ_{K_r} be the restriction of λ to $\mathrm{Gal}(\bar{\mathbb{Q}}/K_r)$. Since the determinant of θ is equal to $\nu\lambda_{K_r}^2$, $\mathfrak{g}$ will have character $\nu\lambda_{K_r}^2$. Moreover, noting that Hypothesis H2 is valid for $\mathfrak{f}$ and ϕ because the conductor of ϕ can only be divisible by primes dividing mp, we conclude from Lemma 2.4 that

$$\mathcal{D}(\mathfrak{f}_{K_r}, \mathfrak{g}, s) = L(f_{K_r}, \theta, s) = L(f, \phi, s). \tag{44}$$

Taking $s = n$ with $1 \leq n \leq k-1$, it then follows from [25, Theorem 4.2] that

$$\mathcal{A}(f, \phi, n) := \frac{L(f, \phi, n)}{(2\pi i)^{d(\phi)(1+2n-k)/2} \times \pi^{kd(\phi)/2} \times \langle \mathfrak{f}_K, \mathfrak{f}_K \rangle_{K_r} \times \tau_{K_r}(\nu\lambda_{K_r}^2)} \tag{45}$$

satisfies

$$\mathcal{A}(f, \phi, n)^\sigma = \mathcal{A}(f, \phi^\sigma, n)$$

for all σ in $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$; here $\tau_{K_r}(\nu\lambda_{K_r}^2)$ is the Gauss sum of the abelian character $\nu\lambda_{K_r}^2$ of K_r, as defined by [25, (3.9)]. Noting that

$$d(\phi) = 2[K_r : \mathbb{Q}],\ d^+(\phi) = d^-(\phi) = [K_r : \mathbb{Q}],$$

we conclude easily from (31) and [1, Proposition 4.5] that the last assertion of Theorem 2.8 will hold if and only if

$$\left(\prod_{q \neq p,\infty} \epsilon_q(\phi)\right)^{\sigma} = \prod_{q \neq p,\infty} \epsilon_q(\phi^{\sigma}), \tag{46}$$

for all σ in $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$. But (46) is an immediate consequence of the fact that ρ can be realized over $\mathbb{Q}$, and the equation

$$\epsilon_q(\phi) = \epsilon_q(\lambda)^{\dim(\rho)} \operatorname{sgn}\left(\det(\rho)(q^{e_q(\rho)})\right),$$

which holds for all $q \neq p$, since λ is unramified at q; here $e_q(\rho) = \mathrm{ord}_q(\mathcal{N}(\rho))$, with $\mathcal{N}(\rho)$ denoting the conductor of ρ. This completes the proof. □

3. Interlude on root numbers

Recall that $F = \mathbb{Q}(\mu_p, m^{1/p})$. From now on, write ρ for the unique irreducible representation of $\mathrm{Gal}(F/\mathbb{Q})$ of dimension $p-1$; it is induced from any non-trivial character of $\mathrm{Gal}(F/\mathcal{K})$. We now describe the local root numbers

$$w_q(f,\rho) = \frac{\epsilon_q(f,\rho)}{|\epsilon_q(f,\rho)|}$$

and the corresponding global root number $w(f,\rho)$ under the hypothesis H2 above. This global root number is the sign in the functional equation of the twisted L-function $L(f,\rho,s)$. A similar computation in weight 2, i.e., for elliptic curves, was carried out by V. Dokchitser [6].

Theorem 3.1. *Let $f = \sum_n a_n e^{2\pi i n z}$ be a primitive cusp form of conductor N with trivial character, and weight $k \geq 2$. Assume that for all primes q such that $q^2 | N$, we have $(q, mp) = 1$. Then, for every finite prime q, the local root number $w_q(f,\rho)$ is given by*

$$w_q(f,\rho) = w_q(\rho)^2 \times \begin{cases} (\frac{q}{p})^{\mathrm{ord}_q(N)} & \text{if } (q,pm) = 1, \\ -\operatorname{sgn} a_p & \text{if } q = p,\ \mathrm{ord}_p(N) = 1 \text{ and } m^{p-1} \equiv 1 \mod p^2, \\ 1 & \text{otherwise.} \end{cases}$$

Further, the global root number is given by

$$w(f,\rho) = (-1)^{\frac{p-1}{2}}\, \delta \prod_{q \nmid pm} \left(\frac{q}{p}\right)^{\mathrm{ord}_q(N)},$$

where $\delta = -\operatorname{sgn} a_p$ when both $\mathrm{ord}_p(N) = 1$ and $m^{p-1} \equiv 1 \bmod p^2$, and 1 otherwise.

Proof. Let l be any prime distinct from q, and as before, let V_l be the l-adic Galois representation attached to f. Put $n(V) = \mathrm{ord}_q(N)$, and let $n(\rho)$ be such that $q^{n(\rho)}$ is the q-part of the conductor of ρ. We note that the determinant $\det\rho$ of ρ equals $(\frac{\cdot}{p})$, the non-trivial quadratic character of $\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$. Recall that the inverse local Euler factors of $L(f,s)$ are

$$P_q(f,T) = \begin{cases} 1 - a_qT + q^{k-1}T^2 & \text{if } \ (q,N) = 1, \\ 1 - a_qT & \text{if } \ \mathrm{ord}_q(N) = 1, \\ 1 & \text{if } \ \mathrm{ord}_q(N) \geq 2. \end{cases}$$

The local root numbers $w_q(f,\rho)$ can be computed as follows:-

Case 1 ($(q,N) = 1$): In this case V_l is unramified, and we can use the unramified twist formula [26, 3.4.6],

$$w_q(f,\rho) = w_q(\rho)^{\dim V_l} \cdot \mathrm{sgn}((\det V_l)(q^{n(\rho)})).$$

Here $\mathrm{sgn}\, z = \frac{z}{|z|}$ for $z \in \mathbb{C}$, and we evaluate the one-dimensional character $\det V$ on a number $q^{n(\rho)} \in \mathbb{Q}_q^\times$ via the local reciprocity map. The second term is trivial since $\det V_l$ is a power of a cyclotomic character which takes positive values on $\mathbb{Q}_q^\times$. Thus $w_q(f,\rho) = w_q(\rho)^2$, as asserted.

Case 2 ($\mathrm{ord}_q(N) = 1$): Here $a_q \neq 0, \dim V_l^{I_q} = 1$, the action of inertia I_q is unipotent $\left(\begin{smallmatrix} 1 & * \\ 0 & 1 \end{smallmatrix}\right)$, and the action of Frobenius is $\left(\begin{smallmatrix} a_q & * \\ 0 & a_q^{-1}p^{k/2} \end{smallmatrix}\right)$, where k is the weight of f; the top left corner can be seen e.g. from the local factor. Write $(V_l \otimes \rho)^{ss}$ for the semi-simplification of $V_l \otimes \rho$. Writing $\tau = \mathrm{Frob}_q$, the semi-simplification formula for ϵ-factors [26, 4.2.4] gives

$$\begin{aligned} w_q(f,\rho) &= w_q((V_l \otimes \rho)^{ss})\, \tfrac{\mathrm{sgn}\det(-\tau|((V_l\otimes\rho)^{ss})^{I_q})}{\mathrm{sgn}\det(-\tau|(V_l\otimes\rho)^{I_q})} \\ &= w_q(\rho \oplus \rho)\tfrac{\mathrm{sgn}\det(-a_q\tau|\rho^{I_q})\mathrm{sgn}\det(-a_q^{-1}p^{k/2}\tau|\rho^{I_q})}{\mathrm{sgn}\det(-a_q\tau|\rho^{I_q})} \\ &= \mathrm{sgn}\det(-a_q\tau|\rho^{I_q})^{-1} \\ &= w_q(\rho)^2\mathrm{sgn}(-a_q)^{d_q}\mathrm{sgn}\det(\tau|\rho^{I_q})^{-1}; \end{aligned}$$

here d_q denotes the dimension of ρ^{I_q}. It remains to determine ρ^{I_q} and the action of Frobenius on it. Let $J = \mathbb{Q}(m^{1/p})$. There is an equality of L-functions

$$\zeta_J(s) = \zeta(s)L(\rho,s).$$

By considering the ramification of q in $J/\mathbb{Q}$ and comparing the local factors at q, we find that

$$P_q(\rho,T) = \begin{cases} 1 + \cdots + (\frac{q}{p})T^{p-1} & \text{if } \ q \nmid pm, \\ 1 & \text{if } \ q|m, \\ 1 - T & \text{if } \ p = q \text{ and } m \text{ is a } p\text{th power in } \mathbb{Z}_p^\times, \\ 1 & \text{if } \ p = q \text{ and } m \text{ is not a } p\text{th power in } \mathbb{Z}_p^\times. \end{cases}$$

In particular, d_q is even (and so $\mathrm{sgn}\,(-a_q)^{d_q} = 1$) in all but the third case, and $\det(\tau|\rho^{I_q}) = 1$ in all but the first case; in the first case,

$$\det(\tau|\rho^{I_q}) = \det(\tau|\rho) = \Big(\frac{q}{p}\Big) = \Big(\frac{q}{p}\Big)^{\mathrm{ord}_q(N)},$$

as asserted by the formula. Finally, if $p \nmid m$, then it is easy to see by Hensel's lemma that m is a pth power in $\mathbb{Z}_p^\times$ if and only if it is a pth power in $(\mathbb{Z}/p^2\mathbb{Z})^\times$, which is in turn equivalent to the condition $m^{p-1} \equiv 1 \mod p^2$.

Case 3 ($\mathrm{ord}_q(N) \geq 2$): By assumption, $q \nmid mp$, so ρ is unramified. Then $w_q(\rho) = 1$, and by the unramified twist formula

$$w_q(f,\rho) \quad = \quad w_q(V_l)^{\dim \rho} \cdot \mathrm{sgn}((\det\rho)(q^{n(V)})) = (\pm 1)^{p-1}(\tfrac{q}{p})^{n(V)} = (\tfrac{q}{p})^{n(V)},$$

as claimed.

Turning to the global root number, we have

$$w(f,\rho) = \prod_v w_v(f,\rho),$$

the product being taken over all places v of $\mathbb{Q}$. As ρ is self-dual,

$$\prod_v w_v(\rho)^2 = w(\rho)^2 = 1,$$

and the remaining contribution from the real place is $(-1)^{\frac{p-1}{2}}$ (see e.g. [6]). This completes the proof. □

Example 3.2. We compute the global root numbers $w(f,\rho)$ when $p = 3$ and f is one of the primitive cusp forms with $(N,k) = (5,4), (5,6), (7,4)$ or $(121,4)$ that we will use in §6 to illustrate the congruences. In these cases, the answer does not actually depend on the weight.

- If f has level 5, then $\delta = 1$ as $(3,N) = 1$, whence
$$w(f,\rho) = (-1)^{\frac{3-1}{2}} \cdot 1 \cdot \begin{cases} (\frac{5}{3}) & \text{if} \quad (5,m) = 1 \\ 1 & \text{if} \quad \mathrm{ord}_5(m) \geq 1 \end{cases} = \begin{cases} 1 & \text{if} \quad (5,m) = 1 \\ -1 & \text{if} \quad \mathrm{ord}_5(m) \geq 1. \end{cases}$$
- Similarly, if f has level 7, then $(\frac{5}{3}) = -1$ is replaced by $(\frac{7}{3}) = +1$ and we get $w(f,\rho) = -1$ for every m. (cf. also [6, §7.1], first example).
- Finally, if f has level 121, then $(\frac{5}{3})$ is replaced by $(\frac{11}{3})^{\mathrm{ord}_{11}(121)} = +1$, and we again get $w(f,\rho) = -1$ for every m.

The congruence that we verify involves the twists of f by ρ and by the regular representation σ of $\mathrm{Gal}(K/\mathbb{Q}) \cong (\mathbb{Z}/p\mathbb{Z})^\times$. It easy to check that the root numbers $w_q(f,\sigma)$ and $w(f,\sigma)$ are given by the formula in Theorem 3.1 with $m = 1$. When $p \nmid N$ the formula becomes

$$w(f,\sigma) = (-1)^{\frac{p-1}{2}} \prod_{q|N} \Big(\frac{q}{p}\Big)^{\mathrm{ord}_q(N)} = (-1)^{\frac{p-1}{2}} \Big(\frac{N}{p}\Big).$$

In particular, for $p = 3$ the global root number $w(f,\sigma)$ is $+1$ for the form of level 5, and -1 for the forms of level 7 and 121.

4. An analogue of a result of Hachimori-Matsuno

The aim of this section is to establish an analogue for our primitive cusp form f of results of Hachimori-Matsuno [10] for elliptic curves, over the fields

$$\mathcal{K}_\infty = \mathbb{Q}(\mu_{p^\infty}),\ F^{cyc} = \mathbb{Q}(\mu_{p^\infty}, m^{1/p}), \tag{47}$$

where again m is an integer > 1 which is p-power free. Such a result has already been established in [20], but we wish to give a slightly more explicit result in order to explain its connexion with the congruence (5). Write χ_p for the character giving the action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ on μ_{p^∞}. As usual, for each $n \in \mathbb{Z}$, write $\mathbb{Z}_p(n)$ for the free $\mathbb{Z}_p$-module of rank one on which $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ acts via χ_p^n. If W is any $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$-module, which is also a $\mathbb{Z}_p$-module, define $W(n) = W \otimes_{\mathbb{Z}_p} \mathbb{Z}_p(n)$, endowed with the natural diagonal action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$.

Let V_p be the underlying $\mathbb{Q}_p$-vector space of the Galois representation τ_p attached to f. Fix once and for all a $\mathbb{Z}_p$-lattice T_p in V_p, which is stable under the action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$. We stress that we always view V_p as the cohomology group, not the homology group of the motive $M(f)$. We assume from now on that p and f satisfy:-

Hypothesis H3: The odd prime p is good ordinary for f, i.e., p is an odd prime such that $(p, N) = (p, a_p) = 1$.

As p is a good ordinary prime, it is shown in [17] that there exists a one dimensional subspace V_p^0 of V_p such that the inertial subgroup of $\mathrm{Gal}(\bar{\mathbb{Q}}_p/\mathbb{Q}_p)$ acts on V_p/V_p^0 by χ_p^{1-k}. Hence if we define

$$A_{p^\infty} = V_p(k-1)/T_p(k-1), \tag{48}$$

and define $A^0_{p^\infty}$ to be the image of $V_p^0(k-1)$ in A_{p^∞}, then $A_{p^\infty}/A^0_{p^\infty}$ is unramified at p. For each finite extension $\mathcal{F}$ of $\mathbb{Q}$, define $\mathcal{F}^{\mathrm{cyc}}$ to be the cyclotomic $\mathbb{Z}_p$-extension of $\mathcal{F}$, i.e., the compositum of $\mathcal{F}$ with the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$. We follow Greenberg and define the Selmer group of A_{p^∞} over $\mathcal{F}^{\mathrm{cyc}}$ by

$$\mathrm{Sel}(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}}) = \mathrm{Ker}\left(H^1(\mathcal{F}^{\mathrm{cyc}}, A_{p^\infty}) \to \prod_{w\nmid p} H^1(\mathcal{F}^{\mathrm{cyc}}_w, A_{p^\infty}) \times \prod_{w\mid p} H^1(\mathcal{F}^{\mathrm{cyc}}_w, A_{p^\infty}/A^0_{p^\infty})\right), \tag{49}$$

where w runs over all finite places of $\mathcal{F}^{\mathrm{cyc}}$, and $\mathcal{F}^{\mathrm{cyc}}_w$ denotes the union of the completions at w of the finite extensions of $\mathbb{Q}$ contained in $\mathcal{F}^{\mathrm{cyc}}$. Write

$$X(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}}) = \mathrm{Hom}(\mathrm{Sel}(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}}), \mathbb{Q}_p/\mathbb{Z}_p) \tag{50}$$

for the compact Pontryagin dual of $\mathrm{Sel}(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}})$. Assuming $\mathcal{F}$ is Galois over $\mathbb{Q}$, both $\mathrm{Sel}(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}})$ and $X(A_{p^\infty}/\mathcal{F}^{\mathrm{cyc}})$ are endowed with canonical left actions of $\mathrm{Gal}(\mathcal{F}^{\mathrm{cyc}}/\mathbb{Q})$, and these extend by continuity to left module structures over the Iwasawa algebra

$$\Lambda(\mathrm{Gal}(\mathcal{F}^{\mathrm{cyc}}/\mathbb{Q})) = \varprojlim \mathbb{Z}_p[\mathrm{Gal}(M/\mathbb{Q})],$$

where M runs over the finite Galois extensions of $\mathbb{Q}$ contained in $\mathcal{F}^{\mathrm{cyc}}$.

We shall need the following fundamental result of Kato (see [13]). Note that for $\mathcal{K} = \mathbb{Q}(\mu_p)$, we have $\mathcal{K}^{\mathrm{cyc}} = \mathbb{Q}(\mu_{p^\infty})$.

Theorem 4.1. *Assume Hypothesis H3. Then* $X(A_{p^\infty}/\mathcal{K}^{\mathrm{cyc}})$ *is a torsion* $\Lambda(\mathrm{Gal}(\mathcal{K}^{\mathrm{cyc}}/\mathbb{Q}))$*-module.*

Theorem 4.1 implies that the quotient

$$X(A_{p^\infty}/\mathcal{K}^{\mathrm{cyc}})/(X(A_{p^\infty}/\mathcal{K}^{\mathrm{cyc}})(p)) \tag{51}$$

is a finitely generated $\mathbb{Z}_p$-module, where $X(A_{p^\infty}/\mathcal{K}^{\mathrm{cyc}})(p)$ denotes the p-primary submodule. Define $\lambda(f/F^{\mathrm{cyc}})$ to be the $\mathbb{Z}_p$-rank of (51). We shall also need to consider the Euler factors of the complex L-function $L(f/\mathcal{K}, s)$ at places v with $(v, Np) = 1$. Let q_v denote the characteristic of the residue field of v, and write $q_v^{r_v}$ for the absolute norm of v. Then these Euler factors are given explicitly by

$$P_v(f/\mathcal{K}, X) = \det(1 - \mathrm{Frob}_v^{-1}X \mid V_p) = 1 - b_vX + q_v^{r_v(k-1)}X^2, \tag{52}$$

where $\mathrm{Frob}_v = \mathrm{Frob}_{q_v}^{r_v}$, and $b_v \in \mathbb{Z}$. Since $q_v^{r_v} \equiv 1 \bmod p$, it is clear that for all integers n, we have

$$P_v(f/\mathcal{K}, q_v^{-r_vn}) \equiv 2 - b_v \bmod p, \tag{53}$$

when both sides are viewed as elements of $\mathbb{Z}_p$. In particular the question whether or not the left hand side lies in $p\mathbb{Z}_p$ is independent of n. Define $\mathcal{P}_2$ to be the set of all places w of $\mathcal{K}^{\mathrm{cyc}}$ such that, writing $v = w \mid \mathcal{K}$, we have

$$\mathcal{P}_2 = \{w : (q_v, Np) = 1,\ q_v \mid m,\ \text{and } \mathrm{ord}_p(2 - b_v) > 0\}. \tag{54}$$

Similarly, suppose v is a place of $\mathcal{K}$, with residue characteristic $q_v \neq p$ and $\mathrm{ord}_{q_v}N = 1$. Then the Euler factor $P_v(f/\mathcal{K}, X)$ is given explicitly by

$$P_v(f/\mathcal{K}, X) = \det(1 - \mathrm{Frob}_v^{-1}X \mid V_p^{I_v}) = 1 - b_vX, \tag{55}$$

where $b_v = a_{q_v}^{r_v}$, with $q_v^{r_v}$ again being the absolute norm of v. Note again that

$$P_v(f/\mathcal{K}, q_v^{-r_vn}) \equiv 1 - b_v \bmod p$$

for all integers n. Also, since $a_{q_v}^2 = q_v^{k-2}$ and $q_v^{r_v} \equiv 1 \bmod p$, we always have $b_v^2 \equiv 1 \bmod p$. Define $\mathcal{P}_1$ to be the set of all places w of $\mathcal{K}^{\mathrm{cyc}}$ such that, writing $v = w \mid \mathcal{K}$, we have

$$\mathcal{P}_1 = \{w : \mathrm{ord}_{q_v}N = 1,\ q_v \mid m \text{ and } b_v \equiv 1 \text{ mod } p\} \tag{56}$$

To establish an analogue for f of the theorem of Hachimori-Matsuno, we shall need the following additional hypothesis.

Hypothesis H4: $X(A_{p^\infty}/\mathcal{K}^{\mathrm{cyc}})$ is a finitely generated $\mathbb{Z}_p$-module.

Recall that $\mathcal{K}^{\mathrm{cyc}} = \mathbb{Q}(\mu_{p^\infty})$ and $\mathcal{F}^{\mathrm{cyc}} = \mathbb{Q}(\mu_{p^\infty}, m^{1/p})$.

Theorem 4.2. *Assume Hypotheses H2, H3 and H4. Then $X(A_{p^\infty}/F^{\mathrm{cyc}})$ is also a finitely generated $\mathbb{Z}_p$-module and*

$$\lambda(f/F^{\mathrm{cyc}}) = p\lambda(f/\mathcal{K}^{\mathrm{cyc}}) + \sum_{w \in \mathcal{P}_2} 2(p-1) + \sum_{w \in \mathcal{P}_1} (p-1). \tag{57}$$

Proof. Put $\Delta = \mathrm{Gal}(F/\mathcal{K}) = \mathrm{Gal}(F^{\mathrm{cyc}}/\mathcal{K}^{\mathrm{cyc}})$. If B is any Δ-module, we recall that the Herbrand quotient $h_\Delta(B)$ is defined by

$$h_\Delta(B) = \frac{\# H^2(\Delta, B)}{\# H^1(\Delta, B)},$$

whenever the cohomology groups are both finite.

Entirely similar arguments to those given for elliptic curves in [10] show that, under the hypotheses H2, H3 and H4, $X(A_{p^\infty}/F^{\mathrm{cyc}})$ is indeed a finitely generated $\mathbb{Z}_p$-module, and we have

$$\lambda(f/F^{\mathrm{cyc}}) = p\lambda(f/\mathcal{K}^{\mathrm{cyc}}) + (p-1)\mathrm{ord}_p(h_\Delta(\mathrm{Sel}(A_{p^\infty}/F^{\mathrm{cyc}})) \tag{58}$$

where $h_\Delta(A_{p^\infty}/F^{\mathrm{cyc}})$ is finite.

Let Σ denote the set of primes of $\mathcal{K}^{\mathrm{cyc}}$ lying above the rational primes dividing Nmp. As in [10, §4], well-known arguments from Galois cohomology show that

$$h_\Delta(\mathrm{Sel}(A_{p^\infty}/F^{\mathrm{cyc}})) = \prod_{w \in \Sigma} h_\Delta\left(\prod_{u \mid w} H^1(F_u^{\mathrm{cyc}}, C_w)\right) \tag{59}$$

where u runs over the places of F^{cyc} above w, and

$$C_w = A_{p^\infty}, \text{ or } A_{p^\infty}/A_{p^\infty}^0 \tag{60}$$

according as w does not or does lie above p. Moreover, since a prime w of $\mathcal{K}^{\mathrm{cyc}}$ either splits completely or has a unique prime above it in F^{cyc}, it is clear that the right hand side of (59) simplifies to a product of the $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w))$, where w now runs over the primes in Σ which do not split completely in F^{cyc}. Assume from now on that w is a prime of $\mathcal{K}^{\mathrm{cyc}}$ which does not split in F^{cyc}. In particular, this means that the residue characteristic q_w of w must divide pm. Since F_u^{cyc} and $\mathcal{K}_w^{\mathrm{cyc}}$ contain μ_{p^∞}, their absolute Galois groups have p-cohomological dimension at most 1. As Δ is cyclic of order p, it then follows easily from the Hochschild-Serre spectral sequence that

$$H^i(\Delta, H^1(F_u^{\mathrm{cyc}}, C_w)) \simeq H^i(\Delta, C_w(F_u^{\mathrm{cyc}})), \tag{61}$$

where $C_w(F_u^{\mathrm{cyc}}) = H^0(F_u^{\mathrm{cyc}}, C_w)$.

Lemma 4.3. *Assume there is a unique prime u of F^{cyc} above p, and put $w = u \mid \mathcal{K}^{\mathrm{cyc}}$. Then we have*

$$h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = 1.$$

Proof. Since C_w is unramified, and F_u^{cyc} is a totally ramified extension of $\mathbb{Q}_p$, we have

$$C_w(F_u^{\mathrm{cyc}}) = H^0(\mathrm{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_p), C_w).$$

But Frob_p acts on C_w by multiplication by the p-adic unit root of $1 - a_pX + p^{k-1}X^2$. However, this unit root cannot be equal to 1 as it has complex absolute value $p^{(k-1)/2}$. Hence $C_w(F_u^{\mathrm{cyc}})$ must be finite, and thus has Herbrand quotient equal to 1. □

Write q_w for the residue characteristic of w.

Lemma 4.4. *Assume that w is a prime of $\mathcal{K}^{\mathrm{cyc}}$ such that $(q_w, Np) = 1$, and q_w divides m. Then there is a unique prime u of F^{cyc} above w, and $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = p^{-2}$ if $w \in \mathcal{P}_2$, and $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = 1$ otherwise.*

Proof. The first assertion of the lemma is clear since w must ramify in F^{cyc} because q_w divides m. As $(q_w, Np) = 1$, we know that the inertial subgroup I_w of the absolute Galois group of $\mathbb{Q}_{q_w}$ acts trivially on V_p. We claim that I_w also acts trivially on $C_w = A_{p^\infty}$. Indeed, we have an exact sequence of Galois modules

$$0 \to T_p \to V_p \to C_w \to 0,$$

whence one obtains the long exact sequence

$$0 \to T_p \to V_p \to C_w^{I_w} \to H^1(I_w, T_p) \to H^1(I_w, V_p). \tag{62}$$

As the inertial action is trivial on T_p and V_p, and $q_w \neq p$, we see that

$$H^1(I_w, T_p) = \mathrm{Hom}(J_w, T_p),\ H^1(I_w, V_p) = \mathrm{Hom}(J_w, V_p),$$

where J_w is the Galois group of the unique tamely ramified $\mathbb{Z}_p$-extension of $\mathcal{K}_w^{\mathrm{cyc}}$. Thus the last map in (62) is injective, and so $C_w^{I_w} = C_w$ as claimed.

Let v be the restriction of w to $\mathcal{K}$. We next show that $C_v(\mathcal{K}_v) \neq 0$ if and only if $v \in \mathcal{P}_2$. Since C_v is unramified, we have the commutative diagram with exact rows

$$\begin{tikzcd}
0 \arrow[r] & T_p \arrow[r] \arrow[d, "\delta_v"'] & V_p \arrow[r] \arrow[d, "\delta_v"'] & C_w \arrow[r] \arrow[d, "\delta_v"'] & 0 \\
0 \arrow[r] & T_p \arrow[r] & V_p \arrow[r] & C_w \arrow[r] & 0
\end{tikzcd}$$

where δ_v is the map given by applying $\mathrm{Frob}_v - 1$. The characteristic polynomial of Frob_v acting on V_p is $X^2P_v(f/\mathcal{K}, X^{-1})$. The roots of this polynomial have complex absolute value $q_v^{r_v(k-1)/2}$, and thus are distinct from 1. Hence the middle vertical map in the above diagram is an isomorphism. It follows from the snake lemma that $C_w(K_v)$ has order equal to the cokernel of the left hand vertical map, which is equal to the exact power of p dividing $P_v(f/\mathcal{K}, 1)$. But

$$P_v(f/\mathcal{K}, 1) = 1 - b_v + q_v^{r_v(k-1)} \equiv (2 - b_v) \bmod p,$$

showing that $C_w(K_v) \neq 0$ if and only if $w \in \mathcal{P}_2$.

Our next claim is that $C_w = C_w(\mathcal{K}^{\mathrm{cyc}})$ if and only if $C_w(\mathcal{K}_v) \neq 0$. As $\mathrm{Gal}(\mathcal{K}_w^{\mathrm{cyc}}/\mathcal{K}_v)$ is pro-p, Nakayama's lemma shows that $C_w(\mathcal{K}_v) = 0$ implies that $C_w(\mathcal{K}_w^{\mathrm{cyc}}) = 0$. Conversely, assume that $C_w(\mathcal{K}_v) \neq 0$. We then assert that the extension $\mathcal{K}_v(C_w)$ is a pro-p extension of $\mathcal{K}_v$. To prove this, let $(C_w)_p$ be the kernel of multiplication by p on C_w. It is easily seen that the extension $\mathcal{K}_v(C_w)/\mathcal{K}_v((C_w)_p)$ is pro-p. On the other hand, choosing an $\mathbb{F}_p$-basis of $(C_w)_p$ in which the first element belongs to $C_w(\mathcal{K}_v)$, and noting that the determinant of $(C_w)_p$ is trivial because it is equal to $\omega^{r_v(k-1)}$, where ω is the cyclotomic character mod p, it follows that the extension $\mathcal{K}_v((C_w)_p)/\mathcal{K}_v$ is a p-extension. Thus $\mathcal{K}_v(C_w)$ is a pro-p extension of $\mathcal{K}_v$, and it is unramified as inertia acts trivially on C_w. Hence we must have $\mathcal{K}_v(C_w) = \mathcal{K}_w^{\mathrm{cyc}}$.

It is now clear from (60) that $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = 0$ if $w \notin \mathcal{P}_2$, and $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = p^{-2}$ if $w \in \mathcal{P}_2$. This completes the proof of the lemma. □

Lemma 4.5. *Assume that w is a prime of $\mathcal{K}^{\mathrm{cyc}}$ such that* $\mathrm{ord}_{q_w} N = 1$ *and q_w divides m. Then there is a unique prime u of F^{cyc} above w, and $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = p^{-1}$ if $w \in \mathcal{P}_1$, and $h_\Delta(H^1(F_u^{\mathrm{cyc}}, C_w)) = 1$ otherwise.*

Proof. The first assertion is clear, since w must ramify in F^{cyc}, because q_v divides m. Again, let v be the restriction of w to $\mathcal{K}$. Since $\mathrm{ord}_{q_w} N = 1$, we have

$$P_v(f/\mathcal{K}, X) = 1 - b_v X$$

where we recall that $b_v^2 \equiv 1 \bmod p$. Let W_p be the subspace $V_p^{I_p}$ of V_p, so that $\mathrm{Gal}(\bar{\mathbb{Q}}_{q_v}/F_v)$ acts on W_p via the unramified character η with $\eta(\mathrm{Frob}_v) = b_v$. Choosing a basis of V_p with the first basis element being a basis of W_p, the representation of $\mathrm{Gal}(\bar{\mathbb{Q}}_{q_v}/F_v)$ on V_p must be of the form $\begin{pmatrix} \eta & * \\ 0 & \lambda \end{pmatrix}$, where λ is a character of $\mathrm{Gal}(\bar{\mathbb{Q}}_{q_v}/F_v)$. As the determinant of V_p is the cyclotomic character to the power $(k-1)$, we conclude that λ is also unramified. Moreover, the image of the restriction of this representation to $\mathrm{Gal}(\bar{\mathbb{Q}}_{q_v}/\mathcal{K}_v^{\mathrm{nr}})$ is infinite, where $\mathcal{K}_v^{\mathrm{nr}}$ is the maximal unramified extension of $\mathcal{K}_v$. Since η takes values in $\mathbb{Z}_p^\times$, it is clear that the restriction of η to $\mathrm{Gal}(\mathcal{K}_v^{\mathrm{nr}}/\mathcal{K}_w^{\mathrm{cyc}})$ is the trivial character if and only if $w \in \mathcal{P}_1$. Similarly, writing v' for the restriction of u to F, and recalling that $F_{v'}/\mathcal{K}_v$ is totally ramified, it follows that the restriction of η to $\mathrm{Gal}(F_{v'}^{\mathrm{nr}}/F_u^{\mathrm{cyc}})$ is the trivial character if and only if $w \in \mathcal{P}_1$. One concludes easily that, if $w \notin \mathcal{P}_1$, then $C_w(F_u^{\mathrm{cyc}})$ must be finite, and if $w \in \mathcal{P}_1$, then the divisible subgroup of $C_w(F_u^{\mathrm{cyc}})$ has $\mathbb{Z}_p$-corank 1. In view of (60), the assertion of the lemma is now clear.

□

Combining (58), (59), and Lemmas 3.3, 3.4 and 3.5, the proof of Theorem 4.2 is now complete. □

5. The congruence from non-commutative Iwasawa theory

As before, let

$$F = \mathbb{Q}(\mu_p, m^{1/p}), \ \mathcal{K} = \mathbb{Q}(\mu_p) \tag{63}$$

where p is an odd prime, and $m > 1$ is an integer which is not divisible by the p-th power of an integer > 1. Assume throughout this section that Hypotheses H1, H2, and H3 are valid.

Let ϕ be an Artin representation of $\mathrm{Gal}(F_\infty/\mathbb{Q})$. For each integer $n = 1, \ldots, k-1$, we recall that $L_p^*(f, \phi, n)$ is defined by (41). By Theorem 2.8, we know that $L_p^*(f, \phi, n)$ is an algebraic number. Very roughly speaking, the non-commutative p-adic L-function seeks to interpolate the numbers $L_p^*(f, \phi, n)$, as ϕ, and n both vary. While there has been important recent progress on the study of these non-commutative p-adic L-functions for the Tate motive over totally real number fields (see [12],[21]), very little is still known about their existence for other motives, including the motive attached to our modular form f. In the present paper, we shall only discuss what is perhaps the simplest congruence between abelian p-adic L-functions, which would follow from the existence of a non-commutative p-adic L-function for the motive of f over the field F_∞. A specialization of this congruence for elliptic curves has been studied in the earlier paper [5].

To state this congruence, we must first make a canonical modification of the values $L_p^*(f, \phi, n)$, given by (41) following [2], [8]. Recall that since $(p, a_pN) = 1$, the Euler factor

$$P_p(f, X) = 1 - a_pX + p^{k-1}X^2$$

can be written as

$$P_p(f, X) = (1 - \alpha X)(1 - \beta X), \tag{64}$$

where α is a unit in $\mathbb{Z}_p$, and $\mathrm{ord}_p(\beta) = k-1$. We shall also need the Euler factors of the complex L-series $L(\phi, s)$ of the Artin representation ϕ, which are defined by

$$P_q(\phi, X) = \det\left(1 - \mathrm{Frob}_q^{-1}X \mid M_l(\phi)^{I_q}\right) \tag{65}$$

where l is any prime distinct from q. As before, let $d(\phi)$ be the dimension of ϕ. Moreover, writing $\mathcal{N}(\phi)$ for the conductor of ϕ, define

$$e_p(\phi) = \mathrm{ord}_p(\mathcal{N}(\phi)). \tag{66}$$

Recall that $P_q(f, \phi, X)$ defined by (17) is the Euler factor at the prime q of the complex L-function $L(f, \phi, s)$. Recall also that, for $n = 1, \ldots k-1$,

$$L_p^*(f, \phi, n) = \frac{L(f, \phi, n)\epsilon_p(\phi)}{\left((2\pi i)^{nd(\phi)} \times \Omega_+(f)^{d_n^+(\phi)} \times |\Omega_-(f)|^{d_n^-(\phi)}\right)}. \tag{67}$$

We then define

$$M_p(f, \phi, n) = \Gamma(n)^{d(\phi)} \times L_p^*(f, \phi, n) \times P_p(f, \phi, p^{-n}) \times \frac{P_p(\hat{\phi}, p^{n-1}/\alpha)}{P_p(\phi, \alpha/p^n)} \times (p^{n-1}/\alpha)^{e_p(\phi)}, \tag{68}$$

and

$$\mathcal{L}_p(f, \phi, n) = M_p(f, \phi, n) \prod_{q \neq p,\, q|m} P_q(f, \phi, q^{-n}), \tag{69}$$

where q runs over the prime factors of m distinct from p. It is these modified L-values, defined using the naive periods $\Omega_+(f)$ and $\Omega_-(f)$, which we shall actually compute in a number of numerical examples.

Secondly, in order to obtain p-adic L-functions which will in the end satisfy the main conjectures of Iwasawa theory, we may also have to adjust the naive periods $\Omega^+(f)$ and $\Omega^-(f)$ by certain non-zero rational numbers. Writing $\Omega_+^{\mathrm{can}}(f)$ and $\Omega_-^{\mathrm{can}}(f)$ for these canonical periods, we will have

$$\Omega_+^{\mathrm{can}}(f) = c_+(f)\Omega_+(f),\ \Omega_-^{\mathrm{can}}(f) = c_-(f)\Omega_-(f) \tag{70}$$

for certain non-zero rational numbers $c_+(f)$ and $c_-(f)$. It is then natural to define

$$\mathcal{L}_p^{\mathrm{can}}(f,\phi,n) = c_+(f)^{-d_n^+(\phi)}c_-(f)^{-d_n^-(\phi)}\mathcal{L}_p(f,\phi,n). \tag{71}$$

It is these modified values $\mathcal{L}_p^{\mathrm{can}}(f,\phi,n)$ which should satisfy the non-abelian congruences for the p-adic L-functions arising in the main conjectures. However, in our present state of knowledge, we do not know in general how to determine $c_+(f)$ and $c_-(f)$ precisely. Nevertheless, as we shall now explain, the work of Manin on the p-adic L-function of f for the extension $\mathcal{K}_\infty/\mathbb{Q}$ provides some partial information on this question.

Theorem 5.1. *Let σ be the sum of the irreducible characters of $\mathrm{Gal}(\mathcal{K}_1/\mathbb{Q})$, where $\mathcal{K}_1 = \mathbb{Q}(\mu_p)$. If $L(f,\sigma,k/2) = 0$, then $\mathcal{L}_p^{\mathrm{can}}(f,\sigma,n)$ belongs to $p\mathbb{Z}_p$ for $n = 1,\dots,k-1$.*

Proof. Let χ_p be the character giving the action of $\mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ on μ_{p^∞}. Fix a topological generator γ of $\mathrm{Gal}(\mathcal{K}^{cyc}/K_1)$ and put $u = \chi_p(\gamma)$. The work of Manin then shows [16] that there exists a power series $g(T)$ in $\mathbb{Z}_p[[T]]$ such that

$$g(u^r - 1) = M_p^{\mathrm{can}}(f,\sigma,k/2+r), \tag{72}$$

for all integers r with $-k/2+1 \le r \le k/2-1$, and where

$$M_p^{\mathrm{can}}(f,\sigma,n) = (c_+(f)c_-(f))^{(1-p)/2}\,M_p(f,\sigma,n).$$

Here it is understood that the canonical periods are those for which we expect $g(T)$ to be a characteristic power series for the dual Selmer group of f over $\mathcal{K}_\infty$. Assuming that $L(f,\sigma,k/2) = 0$, it follows that

$$g(0) = 0,$$

and so $g(u^n - 1) \in p\mathbb{Z}_p$ for all integers n. The assertion of the theorem then follows on noting that

$$\prod_{q\neq p,\, q|m} P_q(f,\sigma,q^{-n})$$

lies in $\mathbb{Z}_p$ for all $n \in \mathbb{Z}$. This completes the proof. □

Example 5.2. Take f to be the unique primitive eigenform of level 7 and weight 4, and $p = 3$. Then $L(f,\sigma,2) = 0$. Moreover, we see from Table II in §6 that $\mathcal{L}_3(f,\sigma,1) \in 3\mathbb{Z}_3$. In view of Theorem 5.1, this strongly suggests that in this case, we must have $\mathrm{ord}_3(c_+(f)) = \mathrm{ord}_3(c_-(f)) = 0$.

Example 5.3. Take f to be the complex multiplication form of level 121 and weight 4, which is attached to the cube of the Grössencharacter of the elliptic curve over E over $\mathbb{Q}$ given by the equation (79), of conductor 121 and with complex multiplication by the full ring of integers of the field $L = \mathbb{Q}(\sqrt{-11})$, and again take $p = 3$. Then $L(f, \sigma, 2) = 0$. However, we see from Table III in §6 that $\mathcal{L}_3(f, \sigma, 1)$ is a 3-adic unit when $m = 3$, 7 or 11. Hence the naive periods $\Omega^+(f)$ and $\Omega^-(f)$ cannot be the good periods, and at least one of $\mathrm{ord}_3(c_+(f))$ or $\mathrm{ord}_3(c_-(f))$ must be strictly less than zero. In fact, in this case we do know the canonical periods for f, since, for all good ordinary primes p for f, we know the periods for which the relevant cyclotomic main conjecture for f over $\mathcal{K}^{cyc}$ is valid. This is because this cyclotomic main conjecture can easily be deduced from the main conjecture for E over the field obtained by adjoining to L the coordinates of all p-power division points on E; and this latter main conjecture is proven for all good ordinary primes p for E by the work of Yager and Rubin. Invoking the Chowla-Selberg formula, we see easily that the explicit values of these canonical periods can be taken as follows. Let

$$\Theta = \Gamma(1/11)\Gamma(3/11)\Gamma(4/11)\Gamma(5/11)\Gamma(9/11).$$

Then

$$\Omega_+^{\mathrm{can}}(f) = \sqrt{11} \times \Theta^3/(2\pi)^9,\ \Omega_-^{\mathrm{can}}(f) = i\Theta^3/(2\pi)^9. \tag{73}$$

Direct computations show that

$$\Omega_+(f)/\Omega_+^{\mathrm{can}}(f) = 1/22,\ \Omega_-(f)/\Omega_-^{\mathrm{can}}(f) = 3, \tag{74}$$

whence

$$\mathrm{ord}_3(c_+(f)) = 0,\ \mathrm{ord}_3(c_-(f)) = -1, \tag{75}$$

precisely as required.

As in the Introduction, let σ be the Artin representation of dimension $(p-1)$ given by the direct sum of the one dimensional characters of $\mathrm{Gal}(\mathcal{K}/\mathbb{Q})$. Define ρ to be the representation of $\mathrm{Gal}(F/\mathbb{Q})$ induced from any non-trivial degree one character of $\mathrm{Gal}(F/\mathcal{K})$. Thus ρ also has dimension $(p-1)$, and is easily seen to be irreducible (cf. [5]). Moreover, both σ and ρ are self-dual, can be realized over $\mathbb{Z}$, and their reductions modulo p are isomorphic. Let $R = \mathbb{Z}_p[[T]]$ be the ring of formal power series in an indeterminate T with coefficients in $\mathbb{Z}_p$. As explained in the Introduction, the work of Manin [16] establishes the existence of a power series $H(\sigma, T)$ in R satisfying the interpolation property (2) It is conjectured that there exists a power series $H(\rho, T)$ in R satisfying the interpolation condition (3).

Conjecture 5.4. *(Congruence Conjecture). Assume Hypotheses H1, H2, H3. Then there exists a power series $H(\rho, T)$ in R satisfying the interpolation property* (3)*, and we have the congruence of power series*

$$H(\rho, T) \ \equiv\ H(\sigma, T) \bmod pR. \tag{76}$$

We are grateful to M. Kakde for pointing out to us that the congruence (76) is simply a special case of the congruences predicted by Kato in [13], and we now briefly explain why this is the case. Assume for simplicity that Hypothesis H4 is also valid. Recall that G denotes the Galois group of F_∞ over $\mathbb{Q}$, and write $\Lambda(G)$ for the Iwasawa algebra of G, S for the canonical Ore set in $\Lambda(G)$, which is defined in [2], and $\Lambda(G)_S$ for its localization at S. In addition, define $\mathfrak{G}_0 = \mathrm{Gal}(\mathcal{K}_\infty/\mathbb{Q})$, and for each integer $n \geq 1$, let $\mathfrak{G}_n$ be the unique closed subgroup of index p^{n-1} in $\mathrm{Gal}(\mathbb{Q}^{\mathrm{cyc}}/\mathbb{Q})$. Write S_n for the canonical Ore set of [2] in the Iwasawa algebra $\Lambda(\mathfrak{G}_n)$. In [13], Kato defines a canonical map

$$\theta_{G,S} : K_1(\Lambda(G)_S) \to \prod_{n\geq 0} K_1(\Lambda(\mathfrak{G}_n)_{S_n}),$$

and characterizes its image by a remarkable set of congruences which we do not state in detail here. In particular, writing $\theta_{G,S}(\alpha) = (\alpha_n)$ for any element α of $K_1(\Lambda(G)_S)$, we always have

$$N(\alpha_0) \equiv \alpha_1 \bmod p, \tag{77}$$

where N denotes the norm map from $K_1(\Lambda(\mathfrak{G}_0)_{S_0})$ to $K_1(\Lambda(\mathfrak{G}_1)_{S_1})$. Now take α to be the conjectural p-adic L-function for f over F_∞, which we denote by $\zeta(f/F_\infty)$. Let us also identify $\Lambda(\mathfrak{G}_1)$ with the formal power series ring $R = \mathbb{Z}_p[[T]]$ by mapping the fixed topological generator γ of $\mathfrak{G}_1$ to $1 + T$. Then it follows essentially from the construction of the map $\theta_{G,S}$ and the interpolation properties of these p-adic L-functions that we will have

$$N(\zeta(f/F_\infty)_0) = H(\sigma, T),\ \zeta(f/F_\infty)_1 = H(\rho, T).$$

Thus the congruence (76) is indeed just a special case of the congruence (77) of Kato, as claimed.

As was pointed out in the Introduction, if we evaluate both sides of the congruence (76) at the appropriate points in $p\mathbb{Z}_p$, we deduce the following congruence of normalized L-values from (2) and (3):-

Conjecture 5.5. *Assume Hypotheses H1, H2 and H3. Then for all integers* $n = 1, \ldots, k-1$*, we have*

$$\mathcal{L}_p^{\mathrm{can}}(f, \rho, n) \equiv \mathcal{L}_p^{\mathrm{can}}(f, \sigma, n) \bmod p. \tag{78}$$

We end this section by explaining how this latter congruence is intimately connected with Theorem 4.2. Let $\mathcal{P}_1$ and $\mathcal{P}_2$ be the set of places of $\mathcal{K}_\infty = \mathbb{Q}(\mu_{p^\infty})$ defined by (56) and (54) respectively.

Lemma 5.6. *Let q be any rational prime with q dividing m and $(q, Np) = 1$. Then all primes of $\mathcal{K}^{\mathrm{cyc}}$ above q belong to $\mathcal{P}_2$ if and only if* $\mathrm{ord}_p(P_q(f, \sigma, q^{-n})) > 0$ *for some integer n.*

Proof. Let q have exact order r_q modulo p, and let v be a prime of $\mathcal{K}$ above q. Then one sees immediately that

$$P_q(f, \sigma, X) = (1 - b_v X^{r_q} + q^{(k-1)r_q} X^{2r_q})^{\frac{p-1}{r_q}},$$

where b_v is defined by (52). Since $q^{r_q} \equiv 1 \bmod p$, the assertion of the lemma is now plain from the definition of $\mathcal{P}_2$. □

Lemma 5.7. *Let q be any rational prime not equal to p such that q divides m and $\mathrm{ord}_q(N) = 1$ .Then all primes of $\mathcal{K}^{\mathrm{cyc}}$ above q belong to $\mathcal{P}_1$ if and only if $\mathrm{ord}_p(P_q(f, \sigma, q^{-n})) > 0$ for some integer n.*

Proof. Let q have exact order r_q and let v be a prime of $\mathcal{K}$ above q. Since σ is unramified at q, one sees easily that

$$P_q(f, \sigma, X) = (1 - b_v X^{r_q})^{\frac{p-1}{r_q}},$$

where b_v is defined by (55), and hence the assertion of the lemma is clear. □

By the work of Manin, we always have $M_p^{\mathrm{can}}(f, \sigma, n)$ is in $\mathbb{Z}_p$ for $n = 1, \ldots, k-1$. Hence we conclude from Lemmas 5.6 and 5.7 that $\mathcal{L}_p^{\mathrm{can}}(f, \sigma, n) \in p\mathbb{Z}_p$ if either $\mathcal{P}_1$ or $\mathcal{P}_2$ is non-empty. On the other hand, assuming Hypotheses H1-H4, Theorem 4.2 shows that $X(A_{p^\infty}/F^{\mathrm{cyc}})$ is infinite if either $\mathcal{P}_1$ or $\mathcal{P}_2$ is non-empty. But $X(A_{p^\infty}/F^{\mathrm{cyc}})$ is infinite if and only if its characteristic element as a $\Lambda(\mathrm{Gal}(F^{\mathrm{cyc}}/F))$-module is not a unit in the Iwasawa algebra. But the main conjecture for $X(A_{p^\infty})$ predicts that the $\mathcal{L}_p^{\mathrm{can}}(f, \rho, n)$ are all values of the characteristic power series of $X(A_{p^\infty}/F^{\mathrm{cyc}})$. Thus it would follow that $\mathcal{L}_p^{\mathrm{can}}(f, \rho, n) \in p\mathbb{Z}_p$ if either $\mathcal{P}_1$ or $\mathcal{P}_2$ is non-empty, in accord with the Congruence Conjecture 5.5.

6. Numerical data

We refer the reader to Section 6 of [5] for a detailed discussion of how the computations are carried out in the case of a primitive form of weight 2. Entirely similar arguments (see [4]) apply to the calculation of the numerical values $\mathcal{L}_p(f, \phi, n)$, for $n = 1, \ldots, k-1$, for our given primitive modular form $f = \sum_{n=1}^{\infty} a_n q^n$ of conductor N. We do not enter into the details here, apart from listing the explicit Euler factors which occur for the primes dividing pm. As before, let

$$\mathcal{K} = \mathbb{Q}(\mu_p), \ F = \mathbb{Q}(\mu_p, m^{1/p}),$$

where m is a p-power free integer > 1. As earlier, we write ϕ for either the direct sum σ of the one dimensional characters of $\mathrm{Gal}(\mathcal{K}/\mathbb{Q})$ or the unique irreducible representation ρ of dimension $p-1$ of $\mathrm{Gal}(F/\mathbb{Q})$, and note that both of these Artin representations are self-dual. We suppose that p is an odd prime number satisfying $(p, a_p) = (p, N) = 1$. In addition, we assume that Hypothesis H2 holds. As earlier, let $P_p(\phi, X)$ denote the polynomial in X giving the inverse Euler factor at p of the complex L-series $L(\phi, s)$ of the Artin representation ϕ, and $P_q(f, \phi, X)$ the polynomial giving the inverse Euler factor at a prime q of the complex L-series $L(f, \phi, s)$.

Lemma 6.1. *We have that $P_p(\sigma, X) = 1 - X$, and $P_p(f, \sigma, X) = P_p(f, X)$. If $m \equiv \pm 1 \bmod p^2$, then $P_p(\rho, X) = 1 - X$, and $P_p(f, \rho, X) = P_p(f, X)$. Otherwise, both $P_p(\rho, X)$ and $P_p(f, \rho, X)$ are equal to 1.*

□

Lemma 6.2. *Let q be any prime factor of m distinct from p, and write r_q for the order of q modulo p. Then we have:-*

1. $P_q(f, \sigma, X) = P_v\left(f/\mathcal{K}, X^{r_q}\right)^{\frac{p-1}{r_q}}$ *, where $P_v(f/\mathcal{K}, X)$ is the Euler factor of f over $\mathcal{K}$ at any prime v of $\mathcal{K}$ above q if $(q, N) = 1$.*
2. $P_q(f, \sigma, X) = \left(1 - a_q^{r_q} X^{r_q}\right)^{\frac{p-1}{r_q}}$ *if* $\mathrm{ord}_q(N) = 1$.
3. $P_q(f, \rho, X) = 1$.

□

We remark that the computations require knowledge of the Fourier coefficients a_n of f for n ranging from 1 up to approximately the square root of the conductor of the complex L-function $L(f, \phi, s)$. Since these conductors are very large even for small N, this explains why we need to know explicitly the a_n for $1 \leq n \leq 10^8$, and why we are essentially restricted to the case of the prime $p = 3$. For our primitive cusp form f of small conductor, we computed these Fourier coefficients a_n using [SAGE] as follows. We use linear algebra to express f explicitly as a polynomial in terms of Eisenstein series (we only used small conductor forms f where this was possible), then we evaluate this expression using arithmetic with polynomials of large degree over the integers. This high precision evaluation took about 1 day of CPU time in some cases, and relies on the fast FFT-based polynomial arithmetic from `http://flintlib.org`, and optimized code for computing coefficients of Eisenstein series due to Craig Citro, along with other optimizations specific to this problem. For evaluation of the CM form of level 121 and weight 4, we computed the Fourier coefficients d_p for the corresponding elliptic curve of weight 2 (using [19]), then obtained the coefficients a_p of the weight 4 form as the sum of the cubes of the roots of $X^2 - d_p X + p$, and finally extended these multiplicatively to obtain all of the coefficients a_n.

For even $k \geq 2$, let $E_k(q) \in \mathbb{Q}[[q]]$ denote the weight k Eisenstein series of level 1, normalized so that the coefficient of q is 1. For integers $t \geq 1$, define $E_2^*(q^t) = E_2(q) - tE_2(q^t)$, which is a holomorphic modular form of level t and weight 2. We consider 4 explicit primitive forms; 3 have expressions in terms of Eisenstein series, and the fourth in terms of an elliptic curve with complex multiplication. The first 3 are the unique primitive forms on $\Gamma_0(p)$ with given weight. The fourth form f is the complex multiplication form of conductor 121 which is attached to the cube of the Grossencharacter of the elliptic curve

$$y^2 + y = x^3 - x^2 - 7x + 10. \tag{79}$$

This curve has complex multiplication by the full ring of integers of $\mathbb{Q}(\sqrt{-11})$, and has conductor 121 when viewed as a curve over $\mathbb{Q}$. The following table gives the first few terms of the q-expansion of these four forms, and note that, in each case, 3 is an ordinary prime because the coefficient of q^3 is not divisible by 3.

Conductor	**Weight**	**Primitive form**
5	4	$-\frac{250}{3}E_4(q^5) - \frac{10}{3}E_4(q) + 13E_2^*(q^5)^2 = q - 4q^2 + 2q^3 + 8q^4 - 5q^5 + \cdots$
7	4	$-\frac{147}{2}E_4(q^7) - \frac{3}{2}E_4(q) + 5E_2^*(q^7)^2 = q - q^2 - 2q^3 - 7q^4 + 16q^5 + \cdots$
5	6	$\frac{521}{6}E_6(q^5) - \frac{1}{30}E_6(q) + 248E_2^*(q^5)E_4(q^5) = q + 2q^2 - 4q^3 - 28q^4 + 25q^5 + \cdots$
121	4	$q + 8q^3 - 8q^4 + 18q^5 + 37q^9 - 64q^{12} + 144q^{15} + 64q^{16} + \cdots$

The first two tables below provide numerical evidence in support of the congruences (5), and the third and fourth table below provides evidence in support of the stronger congruence (7). The notation used in these four tables is as follows. We have taken $p = 3$, and assume that ϕ denotes either σ or ρ, so that $d(\phi) = 2$. For each integer $n = 1, \ldots, k-1$, put

(80)
$$L_3^*(f,\phi,n) = L(f,\phi,n)\epsilon_3(\phi)(2\pi i)^{-2n}(\Omega^+(f)|\Omega^-(f)|)^{-1}, \;\; \mathcal{P}_3(f,\phi,n) = \prod_{q|3m} P_q(f,\phi,q^{-n}),$$

and define

$$\mathcal{L}_3(f,\phi,n) = \Gamma(n)^2 \times L_3^*(f,\phi,n) \times \mathcal{P}_3(f,\phi,n) \times \frac{P_3(\phi,3^{n-1}/\alpha)}{P_3(\phi,\alpha/3^n)} \times (3^{n-1}/\alpha)^{e_3(\phi)}.$$

We also write $N(f,\phi)$ for the conductor of the complex L-function $L(f,\phi,s)$. it is easily seen that $\epsilon_3(\sigma)$ is equal to the positive square root of 3. Moreover, $\epsilon_3(\rho) = 3^5$ when $\mathrm{ord}_3(m) \geq 1$. When $(3,m) = 1$, we have that $\epsilon_3(\rho)$ is equal to 3 when $m \equiv \pm 1 \bmod 3^2$, and is equal to 3^3 otherwise. If r is any integer ≥ 1, and w is an integer, the symbol $w + O(3^r)$ will denote a 3-adic integer which is congruent to w modulo 3^r.

The reader should also bear in mind the following comments about the signs of the values $L_3^*(f,\phi,n)$ given in our tables below. Since ϕ can be realized over $\mathbb{Q}$, it follows from the convergence of the Euler product that $L(f,\phi,n)$ is strictly positive for $n = k/2+1, \ldots, k-1$; in addition, the generalized Riemann hypothesis would also imply that the value at $n = k/2$ should either be zero or strictly positive (and this is the case in all of our numerical examples) Thus, by Theorem (2.8), $L_3^*(f,\phi,n)$ is a rational number,which will have the sign $(-1)^n w(f,\phi)$ for $n = 1, \ldots, k/2-1$ by the functional equation (21); and the sign of $L_3^*(f,\phi,k/2)$ should be $(-1)^{k/2}$ if it is non-zero.

Finally, we recall (see Example 5.3 in section 5) that, for the form f of conductor 121 and weight 4, the periods in Table IV are the naive periods, and that they must be replaced by the canonical periods defined in Example 5.3 to deduce the stronger congruence (7) in this case.

In the remaining four tables, we give some intriguing integrality and squareness assertions for the L-values computed in the previous four tables. Although we do not enter into any detailed discussion in the present paper, it seems highly likely that these phenomena can be explained via the Bloch-Kato conjecture, and Flach's motivic generalization of the Cassels-Tate pairing. We define M to be the product of the distinct primes dividing m, but excluding the prime 3. Let N denote the conductor of our primitive form f. For $n = 1, \ldots, k-1$, we define

$$A_n(f) = |L_3^*(f,\rho,n)|M^n\epsilon_3(\rho)^{(n-1)}/4 \tag{81}$$

In Table V, for the form f of conductor 5 and weight 4, define

$$B_1(f) = A_1(f)/(2^2 \times 5^3 \times 13),$$
$$B_2(f) = A_2(f)/(5^2 \times 13).$$
