EMPIRICAL EVIDENCE FOR THE BIRCH AND SWINNERTON-DYER CONJECTURES FOR MODULAR JACOBIANS OF GENUS 2 CURVES

E. VICTOR FLYNN, FRANCK LEPRÉVOST, EDWARD F. SCHAEFER, WILLIAM A. STEIN, MICHAEL STOLL, AND JOSEPH L. WETHERELL

Abstract. This paper provides empirical evidence for the Birch and Swinnerton-Dyer conjectures for modular Jacobians of genus 2 curves. The second of these conjectures relates six quantities associated to a Jacobian over the rational numbers. One of these six quantities is the size of the Shafarevich-Tate group. Unable to compute that, we computed the five other quantities and solved for the last one. In all 32 cases, the result is very close to an integer that is a power of 2. In addition, this power of 2 agrees with the size of the 2-torsion of the Shafarevich-Tate group, which we could compute.

1. Introduction

The conjectures of Birch and Swinnerton-Dyer, originally stated for elliptic curves over $\mathbf{Q}$, have been a constant source of motivation for the study of elliptic curves, with the ultimate goal being to find a proof. This has resulted not only in a better theoretical understanding, but also in the development of better algorithms for computing the analytic and arithmetic invariants that are so intriguingly related by them. We now know that the first and, up to a non-zero rational factor, the second conjecture hold for modular elliptic curves over $\mathbf{Q}$ [1] in the analytic rank 0 and 1 cases (see [GZ, Ko, Wal1, Wal2]). Furthermore, a number of people have provided numerical evidence for the conjectures for a large number of elliptic curves; see for example [BGZ, BSD, Ca, Cr2].

By now, our theoretical and algorithmic knowledge of curves of genus 2 and their Jacobians has reached a state that makes it possible to conduct similar investigations. The Birch and Swinnerton-Dyer conjectures have been generalized to arbitrary abelian varieties over number fields by Tate [Ta]. If J is the Jacobian of a genus 2 curve over $\mathbf{Q}$, then the first conjecture states that the order of vanishing of the L-series of the Jacobian at $s = 1$ (the *analytic rank*) is equal to the Mordell-Weil rank of the Jacobian. The second conjecture is that

$$\lim_{s\to 1}(s-1)^{-r}L(J,s) = \Omega \cdot \mathrm{Reg} \cdot \prod_p c_p \cdot \#\text{Ш}(J,\mathbf{Q}) \cdot (\#J(\mathbf{Q})_{\mathrm{tors}})^{-2}\,. \tag{1.1}$$

In this equation, $L(J,s)$ is the L-series of the Jacobian J, and r is its analytic rank. We use Ω to denote the integral over $J(\mathbf{R})$ of a particular differential 2-form; the precise choice of this differential is described in Section 3.5. Reg is the regulator of $J(\mathbf{Q})$. For primes p, we use c_p to denote the size of $J(\mathbf{Q}_p)/J^0(\mathbf{Q}_p)$, where $J^0(\mathbf{Q}_p)$ is defined in Section 3.4. We let $\text{Ш}(J,\mathbf{Q})$ be the Shafarevich-Tate group of J over $\mathbf{Q}$, and we let $J(\mathbf{Q})_{\mathrm{tors}}$ denote the torsion subgroup of $J(\mathbf{Q})$.

As in the case of elliptic curves, the first conjecture assumes that the L-series can be analytically continued to $s = 1$, and the second conjecture additionally assumes that the Shafarevich-Tate group is finite. Neither of these assumptions is known to hold for arbitrary genus 2 curves. The analytic continuation of the L-series, however, is known to exist for modular abelian varieties over $\mathbf{Q}$, where an abelian variety is called *modular* if it is a quotient of the Jacobian $J_0(N)$ of the modular curve $X_0(N)$ for some level N. For simplicity, we will also call a genus 2 curve *modular* when its Jacobian is modular in this sense. So it is certainly a good idea to look at modular genus 2 curves over $\mathbf{Q}$, since we then at least know that the statement of the first conjecture makes sense. Moreover, for many modular abelian varieties it is also known that the Shafarevich-Tate group is finite, therefore the statement of the second conjecture also makes sense. As it turns out, all of our examples belong to this class. An additional benefit of choosing modular genus 2 curves is that one can find lists of such curves in the literature.

In this article, we provide empirical evidence for the Birch and Swinnerton-Dyer conjectures for such modular genus 2 curves. Since there is no known effective way of computing the size of the Shafarevich-Tate group, we computed the other five terms in equation (1.1) (in two different ways, if possible). This required several different algorithms, some of which were developed or improved while we were working on this paper. If one of these algorithms is already well described in the literature, then we simply cite it. Otherwise, we describe it here in some detail (in particular, algorithms for computing Ω and c_p).

For modular abelian varieties associated to newforms whose L-series have analytic rank 0 or 1, the first Birch and Swinnerton-Dyer conjecture has been proven. In such cases, the Shafarevich-Tate group is also known to be finite and the second conjecture has been proven, up to a non-zero rational factor. This all follows from results in [GZ, KL, Wal1, Wal2]. In our examples, all of the analytic ranks are either 0 or 1. Thus we already know that the first conjecture holds. Since the Jacobians we consider are associated to a quadratic conjugate pair of newforms, the analytic rank of the Jacobian is twice the analytic rank of either newform (see [GZ]).

The second Birch and Swinnerton-Dyer conjecture has not been proven for the cases we consider. In order to verify equation (1.1), we computed the five terms other than $\#Ш(J, \mathbf{Q})$ and solved for $\#Ш(J, \mathbf{Q})$. In each case, the value is an integer to within the accuracy of our calculations. This number is a power of 2, which coincides with the independently computed size of the 2-torsion subgroup of $Ш(J, \mathbf{Q})$. Hence, we have verified the second Birch and Swinnerton-Dyer conjecture for our curves at least numerically, if we assume that the Shafarevich-Tate group consists of 2-torsion only. (This is an ad hoc assumption based only on the fact that we do not know better.) See Section 6 for circumstances under which the verification is exact.

The curves are listed in Table 1, and the numerical results can be found in Table 2.

2. The Curves

Each of the genus 2 curves we consider is related to the Jacobian $J_0(N)$ of the modular curve $X_0(N)$ for some level N. When only one of these genus 2 curves arises from a given level N, then we denote this curve by C_N; when there are two curves coming from level N we use the notation $C_{N,A}$, $C_{N,B}$. The relationship of, say, C_N to $J_0(N)$ depends on the source. Briefly, from Hasegawa [Hs] we obtain quotients of $X_0(N)$ and from Wang [Wan] we obtain curves whose Jacobians are quotients of $J_0(N)$. In both cases the Jacobian J_N of C_N is isogenous to a 2-dimensional factor of $J_0(N)$. (When not referring to a specific curve, we will typically drop the subscript N from J.) In this way we can also associate C_N with a 2-dimensional subspace of $S_2(N)$, the space of cusp forms of weight 2 for $\Gamma_0(N)$.

We now discuss the precise source of the genus 2 curves we will consider. Hasegawa [Hs] has provided exact equations for all genus 2 curves which are quotients of $X_0(N)$ by a subgroup of the Atkin-Lehner involutions. There are 142 such curves. We are particularly interested in those where the Jacobian corresponds to a subspace of $S_2(N)$ spanned by a quadratic conjugate pair of newforms. There are 21 of these with level $N \leq 200$. For these curves we will provide evidence for the second conjecture. There are seven more such curves with $N > 200$. We can classify the other 2-dimensional subspaces into four types. There are 2-dimensional subspaces of oldforms that are irreducible under the action of the Hecke algebra. There are also 2-dimensional subspaces that are reducible under the action of the Hecke algebra and are spanned by two oldforms, two newforms or one of each. The Jacobians corresponding to the latter three kinds are always isogenous, over $\mathbf{Q}$, to the product of two elliptic curves. Given the small levels, these are elliptic curves for which Cremona [Cr2] has already provided evidence for the Birch and Swinnerton-Dyer conjectures. In Table 5, we describe the kind of cusp forms spanning the 2-dimensional subspace and the signs of their functional equations from the level at which they are newforms. The analytic and Mordell-Weil ranks were always the smallest possible given those signs.

The second set of curves was created by Wang [Wan] and is further discussed in [FM]. This set consists of 28 curves that were constructed by considering the spaces $S_2(N)$ with $N \leq 200$. Whenever a subspace spanned by a pair of quadratic conjugate newforms was found, these newforms were integrated to produce a quotient abelian variety A of $J_0(N)$. These quotients are *optimal* in the sense of [Ma], in that the kernel of the quotient map is connected.

The period matrix for A was created using certain intersection numbers. When all of the intersection numbers have the same value, then the polarization on A

induced from the canonical polarization of $J_0(N)$ is equivalent to a principal polarization. (Two polarizations are *equivalent* if they differ by an integer multiple.) Conversely, every 2-dimensional optimal quotient of $J_0(N)$ in which the induced polarization is equivalent to a principal polarization is found in this way.

Using theta functions, numerical approximations were found for the Igusa invariants of the abelian surfaces. These numbers coincide with rational numbers of fairly small height within the limits of the precision used for the computations. Wang then constructed curves defined over $\mathbf{Q}$ whose Igusa invariants are the rational numbers found. (There is one abelian surface at level $N = 177$ for which Wang was not able to find a curve.) If we assume that these rational numbers are the true Igusa invariants of the abelian surfaces, then it follows that Wang's curves have Jacobians isomorphic, over $\overline{\mathbf{Q}}$, to the principally polarized abelian surfaces in his list. Since the classification given by these invariants is only up to isomorphism over $\overline{\mathbf{Q}}$, the Jacobians of Wang's curves are not necessarily isomorphic to, but can be twists of, the optimal quotients of $J_0(N)$ over $\mathbf{Q}$ (see below).

There are four curves in Hasegawa's list which do not show up in Wang's list (they are listed in Table 1 with an H in the last column). Their Jacobians are quotients of $J_0(N)$, but are not optimal quotients. It is likely that there are modular genus 2 curves which neither are Atkin-Lehner quotients of $X_0(N)$ (in Hasegawa's sense) nor have Jacobians that are optimal quotients. These curves could be found by looking at the optimal quotient abelian surfaces and checking whether they are isogenous to a principally polarized abelian surface over $\mathbf{Q}$.

For 17 of the curves in Wang's list, the 2-dimensional subspace spanned by the newforms is the same as that giving one of Hasegawa's curves. In all of those cases, the curve given by Wang's equation is isomorphic, over $\mathbf{Q}$, to that given by Hasegawa. This verifies Wang's equations for these 17 curves. They are listed in Table 1 with HW in the last column.

The remaining eleven curves (listed in Table 1 with a W in the last column) derive from the other eleven optimal quotients in Wang's list. These are described in more detail in Section 2.1 below.

With the exception of curves C_{63}, $C_{117,A}$ and C_{189}, the Jacobians of all of our curves are absolutely simple, and the canonically polarized Jacobians have automorphism groups of size two. We showed that these Jacobians are absolutely simple using an argument like those in [Le, Sto1]. The automorphism group of the canonically polarized Jacobian of a hyperelliptic curve is isomorphic to the automorphism group of the curve (see [Mi2, Thm. 12.1]). Each automorphism of a hyperelliptic curve induces a linear fractional transformation on x-coordinates (see [CF, p. 1]). Each automorphism also permutes the six Weierstrass points. Once we believed we had found all of the automorphisms, we were able to show that there are no more by considering all linear fractional transformations sending three fixed Weierstrass points to any three Weierstrass points. In each case, we worked with sufficient accuracy to show that other linear fractional transformations did not permute the Weierstrass points.

Let ζ_3 denote a primitive third root of unity. The Jacobians of curves C_{63}, $C_{117,A}$ and C_{189} are each isogenous to the product of two elliptic curves over $\mathbf{Q}(\zeta_3)$, though not over $\mathbf{Q}$, where they are simple. These genus 2 curves have automorphism groups of size 12. In the following table we list the curve at the left. On the right we give one of the elliptic curves which is a factor of its Jacobian. The second factor is the conjugate.

$$\begin{array}{ll} C_{63}: & y^2 = x(x^2 + (9 - 12\zeta_3)x - 48\zeta_3) \\ C_{117,A}: & y^2 = x(x^2 - (12 + 27\zeta_3)x - (48 + 48\zeta_3)) \\ C_{189}: & y^2 = x^3 + (66 - 3\zeta_3)x^2 + (342 + 81\zeta_3)x + 105 + 21\zeta_3 \end{array}$$

Note that these three Jacobians are examples of abelian varieties 'with extra twist' as discussed in [Cr1], where they can be found in the tables on page 409.

2.1. **Models for the Wang-only curves.** As we have already noted, a modular genus 2 curve may be found by either, both, or neither of Wang's and Hasegawa's techniques. Hasegawa's method allows for the exact determination, over $\mathbf{Q}$, of the equation of any modular genus 2 curve it has found. On the other hand, if Wang's technique detects a modular genus 2 curve C_N, his method produces real approximations to a curve C'_N which is defined over $\mathbf{Q}$ and is isomorphic to C_N over $\overline{\mathbf{Q}}$. We will call C'_N a *twisted modular genus 2 curve.*

In this section we attempt to determine equations for the eleven modular genus 2 curves detected by Wang but not by Hasegawa. If we assume that Wang's equations for the twisted modular genus 2 curves are correct, we find that we are able to determine the twists. In turn, this gives us strong evidence that Wang's equations for the twisted curves were correct. Undoing the twist, we determine probable equations for the modular genus 2 curves. We end by providing further evidence for the correctness of these equations.

In what follows, we will use the notation of [Cr2] and recommend it as a reference on the general results that we assume here and in Section 4 and the appendix. Fix a level N and let $f(z) \in S_2(N)$. Then f has a Fourier expansion

$$f(z) = \sum_{n=1}^{\infty} a_n e^{2\pi i n z} .$$

For a newform f, we have $a_1 \neq 0$; so we can normalize it by setting $a_1 = 1$. In our cases, the a_n's are integers in a real quadratic field. For each prime p not dividing N, the corresponding Euler factor of the L-series $L(f,s)$ is $1 - a_p p^{-s} + p^{1-2s}$. Let $N(a_p)$ and $Tr(a_p)$ denote the norm and trace of a_p. The product of this Euler factor and its conjugate is $1 - Tr(a_p)\,p^{-s} + (N(a_p) + 2p)\,p^{-2s} - p\,Tr(a_p)\,p^{-3s} + p^2\,p^{-4s}$. Therefore, the characteristic polynomial of the p-Frobenius on the corresponding abelian variety over $\mathbf{F}_p$ is $x^4 - Tr(a_p)\,x^3 + (N(a_p) + 2p)\,x^2 - p\,Tr(a_p)\,x + p^2$. Let C be a curve, over $\mathbf{Q}$, whose Jacobian, over $\mathbf{Q}$, comes from the space spanned by f and its conjugate. Then we know that $p + 1 - \#C(\mathbf{F}_p) = Tr(a_p)$ and $\frac{1}{2}(\#C(\mathbf{F}_p)^2 + \#C(\mathbf{F}_{p^2})) - (p+1)\#C(\mathbf{F}_p) - p = N(a_p)$ (see [MS, Lemma 3]). For the odd primes less than 200, not dividing N, we computed $\#C(\mathbf{F}_p)$ and $\#C(\mathbf{F}_{p^2})$ for each curve given by one of Wang's equations. From these we could compute the characteristic polynomials of Frobenius and see if they agreed with those predicted by the a_p's of the newforms.

Of the eleven curves, the characteristic polynomials agreed for only four. In each of the remaining seven cases we found a twist of Wang's curve whose characteristic polynomials agreed with those predicted by the newform for all odd primes less than 200 not dividing N. Four of these twists were quadratic and three were of higher degree. It is these twists that appear in Table 1.

We can provide further evidence that these equations are correct. For each curve given in Table 1, it is easy to determine the primes of singular reduction. In

Section 3.4 we will provide techniques for determining which of those primes divides the conductor of its Jacobian. In each case, the primes dividing the conductor of the Jacobian of the curve are exactly the primes dividing the level N; this is necessary. With the exception of curve C_{188}, all the curves come from odd levels. We used Liu's `genus2reduction` program (`ftp://megrez.math.u-bordeaux.fr/pub/liu`) to compute the conductor of the curve. In each case (other than curve C_{188}), the conductor is the square of the level; this is also necessary. For curve C_{188}, the odd part of the conductor of the curve is the square of the odd part of the level.

In addition, since the Jacobians of the Wang curves are optimal quotients, we can compute $k \cdot \Omega$ (where k is the Manin constant, conjectured to be 1) using the newforms. In each case, these agree (to within the accuracy of our computations) with the Ω's computed using the equations for the curves. We can also compute the value of c_p for optimal quotients from the newforms, when p exactly divides N and the eigenvalue of the pth Atkin-Lehner involution is -1. When p exactly divides N and the eigenvalue of the pth Atkin-Lehner involution is $+1$, the component group is either 0, $\mathbf{Z}/2\mathbf{Z}$, or $(\mathbf{Z}/2\mathbf{Z})^2$. These results are always in agreement with the values computed using the equations for the curves. The algorithms based on the newforms are described in Section 4, those based on the equations of the curves are described in Section 3.

Lastly, we were able to compute the Mordell-Weil ranks of the Jacobians of the curves given by ten of these eleven equations. In each case it agrees with the analytic rank of the Jacobian, as deduced from the newforms.

It should be noted that curve $C_{125,B}$ is the $\sqrt{5}$-twist of curve $C_{125,A}$; the corresponding statement holds for the associated 2-dimensional subspaces of $S_2(125)$. Since curve $C_{125,A}$ is a Hasegawa curve, this proves that the equation given in Table 1 for curve $C_{125,B}$ is correct.

The a_p's and other information concerning Wang's curves are currently kept in a database at the Institut für experimentelle Mathematik in Essen, Germany. Most recently, this database was under the care of Michael Müller. William Stein also keeps a database of a_p's for newforms.

Remark 2.1. For the remainder of this paper we will assume that the equations for the curves given in Table 1 are correct; that is, that they are equations for the curves whose Jacobians are isogenous to a factor of $J_0(N)$ in the way described above. Some of the quantities can be computed either from the newform or from the equation for the curve. We performed both computations whenever possible, and view this duplicate effort as an attempt to verify our implementation of the algorithms rather than an attempt to verify the equations in Table 1. For most quantities, one method or the other is not guaranteed to produce a value; in this case, we simply quote the value from whichever method did succeed. The reader who is disturbed by this philosophy should ignore the Wang-only curves, since the equations for the Hasegawa curves can be proven to be correct.

3. Algorithms for genus 2 curves

In this section, we describe the algorithms that are based on the given models for the curves. We give algorithms that compute all terms on the right hand side of equation (1.1), with the exception of the size of the Shafarevich-Tate group. We describe, however, how to find the size of its 2-torsion subgroup. Note that these algorithms are for general genus 2 curves and do not depend on modularity.

3.1. **Torsion Subgroup.** The computation of the torsion subgroup of $J(\mathbf{Q})$ is straightforward. We used the technique described in [CF, pp. 78–82]. This technique is not always effective, however. For an algorithm working in all cases see [Sto3].

3.2. **Mordell-Weil rank and $Ш(J,\mathbf{Q})[2]$.** The group $J(\mathbf{Q})$ is a finitely generated abelian group and so is isomorphic to $\mathbf{Z}^r \oplus J(\mathbf{Q})_{\text{tors}}$ for some r called the Mordell-Weil rank. As noted above (see Section 1), we justifiably use r to denote both the analytic and Mordell-Weil ranks since they agree for all curves in Table 1.

We used the algorithm described in [FPS] to compute $\mathrm{Sel}^2_{\text{fake}}(J,\mathbf{Q})$ (notation from [PSc]), which is a quotient of the 2-Selmer group $\mathrm{Sel}^2(J,\mathbf{Q})$. More details on this algorithm can be found in [Sto2]. Theorem 13.2 of [PSc] explains how to get $\mathrm{Sel}^2(J,\mathbf{Q})$ from $\mathrm{Sel}^2_{\text{fake}}(J,\mathbf{Q})$. Let $M[2]$ denote the 2-torsion of an abelian group M and let $\dim V$ denote the dimension of an $\mathbf{F}_2$ vector space V. We have $\dim \mathrm{Sel}^2(J,\mathbf{Q}) = r + \dim J(\mathbf{Q})[2] + \dim Ш(J,\mathbf{Q})[2]$. In other words,

$$\dim\, Ш(J,\mathbf{Q})[2] = \dim \mathrm{Sel}^2(J,\mathbf{Q}) - r - \dim J(\mathbf{Q})[2].$$

It is interesting to note that in all 30 cases where $\dim Ш(J,\mathbf{Q})[2] \leq 1$, we were able to compute the Mordell-Weil rank independently from the analytic rank. The cases where $\dim Ш(J,\mathbf{Q})[2] = 1$ are discussed in more detail in Section 6. For both of the remaining cases we have $\dim Ш(J,\mathbf{Q})[2] = 2$. One of these cases is $C_{125,B}$. For this curve we computed $\mathrm{Sel}^{\sqrt{5}}(J_{125,B},\mathbf{Q})$ using the technique described in [Sc]. From this, we were able to determine that the Mordell-Weil rank is 0 independently from the analytic rank. For the other case, $C_{133,A}$, we could show that r had to be either 0 or 2 from the equation, but we needed the analytic computation to show that $r = 0$.

3.3. **Regulator.** When the Mordell-Weil rank is 0, then the regulator is 1. When the Mordell-Weil rank is positive, then to compute the regulator, we first need to find generators for $J(\mathbf{Q})/J(\mathbf{Q})_{\text{tors}}$. The regulator is the determinant of the canonical height pairing matrix on this set of generators. An algorithm for computing the generators and canonical heights is given in [FS]; it was used to find generators for $J(\mathbf{Q})/J(\mathbf{Q})_{\text{tors}}$ and to compute the regulators. In that article, the algorithm for computing height constants at the infinite prime is not clearly explained and there are some errors in the examples. A clear algorithm for computing infinite height constants is given in [Sto3]. In [Sto4], some improvements of the results and algorithms in [FS] and [Sto3] are discussed. The regulators in Table 2 have been double-checked using these improved algorithms.

3.4. **Tamagawa Numbers.** Let $\mathcal{O}$ be the integer ring in K which will be $\mathbf{Q}_p$ or $\mathbf{Q}_p^{\text{unr}}$ (the maximal unramified extension of $\mathbf{Q}_p$). Let $\mathcal{J}$ be the Néron model of J over $\mathcal{O}$. Define $\mathcal{J}^0$ to be the open subgroup scheme of $\mathcal{J}$ whose generic fiber is isomorphic to J over K and whose special fiber is the identity component of the closed fiber of $\mathcal{J}$. The group $\mathcal{J}^0(\mathcal{O})$ is isomorphic to a subgroup of $J(K)$ which we denote $J^0(K)$. The group $J(\mathbf{Q}_p^{\text{unr}})/J^0(\mathbf{Q}_p^{\text{unr}})$ is the component group of $\mathcal{J}$ over $\mathcal{O}_{\mathbf{Q}_p^{\text{unr}}}$. We are interested in computing $c_p = \#J(\mathbf{Q}_p)/J^0(\mathbf{Q}_p)$, which is sometimes called the Tamagawa number. Since Néron models are stable under unramified base extension, the $\mathrm{Gal}(\mathbf{Q}_p^{\text{unr}}/\mathbf{Q}_p)$-invariant subgroup of $J^0(\mathbf{Q}_p^{\text{unr}})$

is $J^0(\mathbf{Q}_p)$. Since $H^1(\mathrm{Gal}(\mathbf{Q}_p^{\mathrm{unr}}/\mathbf{Q}_p), J^0(\mathbf{Q}_p^{\mathrm{unr}}))$ is trivial (see [Mi1, p. 58]) we see that the $\mathrm{Gal}(\mathbf{Q}_p^{\mathrm{unr}}/\mathbf{Q}_p)$-invariant subgroup of $J(\mathbf{Q}_p^{\mathrm{unr}})/J^0(\mathbf{Q}_p^{\mathrm{unr}})$ is $J(\mathbf{Q}_p)/J^0(\mathbf{Q}_p)$.

There exist several discussions in the literature on constructing the group $J(\mathbf{Q}_p^{\mathrm{unr}})/J^0(\mathbf{Q}_p^{\mathrm{unr}})$ starting with an integral model of the underlying curve. For our purposes, we especially recommend Silverman's book [Si], Chapter IV, Sections 4 and 7. For a more detailed treatment, see [BLR, chap. 9] and [Ed2, §2]. One can find justifications for what we will do in these sources. While constructing such groups, we ran into a number of difficulties that we did not find described anywhere. For that reason, we will present examples of such difficulties that arose, as well as our methods of resolution. We do not claim that we will describe all situations that could arise.

When computing c_p we need a proper, regular model $\mathcal{C}$ for C over $\mathbf{Z}_p$. Let $\mathbf{Z}_p^{\mathrm{unr}}$ denote the ring of integers of $\mathbf{Q}_p^{\mathrm{unr}}$ and note that $\mathbf{Z}_p^{\mathrm{unr}}$ is a pro-étale Galois extension of $\mathbf{Z}_p$ with Galois group $\mathrm{Gal}(\mathbf{Z}_p^{\mathrm{unr}}/\mathbf{Z}_p) = \mathrm{Gal}(\mathbf{Q}_p^{\mathrm{unr}}/\mathbf{Q}_p)$. It follows that giving a model for C over $\mathbf{Z}_p$ is equivalent to giving a model for C over $\mathbf{Z}_p^{\mathrm{unr}}$ that is equipped with a Galois action. We have found it convenient to always work with the latter description. Thus for us, giving a model over $\mathbf{Z}_p$ will always mean giving a model over $\mathbf{Z}_p^{\mathrm{unr}}$ together with a Galois action.

In order to find a proper, regular model for C over $\mathbf{Z}_p$, we start with the models in Table 1. Technically, we consider the curves to be the two affine pieces $y^2+g(x)y = f(x)$ and $v^2 + u^3g(1/u)v = u^6f(1/u)$, glued together by $ux = 1$, $v = u^3y$. We blow them up at all points that are not regular until we have a regular model. (A point is *regular* if the cotangent space there has two generators.) These curves are all proper, and this is not affected by blowing up.

Let $\mathcal{C}_p$ denote the special fiber of $\mathcal{C}$ over $\mathbf{Z}_p^{\mathrm{unr}}$. The group $J(\mathbf{Q}_p^{\mathrm{unr}})/J^0(\mathbf{Q}_p^{\mathrm{unr}})$ is isomorphic to a quotient of the degree 0 part of the free group on the irreducible components of $\mathcal{C}_p$. Let the irreducible components be denoted $\mathcal{D}_i$ for $1 \le i \le n$, and let the multiplicity of $\mathcal{D}_i$ in $\mathcal{C}_p$ be d_i. Then the degree 0 part of the free group has the form

$$L = \{\sum_{i=1}^n \alpha_i \mathcal{D}_i \mid \sum_{i=1}^n d_i\alpha_i = 0\}\,.$$

In order to describe the group that we quotient out by, we must discuss the intersection pairing. For components $\mathcal{D}_i$ and $\mathcal{D}_j$ of the special fiber, let $\mathcal{D}_i{\cdot}\mathcal{D}_j$ denote their intersection pairing. In all of the special fibers that arise in our examples, distinct components intersect transversally. Thus, if $i \neq j$, then $\mathcal{D}_i \cdot \mathcal{D}_j$ equals the number of points at which $\mathcal{D}_i$ and $\mathcal{D}_j$ intersect. The case of self-intersection ($i = j$) is discussed below.

The kernel of the map from L to $J(\mathbf{Q}_p^{\mathrm{unr}})/J^0(\mathbf{Q}_p^{\mathrm{unr}})$ is generated by divisors of the form

$$[\mathcal{D}_j] = \sum_{i=1}^n (\mathcal{D}_j \cdot \mathcal{D}_i)\mathcal{D}_i$$

for each component $\mathcal{D}_j$. We can deduce $\mathcal{D}_j \cdot \mathcal{D}_j$ by noting that $[\mathcal{D}_j]$ must be contained in the group L. This follows from the fact that the intersection pairing of $\mathcal{C}_p = \sum d_i\mathcal{D}_i$ with any irreducible component is 0.

Example 1. Curve $C_{65,B}$ over $\mathbf{Z}_2$.

The Jacobian of $C_{65,B}$ is a quotient of the Jacobian of $X_0(65)$. Since 65 is odd, $J_0(65)$ has good reducation at 2; however, $C_{65,B}$ has singular reduction at 2. Since the equation for this curve is conjectural (it is a Wang-only curve), it will be nice to verify that 2 does not divide the conductor of its Jacobian, i.e. that the Jacobian has good reduction at 2. In addition, we will need a proper, regular model for this curve in order to find Ω.

We start with the arithmetic surface over $\mathbf{Z}_2^{\text{unr}}$ given by the two pieces $y^2 = f(x) = -x^6 + 10x^5 - 32x^4 + 20x^3 + 40x^2 + 6x - 1$ and $v^2 = u^6 f(1/u)$. (Here and in the following we will not specify the gluing maps.) This arithmetic surface is regular at $u = 0$ so we focus our attention on the first affine piece. The special fiber of $y^2 = f(x)$ over $\mathbf{Z}_2^{\text{unr}}$ is given by $(y + x^3 + 1)^2 = 0 \pmod 2$; this is a genus 0 curve of multiplicity 2 that we denote A. This model is not regular at the two points $(x - \alpha, y, 2)$, where α is a root of $x^2 - 3x - 1$. The current special fiber is in Figure 1 and is labelled *Fiber 1*.

We fix α and move $(x - \alpha, y, 2)$ to the origin using the substitution $x_0 = x - \alpha$. We get

$$y^2 = -x_0^6 + (-6\alpha+10)x_0^5 + (5\alpha-47)x_0^4 + (-28\alpha+60)x_0^3 + (-11\alpha-2)x_0^2 + (-24\alpha-16)x_0$$

which we rewrite as the pair of equations

$$\begin{aligned} g_1(x_0, y, p) &= -x_0^6 + (-3\alpha + 5)px_0^5 + (5\alpha - 47)x_0^4 + (-7\alpha + 15)p^2x_0^3 \\ &\qquad + (-11\alpha - 2)x_0^2 + (-3\alpha - 2)p^3x_0 - y^2 \\ &= 0, \\ p &= 2. \end{aligned}$$

To blow up at (x_0, y, p), we introduce projective coordinates (x_1, y_1, p_1) with $x_0y_1 = x_1y$, $x_0p_1 = x_1p$, and $yp_1 = y_1p$. We look in three affine pieces that cover the blow-up of $g_1(x_0, y, p) = 0$, $p = 2$ and check for regularity.

$x_1 = 1$**:** We have $y = x_0y_1$, $p = x_0p_1$. We get $g_2(x_0, y_1, p_1) = 0$, $x_0p_1 = 2$, where

$$\begin{aligned} g_2(x_0, y_1, p_1) &= x_0^{-2}g_1(x_0, x_0y_1, x_0p_1) \\ &= -x_0^4 + (-3\alpha + 5)p_1x_0^4 + (5\alpha - 47)x_0^2 + (-7\alpha + 15)p_1^2x_0^3 \\ &\qquad + (-11\alpha - 2) + (-3\alpha - 2)p_1^3x_0^2 - y_1^2\,. \end{aligned}$$

In the reduction we have either $x_0 = 0$ or $p_1 = 0$.

$x_0 = 0$**:** $(y_1 + \alpha + 1)^2 = 0$. This is a new component which we denote B. It has genus 0 and multiplicity 2. We check regularity along B at $(x_0, y_1 + \alpha + 1, p_1 - t, 2)$, with t in $\mathbf{Z}_2^{\text{unr}}$, and find that B is nowhere regular.

$p_1 = 0$**:** $(y_1 + x_0^2 + \alpha x_0 + (\alpha + 1))^2 = 0$. Using the gluing maps, we see that this is A.

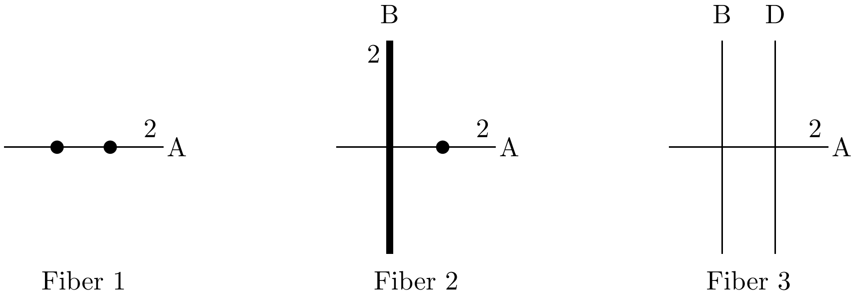
$y_1 = 1$**:** We get no new information from this affine piece.

$p_1 = 1$**:** We have $x_0 = x_1p$, $y = y_1p$. We get $g_3(x_1, y_1, p) = p^{-2}g_1(x_1p, y_1p, p) = 0$, $p = 2$. In the reduction we have

$p = 0$**:** $(y_1 + (\alpha + 1)x_1)^2 = 0$. Using the gluing maps, we see that this is B. It is nowhere regular.

The current special fiber is in Figure 1 and is labelled *Fiber 2*. It is not regular along B and at the other point on A which we have not yet blown up. The component B does not lie entirely in any one affine piece so we will blow up the affine pieces $x_1 = 1$ and $p_1 = 1$ along B.

FIGURE 1. Special fibers of curve $C_{65,B}$ over $\mathbf{Z}_2$; points not regular are thick



To blow up $x_1 = 1$ along B we make the substitution $y_2 = y_1 + \alpha + 1$ and replace each factor of 2 in a coefficient by $x_0 p_1$. We have $g_4(x_0, y_2, p_1) = 0$ and $x_0 p_1 = 2$, and we want to blow up along the line $(x_0, y_2, 2)$. Blowing up along a line is similar to blowing up at a point: since we are blowing up at $(x_0, y_2, 2) = (x_0, y_2)$, we introduce projective coordinates x_3, y_3 together with the relation $x_0 y_3 = x_3 y_2$. We consider two affine pieces that cover the blow-up of $x_1 = 1$.

$x_3 = 1$**:** We have $y_2 = y_3 x_0$. We get $g_5(x_0, y_3, p_1) = x_0^{-2} g_4(x_0, y_3 x_0, p_1) = 0$ and $x_0 p_1 = 2$. In the reduction we have

$x_0 = 0$**:** $y_3^2 + (\alpha + 1) y_3 p_1 + \alpha p_1^3 + p_1^2 + \alpha + 1 = 0$. This is B. It is now a non-singular genus 1 curve.

$p_1 = 0$**:** $(x_0 + y_3 + \alpha)^2 = 0$. This is A. The point where B meets A transversally is regular.

$y_3 = 1$**:** We get no new information from this affine piece.

When we blow up $p_1 = 1$ along B we get essentially the same thing and all points are again regular.

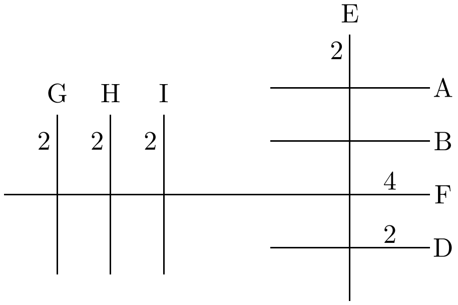
The other non-regular point on A is the conjugate of the one we blew up. Therefore, after performing the conjugate blow ups, it too will be a genus 1 component crossing A transversally. We denote this component D; it is conjugate to B.

We now have a proper, regular model $\mathcal{C}$ of C over $\mathbf{Z}_2$. Let $\mathcal{C}_2$ be the special fiber of this model; a diagram of $\mathcal{C}_2$ is in Figure 1 and is labelled *Fiber 3*. We can use $\mathcal{C}$ to show that the Néron model $\mathcal{J}$ of the Jacobian $J = J_{65,B}$ has good reduction at 2.

We know that the reduction of $\mathcal{J}^0$ is the extension of an abelian variety by a connected linear group. Since $\mathcal{C}$ is regular and proper, the abelian variety part of the reduction is the product of the Jacobians of the normalizations of the components of $\mathcal{C}_2$ (see [BLR, 9.3/11 and 9.5/4]). Thus, the abelian variety part is the product of the Jacobians of B and D. Since this is 2-dimensional, the reduction of $\mathcal{J}^0$ is an abelian variety. In other words, since the sum of the genera of the components of the special fiber is equal to the dimension of J, the reduction is an abelian variety. It follows that $\mathcal{J}$ has good reduction at 2, that the conductor of J is odd, and that $c_2 = 1$. As noted above, this gives further evidence that the equation given in Table 1 is correct.

Example 2. Curve C_{63} over $\mathbf{Z}_3$.

FIGURE 2. Special fiber of curve C_{63} over $\mathbf{Z}_3$



The Tamagawa number is often found using the intersection matrix and subdeterminants. This is not entirely satisfactory for cases where the special fiber has several components and a non-trivial Galois action. Here is an example of how to resolve this (see also [BL]).

When we blow up curve C_{63} over $\mathbf{Z}_3^{\mathrm{unr}}$, we get the special fiber shown in Figure 2. Elements of $\mathrm{Gal}(\mathbf{Q}_3^{\mathrm{unr}}/\mathbf{Q}_3)$ that do not fix the quadratic unramified extension of $\mathbf{Q}_3$ switch H and I. The other components are defined over $\mathbf{Q}_3$. All components have genus 0. The group $J(\mathbf{Q}_3^{\mathrm{unr}})/J^0(\mathbf{Q}_3^{\mathrm{unr}})$ is isomorphic to a quotient of

$$L = \{\alpha A+\beta B+\delta D+\epsilon E+\phi F+\gamma G+\eta H+\iota I \mid \alpha+\beta+2\delta+2\epsilon+4\phi+2\gamma+2\eta+2\iota = 0\}\,.$$

The kernel is generated by the following divisors.

$$\begin{array}{llll}
[A] = & -2A+E & [B] = & -2B+E \\
[D] = & -D+E & [E] = & A+B+D-4E+F \\
[F] = & E-2F+G+H+I & [G] = & F-2G \\
[H] = & F-2H & [I] = & F-2I
\end{array}$$

When we project away from A, we find that $J(\mathbf{Q}_3^{\mathrm{unr}})/J^0(\mathbf{Q}_3^{\mathrm{unr}})$ is isomorphic to

$$\langle B, D, E, F, G, H, I \mid E = 0, E = 2B, D = E, 4E = B + D + F,$$
$$2F = E + G + H + I, F = 2G = 2H = 2I\rangle.$$

At this point, it is straightforward to simplify the representation by elimination. Note that we projected away from A, which is Galois-invariant. It is best to continue eliminating Galois-invariant elements first. We find that this group is isomorphic to $\langle H, I \mid 2H = 2I = 0\rangle$ and elements of $\mathrm{Gal}(\mathbf{Q}_3^{\mathrm{unr}}/\mathbf{Q}_3)$ that do not fix the quadratic unramified extension of $\mathbf{Q}_3$ switch H and I. Therefore $J(\mathbf{Q}_3^{\mathrm{unr}})/J^0(\mathbf{Q}_3^{\mathrm{unr}}) \cong \mathbf{Z}/2\mathbf{Z} \oplus \mathbf{Z}/2\mathbf{Z}$ and $c_3 = \#J(\mathbf{Q}_3)/J^0(\mathbf{Q}_3) = 2$.

3.5. **Computing Ω.** By an *integral differential* (or *integral form*) on J we mean the pullback to J of a global relative differential form on the Néron model of J over $\mathbf{Z}$. The set of integral n-forms on J is a full-rank lattice in the $\mathbf{Q}$-vector space of global holomorphic n-forms on J. Since J is an abelian variety of dimension 2, the integral 1-forms are a free $\mathbf{Z}$-module of rank 2 and the integral 2-forms are a free $\mathbf{Z}$-module of rank 1. Moreover, the wedge of a basis for the integral 1-forms is a generator for the integral 2-forms. The quantity Ω is the integral, over the real points of J, of a generator for the integral 2-forms. (We choose the generator that leads to a positive integral.)

We now translate this into a computation on the curve C. Let $\{\omega_1, \omega_2\}$ be a $\mathbf{Q}$-basis for the holomorphic differentials on C and let $\{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$ be a $\mathbf{Z}$-basis for the homology of $C(\mathbf{C})$. Create a 2×4 complex matrix $M_{\mathbf{C}} = [\int_{\gamma_j} \omega_i]$ by integrating the differentials over the homology and let $M_{\mathbf{R}} = \mathrm{Tr}_{\mathbf{C}/\mathbf{R}}(M_{\mathbf{C}})$ be the 2×4 real matrix whose entries are traces from the complex matrix. The columns of $M_{\mathbf{R}}$ generate a lattice Λ in $\mathbf{R}^2$. If we make the standard identification between the holomorphic 1-forms on J and the holomorphic differentials on C (see [Mi2]), then the notation $\int_{J(\mathbf{R})} |\omega_1 \wedge \omega_2|$ makes sense and its value can be computed as the area of a fundamental domain for Λ.

If $\{\omega_1, \omega_2\}$ is a basis for the integral 1-forms on J, then $\int_{J(\mathbf{R})} |\omega_1 \wedge \omega_2| = \Omega$. On the other hand, the computation of $M_{\mathbf{C}}$ is simplest if we choose $\omega_1 = dX/Y$, and $\omega_2 = X\,dX/Y$ with respect to a model for C of the form $Y^2 = F(X)$; in this case we obtain Ω by a simple change-of-basis calculation. This assumes, of course, that we know how to express a basis for the integral 1-forms in terms of the basis $\{\omega_1, \omega_2\}$; this is addressed in more detail below.

It is worth mentioning an alternate strategy. Instead of finding a $\mathbf{Z}$-basis for the homology of $C(\mathbf{C})$ one could find a $\mathbf{Z}$-basis $\{\gamma_1', \gamma_2'\}$ for the subgroup of the homology that is fixed by complex conjugation (call this the real homology). Integrating would give us a 2×2 real matrix $M_{\mathbf{R}}'$ and the determinant of $M_{\mathbf{R}}'$ would equal the integral of $\omega_1 \wedge \omega_2$ over the connected component of $J(\mathbf{R})$. In other words, the number of real connected components of J is equal to the index of the $\mathbf{C}/\mathbf{R}$-traces in the real homology.

We now come to the question of determining the differentials on C which correspond to the integral 1-forms on J. Call these the integral differentials on C. This computation can be done one prime at a time. At each prime p this is equivalent to determining a $\mathbf{Z}_p^{\mathrm{unr}}$-basis for the global relative differentials on any proper, regular model for C over $\mathbf{Z}_p^{\mathrm{unr}}$. In fact a more general class of models can be used; see the discussion of models with rational singularities in [BLR, §6.7] and [Li, §4.1].

We start with the model $y^2 + g(x)y = f(x)$ given in Table 1. Note that the substitution $X = x$ and $Y = 2y + g(x)$ gives us a model of the form $Y^2 = F(X)$. For integration purposes, our preferred differentials are $dX/Y = dx/(2y + g(x))$ and $X\,dX/Y = x\,dx/(2y + g(x))$. It is not hard to show that at primes of nonsingular reduction for the $y^2 + g(x)y = f(x)$ model, these differentials will generate the integral 1-forms. For each prime p of singular reduction we give the following algorithm. All steps take place over $\mathbf{Z}_p^{\mathrm{unr}}$.

Step 1: Compute explicit equations for a proper, regular model $\mathcal{C}$.

Step 2: Diagram the configuration of the special fiber of $\mathcal{C}$.

Step 3: (Optional) Identify exceptional components and blow them down in the configuration diagram. Repeat step 3 as necessary.

Step 4: (Optional) Remove components with genus 0 and self-intersection -2. Since C has genus greater than 1, there will be a component that is not of this kind.

(This step corresponds to contracting the given components. The model obtained would no longer be regular; it would, however, be a proper model with rational singularities. We will not need a diagram of the resulting configuration.)

Step 5: Determine a $\mathbf{Z}_p^{\mathrm{unr}}$-basis for the integral differentials. It suffices to check this on a dense open subset of each surviving component. Note that we have explicit equations for a dense open subset of each of these components from the model $\mathcal{C}$ in step 1. A pair of differentials $\{\eta_1, \eta_2\}$ will be a basis for the integral differentials (at p) if the following three statements are true.

a: The pair $\{\eta_1, \eta_2\}$ is a basis for the holomorphic differentials on C.

b: The reductions of η_1 and η_2 produce well-defined differentials mod p on an open subset of each surviving component.

c: If $a_1\eta_1 + a_2\eta_2 = 0 \pmod p$ on all surviving components, then $p|a_1$ and $p|a_2$.

Techniques for explicitly computing a proper, regular model are discussed in Section 3.4. A configuration diagram should include the genus, multiplicity and self-intersection number of each component and the number and type of intersections between components. Note that when an exceptional component is blown down, all of the self-intersection numbers of the components intersecting it will go up (towards 0). In particular, components which were not exceptional before may become exceptional in the new configuration.

Steps 3 and 4 are intended to make this algorithm more efficient for a human. They are entirely optional. For a computer implementation it may be easier to simply check every component than to worry about manipulating configurations.

The curves in Table 1 are given as $y^2 + g(x)y = f(x)$. We assumed, at first, that $dx/(2y + g(x))$ and $x\,dx/(2y + g(x))$ generate the integral differentials. We integrated these differentials around each of the four paths generating the complex homology and found a provisional Ω. Then we checked the proper, regular models to determine if these differentials really do generate the integral differentials and adjusted Ω when necessary. There were three curves where we needed to adjust Ω. We describe the adjustment for curve $C_{65,B}$ in the following example. For curve C_{63}, we used the differentials $3\,dx/(2y + g(x))$ and $x\,dx/(2y + g(x))$. For curve $C_{65,A}$, we used the differentials $3\,dx/(2y + g(x))$ and $3x\,dx/(2y + g(x))$.

Example 3. Curve $C_{65,B}$.

The primes of singular reduction for curve $C_{65,B}$ are 2, 5 and 13. In Example 1 of Section 3.4, we found a proper, regular model $\mathcal{C}$ for C over $\mathbf{Z}_2^{\mathrm{unr}}$. The configuration for the special fiber of $\mathcal{C}$ is sketched in Figure 1 under the label *Fiber 3.* Component A is exceptional and can be blown down to produce a model in which B and D cross transversally. Since B and D both have genus 1, we cannot eliminate either of these components. Furthermore, it suffices to check B, since D is its Galois conjugate.

To get from the equation of the curve listed in Table 1 to an affine containing an open subset of B we need to make the substitutions $x = x_0 - \alpha$ and $y = x_0(y_3x_0 - \alpha - 1)$. We also have $x_0p_1 = 2$. Using the substitutions and the relation $dx_0/x_0 = -dp_1/p_1$, we get

$$\frac{dx}{2y} = \frac{-dp_1}{2p_1(y_3x_0 - \alpha - 1)} \quad \text{and} \quad \frac{x\,dx}{2y} = \frac{-(x_0 + \alpha)\,dp_1}{2p_1(y_3x_0 - \alpha - 1)}\,.$$

Note that $p_1 - t$ is a uniformizer at $p_1 = t$ almost everywhere on B. When we multiply each differential by 2, then the denominator of each is almost everywhere non-zero; thus, dx/y and $x\,dx/y$ are integral at 2. Moreover, although the linear combination $(x-\alpha)\,dx/y$ is identically zero on B, it is not identically zero on D (its Galois conjugate is not identically zero on B). Thus, our new basis is correct at 2. We multiply the provisional Ω by 4 to get a new provisional Ω which is correct at 2.

Similar (but somewhat simpler) computations at the primes 5 and 13 show that no adjustment is needed at these primes. Thus, dx/y and $x\,dx/y$ form a basis for the integral differentials of curve $C_{65,B}$, and the correct value of Ω is 4 times our original guess.

4. Modular algorithms

In this section, we describe the algorithms that were used to compute some of the data from the newforms. This includes the analytic rank and leading coefficient of the L-series. For optimal quotients, the value of $k \cdot \Omega$ can also be found (k is the Manin constant), as well as partial information on the Tamagawa numbers c_p and the size of the torsion subgroup.

4.1. **Analytic rank of $L(J,s)$ and leading coefficient at $s=1$.**

Fix a Jacobian J corresponding to the 2-dimensional subspace of $S_2(N)$ spanned by quadratic conjugate, normalized newforms f and $\overline{f}$. Let W_N be the Fricke involution. The newforms f and $\overline{f}$ have the same eigenvalue ϵ_N with respect to W_N, namely $+1$ or -1. In the notation of Section 2, let

$$L(f,s)=\sum_{n=1}^{\infty}\frac{a_n}{n^s}$$

be the L-series of f; then $L(\overline{f},s)$ is the Dirichlet series whose coefficients are the conjugates of the coefficients of $L(f,s)$. (Recall that the a_n are integers in some real quadratic field.) The order of $L(f,s)$ at $s=1$ is even when $\epsilon_N=-1$ and odd when $\epsilon_N=+1$. We have $L(J,s)=L(f,s)L(\overline{f},s)$. Thus the analytic rank of J is 0 modulo 4 when $\epsilon_N=-1$ and 2 modulo 4 when $\epsilon_N=+1$. We found that the ranks were all 0 or 2. To prove that the analytic rank of J is 0, we need to show $L(f,1)\neq 0$ and $L(\overline{f},1)\neq 0$. In the case that $\epsilon_N=+1$, to prove that the analytic rank is 2, we need to show that $L'(f,1)\neq 0$ and $L'(\overline{f},1)\neq 0$. When $\epsilon_N=-1$, we can evaluate $L(f,1)$ as in [Cr2, §2.11]. When $\epsilon_N=+1$, we can evaluate $L'(f,1)$ as in [Cr2, §2.13]. Each appropriate $L(f,1)$ or $L'(f,1)$ was at least 0.1 and the errors in our approximations were all less than 10^{-67}. In this way we determined the analytic ranks, which we denote r. As noted in the introduction, the analytic rank equals the Mordell-Weil rank if $r=0$ or $r=2$. Thus, we can simply call r the rank, without fear of ambiguity.

To compute the leading coefficient of $L(J,s)$ at $s=1$, we note that $\lim_{s\to 1}L(J,s)/(s-1)^r=L^{(r)}(J,1)/r!$. In the $r=0$ case, we simply have $L(J,1)=L(f,1)L(\overline{f},1)$. In the $r=2$ case, we have $L''(J,s)=L''(f,s)L(\overline{f},s)+2L'(f,s)L'(\overline{f},s)+L(f,s)L''(\overline{f},s)$. Evaluating both sides at $s=1$ we get $\frac{1}{2}L''(J,1)=L'(f,1)L'(\overline{f},1)$.

4.2. **Computing $k\cdot\Omega$.**

Let J, f and $\overline{f}$ be as in Section 4.1 and assume J is an optimal quotient. Let V be the 2-dimensional space spanned by f and $\overline{f}$. Choose a basis $\{\omega_1,\omega_2\}$ for the subgroup of V consisting of forms whose q-expansion coefficients lie in $\mathbf{Z}$. Let $k\cdot\Omega$ be the volume of the real points of the quotient of $\mathbf{C}\times\mathbf{C}$ by the lattice of period integrals $(\int_\gamma \omega_1, \int_\gamma \omega_2)$ with γ in the integral homology

$H_1(X_0(N), \mathbf{Z})$. The rational number k is called the *Manin constant*. In practice we compute $k \cdot \Omega$ using modular symbols and a generalization to dimension 2 of the algorithm for computing periods described in [Cr2, §2.10]. When $L(J, 1) \neq 0$ the method of [Cr2, §2.11] coupled with Sections 4.1 and 4.3 can also be used to compute $k \cdot \Omega$.

A slight generalization of the argument of Proposition 2 of [Ed1] proves that k is, in fact, an integer. This generalization can be found in [AS2], where one also finds a conjecture that k must equal 1 for all optimal quotients of Jacobians of modular curves, which generalizes the longstanding conjecture of Manin that k equals 1 for all optimal elliptic curves. In unpublished work, Edixhoven has partially proven Manin's conjecture.

The computations of the present paper verify that k equals 1 for the optimal quotients that we are considering. Specifically, we computed $k \cdot \Omega$ as above and Ω as described in Section 3.5. The quotient of the two values was always well within 0.5 of 1.

4.3. **Computing** $L(J, 1)/(k \cdot \Omega)$**.** We compute the rational number $L(J, 1)/(k \cdot \Omega)$, for optimal quotients, using the algorithm in [AS1]. This algorithm generalizes the algorithm described in [Cr2, §2.8] to dimension greater than 1.

4.4. **Tamagawa numbers.** In this section we assume that p is a prime which exactly divides the conductor N of J. Under these conditions, Grothendieck [Gr] gave a description of the component group of J in terms of a monodromy pairing on certain character groups. (For more details, see Ribet [Ri, §2].) If, in addition, J is a new optimal quotient of $J_0(N)$, one deduces the following. When the eigenvalue for f of the Atkin-Lehner involution W_p is $+1$, then the rational component group of J is a subgroup of $(\mathbf{Z}/2\mathbf{Z})^2$. Furthermore, when the eigenvalue of W_p is -1, the algorithm described in [Ste] can be used to compute the value of c_p.

4.5. **Torsion subgroup.** To compute an integer divisible by the order of the torsion subgroup of J we make use of the following two observations. First, it is a consequence of the Eichler-Shimura relation [Sh, §7.9] that if p is a prime not dividing the conductor N of J and $f(T)$ is the characteristic polynomial of the endomorphism T_p of J, then $\#J(\mathbf{F}_p) = f(p + 1)$ (see [Cr2, §2.4] for an algorithm to compute $f(T)$). Second, if p is an odd prime at which J has good reduction, then the natural map $J(\mathbf{Q})_{\text{tors}} \to J(\mathbf{F}_p)$ is injective (see [CF, p. 70]). This does not depend on whether J is an optimal quotient. To obtain a lower bound on the torsion subgroup for optimal quotients, we use modular symbols and the Abel-Jacobi theorem [La, IV.2] to compute the order of the image of the rational point $(0) - (\infty) \in J_0(N)$.

5. Tables

In Table 1, we list the 32 curves described in Section 2. We give the level N from which each curve arose, an integral model for the curve, and list the source(s) from which it came (H for Hasegawa [Ha], W for Wang [Wan]). Throughout the paper, the curves are denoted C_N (or $C_{N,A}$, $C_{N,B}$).

In Table 2, we list the curve C_N simply by N, the level from which it arose. Let r denote the rank. We list $\lim_{s \to 1}(s - 1)^{-r} L(J, s)$ where $L(J, s)$ is the L-series for the Jacobian J of C_N and round off the results to five digits. The symbol Ω was defined in Section 3.5 and is also rounded to five digits. Let Reg denote the

N	Equation	Source
23	$y^2 + (x^3 + x + 1)y = -2x^5 - 3x^2 + 2x - 2$	HW
29	$y^2 + (x^3 + 1)y = -x^5 - 3x^4 + 2x^2 + 2x - 2$	HW
31	$y^2 + (x^3 + x^2 + 1)y = -x^5 - 5x^4 - 5x^3 + 3x^2 + 2x - 3$	HW
35	$y^2 + (x^3 + x)y = -x^5 - 8x^3 - 7x^2 - 16x - 19$	H

TABLE 1. Levels, integral models and sources for curves

regulator, also rounded to five digits. We list the c_p's by primes of increasing order dividing the level N. We denote $J(\mathbf{Q})_{\text{tors}} = \Phi$ and list its size. We use Ш? to denote the size of $(\lim_{s\to 1}(s-1)^{-r}L(J,s)) \cdot (\#J(\mathbf{Q})_{\text{tors}})^2/(\Omega \cdot \text{Reg} \cdot \prod c_p)$, rounded to the nearest integer. We will refer to this as the *conjectured size of* Ш$(J, \mathbf{Q})$. For rank 0 optimal quotients this integer equals the (a priori) rational number $(L(J,1)/(k \cdot \Omega)) \cdot ((\#J(\mathbf{Q})_{\text{tors}})^2/\prod c_p)$; of course there is no rounding error in this computation. For all other cases the last column gives a bound on the accuracy of the computations; all values of Ш? were at least this close to the nearest integer before rounding.

Table 2. Conjectured sizes of Ш$(J, \mathbf{Q})$

In Table 3 are generators of $J(\mathbf{Q})/J(\mathbf{Q})_{\text{tors}}$ for the curves whose Jacobians have Mordell-Weil rank 2. The generators are given as divisor classes. Whenever possible, we have chosen generators of the form $[P - Q]$ where P and Q are rational points on the curve. Curve 167 is the only example where this is not the case, since the degree zero divisors supported on the (known) rational points on C_{167} generate a subgroup of index two in the full Mordell-Weil group. Affine points are given by their x and y coordinates in the model given in Table 1. There are two points at infinity in the normalization of the curves described by our equations, with the exception of curve C_{188}. These are denoted by ∞_a, where a is the value of the function y/x^3 on the point in question. The (only) point at infinity on curve C_{188} is simply denoted ∞.

TABLE 4. Namikawa and Ueno classification of special fibers

In Table 4 are the reduction types, from the classification of [NU], of the special fibers of the minimal, proper, regular models of the curves for each of the primes of singular reduction for the curve. They are the same as the primes dividing the level except that curve $C_{65,A}$ has singular reduction at the prime 3 and curve $C_{65,B}$ has singular reduction at the prime 2.

6. Discussion of Shafarevich-Tate groups and evidence for the second conjecture

From Section 3.2 we have $\dim Ш(J,\mathbf{Q})[2] = \dim \mathrm{Sel}^2(J,\mathbf{Q}) - r - \dim J(\mathbf{Q})[2]$. With the exception of curves $C_{65,A}$, $C_{65,B}$, $C_{125,B}$, and $C_{133,A}$ we have $\dim Ш(J,\mathbf{Q})[2] = 0$. Thus we expect $\#Ш(J,\mathbf{Q})$ to be an odd square. In each case, the conjectured size of $Ш(J,\mathbf{Q})$ is 1. For curves $C_{65,A}$, $C_{65,B}$, $C_{125,B}$ and $C_{133,A}$ we have $\dim Ш(J,\mathbf{Q})[2] = 1, 1, 2$ and 2 and the conjectured size of $Ш(J,\mathbf{Q}) = 2, 2, 4$ and 4, respectively. We see that in each case, the (conjectured) size of the odd part of $Ш(J,\mathbf{Q})$ is 1 and the 2-part is accounted for by its 2-torsion.

Recall that for rank 0 optimal quotients we are able to exactly determine the value which the second Birch and Swinnerton-Dyer conjecture predicts for $Ш(J,\mathbf{Q})$. From the previous paragraph, we then see that equation (1.1) holds if and only if $Ш(J,\mathbf{Q})$ is killed by 2.

It is also interesting to consider deficient primes. A prime p is *deficient* with respect to a curve C of genus 2, if C has no degree 1 rational divisor over $\mathbf{Q}_p$. From [PSt], the number of deficient primes has the same parity as $\dim Ш(J,\mathbf{Q})[2]$. Curve $C_{65,A}$ has one deficient prime 3. Curve $C_{65,B}$ has one deficient prime 2. Curve $C_{117,B}$ has two deficient primes 3 and ∞. The rest of the curves have no deficient primes.

Since we have found r (analytic rank) independent points on each Jacobian, we have a direct proof that the Mordell-Weil rank must equal the analytic rank if $\dim Ш(J,\mathbf{Q})[2] = 0$. For curves $C_{65,A}$ and $C_{65,B}$, the presence of an odd number of deficient primes gives us a similar result. For $C_{125,B}$ we used a $\sqrt{5}$-Selmer group to get a similar result. Thus, we have an independent proof of equality between analytic and Mordell-Weil ranks for all curves except $C_{133,A}$.

The 2-Selmer groups have the same dimensions for the pairs $C_{125,A}$, $C_{125,B}$ and $C_{133,A}$, $C_{133,B}$. For each pair, the Mordell-Weil rank is 2 for one curve and the 2-torsion of the Shafarevich-Tate group has dimension 2 for the other. In addition, the two Jacobians, when canonically embedded into $J_0(N)$, intersect in their 2-torsion subgroups, and one can check that their 2-Selmer groups become equal under the identification of $H^1(\mathbf{Q}, J_{N,A}[2])$ with $H^1(\mathbf{Q}, J_{N,B}[2])$ induced by the identification of the 2-torsion subgroups. Thus these are examples of the principle of a 'visible part of a Shafarevich-Tate group' as discussed in [CM].

Appendix: Other Hasegawa curves

In Table 5 is data concerning all 142 of Hasegawa's curves in the order presented in his paper. Let us explain the entries. The first column in each set of three columns gives the level, N. The second column gives a classification of the cusp forms spanning the 2-dimensional subspace of $S_2(N)$ corresponding to the Jacobian. When that subspace is irreducible with respect to the action of the Hecke algebra and is spanned by two newforms or two oldforms, we write $2n$ or $2o$, respectively. When that subspace is reducible and is spanned by two oldforms, two newforms or one of each, we write oo, nn and on, respectively. The third column contains the sign of the functional equation at the level M at which the cusp form is a newform. This is the negative of ϵ_M (described in Section 4.1). The order of the two signs in the third column agrees with that of the forms listed in the second column. We

TABLE 5. Spaces of cusp forms associated to Hasegawa's curves

include this information for those who would like to further study these curves. The curves with $N < 200$ classified as $2n$ appeared already in Table 1.

The smallest possible Mordell-Weil ranks corresponding to $++$, $+-$, $-+$ and $--$, predicted by the first Birch and Swinnerton-Dyer conjecture, are 0, 1, 1 and 2 respectively. In all cases, those were, in fact, the Mordell-Weil ranks. This was determined by computing 2-Selmer groups with a computer program based on [Sto2]. Of course, these are cases where the first Birch and Swinnerton-Dyer conjecture is already known to hold. In the cases where the Mordell-Weil rank is positive, the Mordell-Weil group has a subgroup of finite index generated by degree zero divisors supported on rational points with x-coordinates with numerators bounded by 7 (in absolute value) and denominators by 12 with one exception. On the second curve with $N = 138$, the divisor class $[(3+2\sqrt{2}, 80+56\sqrt{2}) + (3-2\sqrt{2}, 80-56\sqrt{2}) - 2\infty]$ generates a subgroup of finite index in the Mordell-Weil group.

Abstract. Let f be a newform of weight 2 on $\Gamma_0(N)$, and let A_f be the corresponding optimal abelian variety quotient of $J_0(N)$. We describe an algorithm to compute the order of the component group of A_f at primes p that exactly divide N. We give a table of orders of component groups for all f of level $N \leq 127$ and five examples in which the component group is very large, as predicted by the Birch and Swinnerton-Dyer conjecture.

1 Introduction

Let $X_0(N)$ be the Riemann surface obtained by compactifying the quotient of the upper half-plane by the action of $\Gamma_0(N)$. Then $X_0(N)$ has a canonical structure of algebraic curve over $\mathbf{Q}$; denote its Jacobian by $J_0(N)$. It is equipped with an action of a commutative ring $\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots]$ of Hecke operators. For more details on modular curves, Hecke operators, and modular forms see, e.g., [8].

Now suppose that $f = \sum_{n=1}^{\infty} a_n q^n$ is a modular newform of weight 2 for the congruence subgroup $\Gamma_0(N)$. The Hecke operators also act on f by $T_n(f) = a_n f$. The eigenvalues a_n generate an order $R_f = \mathbf{Z}[\ldots a_n \ldots]$ in a number field K_f. The kernel I_f of the map $\mathbf{T} \to R_f$ sending T_n to a_n is a prime ideal. Following Shimura [15], we associate to f the quotient $A_f = J_0(N)/I_f J_0(N)$ of $J_0(N)$. Then A_f is an abelian variety over $\mathbf{Q}$ of dimension $[K_f : \mathbf{Q}]$, with bad reduction exactly at the primes dividing N.

One-dimensional quotients of $J_0(N)$ have been intensely studied in recent years, both computationally and theoretically. The original conjectures of Birch and Swinnerton-Dyer [1, 2], for elliptic curves over $\mathbf{Q}$, were greatly influenced by computations. The scale of these computations was extended and systematized by Cremona in [6].

In another direction, Wiles [20] and Taylor-Wiles [18] proved a special case of the conjecture of Shimura-Taniyama, which asserts that every elliptic curve over $\mathbf{Q}$ is a quotient of some $J_0(N)$; this allowed them to establish Fermat's Last Theorem. The full Shimura-Taniyama conjecture was later proved by Breuil, Conrad, Diamond, and Taylor in [4]. This illustrates the central role played by quotients of $J_0(N)$.

2 Component Groups of A_f

The Néron model $\mathcal{A}/\mathbf{Z}$ of an abelian variety $A/\mathbf{Q}$ is by definition a smooth commutative group scheme over $\mathbf{Z}$ with generic fiber A such that for any smooth scheme S over $\mathbf{Z}$, the restriction map

$$\mathrm{Hom}_{\mathbf{Z}}(S, \mathcal{A}) \to \mathrm{Hom}_{\mathbf{Q}}(S_{\mathbf{Q}}, A)$$

is a bijection. For more details, including a proof of existence, see, e.g., [5].

Suppose that A_f is a quotient of $J_0(N)$ corresponding to a newform f on $\Gamma_0(N)$, and let $\mathcal{A}_f$ be the Néron model of A_f. For any prime divisor p of N, the closed fiber $\mathcal{A}_{f/\mathbf{F}_p}$ is a group scheme over $\mathbf{F}_p$, which need not be connected. Denote the connected component of the identity by $\mathcal{A}^{\circ}_{f/\mathbf{F}_p}$. There is an exact sequence

$$0 \to \mathcal{A}^{\circ}_{f/\mathbf{F}_p} \to \mathcal{A}_{f/\mathbf{F}_p} \to \Phi_{A_f,p} \to 0$$

with $\Phi_{A_f,p}$ a finite étale group scheme over $\mathbf{F}_p$ called the *component group* of A_f at p.

The category of finite étale group schemes over $\mathbf{F}_p$ is equivalent to the category of finite groups equipped with an action of $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$ (see, e.g., [19, §6.4]). The *order* of an étale group scheme $G/\mathbf{F}_p$ is defined to be the order of the group $G(\overline{\mathbf{F}}_p)$. In this paper we describe an algorithm for computing the order of $\Phi_{A_f,p}$, when p exactly divides N.

3 The Algorithm

Let $J = J_0(N)$, fix a newform f of weight-two for $\Gamma_0(N)$, and let A_f be the corresponding quotient of J. Because J is the Jacobian of a curve, it is canonically isomorphic to its dual, so the projection $J \to A_f$ induces a polarization $A_f^{\vee} \to A_f$, where $A_f^{\vee}$ denotes the abelian variety dual of A_f. We define the *modular degree* δ_{A_f} of A_f to be the positive square root of the degree of this polarization. This agrees with the usual notion of modular degree when A_f is an elliptic curve.

A *torus* T over a field k is a group scheme whose base extension to the separable closure k_s of k is a finite product of copies of $\mathbf{G}_m$. Every commutative algebraic group over k admits a unique maximal subtorus, defined over k, whose formation commutes with base extension (see IX §2.1 of [9]). The *character group* of a torus T is the group $\mathcal{X} = \mathrm{Hom}_{k_s}(T, \mathbf{G}_m)$ which is a free abelian group of finite rank together with an action of $\mathrm{Gal}(k_s/k)$ (see, e.g., [19, §7.3]).

We apply this construction to our setting as follows. The closed fiber of the Néron model of J at p is a group scheme over $\mathbf{F}_p$, whose maximal torus we denote by $T_{J,p}$. We define $\mathcal{X}_{J,p}$ to be the character group of $T_{J,p}$. Then $\mathcal{X}_{J,p}$ is a free abelian group equipped with an action of both $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$ and the Hecke algebra $\mathbf{T}$ (see, e.g., [14]). Moreover, there exists a bilinear pairing

$$\langle\, , \,\rangle : \mathcal{X}_{J,p} \times \mathcal{X}_{J,p} \to \mathbf{Z}$$

called the *monodromy pairing* such that

$$\Phi_{J,p} \cong \mathrm{coker}(\mathcal{X}_{J,p} \to \mathrm{Hom}(\mathcal{X}_{J,p}, \mathbf{Z})).$$

Let $\mathcal{X}_{J,p}[I_f]$ be the intersection of all kernels $\ker(t)$ for t in I_f, and let

$$\alpha_f : \mathcal{X}_{J,p} \to \mathrm{Hom}(\mathcal{X}_{J,p}[I_f], \mathbf{Z})$$

be the map induced by the monodromy pairing. The following theorem of the second author [16], provides the basis for the computation of orders of component groups.

Theorem 1. *With the notation as above, we have the equality*

$$\#\Phi_{A_f,p} = \frac{\#\mathrm{coker}(\alpha_f) \cdot \delta_{A_f}}{\#(\alpha_f(\mathcal{X}_{J,p})/\alpha_f(\mathcal{X}_{J,p}[I_f]))}\,.$$

3.1 Computing the modular degree $\delta_{A,f}$

Using modular symbols (see, e.g., [6]), we first compute the homology group $H_1(X_0(N), \mathbf{Q}; \mathrm{cusps})$. Using lattice reduction, we compute the $\mathbf{Z}$-submodule $H_1(X_0(N), \mathbf{Z}; \mathrm{cusps})$ generated by all Manin symbols (c, d). Then $H_1(X_0(N), \mathbf{Z})$ is the *integer* kernel of the boundary map.

The Hecke ring $\mathbf{T}$ acts on $H_1(X_0(N), \mathbf{Z})$ and also on the linear dual $\mathrm{Hom}(H_1(X_0(N), \mathbf{Z}), \mathbf{Z})$, where $t \in \mathbf{T}$ acts on $\varphi \in \mathrm{Hom}(H_1(X_0(N), \mathbf{Z}), \mathbf{Z})$ by $(t.\varphi)(x) = \varphi(tx)$. We have a natural restriction map

$$r_f : \mathrm{Hom}(H_1(X_0(N), \mathbf{Z}), \mathbf{Z})[I_f] \to \mathrm{Hom}(H_1(X_0(N), \mathbf{Z})[I_f], \mathbf{Z}).$$

Proposition 1. *The cokernel of r_f is isomorphic to the kernel of the polarization $A_f^\vee \to A_f$ induced by the map $J_0(N) \to A_f$.*

Thus the order of the cokernel of r_f is the square of the modular degree δ_f. We pause to note that the degree of any polarization is a square; see, e.g., [13, Thm. 13.3].

Proof. Let $S = S_2(\mathit{\Gamma}_0(N), \mathbf{C})$ be the complex vector space of weight-two modular forms of level N, and set $H = H_1(X_0(N), Z)$. The integration pairing $S \times H \to \mathbf{C}$ induces a natural map

$$\mathit{\Phi}_f : H \to \mathrm{Hom}(S[I_f], \mathbf{C}).$$

Using the classical Abel-Jacobi theorem, we deduce the following commutative diagram, which has exact columns, but whose rows are not exact.

$$\begin{tikzcd}
0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] \\
H[I_f] \arrow[r] \arrow[d] & H \arrow[r] \arrow[d] & \mathit{\Phi}_f(H) \arrow[d] \\
\mathrm{Hom}(S, \mathbf{C})[I_f] \arrow[r] \arrow[d] & \mathrm{Hom}(S, \mathbf{C}) \arrow[r] \arrow[d] & \mathrm{Hom}(S[I_f], \mathbf{C}) \arrow[d] \\
A_f^{\vee}(\mathbf{C}) \arrow[r] \arrow[d] \arrow[rr, bend right] & J_0(N)(\mathbf{C}) \arrow[r] \arrow[d] & A_f(\mathbf{C}) \arrow[d] \\
0 & 0 & 0
\end{tikzcd}$$

By the snake lemma, the kernel of $A_f^{\vee}(\mathbf{C}) \to A_f(\mathbf{C})$ is isomorphic to the cokernel of the map $H[I_f] \to \mathit{\Phi}_f(H)$. Since

$$\mathrm{Hom}(H/\ker(\mathit{\Phi}_f), \mathbf{Z}) \cong \mathrm{Hom}(H, \mathbf{Z})[I_f],$$

the $\mathrm{Hom}(-, \mathbf{Z})$ dual of the map $H[I_f] \to \mathit{\Phi}_f(H) = H/\ker(\mathit{\Phi}_f)$ is r_f, which proves the proposition.

3.2 Computing the character group $\boldsymbol{\mathcal{X}_{J,p}}$

Let $N = Mp$, where M and p are coprime. If M is small, then the algorithm of Mestre and Oesterlé [12] can be used to compute $\mathcal{X}_{J,p}$. This algorithm constructs the graph of isogenies between $\overline{\mathbf{F}}_p$-isomorphism classes of pairs consisting of a supersingular elliptic curve and a cyclic M-torsion subgroup. In particular, the method is elementary to apply when $X_0(M)$ has genus 0.

In general, the above category of "enhanced" supersingular elliptic curves can be replaced by one of left (or right) ideals of a quaternion order $\mathcal{O}$ of level M in the quaternion algebra over $\mathbf{Q}$ ramified at p. This gives an equivalent category, in which the computation of homomorphisms is efficient. The character group $\mathcal{X}_{J,p}$ is known by Deligne-Rapoport [7] to be canonically isomorphic to the degree zero subgroup $\mathcal{X}(\mathcal{O})$ of the free abelian "divisor group" on the isomorphism classes of enhanced supersingular elliptic curves and of quaternion ideals. Moreover, this isomorphism is compatible with the operation of Hecke operators, which are effectively computable in $\mathcal{X}(\mathcal{O})$ in terms of ideal homomorphisms.

The inner product of two classes in this setting is defined to be the number of isomorphisms between any two representatives. The linear extension to $\mathcal{X}(\mathcal{O})$ gives an inner product which agrees, under the isomorphism, with the monodromy pairing on $\mathcal{X}_{J,p}$. This gives, in particular, an isomorphism $\Phi_{J,p} \cong \mathrm{coker}(\mathcal{X}(\mathcal{O}) \to \mathrm{Hom}(\mathcal{X}(\mathcal{O}), \mathbf{Z}))$, and an effective means of computing $\#\mathrm{coker}(\alpha_f)$ and $\#(\alpha_f(\mathcal{X}_{J,p})/\alpha_f(\mathcal{X}_{J,p}[I_f]))$.

The arithmetic of quaternions has been implemented in Magma [11] by the first author. Additional details and the application to Shimura curves, generalizing $X_0(N)$, can be found in Kohel [10].

3.3 The Galois action on $\Phi_{A_f,p}$

To determine the Galois action on $\Phi_{A_f,p}$, we need only know the action of the Frobenius automorphism Frob_p. However, Frob_p acts on $\Phi_{A_f,p}$ in the same way as $-W_p$, where W_p is the pth Atkin-Lehner involution, which can be computed using modular symbols. Since f is an eigenform, the involution W_p acts as either $+1$ or -1 on $\Phi_{A_f,p}$. Moreover, the operator W_p is determined by an involution on the set of quaternion ideals, so it can be determined explicitly on the character group.

4 Tables

The main computational results of this work are presented below in two tables. The relevant algorithms have been implemented in Magma and will be made part of a future release. They can also be obtained from the second author.

4.1 Component groups at low level

The first table gives the component groups of the quotients A_f of $J_0(N)$ for $N \leq 127$. The column labeled d contains the dimensions of the A_f, and the column labeled $\#\Phi_{A_f,p}$ contains a list of the orders of the component groups of A_f, one for each divisor p of N, ordered by increasing p. An entry of "?" indicates that $p^2 \mid N$, so our algorithm does not apply. A component group order is starred if the $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$-action is nontrivial. More data along these lines can be obtained from the second author.

4.2 Examples of large component groups

Let Ω_{A_f} be the real period of A_f, as defined by J. Tate in [17]. The second author computed the rational numbers $L(A_f, 1)/\Omega_{A_f}$ for every newform f of level $N \leq 1500$. The five largest prime divisors occur in the ratios given in the second table. The Birch and Swinnerton-Dyer conjecture predicts that the large prime divisor of the numerator of each special value must divide the order either of some component group $\Phi_{A_f,p}$ or of the Shafarevich-Tate group of A_f. In each instance $\Phi_{A_f,2}$ is divisible by the large prime divisor, as predicted.

5 Further directions

Further considerations are needed to compute the *group* structure of $\Phi_{A_f,p}$. However, since the action of Frobenius is known, computing the group structure of $\Phi_{A_f,p}$ suffices to determine its structure as a group scheme.

Our methods say nothing about the component group at primes whose *square* divides the level. The free abelian group on classes of nonmaximal orders of index p at a ramified prime gives a well-defined divisor group. Do the resulting Hecke modules determine the component groups for quotients of level p^2M?

Is it possible to define quantities as in Theorem 1 even when the weight of f is *greater than* 2? If so, how are the resulting quantities related to the Bloch-Kato Tamagawa numbers (see [3]) of the higher weight motive attached to f?

Abstract

Explicit approaches to modular abelian varieties

by

William Arthur Stein

Doctor of Philosophy in Mathematics

University of California at Berkeley

Professor Hendrik Lenstra, Chair

I investigate the Birch and Swinnerton-Dyer conjecture, which ties together the constellation of invariants attached to an abelian variety. I attempt to verify this conjecture for certain specific modular abelian varieties of dimension greater than one. The key idea is to use Barry Mazur's notion of visibility, coupled with explicit computations, to produce lower bounds on the Shafarevich-Tate group. I have not finished the proof of the conjecture in these examples; this would require computing explicit upper bounds on the order of this group.

I next describe how to compute in spaces of modular forms of weight at least two. I give an integrated package for computing, in many cases, the following invariants of a modular abelian variety: the modular degree, the rational part of the special value of the L-function, the order of the component group at primes of multiplicative reduction, the period lattice, upper and lower bounds on the torsion subgroup, and the real volume. Taken together, these algorithms are frequently sufficient to compute the odd part of the conjectural order of the Shafarevich-Tate group of an analytic rank 0 optimal quotient of $J_0(N)$, with N square-free. I have not determined the exact structure of the component group, the order of the component group at primes whose square divides the level, or the exact order of the torsion subgroup in all cases. However, I do provide generalizations of some of the above algorithms to higher weight forms with nontrivial character.

Acknowledgements

It is a pleasure to thank my thesis adviser, Hendrik Lenstra, for patiently guiding my intellectual development in innumerable ways. In addition, Robert Coleman, Barry Mazur, and Ken Ribet generously shared their countless ideas and unbounded enthusiasm with me. Robert helped me to understand p-adics, Barry taught me to visualize Shafarevich-Tate groups, and Ken explained congruences, component groups, and tutored me in the elusive art of mathematical exposition.

This thesis would not have been possible without the questions that arose out of exhilarating collaborations with Amod Agashe, Kevin Buzzard, Loïc Merel, David Moulton, Ed Schaefer, Helena Verrill, and Joe Wetherell. I would like to thank Ahmed Abbes, Matt Baker, Brian Conrad, János Csirik, Jordan Ellenberg, Edray Goins, David Jones, Ezra Miller, Bjorn Poonen, and Mak Trifkovic for asking and answering many stimulating questions.

I wish to thank Hendrik Lenstra and Ken Ribet for providing me with financial support during part of the writing of this thesis, Sarah M. Hallam for providing further support, the `Cal@SiliconValley` university fellowship for supporting me throughout my final year, and the MAGMA group for their computational support.

Finally, I would like to thank Bjorn Poonen for thoroughly reading this thesis and pointing out many ways in which it could be improved.

Preface

> The object of numerical computation is theoretical advance.
> *–A. O. L. Atkin, see [5]*

The definition of the spaces of modular forms as functions on the upper half plane satisfying a certain equation is very abstract. The definition of the Hecke operators even more so. Nevertheless, one wishes to carry out explicit investigations into these objects.

We are fortunate that we now have methods available that allow us to transform the vector space of cusp forms of given weight and level into a concrete object, which can be explicitly computed. We have the work of Atkin-Lehner, Birch, Swinnerton-Dyer, Manin, Merel, and many others to thank for this (see [6, 16, 45]). For example, the Eichler-Selberg trace formula, as extended in [30], can be used to compute characteristic polynomials of Hecke operators. One can compute Hecke operators using Brandt matrices and quaternion algebras [32, 52]; another closely related method involves the module of enhanced supersingular elliptic curves [47]. In the course of computing large tables of invariants of elliptic curves in [16], Cremona demonstrated the power of systematic computation using modular symbols.

Various methods often must be used in concert to obtain information about the package of invariants attached to a modular form. For example, computing orders of component groups of optimal quotients of $J_0(N)$ involves computations on the module of supersingular elliptic curves combined with modular symbols techniques (see Chapter 4).

Chapter 1 is an attempt to systematically prove the Birch and Swinnerton-Dyer conjecture for a certain finite list of rank-0 quotients of $J_0(N)$ that have nontrivial Shafarevich-Tate groups. The key idea is to use Barry Mazur's notion of visibility, coupled with explicit computations, to produce lower bounds on the Shafarevich-Tate group. I have not finished the proof of the conjecture in these examples; this would require computing explicit upper bounds on the order of this group. However, I obtain explicit formulas and data that will be helpful in further investigations.

The following three chapters describe the algorithms used in Chapter 1, along with generalizations to eigenforms on $\Gamma_1(N)$ of integral weight greater than two. I have used these algorithms to investigate the Artin Conjecture [12], Serre's conjecture, and many other problems not described in this thesis. I have implemented most of the algorithms that are described in Chapters 2–4 in both MAGMA and C++; this implementation should be available in the standard release of MAGMA in versions 2.7 and greater.

Chapter 1

The Birch and Swinnerton-Dyer conjecture

Now that the Shimura-Taniyama conjecture has been proved, many experts consider the Birch and Swinnerton-Dyer conjecture (BSD conjecture) to be one of the main outstanding problems in the field (see [19, pg. 549] and [68, Intro.]). This conjecture ties together many of the arithmetic and analytic invariants of an elliptic curve. At present, there is no general class of elliptic curves for which the full BSD conjecture is known, though a slightly weakened form is known for a fairly broad class of complex multiplication elliptic curves of analytic rank 0 (see [55]), and several deep partial results have been obtained during the last twenty years (see, e.g., [27] and [33]).

Approaches to the BSD conjecture that rely on congruences between modular forms are likely to require a deeper understanding of the analogue of the BSD conjecture for higher-dimensional abelian varieties. As a first step, this chapter presents theorems and explicit computations of some of the arithmetic invariants of modular abelian varieties.

The reader is urged to also read A. Agashe's 2000 Berkeley Ph.D. thesis which cover similar themes. The paper of Cremona and Mazur's [18] paints a detailed experimental picture of the way in which congruences link Mordell-Weil and Shafarevich-Tate groups of elliptic curves.

1.1 The BSD conjecture

By [10] we now know that every elliptic curve over $\mathbf{Q}$ is a quotient of the curve $X_0(N)$, whose complex points are the isomorphism classes of pairs consisting of a (generalized) elliptic curve and a cyclic subgroup of order N. Let $J_0(N)$ denote the Jacobian of $X_0(N)$; this is an abelian variety of dimension equal to the genus of $X_0(N)$ whose points correspond to the degree 0 divisor classes on $X_0(N)$. The survey article [21] is a good guide to the facts and literature about the family of abelian varieties $J_0(N)$.

Following Mazur [41], we make the following definition.

Definition 1.1 (Optimal quotient). An *optimal quotient* of $J_0(N)$ is a quotient A of $J_0(N)$ by an abelian subvariety.

Consider an optimal quotient A such that $L(A,1) \neq 0$. By [35], $A(\mathbf{Q})$ and $\text{Ш}(A)$ are both finite. The BSD conjectureasserts that

$$\frac{L(A,1)}{\Omega_A} = \frac{\#\text{Ш}(A) \cdot \prod_{p|N} c_p}{\#A(\mathbf{Q}) \cdot \#A^\vee(\mathbf{Q})}.$$

Here the Shafarevich-Tate group

$$\text{Ш}(A) := \ker\left(H^1(\mathbf{Q}, A) \to \prod_v H^1(\mathbf{Q}_v, A)\right)$$

is a measure of the failure of the local-to-global principle; the Tamagawa numbers c_p are the orders of the groups of rational points of the component groups of A (see Chapter 4); the real number Ω_A is the measure of $A(\mathbf{R})$ with respect to a basis of differentials having everywhere nonzero good reduction (see Section 3.12.6); and $A^\vee$ is the abelian variety dual to A (see [50, §9]). This chapter makes a small contribution to the long-term goal of verifying the above conjecture for many specific abelian varieties on a case-by-case basis. In a large list of examples, we compute the conjectured order of $\text{Ш}(A)$, up to a power of 2, and then show that $\text{Ш}(A)$ is at least as big as conjectured. We also discuss methods to obtain upper bounds on $\#\text{Ш}(A)$, but do not carry out any computations in this direction. This is the first step in a program to verify the above conjecture for an infinite family of quotients of $J_0(N)$.

1.1.1 The ratio $L(A,1)/\Omega_A$

Extending classical work on elliptic curves, A. Agashe and the author proved the following theorem.

Theorem 1.2. *Let m be the largest square dividing N. The ratio $L(A,1)/\Omega_A$ is a rational number that can be explicitly computed, up to a unit (conjecturally 1) in $\mathbf{Z}[1/(2m)]$.*

Proof. The proof uses modular symbols combined with an extension of the argument used by Mazur in [41] to bound the Manin constant. The modular symbols part of the proof for L-functions attached to newforms of weight $k \geq 2$ is given in Section 3.10; it involves expressing the ratio $L(A,1)/\Omega_A$ as the lattice index of two modules over the Hecke algebra. The bound on the Manin constant is given in Section 3.11. □

The author has computed $L(A,1)/\Omega_A$ for all simple optimal quotients of level $N \leq 1500$; this table can be obtained from the author's web page.

Remark 1.3. The method of proof should also give similar results for special values of twists of $L(A,s)$, just as it does in the case $\dim A = 1$ (see [16, Prop. 2.11.2]).

1.1.2 Torsion subgroup

We can compute upper and lower bounds on $\#A(\mathbf{Q})_{\text{tor}}$, see Section 3.8; these frequently determine $\#A(\mathbf{Q})_{\text{tor}}$.

These methods, combined with the method used to obtain Theorem 1.2, yield the following corollary, which supports the expected cancellation between torsion and c_p coming from the reduction map sending rational points to their image in the component group of A. The corollary also generalizes to higher weight forms, thus suggesting a geometric way to think about reducibility of modular Galois representations.

Corollary 1.4. *Let n be the order of the image of $(0)-(\infty)$ in $A(\mathbf{Q})$, and let m be the largest square dividing N. Then $n \cdot L(A,1)/\Omega_A \in \mathbf{Z}[1/(2m)]$.*

For the proof, see Corollary 3.48 in Chapter 3.

1.1.3 Tamagawa numbers

We prove the following theorem in Chapter 4.

Theorem 1.5. *When $p^2 \nmid N$, the number c_p can be explicitly computed (up to a power of 2).*

We can compute the order c_p of the group of rational points of the component group, but not its structure as a group. When $p^2 \mid N$ it may be possible to compute c_p using the Drinfeld-Katz-Mazur model of $X_0(N)$, but we have not yet done this. There are also good bounds on the primes that can divide c_p when $p^2 \mid N$.

Systematic computations (see Section 4.7.1) using this formula suggest the following conjectural refinement of a result of Mazur [40].

Conjecture 1.6. *Suppose N is prime and A is an optimal quotient of $J_0(N)$ corresponding to a newform f. Then $A(\mathbf{Q})_{\mathrm{tor}}$ is generated by the image of $(0)-(\infty)$ and $c_p = \#A(\mathbf{Q})_{\mathrm{tor}}$. Furthermore, the product of the c_p over all simple optimal quotients corresponding to newforms equals the numerator of $(N-1)/12$.*

I have checked this conjecture for all $N \leq 997$ and, up to a power of 2, for all $N \leq 2113$. The first part is known when A is an elliptic curve (see [48]). Upon hearing of this conjecture, Mazur reportedly proved it when all "q-Eisenstein quotients" are simple. There are three promising approaches to finding a complete proof. One involves the explicit formula of Theorem 1.5; another is based on Ribet's level lowering theorem (see [53]), and a third makes use of a simplicity result of Merel (see [46]).

The formula that lies behind Theorem 1.5 probably has a natural analogue in weight greater than 2. One could then guess that it produces Tamagawa numbers of motifs attached to eigenforms of higher weight; however, we have no idea if this is really the case. These numbers appear in the conjectures of Bloch and Kato, which generalize the BSD conjecture to motifs (see [7]). Anyone wishing to try to compute them should be aware of Neil Dummigan's paper [22], which gives some information about the Tamagawa numbers of motifs attached by Scholl in [57] to modular eigenforms.

1.1.4 Upper bounds on $\#Ш(A)$

V. Kolyvagin (see [34]) and K. Kato (see, e.g., [58]) constructed Euler systems that were used to prove that $Ш(A)$ is *finite* when $L(A,1) \neq 0$. To verify the full BSD conjecture for certain abelian varieties, we must make the Kolyvagin-Kato finiteness bound explicit. Kolyvagin's bounds involve computations with Heegner points, and Kato's involve a study of the Galois representations associated to A.

Kolyvagin's bounds

In [33], Kolyvagin obtains explicit upper bounds for $\#\text{Ш}(A)$ for a certain (finite) list of elliptic curves A by computing the index in $A(K)$ of the subgroup generated by the Heegner point, where K is a suitable imaginary quadratic extension. In [35], Kolyvagin and Logachev generalize Kolyvagin's earlier results; in Section 1.6, "Unsolved problems", they say that: "If one were to compute the height of a Heegner point y [...] considered in the present paper, then one would have succeeded in obtaining an upper bound for $\#\text{Ш}$ for this curve." (By "curve" they mean abelian variety.) This suggests that explicit computations should yield upper bounds on the order of $\text{Ш}(A)$, but that they had not yet figured out how to carry out such computations.

Kato's bounds

Kato has constructed Euler systems coming from K_2-groups of modular curves. These can be used to prove the following theorem (see, e.g., [56, Cor. 3.5.19]).

Theorem 1.7 (Kato). *Suppose E is an elliptic curve over $\mathbf{Q}$ without complex multiplication that E has conductor N, that E has good reduction at p, that p does not divide $2r_E \prod_{q|N} L_q(q^{-1})\#E(\mathbf{Q}_q)_{\text{tor}}$, and the Galois representation $\rho_{E,p} : G_{\mathbf{Q}} \to \text{Aut}(E[p])$ is surjective. Then*

$$\#\text{Ш}(E)_{p^\infty} \textit{ divides } \frac{L(E,1)}{\Omega_E}.$$

Here $L_q(x)$ is the local Euler factor at q and the constant r_E arises in the construction of Kato's Euler system. Rubin suggests that computing r_E is not very difficult (private communication). Appropriate variants of Kato's arguments give similar results for quotients of $J_0(N)$ of arbitrary dimension, though these have not been written down.

1.1.5 Lower bounds on $\#\text{Ш}(A)$

One approach to showing that $\text{Ш}(A)$ is as *at least* as large as predicted by the BSD conjecture is suggested by Mazur's notion of the visible part $\text{Ш}(A)^\circ$ of $\text{Ш}(A)$ (see [18, 43]). Let $A^\vee \subset J_0(N)$ be the dual to A. The *visible part* of $\text{Ш}(A^\vee)$ is the kernel of the natural map $\text{Ш}(A^\vee) \to \text{Ш}(J_0(N))$. Mazur observed that if an element of order p in $\text{Ш}(A^\vee)$ is visible, then it is explained by a "jump in the rank of Mordell-Weil" in the sense that there is another abelian subvariety $B \subset J_0(N)$ such that $p \mid \#(A^\vee \cap B)$ and the rank of B is positive.

Mazur's observation can be turned around: if there is another abelian variety B of positive rank such that $p \mid \#(A^\vee \cap B)$, then, under mild hypotheses (see Theorem 1.8), there is an element of $\text{Ш}(A^\vee)$ of order p. From a computational point of view it is easy to understand the intersections $A^\vee \cap B$; see Section 3.6. From a theoretical point of view, nontrivial intersections "correspond" to congruences between modular forms. Thus the well-developed theory of congruences between modular forms can be used to obtain a lower bound on $\#Ш(A^\vee)$.

Invisible elements of $\#Ш(A^\vee)$

Numerical experiments suggest that as $A^\vee$ varies, $Ш(A^\vee)$ is often *not* visible inside of $J_0(N)$. For example (see Table 1.2), the BSD conjecture predicts the existence of invisible elements of odd order in $Ш(A^\vee)$ for almost half of the 37 optimal quotients of prime level ≤ 2113.

Visibility at higher level

For every integer M (Ribet [54] tells us which M to choose), we can ask whether $Ш(A^\vee)$ maps to 0 under one of the natural maps $A^\vee \to J_0(NM)$; that is, we can ask whether $Ш(A^\vee)$ "becomes visible at level NM." We have been unable to prove in any particular case that $Ш(A^\vee)$ is not visible at level N, but becomes visible at some level NM. See Section 1.4.1 for some computations which strongly indicate that such examples exist.

Visibility in some Jacobian

Johan de Jong proved that if E is an elliptic curve over a number field K and $c \in H^1(K, E)$ then there is a Jacobian J and an imbedding $E \hookrightarrow J$ such that c maps to 0 under the natural map $H^1(K, E) \to H^1(K, J)$ (see Remark 3 in [18]); de Jong's proof appears to generalize when E is replaced by an abelian variety, but time does not permit going into the details here.

1.1.6 Motivation for considering abelian varieties

If A is an elliptic curve, then explaining $Ш(A)$ using only congruences between elliptic curves will probably fail. This is because pairs of non-isogenous elliptic curves with isomorphic p-torsion for large p are, according to E. Kani's conjecture, extremely rare. It is crucial to understand what happens in all dimensions.

Within the range accessible by computer, abelian varieties exhibit more richly textured structure than elliptic curves. For example, there is a visible element of prime order 83341 in the Shafarevich-Tate group of an abelian variety of prime conductor 2333; in contrast, over all optimal elliptic curves of conductor up to 5500, it appears that the largest order of an element of a Shafarevich-Tate group is 7 (see the discussion in [18]).

1.2 Existence of nontrivial visible elements of $Ш(A)$

The reader who wants to see tables of Shafarevich-Tate groups can safely skip to the next section.

Without relying on any unverified conjectures, we will use the following theorem to exhibit abelian varieties A such that the visible part of $Ш(A)$ is nonzero. In the following theorem we do *not* assume that J is the Jacobian of a curve.

Theorem 1.8. *Let A and B be abelian subvarieties of an abelian variety J such that $A \cap B$ is finite and $A(\mathbf{Q})$ is finite. Assume that B has purely toric reduction at each prime at which J has bad reduction. Let p be an odd prime at which J has good reduction, and assume that p does not divide the orders of any of the (geometric) component groups of A and B, or the orders of the torsion subgroups of $(J/B)(\mathbf{Q})$ and $B(\mathbf{Q})$. Suppose further that $B[p] \subset A \cap B$. Then there exists an injection*

$$B(\mathbf{Q})/pB(\mathbf{Q}) \hookrightarrow Ш(A)^{\circ}$$

of $B(\mathbf{Q})/pB(\mathbf{Q})$ into the visible part of Ш(A).

Proof. Let $C = J/A$. The long exact sequence of Galois cohomology associated to the short exact sequence

$$0 \to A \to J \to C \to 0$$

begins

$$0 \to A(\mathbf{Q}) \to J(\mathbf{Q}) \to C(\mathbf{Q}) \xrightarrow{\delta} H^1(\mathbf{Q}, A) \to \cdots .$$

Because $B[p] \subset A$, the map $B \to C$, obtained by composing the inclusion $B \hookrightarrow J$ with $J \to C$, factors through multiplication-by-p, giving the following commutative diagram:

$$\begin{tikzcd}
 & B \arrow[r, "p"] \arrow[d] & B \arrow[d] \\
A \arrow[r] & J \arrow[r] & C.
\end{tikzcd}$$

Because $B(\mathbf{Q})[p] = 0$ and $B(\mathbf{Q}) \cap A(\mathbf{Q}) = 0$, we deduce the following commutative diagram with exact rows:

$$\begin{tikzcd}
 & 0 \arrow[d] & K_1 \arrow[d] & K_2 \arrow[d] & \\
0 \arrow[r] & B(\mathbf{Q}) \arrow[r, "p"] \arrow[d] & B(\mathbf{Q}) \arrow[r] \arrow[d] \arrow[dr, "\pi"] & B(\mathbf{Q})/pB(\mathbf{Q}) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & J(\mathbf{Q})/A(\mathbf{Q}) \arrow[r] \arrow[d] & C(\mathbf{Q}) \arrow[r] & \delta(C(\mathbf{Q})) \arrow[r] & 0 \\
 & K_3, & & &
\end{tikzcd}$$

where K_1 and K_2 are the indicated kernels and K_3 is the cokernel. We have the snake lemma exact sequence

$$0 \to K_1 \to K_2 \to K_3.$$

Because $B(\mathbf{Q})[p] = 0$ and K_2 is a p-torsion group, we have $K_1 = 0$. The quotient $J(\mathbf{Q})/B(\mathbf{Q})$ has no p-torsion because it is a subgroup of $(J/B)(\mathbf{Q})$; also, $A(\mathbf{Q})$ is a finite group of order coprime to p, so $K_3 = J(\mathbf{Q})/(A(\mathbf{Q}) + B(\mathbf{Q}))$ has no p-torsion. Thus $K_2 = 0$.

The above argument shows that $B(\mathbf{Q})/pB(\mathbf{Q})$ is a subgroup of $H^1(\mathbf{Q}, A)$. However, $H^1(\mathbf{Q}, A)$ contains infinitely many elements of order p (see [59]), whereas $Ш(A)[p]$ is a finite group, so we must work harder to deduce that $B(\mathbf{Q})/pB(\mathbf{Q})$ lies in $Ш(A)[p]$. Fix $x \in B(\mathbf{Q})$. We must show that $\pi(x)$ lies in $Ш(A)[p]$; equivalently, that $\mathrm{res}_v(\pi(x)) = 0$ for all places v of $\mathbf{Q}$.

At the archimedean place $v = \infty$, the restriction $\mathrm{res}_v(\pi(x))$ is killed by 2 and the odd prime p, hence $\mathrm{res}_v(\pi(x)) = 0$.

Suppose that v is a place at which J has bad reduction. By hypothesis, B has purely toric reduction, so over the maximal unramified extension $\mathbf{Q}_v^{\mathrm{ur}}$ of $\mathbf{Q}_v$ there is an isomorphism $B \cong \mathbf{G}_m^d/\Gamma$ of $\mathrm{Gal}(\overline{\mathbf{Q}}_v/\mathbf{Q}_v^{\mathrm{ur}})$-modules, for some "lattice" Γ. For example, when $\dim B = 1$, this is the Tate curve representation of B. Let n be the order of the component group of B at v; thus n equals the order of the cokernel of the valuation map $\Gamma \to \mathbf{Z}^d$. Choose a representative $P = (x_1, \dots, x_d) \in \mathbf{G}_m^d$ for the point x. Then nP can be adjusted by elements of Γ so that each of its components $x_i \in \mathbf{G}_m$ has valuation 0. By assumption, p is a prime at which J has good reduction, so $p \neq v$; it follows that there is a point $Q \in \mathbf{G}_m^d(\mathbf{Q}_v^{\mathrm{ur}})$ such that $pQ = nP$. Thus the cohomology class $\mathrm{res}_v(\pi(nx))$ is unramified at v. By [51, Prop. I.3.8],

$$H^1(\mathbf{Q}_v^{\mathrm{ur}}/\mathbf{Q}_v, A(\mathbf{Q}_v^{\mathrm{ur}})) = H^1(\mathbf{Q}_v^{\mathrm{ur}}/\mathbf{Q}_v, \Phi_{A,v}(\overline{\mathbf{F}}_v)),$$

where $\Phi_{A,v}$ is the component group of A at v. Since the component group $\Phi_{A,v}(\overline{\mathbf{F}}_v)$ has order n, it follows that

$$\mathrm{res}_v(\pi(nx)) = n\,\mathrm{res}_v(\pi(x)) = 0.$$

Since the order p of $\mathrm{res}_v(\pi(x))$ is coprime to n, we conclude that $\mathrm{res}_v(\pi(x)) = 0$.

Next suppose that J has good reduction at v and that v is *odd*, in the sense that the residue characteristic of v is odd. To simplify notation in this paragraph, since v is a non-archimedean place of $\mathbf{Q}$, we will also let v denote the odd prime number which is the residue characteristic of v. Let $\mathcal{A}$, $\mathcal{J}$, $\mathcal{C}$, be the Néron models of A, J, and C, respectively (for more on Néron models, see Chapter 4). Let A, J, C, also denote the sheaves on the étale-site over $\mathrm{Spec}(\mathbf{Z}_v)$ determined by the group schemes $\mathcal{A}$, $\mathcal{J}$, and $\mathcal{C}$, respectively. Since v is odd, $1 = e < v - 1$, so we may apply [8, Thm. 7.5.4] to conclude that the sequence of group schemes

$$0 \to \mathcal{A} \to \mathcal{J} \to \mathcal{C} \to 0$$

is exact; in particular, it is exact as a sequence of sheaves on the étale site (see the proof of [8, Thm. 7.5.4]). Thus it is exact on the stalks, so by [49, 2.9(d)] the sequence

$$0 \to \mathcal{A}(\mathbf{Z}_v^{\mathrm{ur}}) \to \mathcal{J}(\mathbf{Z}_v^{\mathrm{ur}}) \to \mathcal{C}(\mathbf{Z}_v^{\mathrm{ur}}) \to 0$$

is exact; by the Néron mapping property the sequence

$$0 \to A(\mathbf{Q}_v^{\mathrm{ur}}) \to J(\mathbf{Q}_v^{\mathrm{ur}}) \to C(\mathbf{Q}_v^{\mathrm{ur}}) \to 0$$

is also exact. Thus $\mathrm{res}_v(\pi(x))$ in unramified, so it arises by inflation from an element of $H^1(\mathbf{Q}_v^{\mathrm{ur}}/\mathbf{Q}_v, A)$. By [51, Prop. I.3.8],

$$H^1(\mathbf{Q}_v^{\mathrm{ur}}/\mathbf{Q}_v, A) \cong H^1(\mathbf{Q}_v^{\mathrm{ur}}/\mathbf{Q}_v, \Phi_{A,v}),$$

where $\Phi_{A,v}$ is the component group of A at v. Since A has good reduction, $\Phi_{A,v} = 0$, hence $\mathrm{res}_v(\pi(x)) = 0$.

If J has bad reduction at $v = 2$, then we already dealt with 2 above. Consider the case when J has good reduction at 2. Because the absolute ramification index e of $\mathbf{Z}_2$ is 1, which is *not* less than $v - 1 = 1$, we can not apply [8, Thm. 7.5.4]. However, we can modify our situation by an isogeny of degree a power of 2, then apply a different theorem as follows. The 2-primary subgroup Ψ of $A \cap B$ is rational as a subgroup over $\mathbf{Q}$, in the sense that the conjugates of any point in Ψ are also contained in Ψ. The abelian varieties $\tilde{J} = J/\Psi$, $\tilde{A} = A/\Psi$, and $\tilde{B} = B/\Psi$ also satisfy the hypothesis of the theorem we are proving. By [8, Prop. 7.5.3(a)], the corresponding sequence of Néron models

$$0 \to \tilde{\mathcal{A}} \to \tilde{\mathcal{J}} \to \tilde{\mathcal{C}} \to 0$$

is exact, so the sequence

$$0 \to \tilde{A}(\mathbf{Q}_v^{\mathrm{ur}}) \to \tilde{J}(\mathbf{Q}_v^{\mathrm{ur}}) \to \tilde{C}(\mathbf{Q}_v^{\mathrm{ur}}) \to 0$$

is exact. Thus the image of $\mathrm{res}_v(\pi(x))$ in $H^1(\mathbf{Q}_v, \tilde{A})$ is unramified. It equals 0, again by [51, Prop. 3.8], since the component group of $\tilde{A}$ at v has order a power of 2 (in fact it is trivial, since $\tilde{A}$ has good reduction at 2), whereas $\pi(x)$ has odd prime order p. Thus $\mathrm{res}_v(\pi(x)) = 0$, since the kernel of $H^1(\mathbf{Q}_v, A) \to H^1(\mathbf{Q}_v, \tilde{A})$ is a finite group of 2-power order. □

1.3 Description of tables

In this section we describe our tables of optimal quotients of $J_0(N)$, which have nontrivial Shafarevich-Tate group. The tables, which can be found on pages 15–18, were computed using a combination of HECKE [64], LiDIA, NTL, PARI, and most successfully MAGMA [9]. The component group computations at non-prime level rely on Kohel's quaternion algebra package, which was also written in MAGMA.

We compute the conjectural order of the Shafarevich-Tate group of an abelian variety A, and then make assertions about the Shafarevich-Tate group of $A^\vee$. This is justified because the order of $Ш(A^\vee)$ equal the order of $Ш(A)$, since both are finite and the Cassells-Tate pairing sets up a nondegenerate duality between them.

1.3.1 Notation

Each optimal quotient A of $J_0(N)$ is denoted by a label, such as **389E**, which consists of a level N and a letter indicating the isogeny class. In the labeling, N is a positive integer and the isogeny class is given by a letter: the first isogeny class is labeled **A**, the second is labeled **B**, the third labeled **C**, and so on. Thus **389E** is the fifth isogeny class of optimal quotient of $J_0(389)$, corresponding to a Galois-conjugacy class of newforms. The isogeny classes that we consider are in bijection with the Galois-conjugacy classes of newforms in $S_2(\Gamma_0(N))$. The classes of newforms are ordered as described in Section 3.5.5.

WARNING: The *odd part* of a rational number x is $x/2^v$, where $v = \mathrm{ord}_2(x)$. In the tables, only the **odd parts** of the arithmetic invariants of A are given.

1.3.2 Table 1.2: Shafarevich-Tate groups at prime level

Table 1.2 was constructed as follows. Using the results of Section 3.10, we computed the odd part of the conjectural order $\#\text{Ш}_{\text{an}}(A)$ of the Shafarevich-Tate group of every optimal quotient of $J_0(p)$ that corresponds to a single Galois conjugacy-class of eigenforms and has analytic rank 0, for p a prime with $p \leq 2161$. We also computed a few sporadic examples of prime level p with $p > 2161$. The sporadic examples appear at the bottom of the table below a horizontal line.

Notation

The columns of the table contain the following information. The abelian varieties A for which $\#\text{Ш}_{\text{an}}(A)$ is greater than 1 are laid out in the first column of Table 1.2. The second column contains the dimensions of the abelian varieties in the first column. The third column contains the *odd part* (i.e., largest odd divisor) of the order of the Shafarevich-Tate group, as predicted by the BSD conjecture. Column four contains the odd parts of the modular degrees of the abelian varieties in the first column.

The fifth column contains an optimal quotient B of $J_0(p)$ of positive analytic rank, such that the ℓ-torsion of $B^\vee$ is contained in $A^\vee$, when one exists, where ℓ is a divisor of $\#\text{Ш}_{\text{an}}(A)$. We computed this intersection using the algorithm described in Section 3.6. Such a B is called an *explanatory factor*. When no such abelian varieties exists, we write "NONE" in the fifth column. The sixth column contains the dimensions of the abelian varieties in the fifth column, and the seventh column contains the odd parts of the modular degrees of the abelian varieties in the fifth column.

Ranks of the explanatory factors

That the explanatory factors have positive analytic rank follows from our modular symbols computation of $L(B,1)/\Omega_B$. This is supported by the table in [11], except in the case **2333A**, where there is a mistake in [11] (see below).

The explanatory factor **389A** is the first elliptic curve of rank 2. The table in [11] suggests that the explanatory factor **1061B** is the first 2-dimensional abelian variety (attached to a newform) whose Mordell-Weil group when tensored with the field of fractions F of the corresponding ring of Fourier coefficients, is of dimension 2 over F. Similarly **1567B** appears to be the first 3-dimensional one of rank 2, and **2333A** is the first 4-dimensional one of rank 2. It thus seems very likely that the ranks of each explanatory factor is exactly 2, though we have not proved this.

Discussion of the data

There are 23 examples in which $\text{Ш}(A)$ is visible and 18 in which $\text{Ш}(A)$ is invisible. The largest visible $\text{Ш}(A)$ found occurs at level 2333 and has order at least 83341^2 (83341 is prime). The largest invisible $\text{Ш}(A)$ occurs in a 112-dimensional abelian variety at level 2111 and has order at least 211^2.

The example **1283C** demonstrates that $\#\text{Ш}_{\text{an}}(A)$ can divide the modular degree, yet be *invisible*. In this case 5 divides $\#\text{Ш}_{\text{an}}(A)$. Since 5 divides the modular degree, it follows that there must be other non-isogenous subvarieties of $J_0(1283)$ that intersect **1283C** in a subgroup of order divisible by 5. In this case, the only such subvariety is **1283A**, which has dimension 2 and whose 5-torsion is contained in **1283C**. However **1283A** has analytic (hence algebraic) rank 0, so $\#\text{Ш}_{\text{an}}(A)$ cannot be visible.

The cases **1483D**, **1567D**, **2029C**, and **2593B** are interesting because *all* of Ш, even though it has two nontrivial p-primary components in each of these cases, is made visible in a single B. In the case **1913E** only the 5-primary component of Ш is visible in **1913A**, but still *both* the 5-primary and 61-primary components of Ш are visible in **1913C**.

Examples **1091C** and **1429B** were first found in [1] and **1913B** in [18].

Errata to Brumer's paper

Contrary to our computations, [11] suggests that **2333A** has rank 0. However, the author pointed the discrepancy out to Brumer who replied:

> I looked in vain for information about θ-relations on 2333 and have concluded that I never ran the interval from 2300 to 2500 or else had lost all info by the time I wrote up the paper. The punchline: 4 relations for 2333 and 2 relations for 2381 (also missing from the table).

1.3.3 Tables 1.3–1.6: New visible Shafarevich-Tate groups

Let n denote the largest odd square dividing the numerator of $L(A,1)/\Omega_A$. Table 1.3 lists those A such that for some $p \mid n$ there exists a quotient B of $J_0(N)$, corresponding to a *newform* and having positive analytic rank, such that $(A^\vee \cap B^\vee)[p] \neq 0$. Our search was systematic up to level 1001, but there might be omitted examples between levels 1001 and 1028. Table 1.4 contains further arithmetic information about each explanatory factor. Table 1.6 gives the quantities involved in the formula of Chapter 4 for Tamagawa numbers, for each of the abelian varieties A in Table 1.3.

Notation

Most of the notation is the same as in Table 1.2. However the additional columns w_q and c_p contain the signs of the Atkin-Lehner involutions and the Tamagawa numbers, respectively. These are given in order, from smallest to largest prime divisor of N.

In each case B has dimension 1. When $4 \mid N$, we write "a" for c_2 to remind us that we did not compute c_2 because the reduction at 2 is additive. Again only *odd parts* of the invariants are given. Section 4.7.2 contains a discussion of the notation used in the headings of Table 1.6.

Remarks on the data

The explanatory factors B of level ≤ 1028 are *exactly* the set of rank 2 elliptic curves of level ≤ 1028.

Table 1.1: Odd invisible $|Ш_E| > 1$, all $N \leq 5500$ (from Table 1 of [18])

E	$\sqrt{|Ш_E|}$	m_E	**F**	m_F	Remarks
2849A	3	$2^5 \cdot 5 \cdot 61$	**NONE**	–	
3364C	7	$2^6 \cdot 3^2 \cdot 5^2 \cdot 7$	**none**	–	
4229A	3	$2^3 \cdot 3 \cdot 7 \cdot 13$	**none**	–	
4343B	3	$2^4 \cdot 1583$	**NONE**	–	
4914N	3	$2^4 \cdot 3^5$	**none**	–	**E** has rational 3-torsion
5054C	3	$2^3 \cdot 3^3 \cdot 11$	**none**	–	
5073D	3	$2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 23$	**none**	–	
5389A	3	$2^2 \cdot 2333$	**NONE**	–	

1.4 Further visibility computations

1.4.1 Does Ш become visible at higher level?

This section is concerned with whether or not the examples of invisible elements of Shafarevich-Tate groups of elliptic curves of level N that are given in [18] become visible in abelian surfaces inside appropriate $J_0(Np)$. We analyze each of the cases in Table 1 of [18]. For the reader's convenience, the part of this table which concerns us is reproduced as Table 1.1. The most interesting examples we give are **2849A** and **5389A**. As in [18], the assertions below assume the truth of the BSD conjecture.

How we found the explanatory curves

We use a naive heuristic observation to find possible explanatory curves of higher level, even though their conductors are out of the range of Cremona's tables. Note that we have not proved that these factors are actually explanatory in any cases, and expect that in some cases they are not.

First we recall some of the notation from Table 1 of [18], which is partially reproduced below. The "NONE" label in the row corresponding to an elliptic curve E indicates that there are elements in $Ш(E)$ whose order does not divide the modular degree of E, and hence they must be invisible. The label "none" indicates only that no suitable explanatory elliptic curves could be found, so $Ш(E)$ is not visible in an *abelian surface* inside $J_0(N)$; it could, however, be visible in the full abelian variety $J_0(N)$.

Studying the Weierstrass equations corresponding to the curves in [18] reveals that the elliptic curves labeled "NONE" have unusually large height, as compared to their conductors. However, the explanatory factors often have unusually small height. Motivated by this purely heuristic observation, we make a table of all elliptic curves of the form

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6,$$

with $a_1, a_2, a_3 \in \{-1, 0, 1\}$, $|a_4|, |a_6| < 1000$, and conductor bounded by 50000. The bound on the conductor is required only so that the table will fit within computer storage. This table took a few days to generate.

2849A

Barry Mazur and Adam Logan found the first known example of an *invisible* Shafarevich-Tate group. This was $\text{Ш}(E)$, where E is the elliptic curve **2849A**, which has minimal Weierstrass equation

$$E: \quad y^2 + xy + y = x^3 + x^2 - 53484x - 4843180.$$

Consulting our table of curves of small height, we find an elliptic curve F of conductor $8547 = 2849 \cdot 3$ such that $f_E \equiv f_F \pmod 3$, where f_E and f_F are the newforms attached to E and F, respectively. This is a congruence for *all* eigenvalues a_p attached to E and F. The elliptic curve F is defined by the equation

$$F: \quad y^2 + xy + y = x^3 + x^2 - 154x - 478.$$

Cremona's program `mwrank` reveals that the Mordell-Weil group of F has rank 2. Thus maybe $\text{Ш}(E)$ becomes visible at level 8547. Unfortunately, visibility of $\text{Ш}(E)$ is not implied by Theorem 1.8 because the geometric component group of F at 3 has order divisible by 3.

4343B

Consider the elliptic curve E labeled **4343B**. According to Table 1 of [18], $\text{Ш}(E)$ has order 9, but the modular degree prevents $\text{Ш}(E)$ from being visible in $J_0(4343)$. At level $21715 = 5 \cdot 4343$ there is an elliptic curve F of rank 1 that is congruent to E. Its equation is

$$F: \quad y^2 - xy - y = x^3 - x^2 + 78x - 256.$$

5389A

The last curve labeled "NONE" in the table is curve **5389A**, which has minimal Weierstrass equation

$$y^2 + xy + y = x^3 - 35590x - 2587197.$$

The main theorem of [54] implies that there exists a newform that is congruent modulo 3 to the newform corresponding to **5389A** and of level $3 \cdot 5389$. This is because $(-2)^2 = (3+1)^2 \pmod 3$. However, our table of curves of small height does not contain any curve of conductor $3 \cdot 5389$. Next we observe that $(-2)^2 \equiv (7+1)^2 \pmod 3$, so using Ribet's theorem we can instead augment the level by 7. Our table of small-height curves contains just one (up to isogeny) elliptic curve of conductor 37723, and *luckily* the corresponding newform is congruent modulo 3 to the newform corresponding to **5389A** (away from primes dividing the level)! The Weierstrass equation of this curve is

$$F: \quad y^2 - y = x^3 + x^2 + 34x - 248.$$

According to Cremona's program `mwrank`, the rank of F is 2.

3364C, 4229A, 5073D

Perhaps Ш(E) is already visible in some of the cases in which the curve is labeled "none", because the method fails in most of these cases. Each of the curves **3364C**, **4229A**, and **5073D** is labeled "none". In none of these 3 cases are we able to find an explanatory factor at higher level, within the range of our table of elliptic curves of small height.

4194N, 5054C

The curve **4914N** is labeled "none" and we find the remark "E has rational 3-torsion". There is a congruent curve F of conductor 24570 given by the equation

$$F : \quad y^2 - xy = x^3 - x^2 - 15x - 75,$$

and $F(\mathbf{Q}) = \{0\}$. The curve **5054C** is labeled "none" and its Shafarevich-Tate group contains invisible elements of order 3. We find a congruent curve of level 25270 and rank 1. The equation of the congruent curve is

$$F : y^2 - xy = x^3 + x^2 - 178x + 882.$$

1.4.2 Positive rank example

The abelian varieties with nontrivial Ш(A) that one finds in both ours and Cremona's tables all have rank 0. In this section we outline a computation which sugggests, but does not prove, that there is a positive-rank abelian subvariety A of $J_0(5077)$ such that Ш(A) possesses a nontrivial visible element of order 31.

According to [16], the smallest conductor elliptic curve E of rank 3 is found in $J = J_0(5077)$. The number 5077 is prime, and the isogeny decomposition of J is[1]

$$J \sim A \times B \times E,$$

where each of A, B, and E are abelian subvarieties of J associated to newforms, which have dimensions 205, 216, and 1, respectively. Using Remark 3.38 or [69], we find that the modular degree of E is $1984 = 2^6 \cdot 31$. The sign of the Atkin-Lehner involution on E is the same as its sign on A, so $E[31] \subset A$. We have $E(\mathbf{Q}) \cong \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z}$, and the component group of E is trivial. The numerator of $(5077-1)/12$ is $3^2 \cdot 47$, so [40] implies that none of the abelian varieties above have 31-torsion. It might be possible to find an analogue of Theorem 1.8 that applies when A has positive rank, and deduce in this case that Ш(A) contains visible elements of order 31.

[1] This decomposition was found in about one minute using the Mestre-Oesterlé method of graphs (see [47]).

Table 1.2: Shafarevich-Tate groups at prime level. (The entries in the columns "mod deg" and "$\#\text{Ш}_{\mathrm{an}}$" are only really the odd parts of "mod deg" and "$\#\text{Ш}_{\mathrm{an}}$".)

A	dim	$\#\text{Ш}_{\mathrm{an}}(A)$	mod deg(A)	**B**	dim	mod deg(B)
389E	20	5^2	5	**389A**	1	5
433D	16	7^2	$3 \cdot 7 \cdot 37$	**433A**	1	7
563E	31	13^2	13	**563A**	1	13
571D	2	3^2	$3^2 \cdot 127$	**571B**	1	3

Chapter 2

Modular symbols

Modular symbols permeate this thesis. In their simplest incarnation, modular symbols provide a finite presentation for the homology group $H_1(X_0(N), \mathbf{Z})$ of the Riemann surface $X_0(N)$. This presentation is equipped with such a rich structure that from it we can deduce the action of the Hecke operators; this is already sufficient information for us to compute a basis for the space $S_2(\Gamma_0(N), \mathbf{C})$ of cusp forms.

We recall the definition of spaces of modular symbols in Sections 2.1–2.2. Then in Section 2.3, we review the duality between modular symbols and modular forms. In Section 2.4, we see that modular symbols are furnished with analogues of each of the standard operators that one finds on spaces of modular forms, and in Section 2.5 we see that the same is true of the degeneracy maps. Section 2.6 describes Manin symbols, which supply a convenient finite presentation for the space of modular symbols. Finally, Section 2.7 introduces the complex torus attached to a newform, which appears in various guises throughout this thesis.

Before continuing, we offer an apology. We will only consider modular symbols that are already equipped with a fixed Dirichlet character. Though fixing a character complicates the formulas, the resulting increase in efficiency is of extreme value in computational applications. Fixing a character allows us to compute in just the part of the space of modular symbols for $\Gamma_1(N)$ that interests us. We apologize for any inconvenience this may cause the less efficiency minded reader.

Acknowledgment. This chapter and the next were greatly influenced by the publications of Cremona [15, 16] and Merel [45], along with the foundational contributions of Manin [38], Mazur [42, 39], and Shokurov [63]. Cremona's book [16] provides a motivated roadmap that guides the reader who wishes to compute with modular symbols in the familiar context of elliptic curves, and Merel's article provides an accessible overview of the action of Hecke operators on higher weight modular symbols, and the connection between modular symbols and related cohomology theories.

2.1 The definition of modular symbols

Fix a positive integer N, an integer $k \geq 2$, and a continuous homomorphism

$$\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$$

such that $\varepsilon(-1) = (-1)^k$. We call N the *level*, k the *weight*, and ε the *Dirichlet character.*

Consider the quotient of the abelian group generated by all formal symbols $\{\alpha, \beta\}$, with $\alpha, \beta \in \mathbf{P}^1(\mathbf{Q}) = \mathbf{Q} \cup \{\infty\}$, by the following relations:

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0,$$

for all $\alpha, \beta, \gamma \in \mathbf{P}^1(\mathbf{Q})$. Let $\boldsymbol{\mathcal{M}}$ be the torsion-free quotient of this group by its torsion subgroup. Because $\boldsymbol{\mathcal{M}}$ is torsion free, $\{\alpha, \alpha\} = 0$ and $\{\alpha, \beta\} = -\{\beta, \alpha\}$.

Remark 2.1. One is motivated to consider these relations by viewing $\{\alpha, \beta\}$ as the homology class of an appropriate path from α to β in the upper half plane.

Let V_{k-2} be the $\mathbf{Z}$-submodule of $\mathbf{Z}[X, Y]$ made up of all homogeneous polynomials of degree $k-2$, and set $\boldsymbol{\mathcal{M}}_k := V_{k-2} \otimes \boldsymbol{\mathcal{M}}$. For $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbf{Q})$ and $P \in V_{k-2}$, let

$$\begin{aligned} gP(X, Y) &= P\left(\det(g) g^{-1} \begin{pmatrix} X \\ Y \end{pmatrix}\right) = P\left(\begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \begin{pmatrix} X \\ Y \end{pmatrix}\right) \\ &= P(dX - bY, -cX + aY). \end{aligned}$$

This defines a left action of $\mathrm{GL}_2(\mathbf{Q})$ on V_{k-2}; it is a left action because

$$\begin{aligned} (gh)P(v) &= P(\det(gh)(gh)^{-1} v) = P(\det(h) h^{-1} \det(g) g^{-1} v) \\ &= gP(\det(h) h^{-1} v) = g(hP(v)). \end{aligned}$$

Combining this action with the action of $\mathrm{GL}_2(\mathbf{Q})$ on $\mathbf{P}^1(\mathbf{Q})$ by linear fractional transformations gives a left action of $\mathrm{GL}_2(\mathbf{Q})$ on $\boldsymbol{\mathcal{M}}_k$:

$$g(P \otimes \{\alpha, \beta\}) = g(P) \otimes \{g(\alpha), g(\beta)\}.$$

Finally, for $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$, let $\varepsilon(g) := \varepsilon(\overline{a})$, where $\overline{a} \in \mathbf{Z}/N\mathbf{Z}$ is the reduction modulo N of a.

Let

$$\mathbf{Z}[\varepsilon] := \mathbf{Z}[\varepsilon(a) : a \in \mathbf{Z}/N\mathbf{Z}]$$

be the subring of $\mathbf{C}$ generated by the values of the character ε.

Definition 2.2 (Modular symbols). The space of *modular symbols* $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$ of level N, weight k and character ε is the largest torsion-free quotient of $\boldsymbol{\mathcal{M}}_k \otimes \mathbf{Z}[\varepsilon]$ by the $\mathbf{Z}[\varepsilon]$-submodule generated by the relations $gx - \varepsilon(g)x$ for all $x \in \boldsymbol{\mathcal{M}}_k$ and all $g \in \Gamma_0(N)$.

Denote by $P\{\alpha, \beta\}$ the image of $P \otimes \{\alpha, \beta\}$ in $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$. For any $\mathbf{Z}[\varepsilon]$-algebra R, let

$$\boldsymbol{\mathcal{M}}_k(N, \varepsilon; R) := \boldsymbol{\mathcal{M}}_k(N, \varepsilon) \otimes_{Z[\varepsilon]} R.$$

See Section 3.1 for an algorithm which can be used to compute $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; \mathbf{Q}(\varepsilon))$.

2.2 Cuspidal modular symbols

Let $\boldsymbol{\mathcal{B}}$ be the free abelian group generated by the symbols $\{\alpha\}$ for all $\alpha \in \mathbf{P}^1(\mathbf{Q})$. There is a left action of $\mathrm{GL}_2(\mathbf{Q})$ on $\boldsymbol{\mathcal{B}}$ given by $g\{\alpha\} = \{g(\alpha)\}$. Let $\boldsymbol{\mathcal{B}}_k := V_{k-2} \otimes \boldsymbol{\mathcal{B}}$, and let $\mathrm{GL}_2(\mathbf{Q})$ act on $\boldsymbol{\mathcal{B}}_k$ by $g(P\{\alpha\}) = (gP)\{g(\alpha)\}$.

Definition 2.3 (Boundary modular symbols). The space $\boldsymbol{\mathcal{B}}_k(N, \varepsilon)$ of *boundary modular symbols* is the largest torsion-free quotient of $\boldsymbol{\mathcal{B}}_k \otimes \mathbf{Z}[\varepsilon]$ by the relations $gx = \varepsilon(g)x$ for all $g \in \Gamma_0(N)$ and $x \in \boldsymbol{\mathcal{B}}_k$.

Denote by $P\{\alpha\}$ the image of $P \otimes \{\alpha\}$ in $\boldsymbol{\mathcal{B}}_k(N, \varepsilon)$. The *boundary map*

$$\delta : \boldsymbol{\mathcal{M}}_k(N, \varepsilon) \to \boldsymbol{\mathcal{B}}_k(N, \varepsilon)$$

is defined by

$$\delta(P\{\alpha, \beta\}) = P\{\beta\} - P\{\alpha\}.$$

Definition 2.4 (Cuspidal modular symbols). The space $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ of *cuspidal modular symbols* is the kernel of δ.

The three spaces defined above fit together in the following exact sequence:

$$0 \to \boldsymbol{\mathcal{S}}_k(N, \varepsilon) \to \boldsymbol{\mathcal{M}}_k(N, \varepsilon) \xrightarrow{\delta} \boldsymbol{\mathcal{B}}_k(N, \varepsilon).$$

2.3 Duality between modular symbols and modular forms

For any positive integer k, any $\mathbf{C}$-valued function f on the complex upper half plane

$$\mathfrak{h} := \{z \in \mathbf{C} : \mathrm{im}(z) > 0\},$$

and any matrix $\gamma \in \mathrm{GL}_2(\mathbf{Q})$, define a function $f|[\gamma]_k$ on $\mathfrak{h}$ by

$$(f|[\gamma]_k)(z) = \det(\gamma)^{k-1} \frac{f(\gamma z)}{(cz + d)^k}.$$

Definition 2.5 (Cusp forms). Let $S_k(N, \varepsilon)$ be the complex vector space of holomorphic functions $f(z)$ on $\mathfrak{h}$ that satisfy the equation

$$f|[\gamma]_k = \varepsilon(\gamma) f$$

for all $\gamma \in \Gamma_0(N)$, and such that f is holomorphic and vanishes at all cusps, in the sense of [21, pg. 42].

Definition 2.6 (Antiholomorphic cusp forms). Let $\overline{S}_k(N, \varepsilon)$ be the space of *antiholomorphic cusp forms*; the definition is as above, except

$$\frac{f(\gamma z)}{(c\overline{z} + d)^k} = \overline{\varepsilon}(\gamma) f(z)$$

for all $\gamma \in \Gamma_0(N)$.

There is a canonical isomorphism of real vector spaces between $S_k(N,\varepsilon)$ and $\overline{S}_k(N,\varepsilon)$ that associates to f the antiholomorphic cusp form defined by the function $z \mapsto \overline{f(z)}$.

Theorem 2.7 (Merel). *There is a pairing*

$$\langle\ ,\ \rangle : (S_k(N,\varepsilon) \oplus \overline{S}_k(N,\varepsilon)) \times \boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathbf{C}) \to \mathbf{C}$$

given by

$$\langle f \oplus g, P\{\alpha,\beta\}\rangle = \int_{\alpha}^{\beta} f(z)P(z,1)dz + \int_{\alpha}^{\beta} g(z)P(\overline{z},1)d\overline{z},$$

where the path from α to β is, except for the endpoints, contained in $\mathfrak{h}$. The pairing is perfect when restricted to $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathbf{C})$.

Proof. Take the ε part of each side of [45, Thm. 3]. □

2.4 Linear operators

2.4.1 Hecke operators

For each positive integer n and each space V of modular symbols or modular forms, there is a *Hecke operator* T_n, which acts as a linear endomorphism of V. For the definition of T_n on modular symbols, see [45, §2]. Alternatively, because we consider only modular symbols with character, the following recipe completely determines the Hecke operators. First, when $n = p$ is prime, we have

$$T_p(x) = \left[\begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} + \sum_{r \bmod p} \begin{pmatrix} 1 & r \\ 0 & p \end{pmatrix}\right] x,$$

where the first matrix is omitted if $p \mid N$. If m and n are coprime, then $T_{mn} = T_m T_n$. Finally, if p is a prime, $r \geq 2$ is an integer, ε is the Dirichlet character of associated to V, and k is the weight of V, then

$$T_{p^r} = T_p T_{p^{r-1}} - \varepsilon(p)p^{k-1}T_{p^{r-2}}.$$

Definition 2.8. The *Hecke algebra associated to V* is the subring

$$\mathbf{T} = \mathbf{T}_V = \mathbf{Z}[\ldots T_n \ldots]$$

of $\mathrm{End}(V)$ generated by all Hecke operators T_n, with $n = 1, 2, 3, \ldots$.

Proposition 2.9. *The pairing of Theorem 2.7 respects the action of the Hecke operators, in the sense that $\langle fT, x\rangle = \langle f, Tx\rangle$ for all $T \in \mathbf{T}$, $x \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$, and $f \in S_k(N,\varepsilon) \oplus \overline{S}_k(N,\varepsilon)$.*

Proof. See [45, Prop. 10]. □

2.4.2 The $*$-involution

The matrix $j = \left(\begin{smallmatrix}-1&0\\0&1\end{smallmatrix}\right)$ defines an involution $*$ of $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ given by $x \mapsto x^* = j(x)$. Explicitly,

$$(P(X,Y)\{\alpha,\beta\})^* = P(X,-Y)\{-\alpha,-\beta\}.$$

Because the space of modular symbols is constructed as a quotient, it is not obvious that the $*$-involution is well defined.

Proposition 2.10. *The $*$-involution is well defined.*

Proof. Recall that $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ is the largest torsion-free quotient of the free $\mathbf{Z}[\varepsilon]$-module generated by symbols $x = P\{\alpha,\beta\}$ by the submodule generated by relations $\gamma x - \varepsilon(\gamma)x$ for all $\gamma \in \Gamma_0(N)$. In order to check that the operator $*$ is well defined, it suffices to check, for any $x \in \boldsymbol{\mathcal{M}}_k$, that $*(\gamma x - \varepsilon(\gamma)x)$ is of the form $\gamma' y - \varepsilon(\gamma')y$, for some y in $\boldsymbol{\mathcal{M}}_k$. Note that if $\gamma = \left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right) \in \Gamma_0(N)$, then $j\gamma j^{-1} = \left(\begin{smallmatrix}a&-b\\-c&d\end{smallmatrix}\right)$ is also in $\Gamma_0(N)$ and $\varepsilon(j\gamma j^{-1}) = \varepsilon(\gamma)$. We have

$$\begin{aligned} j(\gamma x - \varepsilon(\gamma)x) &= j\gamma x - j\varepsilon(\gamma)x \\ &= j\gamma j^{-1} j x - \varepsilon(\gamma) j x \\ &= (j\gamma j^{-1})(jx) - \varepsilon(j\gamma j^{-1})(jx). \end{aligned}$$

□

If f is a modular form, let f^* be the holomorphic function $\overline{f(-\overline{z})}$, where the bar denotes complex conjugation. The Fourier coefficients of f^* are the complex conjugates of those of f; though f^* is again a holomorphic modular form, its character is $\overline{\varepsilon}$ instead of ε. The pairing of Theorem 2.7 is the restriction of a pairing on the full spaces without character, and we have the following proposition.

Proposition 2.11. *We have*

$$\langle f^*, x^* \rangle = \overline{\langle f, x \rangle}.$$

Definition 2.12 (Plus-one quotient). The *plus-one quotient* $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)_+$ is the largest torsion-free quotient of $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ by the relations $x^* - x = 0$ for all $x \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$. Similarly, the *minus-one quotient* is the quotient of $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ by all relations $x^* + x = 0$, for $x \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$.

WARNING 2.13. We were forced to make a choice in our definition of the operator $*$. Fortunately, it agrees with that of [16, §2.1.3], but *not* with the choice made in [45, §1.6].

2.4.3 The Atkin-Lehner involutions

In this section we assume that k is even and $\varepsilon^2 = 1$. The assumption on ε is necessary only so that the involution we are about to define preserves $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$. More generally, it is possible to define a map which sends $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ to $\boldsymbol{\mathcal{M}}_k(N,\overline{\varepsilon})$.

To each divisor d of N such that $(d, N/d) = 1$ there is an *Atkin-Lehner involution* W_d of $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$, which is defined as follows. Using the Euclidean algorithm, choose integers x, y, z, w such that

$$dxw - (N/d)yz = 1.$$

Next let $g = \left(\begin{smallmatrix} dx & y \\ Nz & dw \end{smallmatrix}\right)$ and define

$$W_d(x) := \frac{1}{d^{\frac{k-2}{2}}} \cdot g(x).$$

For example, when $d = N$ we have $g = \left(\begin{smallmatrix} 0 & -1 \\ N & 0 \end{smallmatrix}\right)$. The factor of $d^{\frac{k-2}{2}}$ is necessary to normalize W_d so that it is an involution.

On modular forms there is an Atkin-Lehner involution, also denoted W_d, which acts by $W_d(f) = f|[W_d]_k$. These two like-named involutions are compatible with the integration pairing:

$$\langle W_d(f), x\rangle = \langle f, W_d(x)\rangle.$$

2.5 Degeneracy maps

In this section, we describe natural maps between spaces of modular symbols of different levels.

Fix a positive integer N and a Dirichlet character $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$. Let M be a positive divisor of N that is divisible by the conductor of ε, in the sense that ε factors through $(\mathbf{Z}/M\mathbf{Z})^*$ via the natural map $(\mathbf{Z}/N\mathbf{Z})^* \to (\mathbf{Z}/M\mathbf{Z})^*$ composed with some uniquely defined character $\varepsilon' : (\mathbf{Z}/M\mathbf{Z})^* \to \mathbf{C}^*$. For any positive divisor t of N/M, let $T = \left(\begin{smallmatrix} 1 & 0 \\ 0 & t \end{smallmatrix}\right)$ and fix a choice $D_t = \{T\gamma_i : i = 1, \ldots, n\}$ of coset representatives for $\Gamma_0(N)\backslash T\Gamma_0(M)$.

WARNING 2.14. There is a mistake in [45, §2.6]: The quotient "$\Gamma_1(N)\backslash\Gamma_1(M)T$" should be replaced by "$\Gamma_1(N)\backslash T\Gamma_1(M)$".

Proposition 2.15. *For each divisor t of N/M there are well-defined linear maps*

$$\alpha_t : \boldsymbol{\mathcal{M}}_k(N, \varepsilon) \to \boldsymbol{\mathcal{M}}_k(M, \varepsilon'), \qquad \alpha_t(x) = (tT^{-1})x = \begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} x$$

$$\beta_t : \boldsymbol{\mathcal{M}}_k(M, \varepsilon') \to \boldsymbol{\mathcal{M}}_k(N, \varepsilon), \qquad \beta_t(x) = \sum_{T\gamma_i \in D_t} \varepsilon'(\gamma_i)^{-1} T\gamma_i x.$$

Furthermore, $\alpha_t \circ \beta_t$ is multiplication by $t^{k-2} \cdot [\Gamma_0(M) : \Gamma_0(N)]$.

Proof. To show that α_t is well defined, we must show that for each $x \in \boldsymbol{\mathcal{M}}_k(N, \varepsilon)$ and $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$, that we have

$$\alpha_t(\gamma x - \varepsilon(\gamma)x) = 0 \in \boldsymbol{\mathcal{M}}_k(M, \varepsilon').$$

We have

$$\alpha_t(\gamma x) = \begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} \gamma x = \begin{pmatrix} a & tb \\ c/t & d \end{pmatrix} \begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} x = \varepsilon'(a) \begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} x,$$

so

$$\alpha_t(\gamma x - \varepsilon(\gamma)x) = \varepsilon'(a)\alpha_t(x) - \varepsilon(\gamma)\alpha_t(x) = 0.$$

We next verify that β_t is well defined. Suppose that $x \in \boldsymbol{\mathcal{M}}_k(M, \varepsilon')$ and $\gamma \in \Gamma_0(M)$; then $\varepsilon'(\gamma)^{-1}\gamma x = x$, so

$$\begin{aligned}\beta_t(x) &= \sum_{T\gamma_i \in D_t} \varepsilon'(\gamma_i)^{-1} T\gamma_i \varepsilon'(\gamma)^{-1}\gamma x \\ &= \sum_{T\gamma_i\gamma \in D_t} \varepsilon'(\gamma_i\gamma)^{-1} T\gamma_i\gamma x.\end{aligned}$$

This computation shows that the definition of β_t does not depend on the choice D_t of coset representatives. To finish the proof that β_t is well defined we must show that, for $\gamma \in \Gamma_0(M)$, we have $\beta_t(\gamma x) = \varepsilon'(\gamma)\beta_t(x)$ so that β_t respects the relations that define $\boldsymbol{\mathcal{M}}_k(M, \varepsilon)$. Using that β_t does not depend on the choice of coset representative, we find that for $\gamma \in \Gamma_0(M)$,

$$\begin{aligned}\beta_t(\gamma x) &= \sum_{T\gamma_i \in D_t} \varepsilon'(\gamma_i)^{-1} T\gamma_i\gamma x \\ &= \sum_{T\gamma_i\gamma^{-1} \in D_t} \varepsilon'(\gamma_i\gamma^{-1})^{-1} T\gamma_i\gamma^{-1}\gamma x \\ &= \varepsilon'(\gamma)\beta_t(x).\end{aligned}$$

To compute $\alpha_t \circ \beta_t$, we use that $\#D_t = [\Gamma_0(N) : \Gamma_0(M)]$:

$$\begin{aligned}\alpha_t(\beta_t(x)) &= \alpha_t\left(\sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1} T\gamma_i x\right) \\ &= \sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1}(tT^{-1})T\gamma_i x \\ &= t^{k-2}\sum_{T\gamma_i} \varepsilon'(\gamma_i)^{-1}\gamma_i x \\ &= t^{k-2}\sum_{T\gamma_i} x \\ &= t^{k-2} \cdot [\Gamma_0(N) : \Gamma_0(M)] \cdot x.\end{aligned}$$

The scalar factor of t^{k-2} appears instead of t, because t is acting on x as an element of $\mathrm{GL}_2(\mathbf{Q})$ *not* as an an element of $\mathbf{Q}$. □

Definition 2.16 (New and old modular symbols). The subspace $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)^{\mathrm{new}}$ of *new modular symbols* is the intersection of the kernels of the α_t as t runs through all positive divisors of N/M and M runs through positive divisors of M strictly less than N and divisible by the conductor of ε. The subspace $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)^{\mathrm{old}}$ of *old modular symbols* is the subspace generated by the images of the β_t where t runs through all positive divisors of N/M and M runs through positive divisors of M strictly less than N and divisible by the conductor of ε.

WARNING: The new and old subspaces need not be disjoint, as the following example illustrates! This is contrary to the statement on page 80 of [45].

Example 2.17. We justify the above warning. Consider, for example, the case $N = 6$, $k = 2$, and trivial character. The spaces $\boldsymbol{\mathcal{M}}_2(2)$ and $\boldsymbol{\mathcal{M}}_2(3)$ are each of dimension 1, and each is generated by the modular symbol $\{\infty, 0\}$. The space $\boldsymbol{\mathcal{M}}_2(6)$ is of dimension 3, and is generated by the 3 modular symbols $\{\infty, 0\}$, $\{-1/4, 0\}$, and $\{-1/2, -1/3\}$. The space generated by the 2 images of $\boldsymbol{\mathcal{M}}_2(2)$ under the 2 degeneracy maps has dimension 2, and likewise for $\boldsymbol{\mathcal{M}}_2(3)$. Together these images generate $\boldsymbol{\mathcal{M}}_2(6)$, so $\boldsymbol{\mathcal{M}}_2(6)$ is equal to its old subspace. However, the new subspace is nontrivial because the two degeneracy maps $\boldsymbol{\mathcal{M}}_2(6) \to \boldsymbol{\mathcal{M}}_2(2)$ are equal, as are the two degeneracy maps $\boldsymbol{\mathcal{M}}_2(6) \to \boldsymbol{\mathcal{M}}_2(3)$. In particular, the intersection of the kernels of the degeneracy maps has dimension at least 1 (in fact, it equals 1).

Computationally, it appears that something similar to this happens if and only if the weight is 2, the character is trivial, and the level is composite. This behavior is probably related to the nonexistence of a characteristic 0 Eisenstein series of weight 2 and level 1.

The following tempting argument is incorrect; the error lies in the fact that an element of the old subspace is a *linear combination* of $\beta_t(y)$'s for various y's and t's: "If x is in both the new and old subspace, then $x = \beta_t(y)$ for some modular symbol y of lower level. This implies $x = 0$ because

$$0 = \alpha_t(x) = \alpha_t(\beta_t(y)) = t^{k-2} \cdot [\Gamma_0(N) : \Gamma_0(M)] \cdot y."$$

Remark 2.18. The map $\beta_t \circ \alpha_t$ cannot in general be multiplication by a scalar since $\boldsymbol{\mathcal{M}}_k(M, \varepsilon')$ usually has smaller dimension than $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$.

2.5.1 Computing coset representatives

Definition 2.19 (Projective line mod N). Let N be a positive integer. Then the *projective line* $\mathbf{P}^1(N)$ is the set of pairs (a, b), with $a, b \in \mathbf{Z}/N\mathbf{Z}$ and $\gcd(a, b, N) = 1$, modulo the eqivalence relation which identifies (a, b) and (a', b') if and only if $ab' \equiv ba' \pmod{N}$.

Let M be a positive divisor of N and t a divisor of N/M. The following *random* algorithm computes a set D_t of representatives for the orbit space $\Gamma_0(M)\backslash T\Gamma_0(N)$. There are deterministic algorithms for computing D_t, but all of the ones the author has found are *vastly* less efficient than the following random algorithm.

Algorithm 2.20. Let $\Gamma_0(N/t, t)$ denote the subgroup of $\mathrm{SL}_2(\mathbf{Z})$ consisting of matrices that are upper triangular modulo N/t and lower triangular modulo t. Observe that two right cosets of $\Gamma_0(N/t, t)$ in $\mathrm{SL}_2(\mathbf{Z})$, represented by $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} a' & b' \\ c' & d' \end{smallmatrix}\right)$, are equivalent if and only if $(a, b) = (a', b')$ as points of $\mathbf{P}^1(t)$ and $(c, d) = (c', d')$ as points of $\mathbf{P}^1(N/t)$. Using the following algorithm, we compute right coset representatives for $\Gamma_0(N/t, t)$ inside $\Gamma_0(M)$.

1. Compute the number $[\Gamma_0(M) : \Gamma_0(N)]$ of cosets.

2. Compute a random element $x \in \Gamma_0(M)$.

3. If x is not equivalent to anything generated so far, add it to the list.

4. Repeat steps (2) and (3) until the list is as long as the bound of step (1).

There is a natural bijection between $\Gamma_0(N)\backslash T\Gamma_0(M)$ and $\Gamma_0(N/t,t)\backslash\Gamma_0(M)$, under which $T\gamma$ corresponds to γ. Thus we obtain coset representatives for $\Gamma_0(N)\backslash T\Gamma_0(M)$ by left multiplying each coset representative of $\Gamma_0(N/t,t)\backslash\Gamma_0(M)$ by T.

2.5.2 Compatibility with modular forms

The degeneracy maps defined above are compatible with the corresponding degeneracy maps $\tilde{\alpha}_t$ and $\tilde{\beta}_t$ on modular forms. This is because the degeneracy maps on modular forms are defined by summing over the same coset representatives D_t. Thus we have the following compatibilities.

$$\begin{aligned}\langle\tilde{\alpha}_t(f),x\rangle &= \langle f,\alpha_t(x)\rangle,\\ \langle\tilde{\beta}_t(f),x\rangle &= \langle f,\beta_t(x)\rangle.\end{aligned}$$

If p is prime to N, then $T_p\alpha_t = \alpha_t T_p$ and $T_p\beta_t = \beta_t T_p$.

2.6 Manin symbols

From the definition given in Section 2.1, it is not obvious that $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ is of finite rank. The Manin symbols provide a finite presentation of $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ that is vastly more useful from a computational point of view.

Definition 2.21 (Manin symbols). The *Manin symbols* are the set of pairs

$$[P(X,Y),(u,v)]$$

where $P(X,Y)\in V_{k-2}$ and $0\le u,v<N$ with $\gcd(u,v,N)=1$.

Define a *right* action of $\mathrm{GL}_2(\mathbf{Q})$ on the free $\mathbf{Z}[\varepsilon]$-module M generated by the Manin symbols as follows. The element $g=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)$ acts by

$$[P,(u,v)]g = [g^{-1}P(X,Y),(u,v)g] = [P(aX+bY,cX+dY),(au+cv,bu+dv)].$$

Let $\sigma=\left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right)$ and $\tau=\left(\begin{smallmatrix}0&-1\\1&-1\end{smallmatrix}\right)$. Let $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)'$ be the largest torsion-free quotient of M by the relations

$$\begin{aligned}x+x\sigma&=0,\\ x+x\tau+x\tau^2&=0,\\ \varepsilon(\lambda)[P,(u,v)]-[P,(\lambda u,\lambda v)]&=0.\end{aligned}$$

Theorem 2.22. *There is a natural isomorphism $\varphi:\boldsymbol{\mathcal{M}}_k(N,\varepsilon)'\longrightarrow\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ given by*

$$[X^iY^{2-k-i},(u,v)]\mapsto g(X^iY^{k-2-i}\{0,\infty\})$$

where $g=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in\mathrm{SL}_2(\mathbf{Z})$ is any matrix such that $(u,v)\equiv(c,d)\pmod N$.

Proof. In [45, §1.2, §1.7] it is proved that $\varphi\otimes_{\mathbf{Z}[\varepsilon]}\mathbf{C}$ is an isomorphism, so φ is injective and well defined. The discussion in Section 2.6.1 below ("Manin's trick") shows that every element in $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ is a $\mathbf{Z}[\varepsilon]$-linear combination of elements in the image, so φ is surjective as well. □

2.6.1 Conversion between modular and Manin symbols

For some purposes it is better to work with modular symbols, and for others it is better to work with Manin symbols. For example, there are descriptions of the Atkin-Lehner involution in terms of both Manin and modular symbols; it appears more efficient to compute this involution using modular symbols. On the other hand, practically Hecke operators can be computed more efficiently using Manin symbols. It is thus essential to be able to convert between these two representations. The conversion from Manin to modular symbols is straightforward, and follows immediately from Theorem 2.22. The conversion back is accomplished using the method used to prove Theorem 2.22; it is known as "Manin's trick", and involves continued fractions.

Given a Manin symbol $[X^iY^{k-2-i},(u,v)]$, we write down a corresponding modular symbol as follows. Choose $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z})$ such that $(c,d) \equiv (u,v) \pmod{N}$. This is possible by Lemma 1.38 of [62, pg. 20]; in practice, finding $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ is not completely trivial, but can be accomplished using the extended Euclidean algorithm. Then

$$\begin{aligned}[X^iY^{k-2-i},(u,v)] \quad \longleftrightarrow \quad & \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)(X^iY^{k-2-i}\{0,\infty\}) \\ &= (dX-bY)^i(-cX+aY)^{2-k-i}\left\{\frac{b}{d},\frac{a}{c}\right\}.\end{aligned}$$

In the other direction, suppose that we are given a modular symbol $P(X,Y)\{\alpha,\beta\}$ and wish to represent it as a sum of Manin symbols. Because

$$P\{a/b,c/d\} = P\{a/b,0\}+P\{0,c/d\},$$

it suffices to write $P\{0,a/b\}$ in terms of Manin symbols. Let

$$0=\frac{p_{-2}}{q_{-2}}=\frac{0}{1},\ \frac{p_{-1}}{q_{-1}}=\frac{1}{0},\ \frac{p_0}{1}=\frac{p_0}{q_0},\ \frac{p_1}{q_1},\ \frac{p_2}{q_2},\ \dots,\ \frac{p_r}{q_r}=\frac{a}{b}$$

denote the continued fraction convergents of the rational number a/b. Then

$$p_jq_{j-1}-p_{j-1}q_j = (-1)^{j-1} \qquad \text{for } -1\le j\le r.$$

If we let $g_j = \begin{pmatrix} (-1)^{j-1}p_j & p_{j-1} \\ (-1)^{j-1}q_j & q_{j-1}\end{pmatrix}$, then $g_j \in \mathrm{SL}_2(\mathbf{Z})$ and

$$\begin{aligned} P(X,Y)\{0,a/b\} &= P(X,Y)\sum_{j=-1}^{r}\left\{\frac{p_{j-1}}{q_{j-1}},\frac{p_j}{q_j}\right\} \\ &= \sum_{j=-1}^{r} g_j((g_j^{-1}P(X,Y))\{0,\infty\}) \\ &= \sum_{j=-1}^{r}[g_j^{-1}P(X,Y),((-1)^{j-1}q_j,q_{j-1})].\end{aligned}$$

Note that in the jth summand, $g_j^{-1}P(X,Y)$, replaces $P(X,Y)$. Since $g_j \in \mathrm{SL}_2(\mathbf{Z})$ and $P(X,Y)$ has integer coefficients, the polynomial $g_j^{-1}P(X,Y)$ also has integer coefficients, so no denominators are introduced.

The continued fraction expansion $[c_1, c_2, \ldots, c_n]$ of the rational number a/b can be computed using the Euclidean algorithm. The first term, c_1, is the "quotient": $a = bc_1 + r$, with $0 \leq r < b$. Let $a' = b$, $b' = r$ and compute c_2 as $a' = b'c_2 + r'$, etc., terminating when the remainder is 0. For example, the expansion of $5/13$ is $[0, 2, 1, 1, 2]$. The numbers

$$d_i = c_1 + \cfrac{1}{c_2 + \frac{1}{c_3 + \cdots}}$$

will then be the (finite) convergents. For example if $a/b = 5/13$, then the convergents are

$$0/1,\ 1/0,\ d_1 = 0,\ d_2 = \frac{1}{2},\ d_3 = \frac{1}{3},\ d_4 = \frac{2}{5},\ d_5 = \frac{5}{13}.$$

2.6.2 Hecke operators on Manin symbols

Thoerem 2 of [45] gives a description of the Hecke operators T_n directly on the space of Manin symbols. This avoids the expense of first converting a Manin symbol to a modular symbol, computing T_n on the modular symbol, and then converting back. For the reader's convenience, we very briefly recall Merel's theorem here, along with an enhancement due to Cremona.

As in [16, §2.4], define R_p as follows. When $p = 2$,

$$R_2 := \left\{ \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix} \right\}.$$

When p is odd, R_p is the set of 2×2 integer matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with determinant p, and either

1. $a > |b| > 0$, $d > |c| > 0$, and $bc < 0$; or
2. $b = 0$, and $|c| < d/2$; or
3. $c = 0$, and $|b| < a/2$.

Proposition 2.23. *For* $[P(X,Y),(u,v)] \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ *and* p *a prime, we have*

$$\begin{aligned} T_p([P(X,Y),(u,v)]) &= \sum_{g \in R_p} [P(X,Y),(u,v)].g \\ &= \sum_{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in R_p} [P(aX+bY, cX+dY), (au+cv, bu+dv)], \end{aligned}$$

where the sum is restricted to matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ *such that* $\gcd(au+cv, bu+dv, N) = 1$.

Proof. For the case $k = 2$ and an algorithm to compute R_p, see [16, §2.4]. The general case follows from [45, Theorem 2] applied to the set $\boldsymbol{\mathcal{S}}$ of [45, §3] by observing that when p is an odd *prime* $\boldsymbol{\mathcal{S}}'_p$ is empty. □

2.6.3 The cuspidal and boundary spaces in terms of Manin symbols

This section is a review of Merel's explicit description of the boundary map in terms of Manin symbols for $\Gamma = \Gamma_1(N)$ (see [45, §1.4]). In the next section, we describe a very efficient way to compute the boundary map.

Let $\mathcal{R}$ be the equivalence relation on $\Gamma\backslash\mathbf{Q}^2$ which identifies the element $[\Gamma\left(\begin{smallmatrix}\lambda u\\ \lambda v\end{smallmatrix}\right)]$ with $\mathrm{sign}(\lambda)^k[\Gamma\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$, for any $\lambda \in \mathbf{Q}^*$. Denote by $B_k(\Gamma)$ the finite dimensional $\mathbf{Q}$-vector space with basis the equivalence classes $(\Gamma\backslash\mathbf{Q}^2)/\mathcal{R}$. The dimension of this space is $\#(\Gamma\backslash\mathbf{P}^1(\mathbf{Q}))$.

Proposition 2.24. *The map*

$$\mu : \boldsymbol{\mathcal{B}}_k(\Gamma) \to B_k(\Gamma), \qquad P\left\{\frac{u}{v}\right\} \mapsto P(u,v)\left[\Gamma\begin{pmatrix}u\\ v\end{pmatrix}\right]$$

is well defined and injective. Here u and v are assumed coprime.

Thus the kernel of $\delta : \boldsymbol{\mathcal{S}}_k(\Gamma) \to \boldsymbol{\mathcal{B}}_k(\Gamma)$ is the same as the kernel of $\mu\circ\delta$.

Proposition 2.25. *Let $P \in V_{k-2}$ and $g = \left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z})$. We have*

$$\mu\circ\delta([P,(c,d)]) = P(1,0)[\Gamma\left(\begin{smallmatrix}a\\ c\end{smallmatrix}\right)] - P(0,1)[\Gamma\left(\begin{smallmatrix}b\\ d\end{smallmatrix}\right)].$$

2.6.4 Computing the boundary map

In this section we describe how to compute the map $\delta : \boldsymbol{\mathcal{M}}_k(N,\varepsilon) \to B_k(N,\varepsilon)$ given in the previous section. The algorithm presented here generalizes the one in [16, §2.2]. To compute the image of $[P,(c,d)]$, with $g = \left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z})$, we must compute the class of $[\left(\begin{smallmatrix}a\\ c\end{smallmatrix}\right)]$ and of $[\left(\begin{smallmatrix}b\\ d\end{smallmatrix}\right)]$. Instead of finding a canonical form for cusps, we use a quick test for equivalence modulo scalars. In the following algorithm, by the ith standard cusp we mean the ith basis vector for a basis of $B_k(N,\varepsilon)$. The basis is constructed as the algorithm is called successively. We first give the algorithm, then prove the facts used by the algorithm in testing equivalence.

Algorithm 2.26. Given a cusp $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$ this algorithm computes an integer i and a scalar α such that $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$ is equivalent to α times the ith standard cusp. First, using Proposition 2.27 and Algorithm 2.28, check whether or not $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$ is equivalent, modulo scalars, to any cusp found so far. If so, return the index of the representative and the scalar. If not, record $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ in the representative list. Then, using Proposition 2.30, check whether or not $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ is forced to equal zero by the relations. If it does not equal zero, return its position in the list and the scalar 1. If it equals zero, return the scalar 0 and the position 1; keep $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ in the list, and record that it is zero.

In the case considered in Cremona's book [16], the relations between cusps involve only the trivial character, so they do not force any cusp classes to vanish. Cremona gives the following two criteria for equivalence.

Proposition 2.27 (Cremona). *Let $\left(\begin{smallmatrix}u_i\\ v_i\end{smallmatrix}\right)$, $i = 1,2$ be written so that* $\gcd(u_i, v_i) = 1$.

1. *There exists $g \in \Gamma_0(N)$ such that $g\left(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix}\right)$ if and only if*

$$s_1 v_2 \equiv s_2 v_1 \pmod{\gcd(v_1 v_2, N)}, \text{ where } s_j \text{ satisfies } u_j s_j \equiv 1 \pmod{v_j}.$$

2. *There exists $g \in \Gamma_1(N)$ such that $g\left(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix}\right)$ if and only if*

$$v_2 \equiv v_1 \pmod{N} \text{ and } u_2 \equiv u_1 \pmod{\gcd(v_1, N)}.$$

Proof. The first is Proposition 2.2.3 of [16], and the second is Lemma 3.2 of [15]. □

Algorithm 2.28. Suppose $\left(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix}\right)$ are equivalent modulo $\Gamma_0(N)$. This algorithm computes a matrix $g \in \Gamma_0(N)$ such that $g\left(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix}\right)$. Let s_1, s_2, r_1, r_2 be solutions to $s_1 u_1 - r_1 v_1 = 1$ and $s_2 u_2 - r_2 v_2 = 1$. Find integers x_0 and y_0 such that $x_0 v_1 v_2 + y_0 N = 1$. Let $x = -x_0(s_1 v_2 - s_2 v_1)/(v_1 v_2, N)$ and $s_1' = s_1 + x v_1$. Then $g = \begin{pmatrix} u_2 & r_2 \\ v_2 & s_2 \end{pmatrix} \cdot \begin{pmatrix} u_1 & r_1 \\ v_1 & s_1' \end{pmatrix}^{-1}$ sends $\left(\begin{smallmatrix} u_1 \\ v_1 \end{smallmatrix}\right)$ to $\left(\begin{smallmatrix} u_2 \\ v_2 \end{smallmatrix}\right)$.

Proof. This follows from the proof of Proposition 2.27 in [16]. □

To see how the ε relations, for nontrivial ε, make the situation more complicated, observe that it is possible that $\varepsilon(\alpha) \neq \varepsilon(\beta)$ but

$$\varepsilon(\alpha)\left[\begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\gamma_\alpha \begin{pmatrix} u \\ v \end{pmatrix}\right] = \left[\gamma_\beta \begin{pmatrix} u \\ v \end{pmatrix}\right] = \varepsilon(\beta)\left[\begin{pmatrix} u \\ v \end{pmatrix}\right];$$

One way out of this difficulty is to construct the cusp classes for $\Gamma_1(N)$, then quotient out by the additional ε relations using Gaussian elimination. This is far too inefficient to be useful in practice because the number of $\Gamma_1(N)$ cusp classes can be unreasonably large. Instead, we give a quick test to determine whether or not a cusp vanishes modulo the ε-relations.

Lemma 2.29. *Suppose α and α' are integers such that $\gcd(\alpha, \alpha', N) = 1$. Then there exist integers β and β', congruent to α and α' modulo N, respectively, such that $\gcd(\beta, \beta') = 1$.*

Proof. By [62, 1.38] the map $\mathrm{SL}_2(\mathbf{Z}) \to \mathrm{SL}_2(\mathbf{Z}/N\mathbf{Z})$ is surjective. By the Euclidean algorithm, there exist integers x, y and z such that $x\alpha + y\alpha' + zN = 1$. Consider the matrix $\left(\begin{smallmatrix} y & -x \\ \alpha & \alpha' \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z}/N\mathbf{Z})$ and take β, β' to be the bottom row of a lift of this matrix to $\mathrm{SL}_2(\mathbf{Z})$. □

Proposition 2.30. *Let N be a positive integer and ε a Dirichlet character of modulus N. Suppose $\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$ is a cusp with u and v coprime. Then $\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$ vanishes modulo the relations*

$$\left[\gamma\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)\right] = \varepsilon(\gamma)\left[\left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)\right], \qquad \text{all } \gamma \in \Gamma_0(N)$$

if and only if there exists $\alpha \in (\mathbf{Z}/N\mathbf{Z})^*$, with $\varepsilon(\alpha) \neq 1$, such that

$$\begin{aligned} v &\equiv \alpha v \pmod{N}, \\ u &\equiv \alpha u \pmod{\gcd(v, N)}. \end{aligned}$$

Proof. First suppose such an α exists. By Lemma 2.29 there exists $\beta, \beta' \in \mathbf{Z}$ lifting α, α^{-1} such that $\gcd(\beta, \beta') = 1$. The cusp $\left(\begin{smallmatrix}\beta u\\ \beta' v\end{smallmatrix}\right)$ has coprime coordinates so, by Proposition 2.27 and our congruence conditions on α, the cusps $\left(\begin{smallmatrix}\beta u\\ \beta' v\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ are equivalent by an element of $\Gamma_1(N)$. This implies that $\left[\left(\begin{smallmatrix}\beta u\\ \beta' v\end{smallmatrix}\right)\right] = [\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$. Since $\left[\left(\begin{smallmatrix}\beta u\\ \beta' v\end{smallmatrix}\right)\right] = \varepsilon(\alpha)\,[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$, our assumption that $\varepsilon(\alpha) \neq 1$ forces $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)] = 0$.

Conversely, suppose $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)] = 0$. Because all relations are two-term relations, and the $\Gamma_1(N)$-relations identify $\Gamma_1(N)$-orbits, there must exists α and β with

$$\left[\gamma_\alpha \begin{pmatrix}u\\ v\end{pmatrix}\right] = \left[\gamma_\beta \begin{pmatrix}u\\ v\end{pmatrix}\right] \qquad \text{and } \varepsilon(\alpha) \neq \varepsilon(\beta).$$

Indeed, if this did not occur, then we could mod out by the ε relations by writing each $[\gamma_\alpha\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$ in terms of $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$, and there would be no further relations left to kill $[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$. Next observe that

$$\left[\gamma_{\beta^{-1}\alpha}\begin{pmatrix}u\\ v\end{pmatrix}\right] = \left[\gamma_{\beta^{-1}}\gamma_\alpha\begin{pmatrix}u\\ v\end{pmatrix}\right] = \varepsilon(\beta^{-1})\left[\gamma_\alpha\begin{pmatrix}u\\ v\end{pmatrix}\right] = \varepsilon(\beta^{-1})\left[\gamma_\beta\begin{pmatrix}u\\ v\end{pmatrix}\right] = \left[\begin{pmatrix}u\\ v\end{pmatrix}\right].$$

Applying Proposition 2.27 and noting that $\varepsilon(\beta^{-1}\alpha) \neq 1$ shows that $\beta^{-1}\alpha$ satisfies the properties of the "α" in the statement of the proposition we are proving. □

We enumerate the possible α appearing in Proposition 2.30 as follows. Let $g = (v, N)$ and list the $\alpha = v \cdot \frac{N}{g} \cdot a + 1$, for $a = 0, \ldots, g-1$, such that $\varepsilon(\alpha) \neq 0$.

Working in the plus one or minus one quotient. Let s be a sign, either $+1$ or -1. To compute $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)_s$ it is necessary to replace $B_k(N, \varepsilon)$ by its quotient modulo the additional relations $[\left(\begin{smallmatrix}-u\\ v\end{smallmatrix}\right)] = s\,[\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)]$ for all cusps $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$. Algorithm 2.26 can be modified to deal with this situation as follows. Given a cusp $x = \left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$, proceed as in Algorithm 2.26 and check if either $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ or $\left(\begin{smallmatrix}-u\\ v\end{smallmatrix}\right)$ is equivalent (modulo scalars) to any cusp seen so far. If not, use the following trick to determine whether the ε and s-relations kill the class of $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$: use the unmodified Algorithm 2.26 to compute the scalars α_1, α_2 and standard indices i_1, i_2 associated to $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}-u\\ v\end{smallmatrix}\right)$, respectively. The s-relation kills the class of $\left(\begin{smallmatrix}u\\ v\end{smallmatrix}\right)$ if and only if $i_1 = i_2$ but $\alpha_1 \neq s\alpha_2$.

2.7 The complex torus attached to a modular form

Fix integers $N \geq 1$, $k \geq 2$, and let ε be a mod N Dirichlet character. For the rest of this section assume that $\varepsilon^2 = 1$.

We construct a lattice in $\mathrm{Hom}(S_k(N, \varepsilon), \mathbf{C})$ that is invariant under complex conjugation and under the action of the Hecke operators. The quotient of $\mathrm{Hom}(S_k(N, \varepsilon), \mathbf{C})$ by this lattice is a complex torus $J_k(N, \varepsilon)$, which is equipped with an action of the Hecke operators and of complex conjugation.

The reader may wish to compare our construction with a closely related construction of Shimura [60]. Shimura observes that the Petersson pairing gives his torus the structure of an abelian variety over $\mathbf{C}$. Note that his torus is, a priori, different than our torus. We do not know if our torus has the structure of abelian variety over $\mathbf{C}$.

When $k = 2$, the torus $J_2(N, \varepsilon)$ is the set of complex points of an abelian variety, which is actually defined over $\mathbf{Q}$; when $k > 2$, the study of these complex tori is of interest in trying to understand the conjectures of Bloch and Kato (see [7]) on motifs attached to modular forms.

Let $\boldsymbol{\mathcal{S}} = \boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ (respectively, $S = S_k(N, \varepsilon)$) be the space of cuspidal modular symbols (respectively, cusp forms) of weight k, level N, and character ε. The Hecke algebra $\mathbf{T}$ acts in a way compatible with the integration pairing $\langle\, ,\rangle : S \times \boldsymbol{\mathcal{S}} \to \mathbf{C}$. This pairing induces a $\mathbf{T}$-module homomorphism $\Phi : \boldsymbol{\mathcal{S}} \to S^* = \mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C})$, called the *period mapping.* Because $\varepsilon^2 = 1$, the $*$-involution preserves S.

Proposition 2.31. *The period mapping Φ is injective and $\Phi(\boldsymbol{\mathcal{S}})$ is a lattice in S^*.*

Proof. By Theorem 2.7,

$$\boldsymbol{\mathcal{S}} \otimes_{\mathbf{R}} \mathbf{C} \cong \mathrm{Hom}_{\mathbf{C}}(S \oplus \overline{S}, \mathbf{C}).$$

Because $\varepsilon^2 = 1$, we have $S = S_k(N, \varepsilon; \mathbf{R}) \otimes_{\mathbf{R}} \mathbf{C}$. Set $S_{\mathbf{R}} := S_k(N, \varepsilon; \mathbf{R})$ and likewise define $\overline{S}_{\mathbf{R}}$. We have

$$\mathrm{Hom}_{\mathbf{C}}(S \oplus \overline{S}, \mathbf{C}) = \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}} \oplus \overline{S}_{\mathbf{R}}, \mathbf{R}) \otimes_{\mathbf{R}} \mathbf{C}.$$

Let $\boldsymbol{\mathcal{S}}_{\mathbf{R}} = \boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{R})$ and $\boldsymbol{\mathcal{S}}_{\mathbf{R}}^+$ be the subspace fixed under $*$. By Proposition 2.11 we have maps

$$\boldsymbol{\mathcal{S}}_{\mathbf{R}}^+ \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}} \oplus \overline{S}_{\mathbf{R}}, \mathbf{R}) \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, \mathbf{R})$$

and

$$\boldsymbol{\mathcal{S}}_{\mathbf{R}}^- \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}} \oplus \overline{S}_{\mathbf{R}}, i\mathbf{R}) \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, i\mathbf{R}).$$

The map $\boldsymbol{\mathcal{S}}_{\mathbf{R}}^+ \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, \mathbf{R})$ is an isomorphism: the point is that if $\langle \bullet, x\rangle$, for $x \in \boldsymbol{\mathcal{S}}_{\mathbf{R}}^+$, vanishes on $S_{\mathbf{R}}$ then it vanishes on the whole of $S \oplus \overline{S}$. Likewise, the map $\boldsymbol{\mathcal{S}}_{\mathbf{R}}^- \to \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, i\mathbf{R})$ is an isomorphism. Thus

$$\boldsymbol{\mathcal{S}} \otimes \mathbf{R} = \boldsymbol{\mathcal{S}}_{\mathbf{R}} \cong \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, \mathbf{R}) \oplus \mathrm{Hom}_{\mathbf{R}}(S_{\mathbf{R}}, i\mathbf{R}) \cong \mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C}).$$

Finally, we observe that $\boldsymbol{\mathcal{S}}$ is by definition torsion free, which completes the proof. □

The torus $J_k(N, \varepsilon)$ fits into an exact sequence

$$0 \longrightarrow \boldsymbol{\mathcal{S}} \xrightarrow{\ \Phi\ } \mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C}) \longrightarrow J_k(N, \varepsilon) \longrightarrow 0.$$

Let $f \in S$ be a newform and S_f the complex vector space spanned by the Galois conjugates of f. The period map Φ_f associated to f is the map $\boldsymbol{\mathcal{S}} \to \mathrm{Hom}_{\mathbf{C}}(S_f, \mathbf{C})$ obtained by composing Φ with restriction to S_f. Set

$$A_f := \mathrm{Hom}_{\mathbf{C}}(S_f, \mathbf{C})/\Phi_f(\boldsymbol{\mathcal{S}}).$$

We associate to f a subtorus of J as follows. Let $I_f = \mathrm{Ann}_{\mathbf{T}}(f)$ be the annihilator of f in the Hecke algebra, and set

$$A_f^\vee := \mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C})[I_f]/\Phi(\boldsymbol{\mathcal{S}}[I_f])$$

where $\mathrm{Hom}_{\mathbf{C}}(S,\mathbf{C})[I_f] = \cap_{t\in I_f}\ker(t)$.

The following diagram summarizes the tori just defined; its columns are exact but its rows need not be.

$$\begin{tikzcd}
0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] \\
\boldsymbol{\mathcal{S}}[I_f] \arrow[r] \arrow[d] & \boldsymbol{\mathcal{S}} \arrow[r] \arrow[d] & \Phi_f(\boldsymbol{\mathcal{S}}) \arrow[d] \\
\mathrm{Hom}_{\mathbf{C}}(S,\mathbf{C})[I_f] \arrow[r] \arrow[d] & \mathrm{Hom}_{\mathbf{C}}(S,\mathbf{C}) \arrow[r] \arrow[d] & \mathrm{Hom}_{\mathbf{C}}(S[I_f],\mathbf{C}) \arrow[d] \\
A_f^{\vee} \arrow[r] \arrow[d] & J_k(N,\varepsilon) \arrow[r] \arrow[d] & A_f \arrow[d] \\
0 & 0 & 0
\end{tikzcd} \tag{2.1}$$

2.7.1 The case when the weight is 2

When $k = 2$ and $\varepsilon = 1$ the above is just Shimura's classical association of an abelian variety to a modular form; see [62, Thm. 7.14] and [61]. In this case A_f and $A_f^{\vee}$ are abelian varieties that are defined over $\mathbf{Q}$. Furthermore A_f is an *optimal quotient* of J, in the sense that the kernel of the map $J \to A_f$ is connected. For a summary of the main results in this situation, see Section 4.6.

Chapter 3

Applications of modular symbols

In the previous chapter we introduced several spaces of modular symbols, and observations such as "Manin's trick" suggested that we could compute with them. The duality between modular symbols and modular forms hints that modular symbols might be useful in computing information about modular forms. In the present chapter, we gather together the fruits of our investigation into this connection.

Sections 3.1–3.5 of this chapter give a method to compute the irreducible components of the spaces $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ of modular symbols. In Section 3.6 we observe that computing intersections of certain abelian varieties can be reduced to linear algebra over $\mathbf{Z}$ by viewing the abelian varieties as complex tori and considering the appropriate diagrams. In Sections 3.7, we continue this trend by pointing out that many invariants of the complex torus attached to a modular form can be computed without computing any approximate period lattices. In Section 3.8, we discuss well-known methods for computing both an upper and lower bound on the order of the torsion subgroup of certain abelian varieties. Section 3.9 presents an algorithm for computing the modular degree of the complex torus associated to a newform.

In Section 3.10 we aim squarely at the problem of gathering data related to the Birch and Swinnerton-Dyer conjecture and its generalizations, where we give a formula for the rational numbers $|L(A_f,j)/\Omega_j|$ attached to a newform. In Section 3.11 we compare the ratio computed in the previous section to the one considered in the Birch and Swinnerton-Dyer conjecture; the two numbers differ by a Manin constant, which we bound. Finally, in Section 3.12 we give algorithms for approximating the period lattice and related numerical quantities associated to a newform of arbitrary weight.

3.1 Computing the space of modular symbols

Definition 3.1. Let W be a subspace of a finite-dimensional vector space V. To *compute* the quotient V/W means to give a matrix representing the projection $V \to V/W$, with respect to some basis for V and some basis B for V/W, along with a lift to V of each element of B.

In other words, to compute V/W means to create a reduction function that assigns to each element of V its canonical representative on the "free basis" B.

Let N be a positive integer, fix a mod N Dirichlet character ε, let $K := \mathbf{Q}[\varepsilon]$ be the smallest extension containing the values of ε, and let $\mathcal{O} := \mathbf{Z}[\varepsilon]$.

Algorithm 3.2. Given a positive integer N, a Dirichlet character ε, and an integer $k \geq 2$ this algorithm computes $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)$. We compute the quotient presentation given in Theorem 2.22 in three steps.

1. Let V_1 be the finite-dimensional K-vector space generated by the Manin symbols $[X^iY^{k-2-i}, (u, v)]$ for $i = 0, \dots, k-2$ and $0 \leq u, v < N$ with $\gcd(u, v, N) = 1$. Let W_1 be the subspace of V_1 generated by all differences
$$[X^iY^{k-2-i}, (\lambda u, \lambda v)] - \varepsilon(\lambda)[X^iY^{k-2-i}, (u, v)].$$
Because all relations are two-term, it is easy to compute $V_2 := V_1/W_1$. In computing this quotient, we do not have to explicitly compute the *large* matrix representing the linear map $V_1 \to V_2$, as it can be replaced by a suitable "reduction procedure" involving arithmetic in $\mathbf{Z}/N\mathbf{Z}$.

2. Let σ act on the set of Manin symbols as in Section 2.6; thus
$$[X^iY^{k-2-i}, (u, v)]\sigma = (-1)^i[Y^iX^{k-2-i}, (v, -u)].$$
Let W_2 be the subspace of V_2 generated by the sums $x + x\sigma$ for $x \in V_2$. Because all relations are two-term relations, it is easy to compute $V_3 := V_2/W_2$.

3. Let τ act on Manin symbols as in Section 2.6; thus
$$[X^iY^{k-2-i}, (u, v)]\tau = [(-Y)^i(X-Y)^{k-2-i}, (v, -u-v)].$$
Note that the symbol on the right can be written as a sum of generating Manin symbols. Let W_3 be the subspace of V_3 generated by the sums $x + x\tau + x\tau^2$ where x varies over the images of a basis of V_2 (*not* just a basis for V_3!). Using some form of Gaussian elimination, we compute V_3/W_3. Finally, $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K) \approx V_3/W_3$.

Proof. For $\lambda \in (\mathbf{Z}/N\mathbf{Z})^*$, denote by $\langle\lambda\rangle$ the right action of λ on Manin symbols; thus
$$[X^iY^{k-2-i}, (u, v)]\langle\lambda\rangle = [X^iY^{k-2-i}, (\lambda u, \lambda v)].$$
By Theorem 2.22 the space $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)$ is isomorphic to the quotient of the vector spaces V_1 of Step 1 modulo the relations $x + x\sigma = 0$, $x + x\tau + x\tau^2 = 0$, and $x\langle\lambda\rangle = \lambda x$ as x varies over all Manin symbols and λ varies over $(\mathbf{Z}/N\mathbf{Z})^*$.

As motivation, we note that a naive computation of V_1 modulo the σ, τ, and $\langle\lambda\rangle$ relations using Gaussian elimination is far too inefficient. This is why we compute the quotient in three steps. The complexity of Steps 1 and Steps 2 are negligible. The difficulty occurs in Step 3; at least the relations of this step occur in a space of dimension much smaller than that of V_1.

To see that the algorithm is correct, it is necessary only to observe that σ and τ both commute with all diamond-bracket operators $\langle\lambda\rangle$; this is an immediate consequence of the above formulas. We remark that in Step 3 it is in general *necessary* to compute the quotient by all relations $x + x\tau + x\tau^2$ with x the image of a basis vector for V_2 instead of just x in V_3 because σ and τ do not commute. □

Remark 3.3. In implementing the above algorithm, one should take special care in Steps 1 and 2 because the relations can together force certain of the Manin symbols to equal 0. For example, there might be relations of the form $x_1 + x_2 = 0$ and $x_1 - x_2 = 0$ which together force $x_1 = x_2 = 0$.

Remark 3.4. To compute the plus-one quotient $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)_+$, it is necessary to modify Step 2 of Algorithm 3.2 by including in W_2 the differences $x - xI$ where $I = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and

$$[X^i Y^{k-2-i}, (u, v)]I = (-1)^i [X^i Y^{k-2-i}, (-u, v)].$$

Likewise, to compute the minus-one quotient we include the sums $x + xI$. Note, as in the remarks in the proof of Algorithm 3.2, we can not add in the I relations in Step 1 because I and σ do not commute.

Algorithm 3.5. Given a positive integer N, a Dirichlet character ε, and an integer $k \geq 2$, this algorithm computes the $\mathcal{O}$-modules $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$ and $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$. (We assume as given algorithms for performing standard operations on $\mathcal{O}$-modules.)

1. Using Algorithm 3.2 compute the K-vector space $V := \boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)$.
2. Compute the $\mathcal{O}$-lattice L in V generated by the classes of the finitely many symbols $[X^i Y^{k-2-i}, (u, v)]$ for $i = 0, \dots, k-2$ and $0 \leq u, v < N$ with $\gcd(u, v, N) = 1$. It is only necessary to take one symbol in each ε-equivalence class, so there are $(k - 2 + 1) \cdot \#\mathbf{P}^1(\mathbf{Z}/N\mathbf{Z})$ generating symbols. This computes $\boldsymbol{\mathcal{M}}_k(N, \varepsilon)$.
3. To compute the submodule $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ of L, we use the algorithm of Section 2.6.4 to compute the boundary map $\delta : \boldsymbol{\mathcal{M}}_k(N, \varepsilon; K) \to B_k(N, \varepsilon; K)$. Then $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ is the kernel of δ restricted to the lattice L.

As a check, using the formulas of Section 3.4, we compute the dimension of the space $S_k(N, \varepsilon)$ of cusp forms and compare with the dimension of $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)$ computed in Algorithm 3.5. The latter dimension must equal twice the former one.

3.2 Computing the Hecke algebra

In this section we give an upper bound on the number of Hecke operators needed to generate the Hecke algebra as a $\mathbf{Z}$-module. The bound on Hecke operators is an application of [66], which was described to the author by Ribet and Agashe when $k = 2$ and the level is prime. There are much better bounds on the number of Hecke operators needed to generate the Hecke algebra as a *ring*, but we do not investigate them here.

Let Γ be a subgroup of $\mathrm{SL}_2(\mathbf{Z})$ that contains $\Gamma_1(N)$ for some N. Let $S_k(\Gamma; \mathbf{C})$ be the space of weight-k cuspforms for Γ, and let $\mathbf{T} \subset \mathrm{End}(S_k(\Gamma; \mathbf{C}))$ be the corresponding Hecke algebra. We now give a bound r such that the Hecke operators T_n, with $n \leq r$, generate $\mathbf{T}$ as a $\mathbf{Z}$-module.

For any ring $R \subset \mathbf{C}$, let $S_k(\Gamma; R)$ denotes the space of cuspforms for Γ with Fourier coefficients in R. Since $S_k(\Gamma; \mathbf{C}) = S_k(\Gamma; \mathbf{Z}) \otimes_{\mathbf{Z}} \mathbf{C}$, it makes sense to define

$$S_k(\Gamma; R) := S_k(\Gamma; \mathbf{Z}) \otimes_{\mathbf{Z}} R$$

for *any* ring R. The following proposition is well known.

Proposition 3.6. *For any ring R, the pairing*

$$\mathbf{T}_R \otimes_R S_k(N;R) \to R$$

that sends (T,f) to $a_1(Tf)$ is a perfect pairing, where $\mathbf{T}_R = \mathbf{T} \otimes_{\mathbf{Z}} R$. Furthermore, we have $(T_n, f) = a_n(f)$, where T_n is the nth Hecke operator.

Let

$$\mu = [\mathrm{SL}_2(\mathbf{Z}) : \Gamma],$$

and denote by $\lceil x \rceil$ the smallest integer $\geq x$.

Theorem 3.7 (Sturm). *Let λ be a prime ideal in the ring $\mathcal{O}$ of integers in some number field. If $f \in S_k(\Gamma;\mathcal{O})$ satisfies $a_n(f) \equiv 0 \pmod{\lambda}$ for $n \leq \lceil \frac{k}{12}\mu \rceil$, then $f \equiv 0 \pmod{\lambda}$.*

Proof. Theorem 1 of [66]. □

Proposition 3.8. *If $f \in S_k(\Gamma)$ satisfies $a_n(f) = 0$ for $n \leq r = \left\lceil \frac{k}{12}\mu \right\rceil$, then $f = 0$.*

Proof. We must show that the composite map $S_k(\Gamma) \hookrightarrow \mathbf{C}[[q]] \to \mathbf{C}[[q]]/(q^{r+1})$ is injective. Because $\mathbf{C}$ is a flat $\mathbf{Z}$-module and $S_k(\Gamma;\mathbf{Z}) \otimes \mathbf{C} = S_k(\Gamma)$, it suffices to show that the map $F : S_k(\Gamma;\mathbf{Z}) \to \mathbf{Z}[[q]]/(q^{r+1})$ is injective. Suppose $F(f) = 0$, and let p be a prime number. Then $a_n(f) = 0$ for $n \leq r$, hence plainly $a_n(f) \equiv 0 \pmod{p}$ for any such n. Theorem 3.7 implies that $f \equiv 0 \pmod{p}$. Duplicating this argument shows that the coefficients of f are divisible by all primes p, so they are 0. □

Theorem 3.9. *As a $\mathbf{Z}$-module, $\mathbf{T}$ is generated by $T_1, \ldots, T_r$, where $r = \lceil \frac{k}{12}\mu \rceil$.*

Proof. Let Z be the submodule of $\mathbf{T}$ generated by $T_1, T_2, \ldots, T_r$. Consider the exact sequence of additive abelian groups $0 \to Z \xrightarrow{i} \mathbf{T} \to \mathbf{T}/Z \to 0$. Let p be a prime and tensor this sequence with $\mathbf{F}_p$ to obtain the exact sequence

$$Z \otimes \mathbf{F}_p \xrightarrow{\bar{i}} \mathbf{T} \otimes \mathbf{F}_p \to (\mathbf{T}/Z) \otimes \mathbf{F}_p \to 0.$$

Put $R = \mathbf{F}_p$ in Proposition 3.6, and suppose that $f \in S_k(N, \mathbf{F}_p)$ pairs to 0 with each of $T_1, \ldots, T_r$. Then by Proposition 3.6, $a_m(f) = a_1(T_m f) = 0$ in $\mathbf{F}_p$ for each m, $1 \leq m \leq r$. Theorem 3.7 then asserts that $f = 0$. Thus the pairing, when restricted to the image of $Z \otimes \mathbf{F}_p$ in $\mathbf{T} \otimes \mathbf{F}_p$, is also perfect. Thus $\dim_{\mathbf{F}_p} \bar{i}(Z \otimes \mathbf{F}_p) = \dim_{\mathbf{F}_p} S_k(N, \mathbf{F}_p) = \dim_{\mathbf{F}_p} \mathbf{T} \otimes \mathbf{F}_p$, so $(\mathbf{T}/Z) \otimes \mathbf{F}_p = 0$; repeating this argument for all p shows that $\mathbf{T}/Z = 0$. □

3.3 Representing and enumerating Dirichlet characters

Recall that a *Dirichlet character* is a homomorphism $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$.

The following lemma is well known.

Lemma 3.10. *If p is an odd prime, then $(\mathbf{Z}/p^n\mathbf{Z})^*$ is a cyclic group. The group $(\mathbf{Z}/2^n\mathbf{Z})^*$ is generated by -1 and 5.*

We use the following representation of Dirichlet characters. Factor N as a product of prime powers: $N = \prod_{i=1}^{r} p_i^{e_i}$ with $p_i < p_{i+1}$ and each $e_i > 0$; then $(\mathbf{Z}/N\mathbf{Z})^* \cong \prod_{i=1}^{r}(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$. If p_i is odd then the lemma implies that $(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$ is cyclic. If $p_1 = 2$, then $(\mathbf{Z}/p_1^{e_1}\mathbf{Z})^*$ is a product $\langle -1\rangle \times \langle 5\rangle$ of two cyclic groups, both possibly trivial. For each i, we let $a_i \in (\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$ be the smallest generator of the ith factor $(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$. If $p_1 = 2$, let a_1 and a_2 correspond to the two factors $\langle -1\rangle$ and $\langle 5\rangle$, respectively; then a_3 corresponds to p_2, etc. Here a_i is smallest in the sense that the minimal lift $\tilde{a}_i \in \mathbf{Z}_{>0}$ is smallest. Let n be the exponent of $(\mathbf{Z}/N\mathbf{Z})^*$, and let $\zeta = e^{2\pi i/n} \in \mathbf{C}^*$. To give ε is the same as giving the images of each generator of a_i as a power of ζ. We thus represent ε as a vector of elements of $\mathbf{C}^*$ with respect to a canonically chosen, but unnatural, basis.

Alternatively, the vector representing a character ε can be equivalently viewed as a vector in $(\mathbf{Z}/n\mathbf{Z})^r$, where again n is the exponent of $(\mathbf{Z}/N\mathbf{Z})^*$. Such a vector represents a character if and only if the ith component of the vector has additive order dividing $\varphi(p_i^{e_i})$. If $p_1 = 2$, then there are $r + 1$ entries instead of r entries, and the condition is suitably modified. If a vector $v = [d_1, \ldots , d_r]$ represents a character ε, then each of the Galois conjugate characters is represented by $[md_1, \ldots , md_r]$ where m varies over elements of $(\mathbf{Z}/n\mathbf{Z})^*$.

When performing actual machine computations, we work in the smallest field that contains all of the values of ε. Thus if $d = \gcd(d_1, \ldots , d_r, n)$, then we work in the subfield $\mathbf{Q}(\zeta^d)$, which is cheaper than working in $\mathbf{Q}(\zeta)$.

It is sometimes important to work in characteristic ℓ. Then the notation is as above, except ζ is replaced by a primitive mth root of unity, where m is the prime-to-ℓ part of n. Note that the primitive nth roots of unity in characteristic ℓ need not be conjugate; for example, both 2 and 3 are square roots of -1 in $\mathbf{F}_5$, but they are not conjugate. Thus we must specify ζ as part of the notation when giving a mod ℓ Dirichlet character.

Example 3.11. Suppose $N = p$ is an odd prime. The group of mod p Dirichlet characters (in characteristic 0) is isomorphic to $\mathbf{Z}/(p - 1)\mathbf{Z}$, and two characters a and b are Galois conjugate if and only if there is an element $x \in (\mathbf{Z}/(p-1)\mathbf{Z})^*$ such that $xa = b$. A character is determined up to Galois conjugacy by its order, so the set of classes of mod p Dirichlet characters are in bijection with the set of divisors d of $p - 1 = \#(\mathbf{Z}/p\mathbf{Z})^*$.

Let p be an odd prime. The quadratic mod p character is denoted $[(p - 1)/2]$. The quadratic mod $2p$ character is denoted by $[0, 0, (p - 1)/2]$; the quadratic mod $4p$ character is denoted $[(p - 1)/2, 0, (p - 1)/2]$. If $n \geq 3$, then the exponent of $(\mathbf{Z}/2^n\mathbf{Z})^*$ is 2^{n-2}, so the nontrivial mod 2^n character that factors through $(\mathbf{Z}/4\mathbf{Z})^*$ is denoted $[2^{n-3}, 0]$.

Definition 3.12. The *conductor* of a character $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ is the smallest divisor M of N such that ε factors through the natural reduction map $(\mathbf{Z}/N\mathbf{Z})^* \to (\mathbf{Z}/M\mathbf{Z})^*$.

For simplicity, we assume that N is odd. To compute the conductor of ε, let v be the vector in $(\mathbf{Z}/n\mathbf{Z})^r$ that represents ε, as above. Since both $(\mathbf{Z}/p_i^{e_i}\mathbf{Z})^*$ and $(\mathbf{Z}/p_i^{d}\mathbf{Z})^*$ are cyclic and the reduction map is surjective, we find that p_i^d, with $d \leq e_i$, divides the conductor of ε if and only if the ith component of v has additive order dividing $\varphi(p_i^d)$. We can thus compute the power of p_i dividing the conductor of ε by computing the smallest d such that $p_i^d \equiv p_i^{d-1}$ modulo the order of the ith component of v.

3.4 The dimension of $S_k(N, \varepsilon)$

An explicit formula for the dimension of $S_k(N, \varepsilon)$ is given in [13], without proof. For the reader's convenience, we reproduce it here.

Theorem 3.13 (Cohen-Oesterlé). *Let $k \geq 2$ be an integer and $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ be a Dirichlet character such that $\varepsilon(-1) = (-1)^k$. Then*

$$\begin{aligned}\dim S_k(N, \varepsilon) = \delta + \frac{k-1}{12} \cdot N \cdot \prod_{p \mid N} \left(1 + \frac{1}{p}\right) \quad &- \quad \frac{1}{2} \cdot \prod_{p \mid N} \lambda(r_p, s_p, p) \\ + \gamma_k \sum_{\{x \in (\mathbf{Z}/N\mathbf{Z})^* \,:\, x^2+1=0\}} \varepsilon(x) \quad &+ \quad \mu_k \sum_{\{x \in (\mathbf{Z}/N\mathbf{Z})^* \,:\, x^2+x+1=0\}} \varepsilon(x).\end{aligned}$$

Let f be the conductor of ε, i.e., the smallest M such that ε factors through $(\mathbf{Z}/M\mathbf{Z})^*$. If $p \mid N$, then r_p (resp. s_p) denotes the exponent of p in the prime factorization of N (resp. f). Furthermore,

$$\lambda(r_p, s_p, p) := \begin{cases} p^{r'} + p^{r'-1} & \text{if } 2s_p \leq r_p = 2r' \\ 2p^{r'} & \text{if } 2s_p \leq r_p = 2r' + 1 \\ 2p^{r_p - s_p} & \text{if } 2s_p > r_p \end{cases}$$

$$\gamma_k := \begin{cases} 0 & \text{if } k \text{ is odd} \\ -\frac{1}{4} & \text{if } k \equiv 2 \pmod 4 \\ \frac{1}{4} & \text{if } k \equiv 0 \pmod 4 \end{cases}$$

$$\mu_k := \begin{cases} 0 & \text{if } k \equiv 1 \pmod 3 \\ -\frac{1}{3} & \text{if } k \equiv 2 \pmod 3 \\ \frac{1}{3} & \text{if } k \equiv 0 \pmod 3 \end{cases}$$

$$\delta := \begin{cases} 1 & \text{if } k = 2 \text{ and } \varepsilon \text{ is trivial} \\ 0 & \text{otherwise} \end{cases}$$

3.5 Decomposing the space of modular symbols

Consider the space $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ of cuspidal modular symbols of level N and character ε over $K = \mathbf{Q}(\varepsilon)$. In this section we describe how to decompose the new part of $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ as a direct sum of $\mathbf{T}$-modules corresponding to the Galois conjugacy classes of newforms with character ε. As an application, we can compute the q-expansions of the normalized cuspidal newforms of level N and character ε. Using the theory of Atkin-Lehner [4] as extended by Li [37], it is then possible to construct a basis for the space $S_k(N, \varepsilon; \mathbf{C})$ of cusp forms.

The algorithm is, for the most part, a straightforward generalization of the method used by Cremona [16] to enumerate the $\mathbf{Q}$-rational weight-two newforms corresponding to modular elliptic curves. Nevertheless, we present several tricks learned in the course of doing computations, which speed up the algorithm. One useful trick that Cremona also made use of is to work in the space dual to modular symbols as described in the next section.

3.5.1 Duality

Let $K = \mathbf{Q}[\varepsilon]$, and let $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp$ denote $\mathrm{Hom}_K(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K),K)$ equipped with its natural right $\mathbf{T}$-action: for $\varphi \in \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp$,

$$(\varphi T)(x) = \varphi(Tx).$$

The natural pairing

$$\langle\, ,\, \rangle : \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp \times \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K) \to K \tag{3.1}$$

given by $\langle \varphi, x\rangle = \varphi(x)$ satisfies $\langle \varphi T, x\rangle = \langle \varphi, Tx\rangle$.

Viewing the elements $T \in \mathbf{T}$ as sitting inside $\mathrm{End}(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K))$, the transpose map $T \mapsto T^t$ allows us to view $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp$ as a left $\mathbf{T}$-module.

Proposition 3.14. *Let $V \subset \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\mathrm{new}}$ be an irreducible new $\mathbf{T}$-submodule and set $I = \mathrm{Ann}_{\mathbf{T}} V$. Then the characteristic polynomial of each T_p on $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp[I]$ is the same as the characteristic polynomial of T_p on V.*

Proof. We may assume for the purposes of proving the proposition that $K = \overline{\mathbf{Q}}$. There is a basis of simultaneous $\mathbf{T}$-eigenvectors for $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\mathrm{new}}$. With respect to this basis, $\mathbf{T}$ acts via diagonal matrices. The systems of eigenvalues coming from the old subspace are distinct from the systems of eigenvalues on the new space. Thus the dimension of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp[I]$ is the same as the dimension of V, instead of being too large. The proposition now follows by noting that the characteristic polynomial of a matrix is the same as the characteristic polynomial of its transpose. □

The degeneracy maps α_t and β_t of Section 2.5 give rise to maps $\alpha_t^\perp$ and $\beta_t^\perp$ between the dual spaces and having the dual properties to those of α_t and β_t. In particular, they commute with the Hecke operators T_p for p prime to N. The new and old subspace of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^\perp$ are defined as in Definition 2.16.

Algorithm 3.15. This algorithm computes a decomposition of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\perp\,\mathrm{new}}$ into irreducible submodules V.

Using Algorithm 3.2 compute $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)$. Then compute the maps β_t using Algorithm 2.20 and intersect the transposes of their kernels in order to obtain $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)^{\perp\,\mathrm{new}}$. Compute the boundary map $\delta : \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K) \to B_k(N,\varepsilon;K)$ using Algorithm 2.26. We cut out the cuspidal submodule $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\perp\,\mathrm{new}}$ using the Hecke operators, Algorithm 3.17, and Proposition 3.14. Set $p = 2$ and perform the following steps.

1. Using Algorithm 3.17, compute a matrix A representing the Hecke operator T_p on $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\perp\,\mathrm{new}}$.

2. Compute and factor the characteristic polynomial F of A.

3. For each irreducible factor f of F compute $V_f = \ker(f(A))$. Then, compute the $+1$ and -1 eigen-subspaces V_f^+ and V_f^- for the star involution. Let W denote one of these two eigen-subspaces, and use the following criteria to determine whether or not W is irreducible:

(a) If p is greater than the Sturm bound (see Theorem 3.9) then W must be irreducible.

(b) If the characteristic polynomial of some element $T \in \mathbf{T}$ acting on W is irreducible, then W is irreducible.

4. If W is irreducible, record W and consider the next factor of the characteristic polynomial in step 3. Otherwise, replace p by the next prime larger than p and replace $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)^{\perp\,\mathrm{new}}$ by W, then repeat the above sequence of steps, beginning with step 1.

3.5.2 Efficient computation of Hecke operators on the dual space

In this section we give a method for computing the action of the Hecke operators $T_p \in \mathbf{T}$ on an invariant subspace $V \subset \boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)^{\perp}$. A naive way to compute the right action of T_p on V is to compute a matrix representing T_p on $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)$, transpose to obtain T_p on $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)^{\perp}$, and then restrict to V using Gaussian elimination. To compute T_p on $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)$, observe that $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)$ has a basis $e_1, \ldots, e_n$, where each e_i is a Manin symbol $[P, (c, d)]$, and that the action of T_p on $[P, (c, d)]$ can be computed using Section 2.6.2.

In practice, $d = \dim V$ will often be much less than n; we now describe how to compute T_p on V in d/n of the time it takes using the above naive method. This is a substantial savings when d is small. Transposing the injection $V \hookrightarrow \boldsymbol{\mathcal{S}}_k(N, \varepsilon; K)^{\perp}$, we obtain a surjection $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; K) \to V^{\perp}$. There exists a subset $e_{i_1}, \ldots, e_{i_d}$ of the e_i whose image forms a basis for $V^{\perp}$. With some care, it is then possible to compute T_p on $V^{\perp}$ by computing T_p on each of $e_{i_1}, \ldots, e_{i_d}$.

In the rest of this section, we describe in terms of matrices a definite way to carry out this computation. Let V be an $n \times m$ matrix whose rows generate an n-dimensional subspace of an m-dimensional space of row vectors. Let T be an $m \times m$-matrix and suppose that V has rank n and that VT is contained in the row space of V. Let E be an $m \times n$ matrix with the property that the $n \times n$ matrix VE is invertible, with inverse D.

Proposition 3.16. *$VT = VTEDV$.*

Proof. Observe that

$$V(EDV) = (VED)V = IV = V.$$

Thus right multiplication by EDV

$$v \mapsto vEDV$$

induces the *identity map* on the row space of V. Since VT is contained in the row space of V, we have

$$(VT)EDV = VT,$$

as claimed. □

We have not computed T, but we can compute T on each basis element $e_1, \ldots, e_d$ of the ambient space–unfortunately, d is extremely large. Our problem: quickly compute the action of T^t on the invariant subspace spanned by the rows of V. Can this be done without having to compute T on all e_i? Yes, the following algorithm shows how using a subset of only $n = \dim V$ of the e_i.

Algorithm 3.17. Let T be any linear transformation which leaves V invariant and for which we can compute $T(e_i)$ for $i = 1, \ldots, d$. This algorithm computes the matrix representing the action of T on V while computing $T(e_i)$ for only $\dim V$ of the i.

Choose any $m \times n$ matrix E whose columns are sparse linear combinations of the e_i and such that VE is invertible. For this we find a set of positions so that elements of the space spanned by the columns of V are determined by the entries in these spots. This is accomplished by row reducing, and setting E equal to the pivot columns. Using Gaussian elimination, compute the inverse D of the $n \times n$ matrix VE. The matrix representing the action of T with respect to V is then

$$V(TE)D = V(TE)(VE)^{-1}.$$

Proof. Let A be any matrix so that VA is the $n \times n$ identity matrix. By the proposition we have

$$VTA = (VTEDV)A = VTED(VA) = VTED = V(TE)D.$$

To see that VTA represents T, observe that by the proposition,

$$\begin{aligned} VTAV &= (VTEDV)AV = (VTEDVA)V \\ &= (VTED)(VA)V = (VTED)V = VT \end{aligned}$$

so that VTA gives the correct linear combination of the rows of V. □

3.5.3 Eigenvectors

Once a $\mathbf{T}$-simple subspace of $\boldsymbol{\mathcal{S}}^*$ has been identified, the following algorithm, which was suggested to the author by H. Lenstra, produces an eigenvector defined over an extension of the base field.

Algorithm 3.18. Let A be an $n \times n$ matrix over an arbitrary field K and suppose that the characteristic polynomial $f(x) = x^n + \cdots + a_1 x + a_0$ of A is irreducible. Let α be a root of $f(x)$ in an algebraic closure $\overline{K}$ of K. Factor $f(x)$ over $K(\alpha)$ as $f(x) = (x - \alpha)g(x)$. Then for any element $v \in K^n$ the vector $g(A)v$ is either 0 or it is an eigenvector of A with eigenvalue α. The vector $g(A)v$ can be computed by finding Av, $A(Av)$, $A(A(Av))$, and then using that

$$g(x) = x^{n-1} + c_{n-2}x^{n-2} + \cdots + c_1 x + c_0,$$

where the coefficients c_i are determined by the recurrence

$$c_0 = -a_0/\alpha, \qquad c_i = (c_{i-1} - a_i)/\alpha.$$

We will prove below that $g(A)v \neq 0$ for all vectors v not in a proper subspace of K^n. Thus with high probability, a "randomly chosen" v will have the property that $g(A)v \neq 0$. Alternatively, if $v_1, \ldots v_n$ form a basis for K^n, then $g(A)v_i$ must be nonzero for some i.

Proof. By the Cayley-Hamilton theorem [36, XIV.3] we have that $f(A) = 0$. Consequently, for any $v \in K^n$, we have $(A - \alpha)g(A)v = 0$ so that $Ag(A)v = \alpha v$. Since f is irreducible it is the polynomial of least degree satisfied by A and so $g(A) \neq 0$. Therefore $g(A)v \neq 0$ for all v not in the proper closed subset $\ker(g(A))$. □

3.5.4 Eigenvalues

In this section we give an algorithm for computing the q-expansion of one of the newforms corresponding to a factor of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\mathrm{new}}$. This is a generalization of the algorithm described in [16, §2.9].

Algorithm 3.19. Given a factor $V \subset \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)^{\perp\,\mathrm{new}}$ as computed by Algorithm 3.15 this algorithm computes the q-expansion of one of the corresponding Galois conjugate newforms.

1. Using Algorithm 3.17 compute the action of the $*$-involution (Section 2.4) on V. Then compute the $+1$ eigenspace $V^+ \subset V$.

2. Find an element $T \in \mathbf{T}$ such that the characteristic polynomial of the matrix A of T acting on V^+ is irreducible. Such a T must exist by the primitive element theorem [36, V.4]. (Note: It is *not* always the case that T can be taken to equal some Hecke operator T_n. The first example with $k=2$ and $\varepsilon=1$ occurs at level $N=512$.)

3. Using Algorithm 3.5.3 compute an eigenvector e for A over an extension of K.

4. Because e is an eigenvector and the pairing given in Equation 3.1 respects the Hecke action, we have that for any Hecke operator T_n and element $w \in \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)$, that

$$a_n\langle e,w\rangle = \langle eT_n,w\rangle = \langle e,T_nw\rangle.$$

Choose w so that $\langle e,w\rangle \neq 0$. Then

$$a_n = \frac{\langle e,T_nw\rangle}{\langle e,w\rangle}.$$

The a_n can now be computed by computing $\langle e,w\rangle$ once and for all, and then computing $\langle e,T_nw\rangle$ for each n. It is best to choose w in such a way that T_nw can be computed quickly.

The beauty of this algorithm is that when w is a Manin symbol $[P(X,Y),(c,d)]$ the computation of $T_pw = \sum_{x\in R_p} wx$ is very quick, requiring us to only sum over the Heilbronn matrices of determinant p once.

In practice we compute only the eigenvalues a_p using the above algorithm, then use the following recurrences to obtain the a_n:

$$\begin{aligned} a_{nm} &= a_n a_m \qquad \text{if } (n,m)=1, \text{ and}\\ a_{p^r} &= a_{p^{r-1}}a_p - \varepsilon(p)p^{k-2}a_{p^{r-2}}. \end{aligned}$$

3.5.5 Sorting and labeling eigenforms

Systematically ordering the factors is essential, so that we can later refer to them. In Section 3.5.4 we saw how to associate to each new factor a sequence a_n of Hecke eigenvalues. These can be used to sort the factors.

Except in the case of weight 2 and trivial character, we use the following ordering. To each eigenvector associate the following sequence of integers

$$\mathrm{tr}(a_1), \mathrm{tr}(a_2),\ \mathrm{tr}(a_3),\ \mathrm{tr}(a_4),\ \mathrm{tr}(a_5),\ \mathrm{tr}(a_6),\ \ldots$$

where the trace is from $K_f = \mathbf{Q}(\ldots a_n \ldots)$ down to $\mathbf{Q}$. Sort the eigenforms by ordering the sequences in dictionary order with minus coming before plus. Since we included $\mathrm{tr}(a_1)$, this ordering gathers together factors of the same dimension. Furthermore, the sequence of traces determines the Galois conjugacy class of f, because the $g = \sum_{n\geq 1} \mathrm{tr}(a_n)q^n$ is the trace of f, hence g lies in the $\mathbf{C}$-vector space spanned by the Galois conjugates of f.

When $k = 2$ and the character is trivial we use a different and somewhat complicated ordering because it extends the notation for elliptic curves that was introduced in the second edition of [16] and has since become standard. Sort the factors of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)^{\mathrm{new}}$ as follows. First by dimension, with smallest dimension first. Within each dimension, sort in binary order, by the signs of the Atkin-Lehner involutions with $-$ corresponding to 0 and $+$ to 1. For example, if there are three Atkin-Lehner involutions then the sign patterns are sorted as follows:

$$+++, -++, +-+, --+, ++-, -+-, +--, ---.$$

Finally, let p be the smallest prime not dividing N. Within each of the Atkin-Lehner classes, sort by the magnitudes of the $K_f/\mathbf{Q}$-trace of a_p breaking ties by letting the positive trace be first. If there are still any ties, repeat the final step with the next smallest prime not dividing N, etc. (Note: It's not clear to the author that ties will always eventually be broken, though in his computation they always have been.)

3.6 Intersections and congruences

Consider a complex torus $J = V/\Lambda$, and let $A = V_A/\Lambda_A$ and $B = V_B/\Lambda_B$ be subtori whose intersection $A \cap B$ is finite.

Proposition 3.20. *There is a natural isomorphism of groups*

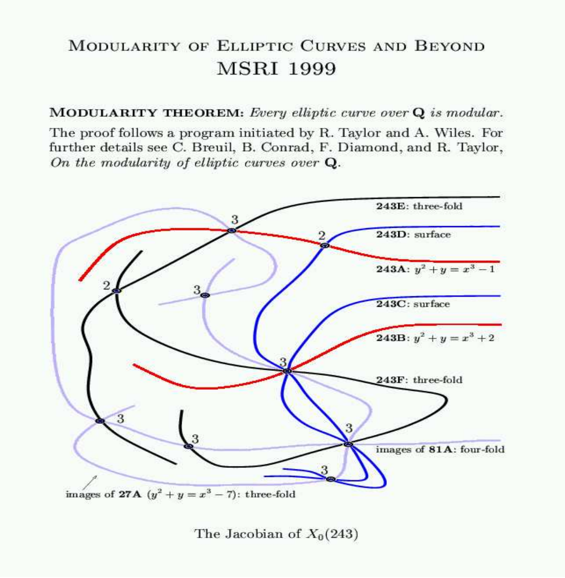
$$A \cap B \cong \left(\frac{\Lambda}{\Lambda_A + \Lambda_B}\right)_{\mathrm{tor}}.$$

Proof. There is an exact sequence

$$0 \to A \cap B \to A \oplus B \to J.$$

Consider the diagram

$$\begin{tikzcd}
 & \Lambda_A \oplus \Lambda_B \arrow[r] \arrow[d] & \Lambda \arrow[r] \arrow[d] & \Lambda/(\Lambda_A + \Lambda_B) \arrow[d] \\
 & V_A \oplus V_B \arrow[r] \arrow[d] & V \arrow[r] \arrow[d] & V/(V_A + V_B) \arrow[d] \\
A \cap B \arrow[r] & A \oplus B \arrow[r] & J \arrow[r] & J/(A+B).
\end{tikzcd}$$



MODULARITY OF ELLIPTIC CURVES AND BEYOND
MSRI 1999

MODULARITY THEOREM: *Every elliptic curve over* $\mathbf{Q}$ *is modular.*

The proof follows a program initiated by R. Taylor and A. Wiles. For further details see C. Breuil, B. Conrad, F. Diamond, and R. Taylor, *On the modularity of elliptic curves over* $\mathbf{Q}$.

Figure 3.1: T-shirt design

The snake lemma gives an exact sequence

$$0 \to A \cap B \to \Lambda/(\Lambda_A + \Lambda_B) \to V/(V_A + V_B).$$

Since $V/(V_A + V_B)$ is a $\mathbf{C}$-vector space, the torsion part of $\Lambda/(\Lambda_A + \Lambda_B)$ must map to 0. No non-torsion in $\Lambda/(\Lambda_A + \Lambda_B)$ could map to 0, because if it did then $A \cap B$ would not be finite. The lemma follows. □

The following formula for the intersection of n subtori is obtained in a similar way.

Proposition 3.21. *For $i = 1, \ldots, n$ let $A_i = V_i/\Lambda_i$ be a subtorus of $J = V/\Lambda$, and assume that each pairwise intersection $A_i \cap A_j$ is finite. Then*

$$A_1 \cap \cdots \cap A_n \cong \left(\frac{\Lambda \oplus \cdots \oplus \Lambda}{f(\Lambda_1 \oplus \cdots \oplus \Lambda_n)} \right),$$

where $f(x_1, \ldots, x_n) = (x_1 - x_2, x_2 - x_3, x_3 - x_4, \ldots, x_{n-1} - x_n)$.

Remark 3.22. Using this proposition the author constructed the T-shirt design in Figure 3.1.

Example 3.23. L. Kilford of London, England has recently discovered an example at prime level 503 in which "multiplicity one" fails. One verification of his example uses the above proposition. Let E_1, E_2, and E_3 be the three elliptic curves of conductor 503, and for each $i = 1, 2, 3$, let $\mathfrak{m}_i$ be the maximal ideal of $\mathbf{T} \subset \mathrm{End}(J_0(503))$ generated by 2 and all $T_p - a_p(E_i)$, with p prime. Each of the Galois representations $E_i[2]$ is irreducible, and one can check that $\mathfrak{m}_1 = \mathfrak{m}_2 = \mathfrak{m}_3$. If multiplicity one holds, then $E_1[2] = E_2[2] = E_3[2]$ inside of $J_0(503)$. However, this is not the case, as a modular symbols computation in the integral homology $H_1(X_0(N), \mathbf{Z})$ reveals that $E_1 \cap E_2 = \{0\}$.

3.6.1 A strategy for computing congruences

Let N be a positive integer, $k \geq 2$ an integer, and ε a mod N Dirichlet character. Suppose f and g are newforms in $S_k(N, \varepsilon; \overline{\mathbf{Q}})$. The following proposition gives rise to an algorithm for computing most congruences between infinite Fourier expansions.

The advantage of the algorithm is that it only involves finite exact computations and does not rely on the computation of q-expansions. A disadvantage is that congruences between q-expansions need not be reflected by the corresponding modular symbols, so the proposition need not give all congruences. This is illustrated in Example 3.23.

The author first learned about this strategy from the section entitled "First strategy: Computing m-congruences of period lattices" in [18].

Proposition 3.24. *Suppose f and g are newforms in $S_k(N, \varepsilon; \overline{\mathbf{Q}})$. Let I_f and I_g be the corresponding annihilators in the Hecke algebra $\mathbf{T}$. Let $\Lambda = \boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathcal{O})$, and set $\Lambda_f = \Lambda[I_f]$ and $\Lambda_g = \Lambda[I_g]$. If $p \mid \# \left(\frac{\Lambda}{\Lambda_f + \Lambda_g}\right)_{\text{tor}}$ then there is a prime $\wp$ of residue characteristic p such that $f \equiv g \pmod{\wp}$.*

Proof. Consider the exact sequence

$$0 \to \Lambda_f \oplus \Lambda_g \to \Lambda \to \Lambda/(\Lambda_f + \Lambda_g) \to 0$$

where the first map is $(a, b) \mapsto a - b$. Upon tensoring this sequence with $\mathbf{F}_p$ we obtain:

$$Z \to (\Lambda_f \otimes \mathbf{F}_p) \oplus (\Lambda_g \otimes \mathbf{F}_p) \to \Lambda \otimes \mathbf{F}_p \to (\Lambda/(\Lambda_f + \Lambda_g)) \otimes \mathbf{F}_p \to 0,$$

where $Z = \mathrm{Tor}^1(\Lambda/(\Lambda_f + \Lambda_g), \mathbf{F}_p)$. Denote by $\mathrm{im}(\Lambda_f)$ the image of $\Lambda_f \otimes \mathbf{F}_p$ in $\Lambda \otimes \mathbf{F}_p$ and likewise for Λ_g. Our assumption that p divides the torsion part of $\Lambda/(\Lambda_f + \Lambda_g)$ implies that Z is nonzero, so $\mathrm{im}(\Lambda_f)$ and $\mathrm{im}(\Lambda_g)$ have nonzero intersection inside the $\mathbf{F}_p$-vector space $\Lambda \otimes \mathbf{F}_p$. The Hecke algebra $\mathbf{T}$ acts on $\mathrm{im}(\Lambda_f)$ through its action on f, that is, through the quotient $\mathbf{T}/I_f$; similarly, $\mathbf{T}$ acts on $\mathrm{im}(\Lambda_g)$ through $\mathbf{T}/I_g$. Thus $\mathbf{T}$ acts on the nonzero $\mathbf{T} \otimes \mathbf{F}_p$-module $\mathrm{im}(\Lambda_f) \cap \mathrm{im}(\Lambda_g)$ through $\mathbf{T}/(I_f + I_g + p)$. This implies that $I_f + I_g + p$ is not the unit ideal, which is equivalent to the assertion of the proposition. □

3.7 The rational period mapping

Consider a triple (N, k, ε), and let $K = \mathbf{Q}[\varepsilon]$. Let I be an ideal in the Hecke algebra $\mathbf{T}$ associated to (N, k, ε). The rational period mapping associated to I is a map from the space $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)$ of modular symbols to a finite dimensional K-vector space. It is a computable analogue of the classical integration pairing, and is of great value in extracting the rational parts of analytic invariants; e.g., of special values of L-functions. In the next section we use it to compute the image of cuspidal points on $J(N, k, \varepsilon)$.

Definition 3.25. Let $D := \mathrm{Hom}_K(\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K), K)[I]$; the *rational period mapping* is the natural quotient map

$$\Theta_I : \boldsymbol{\mathcal{M}}_k(N, \varepsilon; K) \to \frac{\boldsymbol{\mathcal{M}}_k(N, \varepsilon; K)}{\bigcap \{\ker(\varphi) : \varphi \in D\}}.$$

If $f \in S_k(N,\varepsilon)$ is a newform, set $\Theta_f := \Theta_{I_f}$ where I_f is the annihilator of f in the Hecke algebra.

Algorithm 3.26. This algorithm computes Θ_I. Choose a basis for $W = \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)$ and use it to view W as a space of column vectors equipped with a left action of $\mathbf{T}$. View $W^* = \mathrm{Hom}_K(\boldsymbol{\mathcal{M}}_k(N,\varepsilon;K),K)$ as the space of row vectors of length equal to $\dim \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)$; thus W^* is dual to W via the natural pairing between row and column vectors. The Hecke operators act on W^* on the right. Compute a basis $\varphi_1,\ldots,\varphi_n$ for the K-vector space $W^*[I]$. Then the rational period mapping with respect to this basis is $\varphi_1 \times \cdots \times \varphi_n$; it is given by the matrix whose rows are $\varphi_1,\ldots,\varphi_n$.

Proof. The kernels of $\varphi_1 \times \cdots \times \varphi_n$ and Θ_I are the same. □

Example 3.27. Let I be the annihilator of the newform $f = q - 2q^2 + \cdots \in M_2(37,1;\mathbf{Q})$ corresponding to the elliptic curve **37k2A**. There is a basis for $W = \boldsymbol{\mathcal{M}}_2(37,1;\mathbf{Q})$ such that

$$T_2 = \begin{pmatrix} -1 & 1 & 1 & -1 & 0 \\ 1 & -1 & 1 & 0 & 0 \\ 0 & 0 & -2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 3 \end{pmatrix}$$

The characteristic polynomial of T_2 is $x^2(x+2)^2(x-3)$. Thus $W[I] = \ker(T_2+2)$ is spanned by the column vectors $(1,-1,0,1/2,0)^t$ and $(0,0,1,-1/2,0)^t$, and $W^*[I] = \ker(T_2^t+2)$ is spanned by the row vectors $(1,0,-1,0,0)$ and $(0,1,-1,0,0)$. The rational period mapping is $\Theta_I((a,b,c,d,e)^t) = (a-c, b-c)$.

Lemma 3.28.

$$\dim \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)[I] = \dim \mathrm{Hom}_K(\boldsymbol{\mathcal{M}}_k(N,\varepsilon;K),K)[I].$$

Proof. Let $W = \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)$ and W^* be its dual. Let $a_1,\ldots,a_n$ be a set of generators for I. Choose a basis for W that is compatible with the following filtration:

$$0 \subset (\ker(a_1)\cap\cdots\cap\ker(a_n)) \subset (\ker(a_1)\cap\cdots\cap\ker(a_{n-1})) \subset \cdots \subset \ker(a_1) \subset W.$$

The rank of a matrix equals the rank of its transpose, so the dimension of $\ker(a_1)$ is the same as the dimension of $\ker(a_1^t)$, that is, $\dim W[(a_1)] = \dim W^*[(a_1)]$. Since $\mathbf{T}$ is commutative, a_2 leaves $\ker(a_1)$ invariant; because of how we chose our basis for W, the transpose of $a_2|_{\ker(a_1)}$ is $a_2^t|_{\ker(a_1^t)}$. Thus again, $\dim(\ker(a_2|_{\ker(a_1)}))$ equals $\dim(\ker(a_2^t|_{\ker(a_1^t)}))$. Proceeding inductively, we prove the lemma. □

Corollary 3.29. *Suppose* $\boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)[I] \subset \boldsymbol{\mathcal{S}}_k(N,\varepsilon;K)$, *and let* $P : \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K) \to \mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon;\mathbf{C})[I],\mathbf{C})$ *be the classical period map induced by the integration pairing. Then* $\ker(P) = \ker(\Theta_I)$.

Proof. Since $P(\boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathcal{O}))$ is known to be a finite-covolume $\mathcal{O}$-lattice in the complex vector space $\mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon;\mathbf{C})[I],\mathbf{C})$, the K-dimension of $\mathrm{im}(P)$ equals $2\cdot\dim_{\mathbf{C}} S_k(N,\varepsilon;\mathbf{C})[I]$, which in turn equals $\dim_K \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)[I]$. Thus by Lemma 3.28 the images $\mathrm{im}(P)$ and $\mathrm{im}(\Theta_I)$ have the same dimension, hence $\ker(P)$ and $\ker(\Theta_I)$ also have the same dimension. It thus suffices to prove the inclusion $\ker(\Theta_I) \subset \ker(P)$. Suppose $\Theta_I(x) = 0$; then $\varphi(x) = 0$ for all $x \in W^*[I]$, where $W = \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K)$. Thus $\varphi(x) = 0$ for all $\varphi \in (W \otimes \mathbf{C})^*[I]$. Since the integration pairing that defines P respects the action of $\mathbf{T}$, the composition of P with any linear functional lies in $(W \otimes \mathbf{C})^*[I]$. Thus $P(x) = 0$, as required. □

3.8 The images of cuspidal points

Consider a triple (N,k,ε), and let $K = \mathbf{Q}[\varepsilon]$. Recall that integration defines a period mapping

$$P : \boldsymbol{\mathcal{M}}_k(N,\varepsilon;K) \to \mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon;\mathbf{C}),\mathbf{C}).$$

A *cuspidal point* of

$$J = J(N,k,\varepsilon) := \frac{\mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon;\mathbf{C}),\mathbf{C})}{P(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathcal{O}))}$$

is a point that is in the image under P of $\boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathcal{O})$. It is of great interest to compute the structure of the cuspidal subgroup of J and of the quotients of J. For example, when $k=2$ and $\varepsilon = 1$, the torus J can be identified with $J_0(N)(\mathbf{C})$. In this case, Manin proved (see [38]) that the cuspidal point $\{0,\infty\}$ is a torsion point in $J_0(N)(\mathbf{Q})$, so its order gives a lower bound on $J_0(N)(\mathbf{Q})_{\mathrm{tor}}$.

Algorithm 3.30 (Cuspidal subgroup). Let I be an ideal in the Hecke algebra $\mathbf{T}$. This algorithm computes the cuspidal subgroup of the quotient A_I of J. Using Algorithm 3.5 compute $\boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathcal{O})$ and $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathcal{O})$. Using Algorithm 3.26, compute the rational period mapping Θ_I. Then the cuspidal subgroup is the subgroup of $\Theta_I(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathcal{O}))$ generated by the elements $\Theta_I(x)$ for $x \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathcal{O})$. In particular, the point of $A_I(\mathbf{C})$ corresponding to $X^iY^{k-2-i}\{\alpha,\beta\}$ is the image of $\Theta_I(X^iY^{k-2-i}\{\alpha,\beta\})$ in the quotient of $\Theta_I(\boldsymbol{\mathcal{M}}_k(N,\varepsilon;\mathcal{O}))$ by $\Theta_I(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathcal{O}))$.

Example 3.31. This example continues Example 3.27. The basis chosen is also a basis for $\boldsymbol{\mathcal{M}}_2(37,1;\mathbf{Z})$, so by computing the boundary map, or the integer kernel of $T_2(T_2+2)$, we find that $\boldsymbol{\mathcal{S}}_2(37,1;\mathbf{Z})$ is spanned by $(1,0,0,0,0)$, $(0,1,0,0,0)$, $(0,0,1,0,0)$, and $(0,0,0,1,0)$. Thus $\Theta_I(\boldsymbol{\mathcal{S}}_2(37,1;\mathbf{Z}))$ is generated by $(1,0)$ and $(0,1)$. The modular symbols $\{0,\infty\}$ is represented by $(0,0,0,0,-1)$, so the image of the cusp $(0)-(\infty) \in J_0(37)$ is 0 in **37k2A**.

The rational period mapping associated to **37k2B** (with respect to some basis) is

$$\Theta_I((a,b,c,d,e)^t) = (a - c - 2d + \frac{2}{3}e,\ b + c + 2d - \frac{2}{3}e).$$

Thus $\Theta_I(\boldsymbol{\mathcal{S}}_2(37,1;\mathbf{Z}))$ is generated by $(1,0)$ and $(0,1)$. The image of $\{0,\infty\}$ is is $\frac{2}{3}(1,-1)$, so the image of $(0)-(\infty)$ in **37k2B** has order 3.

3.8.1 Rational torsion

Let f be a newform of weight 2, and suppose $\varepsilon = 1$. Manin proved that $(0)-(\infty)$ defines an element of $J_0(N)(\mathbf{Q})_{\mathrm{tor}}$. Thus the order of the image of $(0)-(\infty)$ provides a lower bounds on $\#A_f(\mathbf{Q})_{\mathrm{tor}}$. In general, many other points in the cuspidal subgroup can be rational. Determining which would give a better lower bound on the rational subgroup; the author has not yet carried out such computations (see, however, [65]).

3.8.2 Upper bound on torsion: Counting points mod p

Let f be a newform of weight 2, and suppose $\varepsilon = 1$. The Hecke algebra $\mathbf{T}$ acts through a quotient $\overline{\mathbf{T}}$ on the subspace of $S_2(\Gamma_0(N))$ spanned by the Galois conjugates of f. Let $\chi_p(X)$ be the characteristic polynomial of the image of T_p in $\overline{\mathbf{T}}$. Suppose $p \nmid N$ and let $N_p = \#A_f(\mathbf{F}_p)$ be the number of points on the mod p reduction of the abelian variety A_f.

Proposition 3.32. *For each prime p not dividing N,*

$$N_p = \chi_p(p+1).$$

Proof. This is probably well-known, but we give a proof (which was suggested to the author by Matt Baker). It follows from the Eichler-Shimura theorem that the following relation holds in the endomorphism ring of $A_f/\mathbf{F}_p$:

$$T_p = \mathrm{Frob} + \mathrm{Ver} = \mathrm{Frob} + p/\mathrm{Frob}\,.$$

Let $\ell \neq p$ be a prime. If the characteristic polynomial of Frob on an ℓ-adic Tate module of $A_f/\mathbf{F}_p$ is $F(t)$, and the characteristic polynomial of T_p on differentials $H^0(A_f/\mathbf{F}_p, \Omega)$ is $f(t)$, then we have $f(t) = x^{-d}F(x)$, where $t = x + (p/x)$ and $d = \dim A_f$. In other words, the relation above gives an easy conversion between f and F. Since it's a general fact that $\#A_f(\mathbf{F}_p) = F(1)$, we have $\#A_f(\mathbf{F}_p) = f(p+1)$. □

The following theorem is proved using formal groups.

Theorem 3.33. *Let A be an abelian variety over $\mathbf{Q}$, with good reduction outside N. Suppose $p \nmid N$. Then the kernel of the reduction map $A(\mathbf{Q})_{\mathrm{tor}} \to A(\mathbf{F}_p)$ is killed by p. If $p > 2$ then the kernel is trivial.*

By taking gcd's we obtain an upper bound on $\#A(\mathbf{Q})_{\mathrm{tor}}$. This upper bound is not in general sharp; in fact, it is unchanged if A is replaced by any isogenous abelian variety. For example, $X_0(11)$ and $X_1(11)$ are isogenous, but have different torsion subgroups.

3.9 The modular degree

Let f be a newform of level N, weight $k \geq 2$ and character ε such that $\varepsilon^2 = 1$. In this section we define and give an algorithm to compute the modular degree of the torus A_f attached to f.

Definition 3.34. The *modular map* is the map $\theta_f : A_f^{\vee} \to A_f$ that is induced by the bottom row of Diagram 2.1 on page 34. The *modular degree* m_f of f (or of A_f) is the degree of this map. If f has weight two, then θ_f is a polarization so by [50, Thm. 13.3] its degree is a perfect square; in this case we *instead* define the modular degree m_f to be the positive square root of the degree of θ_f.

Remark 3.35. When $E/\mathbf{Q}$ be a modular elliptic curve of conductor N that is an optimal quotient of $J_0(N)$, then m_f is the usual modular degree, which is the least degree of a map $X_0(N) \to E$.

Remark 3.36. When $k \neq 2$, the degree of θ_f need not be a perfect square. For example, there is a one-dimensional quotient A_f associated to the unique rational newform

$$f = q + 2q^2 - 8q^3 + 4q^4 + 5q^5 - 16q^6 - 4q^7 + \cdots \in S_4(10)$$

such that the kernel of θ_f is isomorphic to $\mathbf{Z}/10\mathbf{Z}$.

Next, for a newform f let θ'_f be the part of $\#\ker(\theta_f)$ that is coprime to the level. There is a newform in $f \in S_4(\Gamma_0(77))$ such that θ'_f is not a perfect square at 2. For identification purposes, we remark that the field generated by the Fourier coefficients of f has discriminant $2^3 \cdot 3^3 \cdot 2417$.

Algorithm 3.37. Let I_f be the annihilator of f in the Hecke algebra. The modular kernel $\ker(\theta_f)$ is isomorphic to the cokernel of the natural map $\boldsymbol{\mathcal{S}}[I_f] \to \Phi_f(\boldsymbol{\mathcal{S}})$ of Diagram 2.1 on page 34. This cokernel can be computed by replacing Φ_f by the rational period map Θ_{I_f}.

Proof. For concreteness, we give the proof only in the case of weight-two and trivial character. The proof in the general case is similar. Let $S = S_2(\Gamma_0(N), \mathbf{C})$ be the complex vector space of weight-two modular forms of level N, and set $H = H_1(X_0(N), Z)$. The integration pairing $S \times H \to \mathbf{C}$ induces a natural map

$$\Phi_f : H \to \mathrm{Hom}(S[I_f], \mathbf{C}).$$

Using the classical Abel-Jacobi theorem, we deduce the following commutative diagram, which has exact columns, but whose rows are not exact.

$$\begin{tikzcd}
0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] \\
H[I_f] \arrow[r] \arrow[d] & H \arrow[r] \arrow[d] & \Phi_f(H) \arrow[d] \\
\mathrm{Hom}(S, \mathbf{C})[I_f] \arrow[r] \arrow[d] & \mathrm{Hom}(S, \mathbf{C}) \arrow[r] \arrow[d] & \mathrm{Hom}(S[I_f], \mathbf{C}) \arrow[d] \\
A_f^{\vee}(\mathbf{C}) \arrow[r] \arrow[d] \arrow[rr, bend right=60] & J_0(N)(\mathbf{C}) \arrow[r] \arrow[d] & A_f(\mathbf{C}) \arrow[d] \\
0 & 0 & 0
\end{tikzcd}$$

By the snake lemma, the kernel of $A_f^{\vee}(\mathbf{C}) \to A_f(\mathbf{C})$ is isomorphic to the cokernel of the map $H[I_f] \to \Phi_f(H)$, which proves the proposition. □

Remark 3.38. Suppose E is an optimal quotient of $J_0(p)$, with p prime. The surjectivity result in [48] implies that it is possible to efficiently compute the modular degree using only the method of graphs. For more details, see Chapter 4.

3.10 The rational part of $L(A_f, j)$

Let $k \geq 2$ be an integer, and let $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ be a Dirichlet character such that $\varepsilon^2 = 1$. This assumption on ε is made only for simplicity; there is no fundamental obstruction to considering arbitrary characters. For the remainder of this section we fix a newform $f \in S_k(N, \varepsilon)$. We will compute certain rational numbers associated to f.

The author was motivated to prove the results of this section after seeing Agashe's results in the case $k = 2$ and $\varepsilon = 1$; see [2, Ch. 4].

3.10.1 L-functions

Definition 3.39. The L-series associated to f is the complex-analytic function

$$L(f, s) := \sum_{n=1}^{\infty} a_n n^{-s}.$$

Hecke proved that $L(f, s)$ has an analytic continuation to the whole complex plane. In particular, it makes sense to consider the values $L(f, j)$ where $j \in \{1, 2, \ldots, k-1\}$ is an integer in the "critical strip." The general consesus is that these special values have deep arithmetic significance, in the sense that the quotients $L(f, j)/\omega_{f,j}$ should be algebraic numbers, where $\omega_{f,j}$ is an appropriate period of f, and that these algebraic numbers should encode deep arithmetic properties of the motive attached to f.

For simplicity, especially when doing explicit computations, it is desirable to work exclusively with ratios that are rational numbers instead of algebraic numbers. For this purpose, we consider instead the complex torus A_f attached to f, and introduce

$$L(A_f, s) := \prod_{i=1}^{d} L(f_i, s),$$

where $f_1, \ldots, f_d$ are the distinct Galois-conjugates of f. As we will see, $L(A_f, j)/\Omega_j \in \mathbf{Q}$, where Ω_j will be defined below.

Though the notation $L(A_f, s)$ suggests that there might be a way to attach an L-function to a general complex torus, this is definitely *not* what we have in mind. For our present purposes, the notation $L(A_f, s)$ is nothing more than a convenient shorthand for the product of the L-functions attached to the Galois conjugates of f. However, in the case when $k = 2$ and $\varepsilon = 1$, the L-function $L(A_f, s)$ is known to be the canonical L-series associated to the abelian variety $A_f/\mathbf{Q}$; see, e.g., the discussion in [20, Sec. 7].

3.10.2 Winding elements

Generalizing Mazur and Merel's terminology when $k = 2$, we define winding elements as follows.

Definition 3.40 (Winding element). For $1 \leq i \leq k-1$, the ith *winding element* is

$$\mathbf{e}_i := X^{i-1} Y^{k-2-(i-1)} \{0, \infty\} \in \boldsymbol{\mathcal{M}}_k(N, \varepsilon; \mathbf{Z}).$$

For example, when $k = 2$ there is one winding element $\mathbf{e} = \mathbf{e}_1 = \{0, \infty\}$. See [44, §2.2] for a topologically motivated discussion of the terminology "winding element."

3.10.3 Real and minus volumes

We briefly review the association of a complex torus to a Galois-conjugacy class of newforms. Consider the space $S_k(N, \varepsilon; \mathbf{Z})$ of cusp forms in $S_k(N, \varepsilon)$ whose q-expansion at infinity has Fourier coefficients which lie in $\mathbf{Z}$. Let V be the $\mathbf{C}$-vector space spanned by the Galois conjugates $f_1, \ldots, f_d$ of f, and choose a $\mathbf{Z}$-basis $g_1, \ldots, g_d$ for the intersection $V \cap S_k(N, \varepsilon; \mathbf{Z})$. Then integration via the pairing of Theorem 2.7 against $g_1, \ldots, g_d$ defines a map $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z}) \to \mathbf{C}^d$ whose cokernel is $A_f(\mathbf{C})$. Viewing $A_f(\mathbf{C})$ in this way, the standard measure on $\mathbf{C}^d$ defines a measure on $A_f(\mathbf{C})$.

Because $\varepsilon^2 = 1$, the complex torus $A(\mathbf{C})$ is equipped with an action of complex conjugation. There are two distinguished additive subgroups of $A(\mathbf{C})$: the subgroup $A(\mathbf{R})$ of elements fixed under complex conjugation, and the subgroup $A(\mathbf{C})^-$ of elements sent to their additive inverse by complex conjugation. When j is odd, let Ω_j be the measure of the subgroup fixed under conjugation, and when j is even, let Ω_j be the measure of the subgroup sent to its inverse under conjugation, times i^d, where d is the dimension of A. When j is odd, we call Ω_j the *real volume*; otherwise, we call Ω_j the *minus volume* (see Definition 3.58).

3.10.4 The theorem

We are now prepared to state a theorem that gives a computable expression for the ratio $|L(A_f, j)/\Omega_j|$. This theorem grew out of joint work with Agashe. It generalizes Cremona's method for computation $L(E, 1)/\Omega_E$ when E is an elliptic curve (see [16, §2.8]).

As an immediate corollary of the formula, we see that $|L(A_f, j)/\Omega_j|$ is a rational number. This was already known when $f \in S_2(\Gamma_0(N))$ (see [28, §2]). The author remains ignorant as to whether or not the general corollary was known before, or even if the real numbers Ω_j, exactly as defined here, had been previously considered. However, rationality of certain related period ratios has been known for some time, due to work of Manin, Shimura, and Hatada. For a clear historical summary of these rationality results see Li's MathSciNet review of [29]. See also [42, 44].

We take the absolute value of $L(A_f, j)/\Omega_j$ for simplicity only because at present we do not wish to worry about powers of the 4th root of unity i.

Theorem 3.41. *Let $f \in S_k(N, \varepsilon)$ be a newform, where $k \geq 2$ and $\varepsilon^2 = 1$, and let $j \in \{1, 2, \ldots, k-1\}$ be an integer in the critical strip. Let $\sigma = (-1)^{j-1}$, and let Θ_f be the rational periopd mapping associated to f (see Definition 3.25). Then*

$$\left| \frac{L(A_f, j)}{\Omega_j} \right| = [\Theta_f(\boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z})^\sigma) : \Theta_f(\mathbf{T}\mathbf{e}_j)],$$

where $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z})^\sigma$ denotes the submodule of $\boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z})$ on which the $*$-involution acts as σ, and Ω_j is the real or minus volume of A_f, as in Section 3.10.3. The right hand expression in the formula is a lattice index, whose definition is given below.

Remark 3.42. In the context of the BSD conjecture, $\Omega_{A_f} = \Omega_1 \cdot c_\infty$, where c_∞ is the number of connected components of $A_f(\mathbf{R})$.

The theorem involves lattice indexes, which we define as follows.

Definition 3.43. Let V be a finite-dimensional vector space over $\mathbf{R}$. A *lattice* $L \subset V$ is a free abelian group of rank equal to the dimension of V such that $\mathbf{R}L = V$. If $L, M \subset V$ are lattices, the *lattice index* $[L : M] \in \mathbf{R}$ is the absolute value of the determinant of an automorphism of V taking L isomorphically onto M. For convenience we set $[L : M] = 0$ for any lattice L and additive abelian group M contained in V and of rank strictly smaller than $\dim V$.

The following fact allows us to compute the lattice the index without using complex numbers.

Lemma 3.44. *Suppose $\tau_i : V \to W_i$, $i = 1, 2$, are surjective linear maps such that $\ker(\tau_1) = \ker(\tau_2)$. Let L and M be lattices in V such that $\tau_i(L)$ and $\tau_i(M)$ are both lattices for $i = 1, 2$. Then*

$$[\tau_1(L) : \tau_1(M)] = [\tau_2(L) : \tau_2(M)].$$

Proof. Surjectivity and equality of kernels insures that there is a unique isomorphism $\iota : W_1 \to W_2$ such that $\iota\tau_1 = \tau_2$. Let σ be an automorphism of W_1 such that $\sigma(\tau_1(L)) = \tau_1(M)$. Then

$$\iota\sigma\iota^{-1}(\tau_2(L)) = \iota\sigma\tau_1(L) = \iota\tau_1(M) = \tau_2(M).$$

Since conjugation does not change the determinant,

$$[\tau_2(L) : \tau_2(M)] = |\det(\iota\sigma\iota^{-1})| = |\det(\sigma)| = [\tau_1(L) : \tau_1(M)].$$

□

Proof of Theorem 3.41. Let $\Phi = \Phi_f$ be the period map $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; \mathbf{Z}) \to \mathbf{C}^d$ defined by fixing a basis $f_1, f_2, \ldots, f_d$ of the conjugates of the *newform* f; thus

$$\Phi(x) = (\langle f_1, x\rangle, \langle f_2, x\rangle, \ldots \langle f_d, x\rangle) \in \mathbf{C}^d.$$

We view $\mathbf{C}^d$ as an algebra with unit element $\mathbf{1} = (1, \ldots, 1)$ equipped with an action of the Hecke operators. The operator T_p acts as $(a_p^{(1)}, \ldots, a_p^{(d)})$, where the components $a_p^{(j)}$ are the Galois conjugates of a_p. Let $\mathbf{Z}^d \subset \mathbf{R}^d \subset \mathbf{C}^d$ be the standard submodules.

For brevity, set $\boldsymbol{\mathcal{S}} = \boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z})$. Let $\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma))$ be the measure of a fundamental domain for the lattice $\Phi(\boldsymbol{\mathcal{S}}^\sigma)$; equivalently, $\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma))$ is the absolute value of the determinant of a basis for $\Phi(\boldsymbol{\mathcal{S}}^\sigma)$. Observe that $\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma)) = [\mathbf{Z}^d : \Phi(\boldsymbol{\mathcal{S}}^\sigma)]$ and $|L(A_f, j)| = [\mathbf{Z}^d : \Phi(\mathbf{e}_j)\mathbf{Z}^d]$.

Let $W \subset \mathbf{C}^d$ be the $\mathbf{Z}$-module spanned by the "columns" of a basis for $S_k(N, \varepsilon; \mathbf{Z})[I_f]$. More precisely, if $g_1, \ldots, g_d$ is a basis, then the nth column is the vector $(a_n(g_1), \ldots, a_n(g_d))$, where $a_n(g_i)$ is the coefficient of q^n in the q-expansion of g_i at infinity. Because Ω_j is computed with respect to a basis for $S_k(N, \varepsilon; \mathbf{Z})[I_f]$,

$$\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma)) = [W : \mathbf{T}\mathbf{1}] \cdot \Omega_j.$$

Observe that $S_k(N,\varepsilon;\mathbf{Z})$ is saturated, in the sense that there are no nontrivial linear relations between the g_i when reduced modulo any prime p. To see this, note that if $\sum a_i g_i \equiv 0 \pmod{p}$, then $\frac{1}{p}\sum a_i g_i \in S_k(N,\varepsilon;\mathbf{Z})$ which, if the a_i are not all 0, is contrary to our assumption that $g_1,\ldots,g_d$ are a $\mathbf{Z}$-basis. Because "row rank = column rank", the same must be true for the "columns" defined in the previous paragraph, so $[\mathbf{Z}^d : W] = 1$. It follows that $[\mathbf{Z}^d : \mathbf{T1}] = [W : \mathbf{T1}]$.

The following calculation combines together the above observations using properties of the lattice index:

$$\begin{aligned}
[\Phi(\boldsymbol{\mathcal{S}}^\sigma) : \Phi(\mathbf{Te}_j)] &= [\Phi(\boldsymbol{\mathcal{S}}^\sigma) : \mathbf{Z}^d]\cdot[\mathbf{Z}^d : \Phi(\mathbf{Te}_j)]\\
&= \frac{1}{[\mathbf{Z}^d : \Phi(\boldsymbol{\mathcal{S}}^\sigma)]}\cdot[\mathbf{Z}^d : \Phi(\mathbf{Te}_j)]\\
&= \frac{1}{\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma))}\cdot[\mathbf{Z}^d : \Phi(\mathbf{e}_j)\mathbf{Z}^d]\cdot[\Phi(\mathbf{e}_j)\mathbf{Z}^d : \Phi(\mathbf{Te}_j)]\\
&= \frac{|L(A_f,j)|}{\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma))}\cdot[\Phi(\mathbf{e}_j)\mathbf{Z}^d : \Phi(\mathbf{Te}_j)]\\
&= \frac{|L(A_f,j)|}{\mu(\Phi(\boldsymbol{\mathcal{S}}^\sigma))}\cdot[\Phi(\mathbf{e}_j)\mathbf{Z}^d : \Phi(\mathbf{e}_j)\mathbf{T1}]\\
&= \frac{|L(A_f,j)|}{|\Omega_j|\cdot[W : \mathbf{T1}]}\cdot[\mathbf{Z}^d : \mathbf{T1}]\\
&= \frac{|L(A_f,j)|}{|\Omega_j|}.
\end{aligned}$$

Theorem 3.41 now follows by using Lemma 3.44, to replace Φ by Θ_f. □

3.10.5 Bounding the denominator of the ratio

In this section we bound the denominators of the ratios appearing in the previous section. We begin with the following lemma, which follows easily from the alternative description of the boundary map given in Proposition 2.25.

Lemma 3.45. *For $j = 2,\ldots,k-2$ the winding element $\mathbf{e}_j$ lies in $\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathbf{Z})$.*

Proof. Recall that $\mathbf{e}_j = P(X,Y)\{0,\infty\}$ where $P(X,Y) = X^{j-1}Y^{k-2-(j-1)}$. Since $2 \le j \le k-2$, it follows that $P(1,0) = P(0,1) = 0$, so Propositison 2.25 implies that $\mathbf{e}_j$ maps to 0 under the boundary map. □

Proposition 3.46. *For $j = 2,\ldots,k-2$,*

$$\frac{L(A_f,j)}{\Omega_j} \in \mathbf{Z}.$$

Proof. This follows from Theorem 3.41 because $\Theta_f(\mathbf{Te}_j) \subset \Theta_f(\boldsymbol{\mathcal{S}}_k(N,\varepsilon;\mathbf{Z})^\sigma)$, so the lattice index is an integer. □

For the rest of this section, we assume for simplicity that $\varepsilon = 1$.

Lemma 3.47. *For $j = 1$ and $j = k - 1$, we have for each $p \nmid N$ that*

$$(T_p - (1 + p^{k-1}))\mathbf{e}_j \in \boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z}).$$

Proof. This is a standard calculation; see, e.g., [16, §2.8] for the case when $k = 2$. □

Proposition 3.48. *Let $j \in \{1, \ldots, k-1\}$, and let n be the order of the image in $A_f(\mathbf{C})$ of the modular symbol $\mathbf{e}_j$, so $n = 1$ if $j \notin \{1, k-1\}$. Then*

$$\frac{L(A_f, j)}{\Omega_j} \in \frac{1}{n}\mathbf{Z}.$$

Proof. Let x denote the image of $\mathbf{e}_j \in A_f(\mathbf{C})$, and set $I = \mathrm{Ann}(x) \subset \mathbf{T}$. Though we write $A_f(\mathbf{C})$ here and below, we will always work within the subgroup of $A_f(\mathbf{C})$ generated by the image of $\boldsymbol{\mathcal{M}}_k(N, \varepsilon; \mathbf{Z})$ under the period map.

First we check that the Hecke operators all act as scalars on x. Since f is a *newform*, the Hecke operators T_p, for $p \mid N$, act as 0 or $\pm p^{k/2-1}$ on f, and hence in the same way on $A_f(\mathbf{C})$ (see, e.g., the end of section 6 of [21]). If $p \nmid N$, Lemma 3.47 shows that $T_p(x) = (1+p^{k-1})x$.

Let $C = \mathbf{Z}x$ denote the cyclic subgroup of $A_f(\mathbf{C})$ generated by x, so n is the order of C. Since the Hecke operators act as scalars on C, we are pleased to find that there is an injection $\mathbf{T}/I \hookrightarrow C$ which sends T_p to $T_p(x)$.

Setting $\boldsymbol{\mathcal{S}} = \boldsymbol{\mathcal{S}}_k(N, \varepsilon; \mathbf{Z})$ and applying Theorem 3.41 we find that

$$\begin{aligned}
\pm\frac{L(A_f, j)}{\Omega_j} &= [\Theta_f(\boldsymbol{\mathcal{S}}^+) : \Theta_f(\mathbf{T}e)] \\
&= [\Theta_f(\boldsymbol{\mathcal{S}}^+) : \Theta_f(I\mathbf{e})] \cdot [\Theta_f(I\mathbf{e}) : \Theta_f(\mathbf{Te})] \\
&= [\Theta_f(\boldsymbol{\mathcal{S}}^+) : I\Theta_f(\mathbf{e})] \cdot [I\Theta_f(\mathbf{e}) : \mathbf{T}\Theta_f(\mathbf{e})] \\
&= \frac{[\Theta_f(\boldsymbol{\mathcal{S}}^+) : I\Theta_f(\mathbf{e})]}{[\mathbf{T}\Theta_f(\mathbf{e}) : I\Theta_f(\mathbf{e})]}.
\end{aligned}$$

To conclude that

$$\frac{[\Theta_f(\boldsymbol{\mathcal{S}}^+) : I\Theta_f(\mathbf{e})]}{[\mathbf{T}\Theta_f(\mathbf{e}) : I\Theta_f(\mathbf{e})]} \in \frac{1}{n}\mathbf{Z}$$

we make two observations. By the construction of $A_f(\mathbf{C})$, the ideal I consists of those elements of $\mathbf{T}$ that send $\Theta_f(\mathbf{e})$ into $\Theta_f(\boldsymbol{\mathcal{S}}^+)$, so $[\Theta_f(\boldsymbol{\mathcal{S}}^+) : I\Theta_f(\mathbf{e})] \in \mathbf{Z}$. Second, there is a surjective map

$$\mathbf{T}/I \to \frac{\mathbf{T}\Theta_f(\mathbf{e})}{I\Theta_f(\mathbf{e})}$$

sending t to $t\Theta_f(\mathbf{e})$, so $[\mathbf{T}\Theta_f(\mathbf{e}) : I\Theta_f(\mathbf{e})]$ divides $n = \#C = \#(\mathbf{T}/I)$. □

Remark 3.49 (Historical notes). In the special case when $k = 2$, the modular symbol $\mathbf{e}_1$ corresponds to $(0) - (\infty) \in J_0(N)$. In this situation, Manin proves at the bottom of page 28 of [38] that $(0) - (\infty) \in J_0(N)(\mathbf{Q})$, and asserts in the footnote to [38, Cor. 3.6] that $(0) - (\infty)$ has finite order. Based on observations such as a special case of the above proposition, he declares: "These explicit formulas have the structure predicted by the Birch-Swinnerton-Dyer conjectures."

The main result of this section was inspired by a weaker result of Agashe, which can be found in Chapter 4 of [2]. Agashe considers only the case $k = 2$ and replaces n by the order of the subgroup of $J_0(N)(\overline{\mathbf{Q}})$ generated by *all* cusps.

3.11 The Manin constant

In this section $k = 2$ and $\varepsilon = 1$; we sometimes omit k and ε from the notation. The assumption that $k = 2$ will be essential, because we do not know how to define a Manin constant in other weights, let alone bound it.

Consider the optimal quotient A of $J_0(N)$ corresponding to a *newform* f on $\Gamma_0(N)$ of weight 2. Let I_A be the kernel of the natural map from the Hecke algebra to $\mathrm{End}(A)$. The *Manin constant* c_A of A is the lattice index

$$c_A := [S_2(\Gamma_0(N); \mathbf{Z})[I_A] : H^0(\mathcal{A}, \Omega_{\mathcal{A}/\mathbf{Z}})]$$

taken inside of $S_2(\Gamma_0(N); \mathbf{Q})$. Though, a priori, c_A is a rational number, the work of [31] implies that $c_A \in \mathbf{Z}$ (see, e.g., [3]).

Generalizing a theorem of Mazur, we prove that c_A is a unit in $\mathbf{Z}[\frac{1}{2m}]$, where m is the largest square dividing N. Essentially no new ideas beyond what Mazur used are involved. We then conjecture that $c_A = 1$, and give supporting numerical evidence.

For related results involving modular "building blocks" for $J_1(N)$, we refer the reader to [26, §4].

3.11.1 The primes that might divide c_A

In the special case $\dim A = 1$, the Manin constant is the classical Manin constant of A, and in [41] Mazur proved that c_A is a unit in $\mathbf{Z}[\frac{1}{2m}]$. We generalize his proof to obtain the analogous result in dimension greater than 1.

Theorem 3.50. *Let A be the new optimal quotient of $J_0(N)$ corresponding to a newform f. Then the Manin constant c_A is a unit in $\mathbf{Z}[\frac{1}{2m}]$, where m is the largest square dividing N.*

Proof. The reader is strongly recommended to keep the proof of Proposition 3.1 in [41] at hand while reading the following argument.

Let π denote the map $J_0(N) \to A$; let $\mathcal{A}$ denote the Néron model of A over $R := \mathbf{Z}[\frac{1}{2m}]$, and $\mathcal{J}$ the Néron model of $J_0(N)$ over R. Let $\mathcal{X}$ be the minimal proper regular model for $X_0(N)$ over R. As in Mazur's proof in [41], consider the diagram

$$H^0(\mathcal{A}, \Omega_{\mathcal{A}}) \xrightarrow{\pi^*} H^0(\mathcal{J}, \Omega_{\mathcal{J}}) \cong H^0(\mathcal{X}, \Omega_{\mathcal{X}}^{\mathrm{reg}}) \xrightarrow{q\text{-exp}} R[[q]]. \tag{3.2}$$

(Note that "$\Omega_{\mathcal{X}}^{\mathrm{reg}}$" is not defined to be the usual sheaf of differentials; see, e.g., the discussion in [40, pg. 67].) The map π^* must be an inclusion, by [41, Cor. 1.1]. To show that the Manin constant is a unit in R, it suffices to check that the image of $H^0(\mathcal{A}, \Omega_{\mathcal{A}})$ in $R[[q]]$ is *saturated*, in the sense that the cokernel is torsion free; indeed, the image of $S_2(\Gamma_0(N); R)[I]$ is saturated and $S_2(\Gamma_0(N); R)[I] \otimes \mathbf{Q} = q\text{-exp}(\pi^*(H^0(\mathcal{A}, \Omega_{\mathcal{A}}))) \otimes \mathbf{Q}$.

For the image of $H^0(\mathcal{A},\Omega_{\mathcal{A}})$ in $R[[q]]$ to be saturated means that the quotient D is torsion free. Let ℓ be a prime not dividing $2m$; tensoring

$$0 \to H^0(\mathcal{A},\Omega_{\mathcal{A}}) \xrightarrow{q\text{-exp}} R[[q]] \to D \to 0$$

with $\mathbf{F}_\ell$ we obtain

$$0 \to D[\ell] \to H^0(\mathcal{A},\Omega_{\mathcal{A}}) \otimes \mathbf{F}_\ell \to \mathbf{F}_\ell[[q]] \to D \otimes \mathbf{F}_\ell \to 0.$$

Here we have used that $\mathrm{Tor}^1(D,\mathbf{F}_\ell)$ is the ℓ-torsion in D, and that $\mathrm{Tor}^1(-,\mathbf{F}_\ell)$ vanishes on the torsion-free group $R[[q]]$. (Alternatively, we could have used the snake lemma.) To show that $D[\ell]=0$, it suffices to prove that the map $\Psi : H^0(\mathcal{A},\Omega_{\mathcal{A}}) \otimes \mathbf{F}_\ell \to \mathbf{F}_\ell[[q]]$ is injective.

Since $\ell \neq 2$ and A is an optimal quotient, [41, Cor 1.1] gives an exact sequence

$$0 \to H^0(\mathcal{A}/\mathbf{Z}_\ell,\Omega_{\mathcal{A}/\mathbf{Z}_\ell}) \to H^0(\mathcal{J}/\mathbf{Z}_\ell,\Omega_{\mathcal{J}/\mathbf{Z}_\ell}) \to H^0(\mathcal{B}/\mathbf{Z}_\ell,\Omega_{\mathcal{B}/\mathbf{Z}_\ell}) \to 0$$

where $\mathcal{B}$ is the Néron model of $\ker(J \to A)$. In particular, $H^0(\mathcal{B}/\mathbf{Z}_\ell,\Omega_{\mathcal{B}/\mathbf{Z}_\ell})$ is torsion free, so

$$\begin{aligned} H^0(\mathcal{A}/\mathbf{Z}_\ell,\Omega_{\mathcal{A}/\mathbf{Z}_\ell}) \otimes \mathbf{F}_\ell \to H^0(\mathcal{J}/\mathbf{Z}_\ell,\Omega_{\mathcal{J}/\mathbf{Z}_\ell}) \otimes \mathbf{F}_\ell &\cong H^0(\mathcal{X}/\mathbf{Z}_\ell,\Omega^{\mathrm{reg}}_{\mathcal{X}/\mathbf{Z}_\ell}) \otimes \mathbf{F}_\ell \\ &\cong H^0(\mathcal{X}/\mathbf{F}_\ell,\Omega^{\mathrm{reg}}_{\mathcal{X}/\mathbf{F}_\ell}) \end{aligned}$$

is injective. (The last isomorphism is by [40, Prop. 3.3, pg. 68].) We also remark that

$$H^0(\mathcal{A},\Omega_{\mathcal{A}}) \otimes \mathbf{F}_\ell \cong H^0(\mathcal{A}/\mathbf{Z}_\ell,\Omega_{\mathcal{A}/\mathbf{Z}_\ell}) \otimes \mathbf{F}_\ell,$$

because $\mathbf{Z}_\ell$ is torsion free, hence flat over R. Thus the map

$$H^0(\mathcal{A},\Omega_{\mathcal{A}}) \otimes \mathbf{F}_\ell \to H^0(\mathcal{X}/\mathbf{F}_\ell,\Omega^{\mathrm{reg}}_{\mathcal{X}/\mathbf{F}_\ell})$$

is injective.

If $\ell \nmid N$, then injectivity of Ψ now follows from the q-expansion principle, which asserts that the q-expansion map $H^0(\mathcal{X}/\mathbf{F}_\ell,\Omega^{\mathrm{reg}}_{\mathcal{X}/\mathbf{F}_\ell}) \to \mathbf{F}_\ell[[q]]$ is injective.

Suppose ℓ does divide N, and let $\omega \in \ker(\Psi)$. Since $\ell \mid N$ and $\ell \nmid 2m$, we have that $\ell \mid\mid N$; thus $\mathcal{X}/\mathbf{F}_\ell$ breaks up into a union of two irreducible components, and the q-expansion principle implies only that ω vanishes on the irreducible component containing the cusp ∞. However, since A is *new* and corresponds to a *single* eigenform, ω is an eigenvector for the involution W_N (since f and all of its conjugates are). Since W_N permutes the two components, ω must be 0 on all $\mathcal{X}/\mathbf{F}_\ell$. Therefore $\omega = 0$, and hence Ψ is injective. □

3.11.2 Numerical evidence for the $c_A = 1$ conjecture

In the paper [24], the authors show that $c_A = 1$ for 28 two-dimensional optimal quotients of $J_0(N)$ (see Section 3.12.8). The non-square-free levels treated are:

$$N = 3^2\cdot 7,\quad 3^2\cdot 13,\quad 5^3,\quad 3^3\cdot 5,\quad 3\cdot 7^2,\quad 5^2\cdot 7,\quad 2^2\cdot 47,\quad 3^3\cdot 7.$$

In every case, $c_A = 1$.

Conjecture 3.51 (Agashe). *Let A be an optimal quotient of $J_0(N)$, and let c_A be the corresponding Manin constant. Then $c_A = 1$.*

3.12 Analytic invariants

Fix a newform

$$f = \sum_{n\geq 1} a_n q^n \in S_k(N,\varepsilon),$$

and assume that $\varepsilon^2 = 1$.

Remark 3.52. Our assumption that $\varepsilon^2 = 1$ does not imply that f has totally real Fourier coefficients. There is an eigenform in $S_2(24,\varepsilon)$ whose Fourier coefficients are not totally real, where ε is one of the characters of conductor 8.

Let $K_f = \mathbf{Q}(\ldots a_n \ldots)$ and let $f_1, \ldots, f_d$ be the Galois conjugates of f, where $d = [K_f : \mathbf{Q}]$. As in Section 2.7, we consider the complex torus A_f attached to f. In this section we describe how to compute the torus A_f and the special values at the critical integers $1, 2, \ldots, k-1$ of the L function $L(A_f, s)$ associated to A_f. (See 3.39 for the definition of $L(A_f, s)$.)

Let

$$f = \sum_{n\geq 1} a_n q^n \in M_k(N,\varepsilon)$$

be a modular form (we do not assume that f is an eigenform). We recall the integration pairing of Theorem 2.7:

$$\langle\, , \rangle : M_k(N,\varepsilon) \times \boldsymbol{\mathcal{M}}_k(N,\varepsilon) \longrightarrow \mathbf{C}$$

$$\langle f, P\{\alpha,\beta\}\rangle = 2\pi i \int_{\alpha}^{\beta} f(z)P(z,1)dz.$$

Let $I_f \subset \mathbf{T}$ be the kernel of the map $\mathbf{T} \to K_f$ sending T_n to a_n. The integration pairing gives rise to the period mapping

$$\Phi_f : \boldsymbol{\mathcal{M}}_k(N,\varepsilon) \to \mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon)[I_f], \mathbf{C}),$$

and $A_f = \mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon)[I_f], \mathbf{C})/\Phi_f(\boldsymbol{\mathcal{S}}_k(N,\varepsilon))$ is the cokernel.

3.12.1 Extended modular symbols

For the purposes of computing periods, it is advantageous to extend the notion of modular symbols to allows symbols of the form $P\{z,w\}$ where z and w are now arbitrary elements of $\mathfrak{h}^* = \mathfrak{h} \cup \mathbf{P}^1(\mathbf{Q})$. The free abelian group $\overline{\boldsymbol{\mathcal{M}}}_k$ of *extended modular symbols* is spanned by such symbols, and is of uncountable rank over $\mathbf{Z}$. However, it is still equipped with an action of $\Gamma_0(N)$ and we can form the largest torsion-free quotient $\overline{\boldsymbol{\mathcal{M}}}_k(N,\varepsilon)$ of $\overline{\boldsymbol{\mathcal{M}}}_k$ by the relations $\gamma x = \varepsilon(\gamma)x$ for $\gamma \in \Gamma_0(N)$.

The integration pairing extends to $\overline{\boldsymbol{\mathcal{M}}}_k(N,\varepsilon)$. There is a natural embedding $\iota : \boldsymbol{\mathcal{M}}_k(N,\varepsilon) \hookrightarrow \overline{\boldsymbol{\mathcal{M}}}_k(N,\varepsilon)$ which respects the pairing in the sense that $\langle f, \iota(x)\rangle = \langle f, x\rangle$. In many cases it is advantageous to replace $x \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ first by $\iota(x)$, and then by an equivalent sum $\sum y_i$ of symbols $y_i \in \overline{\boldsymbol{\mathcal{M}}}_k(N,\varepsilon)$. The period $\langle f, x\rangle$ is then replaced by the equivalent sum of periods $\sum\langle f, y_i\rangle$. The latter is frequently *much* easier to approximate numerically.

3.12.2 Numerically computing period integrals

Consider a point α in the upper half plane and any one of the (extended) modular symbols $X^mY^{k-2-m}\{\alpha,\infty\}$. Given a cusp form $g=\sum_{n\geq 1} b_nq^n \in S_k(N,\varepsilon)$ and an integer $m\in\{0,1,\ldots,k-2\}$, we find that

$$\langle g,\, X^mY^{k-2-m}\{\alpha,\infty\}\rangle = 2\pi i\int_{\alpha}^{i\infty} g(z)z^m dz = 2\pi i\sum_{n=1}^{\infty} b_n\int_{\alpha}^{i\infty} e^{2\pi i n z}z^m dz. \tag{3.3}$$

The reversal of summation and integration is justified because the imaginary part of α is positive so that the sum converges absolutely. This is made explicit in the following lemma, which can be proved using repeated integration by parts.

Lemma 3.53.

$$\int_{\alpha}^{i\infty} e^{2\pi i n z}z^m dz \;=\; e^{2\pi i n\alpha}\sum_{s=0}^{m}\left(\frac{(-1)^s\alpha^{m-s}}{(2\pi i n)^{s+1}}\prod_{j=(m+1)-s}^{m} j\right). \tag{3.4}$$

The following proposition is the higher weight analogue of [16, Prop. 2.1.1(5)].

Proposition 3.54. *For any $\gamma\in\Gamma_0(N)$, $P\in V_{k-2}$ and $\alpha\in\mathfrak{h}^*$ the following holds:*

$$\begin{aligned} P\{\infty,\gamma(\infty)\} &= P\{\alpha,\gamma(\alpha)\} + (P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\} && (3.5)\\ &= \varepsilon(\gamma)(\gamma^{-1}P)\{\alpha,\infty\} - P\{\gamma(\alpha),\infty\}. && (3.6)\end{aligned}$$

Proof. By definition, if $x\in\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ is a modular symbol and $\gamma\in\Gamma_0(N)$ then $\gamma x=\varepsilon(\gamma)x$; in particular, $\varepsilon(\gamma)\gamma^{-1}x = x$, so

$$\begin{aligned} P\{\infty,\gamma(\infty)\} &= P\{\infty,\alpha\}+P\{\alpha,\gamma(\alpha)\}+P\{\gamma(\alpha),\gamma(\infty)\}\\ &= P\{\infty,\alpha\}+P\{\alpha,\gamma(\alpha)\}+\varepsilon(\gamma)\gamma^{-1}(P\{\gamma(\alpha),\gamma(\infty)\})\\ &= P\{\infty,\alpha\}+P\{\alpha,\gamma(\alpha)\}+\varepsilon(\gamma)(\gamma^{-1}P)\{\alpha,\infty\}\\ &= P\{\alpha,\gamma(\alpha)\}+P\{\infty,\alpha\}-\varepsilon(\gamma)(\gamma^{-1}P)\{\infty,\alpha\}\\ &= P\{\alpha,\gamma(\alpha)\}+(P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\}.\end{aligned}$$

The second equality in the statement of the proposition now follows easily. □

In the classical case of weight two and trivial character, the error term $(P-\varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\}$ vanishes. In general this term does not vanish, instead perturbing the analogues of the formulas found in [16, 2.10].

Algorithm 3.55. Given a triple $\gamma\in\Gamma_0(N)$, $P\in V_{k-2}$ and $g\in S_k(N,\varepsilon)$ (as a q-expansion to some precision) this algorithm computes the period integral $\langle g,\, P\{\infty,\gamma(\infty)\}\rangle$. Express γ as $\left(\begin{smallmatrix} a & b\\ cN & d\end{smallmatrix}\right)\in\Gamma_0(N)$ and take $\alpha=\frac{-d+i}{cN}$ in Proposition 3.54. Replacing γ by $-\gamma$ if necessary, we find that the imaginary parts of α and $\gamma(\alpha)=\frac{a+i}{cN}$ are both equal to $1/(cN)$ which is positive. Equation 3.3 and Lemma 3.53 can now be used to compute the period integrals of Proposition 3.54.

With the goal of computing period lattices in mind, it is reassuring to know that every element of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$ can be written as a linear combination of symbols of the form $P\{\infty,\gamma(\infty)\}$. The author asked Helena Verrill if this is the case and she was eventually able to prove that it is; the proof is given below. In the special case of weight two and trivial character, this is the assertion, which was proved by Manin [38], that the group homomorphism $\Gamma_0(N) \to H_1(X_0(N),\mathbf{Z})$ sending γ to $\{0,\gamma(0)\}$ is surjective. When the weight is greater than two, we have not found any similar group-theoretic statement.

Proposition 3.56. *Any element of $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$ can be written in the form*

$$\sum_{i=1}^{n} P_i\{\infty,\gamma_i(\infty)\}$$

with $P_i \in V_{k-2}$ and $\gamma_i \in \Gamma_0(N)$. Moreover, P_i and γ_i can be chosen so that $\sum \varepsilon(\gamma_i)P_i = \sum \gamma_i^{-1}P_i$.

Proof.[1] First recall the definition of the spaces $\boldsymbol{\mathcal{M}}$, $\boldsymbol{\mathcal{M}}_k = V_{k-2}\otimes\boldsymbol{\mathcal{M}}$ and $\boldsymbol{\mathcal{M}}_k(N,\varepsilon) = \boldsymbol{\mathcal{M}}_k/I$ (see Section 2.1). Let $I = I_{N,\varepsilon}$ be the ideal in the group ring of $\Gamma_0(N)$ generated by all elements of the form $\varepsilon(\gamma)-\gamma$ for $\gamma\in\Gamma_0(N)$.

Suppose $v \in \boldsymbol{\mathcal{S}}_k(N,\varepsilon)$. Use the relation $\{\alpha,\beta\} = \{\infty,\beta\} - \{\infty,\alpha\} \in \boldsymbol{\mathcal{M}}$ to see that any v is the image of an element $\tilde{v} \in \boldsymbol{\mathcal{M}}_k$ of the form

$$\tilde{v} = \sum_{\beta\in\mathbf{Q}} P_\beta \otimes \{\infty,\beta\} \in \boldsymbol{\mathcal{M}}_k$$

with only finitely many P_β nonzero. The boundary map δ lifts in a natural way to $V_{k-2}\otimes\boldsymbol{\mathcal{M}}$, as illustrated.

$$\begin{tikzcd}
 & I(V_{k-2}\otimes\boldsymbol{\mathcal{M}}) \arrow[r] \arrow[d] & I(V_{k-2}\otimes\boldsymbol{\mathcal{B}}) \arrow[d] \\
 & V_{k-2}\otimes\boldsymbol{\mathcal{M}} \arrow[r, "\tilde{\delta}"] \arrow[d] & V_{k-2}\otimes\boldsymbol{\mathcal{B}} \arrow[d] \\
\boldsymbol{\mathcal{S}}_k(N,\varepsilon) \arrow[r, hook] & \boldsymbol{\mathcal{M}}_k(N,\varepsilon) \arrow[r, "\delta"] & \boldsymbol{\mathcal{B}}_k(N,\varepsilon)
\end{tikzcd}$$

Our assumption that $\delta(v)=0$ implies that $\tilde{\delta}(\tilde{v}) \in I(V_{k-2}\otimes\boldsymbol{\mathcal{B}})$. So there are $Q_{\gamma,\beta}\in V_{k-2}$, for $\gamma\in\Gamma_0(N)$ and $\beta\in\mathbf{P}^1(\mathbf{Q})$, only finitely many nonzero, such that

$$\tilde{\delta}(\tilde{v}) = \sum_{\gamma,\beta}(\varepsilon(\gamma)-\gamma)(Q_{\gamma,\beta}\otimes\{\beta\}).$$

[1] The author thanks Helena Verrill for permission to reproduce her proof here.

We now use a summation trick.

$$\begin{aligned}\sum_{\beta\in\mathbf{Q}}\tilde{\delta}(\tilde{v}) = P_\beta\otimes\{\beta\} - P_\beta\otimes\{\infty\} &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\otimes\{\beta\} - (\gamma Q_{\gamma,\beta})\otimes\{\gamma\beta\}\\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\otimes\{\beta\} - (\gamma Q_{\gamma,\gamma^{-1}\beta})\otimes\{\beta\}\\ &= \sum_{\gamma,\beta}\Big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\Big)\otimes\{\beta\}.\end{aligned}$$

Equating terms we deduce that for $\beta\neq\infty$,

$$P_\beta = \sum_{\gamma}\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}.$$

Using this expression for P_β and that $\varepsilon(\gamma)\gamma^{-1}$ acts trivially on $\boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ we find that

$$\begin{aligned}v = \sum_{\beta}P_\beta\{\infty,\beta\} &= \sum_{\gamma,\beta}\Big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\Big)\{\infty,\beta\}\\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta} - \varepsilon(\gamma)\gamma^{-1}\Big(\gamma Q_{\gamma,\gamma^{-1}\beta}\Big)\{\infty,\beta\}\\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty,\beta\} - \varepsilon(\gamma)Q_{\gamma,\gamma^{-1}\beta}\{\gamma^{-1}\infty,\gamma^{-1}\beta\}\\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty,\beta\} - \varepsilon(\gamma)Q_{\gamma,\beta}\{\gamma^{-1}\infty,\beta\}\\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty,\gamma^{-1}\infty\}.\end{aligned}$$

This is of the desired form. □

Unlike the case of weight two and trivial character, Proposition 3.56 does not give generators for $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$. This is because not every element of the form $P\{\infty,\gamma(\infty)\}$ must lie in $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$. However, if $\gamma P = P$ then $P\{\infty,\gamma(\infty)\}$ does lie in $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$. It would be interesting to know under what circumstances $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$ is generated by symbols of the form $P\{\infty,\gamma(\infty)\}$ with $\gamma P = P$. This sometimes fails for k odd; for example, when $k=3$ the condition $\gamma P = P$ implies that $\gamma\in\Gamma_0(N)$ has an eigenvector with eigenvalue 1, hence is of finite order. When k is even the author can see no obstruction to generating $\boldsymbol{\mathcal{S}}_k(N,\varepsilon)$ using such symbols.

3.12.3 The W_N-trick

In this section we assume that k is even. Consider the involution W_N defined in Section 2.4.3. This is an involution that acts on both modular symbols and modular forms. The follow proposition shows how to compute $\langle g, P\{\infty,\gamma(\infty)\}\rangle$ under certain restrictive assumptions. It generalizes the main result of [17] to higher weight. (Compare also [25].)

Proposition 3.57. *Let $g \in S_k(N, \varepsilon)$ be a cusp form which is an eigenform for the Atkin-Lehner involution W having eigenvalue $w \in \{\pm 1\}$. Then for any $\gamma \in \Gamma_0(N)$ and any $P \in V_{k-2}$, with the property that $\gamma P = \varepsilon(\gamma) P$, we have for any $\alpha \in \mathfrak{h}$ the following formula:*

$$\langle g, P\{\infty, \gamma(\infty)\}\rangle =$$

$$\langle g, w\frac{P(Y,-NX)}{N^{k/2-1}}\{W(\alpha),\infty\} + (P - w\frac{P(Y,-NX)}{N^{k/2-1}})\{i/\sqrt{N},\infty\} - P\{\gamma(\alpha),\infty\}\rangle.$$

Here $W(\alpha) = -1/(N\alpha)$.

Proof. By Proposition 3.54 our condition on P implies that $P\{\infty, \gamma(\infty)\} = P\{\alpha, \gamma(\alpha)\}$. The steps of the following computation are described below.

$$\begin{aligned}
&\langle g, P\{\alpha, \gamma(\alpha)\}\rangle \\
&\quad= \langle g, P\{\alpha, i/\sqrt{N}\} + P\{i/\sqrt{N}, W(\alpha)\} + P\{W(\alpha), \gamma(\alpha)\}\rangle \\
&\quad= \langle g, w\frac{W(P)}{N^{k/2-1}}\{W(\alpha), i/\sqrt{N}\} + P\{i/\sqrt{N}, W(\alpha)\} + P\{W(\alpha), \gamma(\alpha)\}\rangle \\
&\quad= \langle g, (w\frac{W(P)}{N^{k/2-1}} - P)\{W(\alpha), i/\sqrt{N}\} + P\{W(\alpha), \infty\} - P\{\gamma(\alpha), \infty\}\rangle \\
&\quad= \langle g, w\frac{W(P)}{N^{k/2-1}}\{W(\alpha), \infty\} + (P - w\frac{W(P)}{N^{k/2-1}})\{i/\sqrt{N}, \infty\} - P\{\gamma(\alpha), \infty\}\rangle.
\end{aligned}$$

For the first step, we break the path into three paths. In the second step, we apply the W-involution to the first term, and use that the action of W is compatible with the pairing $\langle\, , \rangle$. The third step involves combining the first two terms and breaking up the third. In the final step, we replace $\{W(\alpha), i/\sqrt{N}\}$ by $\{W(\alpha), \infty\} + \{\infty, i/\sqrt{N}\}$ and regroup. □

A good choice for α is $\alpha = \gamma^{-1}\left(\frac{b}{d} + \frac{i}{d\sqrt{N}}\right)$, so that $W(\alpha) = \frac{c}{d} + \frac{i}{d\sqrt{N}}$. This maximizes the minimum of the imaginary parts of α and $W(\alpha)$.

Let $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$. A polynomial P for which $\gamma(P) = P$ is given by

$$P(X, Y) = (cX^2 + (d-a)XY - bY^2)^{\frac{k-2}{2}}.$$

This formula was obtained by viewing V_{k-2} as the $(k-2)$th symmetric product of the two-dimensional space on which $\Gamma_0(N)$ acts naturally. For example, observe that since $\det(\gamma) = 1$ the symmetric product of two eigenvectors for γ is an eigenvector in V_2 having eigenvalue 1. For the same reason, if $\varepsilon(\gamma) \neq 1$, there is often no polynomial $P(X, Y)$ such that $\gamma(P) = \varepsilon(\gamma)P$. When this is the case, first choose γ so that $\varepsilon(\gamma) = 1$.

Since the imaginary parts of the terms $i/\sqrt{N}$, α and $W(\alpha)$ in the proposition are all relatively large, the sums appearing in Equation 3.3 converge quickly if d is small. Let us emphasize, that *it is* **extremely** *important to choose γ in Proposition 3.57 with d small, otherwise the series will converge* very *slowly.*

3.12.4 Computing the period mapping

Let $I \subset \mathbf{T}$ be the kernel of the map $\mathbf{T} \to K_f$ sending T_n to a_n. As in Section 3.7, let $\Theta_f = \Theta_I$ be the rational period mapping associated to f. We have a commutative diagram

$$\begin{tikzcd}
\boldsymbol{\mathcal{M}}_k(N,\varepsilon) \arrow[rr, "\Phi_f"] \arrow[dr, "\Theta_f"'] & & \mathrm{Hom}_{\mathbf{C}}(S_k(N,\varepsilon)[I],\mathbf{C}) \\
& \dfrac{\boldsymbol{\mathcal{M}}_k(N,\varepsilon)}{\ker(\Phi_f)} \arrow[ur, "i_f"] &
\end{tikzcd}$$

Using Algorithm 3.26, we can compute Θ_f so to compute Φ_f we need to compute i_f. Let $g_1, \ldots, g_d$ be a basis for the $\mathbf{Q}$-vector space $S_k(N,\varepsilon;\mathbf{Q})[I]$. We will compute the period mapping with respect to the basis of $\mathrm{Hom}_{\mathbf{Q}}(S_k(N,\varepsilon;\mathbf{Q})[I],\mathbf{C})$ dual to this basis. Choose elements $x_1, \ldots, x_d \in \boldsymbol{\mathcal{M}}_k(N,\varepsilon)$ with the following properties:

1. Using Proposition 3.54 or Proposition 3.57 it is possible to compute the period integrals $\langle g_i, x_j\rangle$, $i, j \in \{1, \ldots d\}$ efficiently.
2. The $2d$ elements $v + *v$ and $v - *v$ for $v = \Theta_f(x_1), \ldots, \Theta_f(x_d)$ span a space of dimension $2d$.

Given this data, we can compute

$$i_f(v + *v) = 2\mathrm{Re}(\langle g_1, x_i\rangle, \ldots, \langle g_d, x_i\rangle)$$

and

$$i_f(v - *v) = 2i\mathrm{Im}(\langle g_1, x_i\rangle, \ldots, \langle g_d, x_i\rangle).$$

We break the integrals into real and imaginary parts because this increases the precision of our answers. Since the vectors $v_n + *v_n$ and $v_n - *v_n$, $n = 1, \ldots, d$ span $\frac{\boldsymbol{\mathcal{M}}_k(N,\varepsilon)}{\ker(\Phi_f)}$ we have computed i_f.

It is advantageous when possible to find symbols x_i satisfying the conditions of Proposition 3.57. This is usually possible when d is very small, but in practice we have had problems doing this when d is large, for example with **131k2B**, in which case the dimension is 10.

3.12.5 Computing special values

For $s = 1, \ldots, k-1$ we have

$$L(f,s) = \frac{-2\pi^{s-1}i^{s-1}}{(s-1)!} \cdot \langle f, X^{s-1}Y^{k-1-s}\{0,\infty\}\rangle, \tag{3.7}$$

$$L(A_I, s) = \prod_{i=1}^{d} L(f_i, s). \tag{3.8}$$

Let

$$\mathbf{e}_i := X^{i-1}\{0,\infty\}$$

denote the ith *winding element*. In section 3.12.4 we computed the period map Φ_f with respect to a basis $g_1, \ldots, g_d$ for $S_k(N, \varepsilon; \mathbf{Q})[I]$. Upon writing f as a K_f-linear combination $\alpha_1 g_1 + \cdots + \alpha_d g_d$ we find that

$$\begin{aligned}\langle f, \mathbf{e}_i\rangle &= \langle \alpha_1 g_1 + \cdots + \alpha_d g_d, \mathbf{e}_i\rangle\\ &= \alpha_1\langle g_1, \mathbf{e}_i\rangle + \cdots + \alpha_d\langle g_d, \mathbf{e}_i\rangle\\ &= \alpha_1 \Phi_f(\mathbf{e}_i)_1 + \cdots + \alpha_d \Phi_f(\mathbf{e}_i)_d\end{aligned}$$

Here $\Phi_f(\mathbf{e}_i)_j$ denotes the jth coordinate of $\Phi_f(\mathbf{e}_i)$. Finally using Equation 3.7 we compute the special value.

3.12.6 The real and minus volume associated to A_f

Fix a choice of basis $g_1, \ldots, g_d$ for the free $\mathbf{Z}$-module $S_k(N, \varepsilon; \mathbf{Z})[I]$, where I is the annihilator in the Hecke algebra of our fixed newform f.

For any $x \in \boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ we have, by Proposition 2.11,

$$\begin{aligned}\overline{\Phi_f(x)} &= (\overline{\langle g_1, x\rangle}, \ldots, \overline{\langle g_d, x\rangle})\\ &= (\langle g_1^*, x^*\rangle, \ldots, \langle g_d^*, x^*\rangle)\\ &= (\langle g_1, x^*\rangle, \ldots, \langle g_d, x^*\rangle) \in \Phi_f(\boldsymbol{\mathcal{S}}_k(N, \varepsilon)),\end{aligned}$$

so complex conjugation leaves invariant the period lattice

$$\Lambda_f = \Phi_f(\boldsymbol{\mathcal{S}}_k(N, \varepsilon)) \subset \mathrm{Hom}_{\mathbf{C}}(S_k(N, \varepsilon)[I], \mathbf{C}).$$

Fix a $\mathbf{Z}$-basis for $S_k(N, \varepsilon; \mathbf{Z})[I]$, thus making an identification $\mathrm{Hom}_{\mathbf{C}}(S_k(N, \varepsilon)[I], \mathbf{C}) \cong \mathbf{C}^d$. The above observation implies that $A_f(\mathbf{C}) \cong \mathbf{C}^d/\Lambda_f$ is equipped with an action of complex conjugation. Our choice of basis defines a real-valued measure μ on $A_f(\mathbf{C})$, coming from the standard measure on $\mathbf{C}^d$. The measure does not depend on the choice of $\mathbf{Z}$-basis.

Definition 3.58 (Real and minus volume). The *real measure* Ω_f^+ is the measure $\mu(A_f(\mathbf{R}))$. The *minus measure* Ω_f^- is the measure $\mu(A_f(\mathbf{C})^-)$ times i^d, where $A_f(\mathbf{C})^-$ is the set of points in $A_f(\mathbf{C})$ on which complex conjugation acts as -1.

Thus, in connection with Section 3.10.3, $|\Omega_f^+| = |\Omega_1|$ and $|\Omega_f^-| = |\Omega_2|$.

Algorithm 3.59. To compute Ω_f^+ and Ω_f^-, proceed as follows. Using Algorithm 3.26, compute $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)/\mathrm{Ker}(\Phi_f)$. Next, compute a basis for the kernel $(\boldsymbol{\mathcal{S}}_k(N, \varepsilon)/\mathrm{Ker}(\Phi_f))^+$ of the map induced by the $*$-involution. Using Section 3.12.4 compute the image of this basis under i_f; this is a basis for Λ_f^+. The determinant of this latter basis then gives the measure $(\Omega_f^+)^0$ of the identity component $A_f(\mathbf{R})^0$ of $A_f(\mathbf{R})$. Finally $\Omega_f^+ = c_\infty^+ \cdot (\Omega_f^+)^0$, where the number c_∞^+ of real components can be computed using the algorithm in Section 3.12.7

Remark 3.60 (Alternative method). Suppose s is an integer in the set $\{1, \ldots, k-1\}$, and let $\sigma = +$ or $\sigma = -$, depending on whether s is odd or even, respectively. Section 3.10 contains a formula for the ratio $L(A_f, s)/\Omega_f^\sigma$. When this ratio is nonzero, Ω_f^σ can be determined by computing $L(A_f, s)/\Omega_f^\sigma$ and $L(A_f, s)$, using Section 3.12.5.

Remark 3.61. When $k = 2$ and ε is trivial, A_f has the structure of abelian variety over $\mathbf{Q}$. The quantity Ω_f^+ above is related to the quantity Ω_A appearing in the Birch and Swinnerton-Dyer conjecture [67] for A_f. The latter quantity is the measure of $A_f(\mathbf{R})$ with respect to a basis of integral differentials on the Néron model of A_f over $\mathrm{Spec}(\mathbf{Z})$. The two quantities are related by the Manin constant, which the author conjectures is always 1 (see Section 3.11).

3.12.7 The component groups c_∞^+ and c_∞^-

Assume in this section that f has *totally real* Fourier coefficients and continue to assume that $\varepsilon^2 = 1$.

Definition 3.62. Let c_∞^+ be the number of components of the topological space $A_f(\mathbf{R})$. Let c_∞^- be the number of components of $A_f(\mathbf{C})^-$, where $A_f(\mathbf{C})^-$ is the set of points $z \in A_f(\mathbf{C})$ such that $\overline{z} = -z$.

Proposition 3.63. *Let $\overline{C}$ be the map induced by complex conjugation on $\Lambda_f/2\Lambda_f = \Lambda_f \otimes \mathbf{F}_2$. Then*

$$c_\infty^+ = c_\infty^- = 2^{\dim(\ker(\overline{C}-1))-d},$$

where d is the dimension of A_f.

Proof. We must compute the order of the component group

$$\Psi = \frac{A_f(\mathbf{R})}{A_f(\mathbf{R})^0} = \frac{(\mathbf{C}^d/\Lambda_f)^+}{\mathbf{R}^d/\Lambda_f^+},$$

where $\mathbf{R}^d/\Lambda_f^+$ is the identity component because it is the continuous image of the connected set $\mathbf{R}^d$. For $v \in \mathbf{C}^d$ denote by $\overline{v}$ its complex conjugate and by $[v]$ its image in $\mathbf{C}^d/\Lambda_f$. Suppose $[v] \in (\mathbf{C}^d/\Lambda_f)^+$; this means that $[v] = [\overline{v}]$, so since $v + \overline{v} \in \mathbf{R}^d$ we have

$$2[v] = [v] + [\overline{v}] \in \mathbf{R}^d/\Lambda_f^+,$$

so Ψ is annihilated by 2. Thus there is $\lambda \in \Lambda_f$ so that $2v + \lambda \in \mathbf{R}^d$, and so $v + \frac{1}{2}\lambda \in \mathbf{R}^d$, i.e., v can be written as an element of $\frac{1}{2}\Lambda_f$ plus an element of $\mathbf{R}^d$. This means that Ψ is generated by the image of $(\frac{1}{2}\Lambda_f/\Lambda_f)^+$. Thus

$$\Psi \cong \frac{(\frac{1}{2}\Lambda_f/\Lambda_f)^+}{(\frac{1}{2}\Lambda_f \cap \mathbf{R}^d)/\Lambda_f^+} \cong \frac{(\Lambda_f/2\Lambda_f)^+}{\Lambda_f^+/2\Lambda_f^+}$$

Consequently

$$\dim_{\mathbf{F}_2} \Psi = \dim(\Lambda_f/2\Lambda_f)^+ - \dim \Lambda_f^+/2\Lambda_f^+ = \dim(\ker(\overline{C} - 1)) - d.$$

Here $\Lambda_f^+/2\Lambda_f^+$ has dimension d because Λ_f^+ is a lattice in $\mathbf{R}^d$, hence a free $\mathbf{Z}$-module of rank d.

The argument for c_∞^- proceeds in the same way, and results in the same answer because

$$\dim(\ker(\overline{C} - 1)) = \dim(\ker(\overline{C} + 1)).$$

□

To compute C on Λ_f, use Algorithm 3.26 to compute the action of $*$ on

$$\boldsymbol{\mathcal{S}}_k(N, \varepsilon)/\operatorname{Ker}(\Phi_f) \cong \Lambda_f.$$

3.12.8 Examples

Jacobians of genus-two curves

The author is among the the six authors of [24], who gather empirical evidence for the BSD conjecture for Jacobian of genus two curves. Of the 32 Jacobians considered, all but four are optimal quotients of $J_0(N)$ for some N. The methods of this section can be used to compute Ω_f^+ for the Jacobians of these 28 curves. Using explicit models for the genus two curves, the authors of [24] computed the measure of A with respect to a basis for the Néron differentials of A. In all 28 cases our answers agreed to the precision computed. Thus in these cases we have numerically verified that the Manin constant equals 1.

The first example considered in [24] is the Jacobian $A = J_0(23)$ of the modular curve $X_0(23)$. This curve has as a model

$$y^2 + (x^3 + x + 1)y = -2x^5 - 3x^2 + 2x - 2$$

from which one can compute the BSD $\Omega_A = 2.7328....$ The following is an integral basis of cusp forms for $S_2(23)$.

$$\begin{aligned} g_1 &= q - q^3 - q^4 - 2q^6 + 2q^7 + \cdots \\ g_2 &= q^2 - 2q^3 - q^4 + 2q^5 + q^6 + 2q^7 + \cdots \end{aligned}$$

The space $\boldsymbol{\mathcal{M}}_2(23;\mathbf{Q})$ of modular symbols has dimension five and is spanned by $\{-1/19, 0\}$, $\{-1/17, 0\}$, $\{-1/15, 0\}$, $\{-1/11, 0\}$ and $\{\infty, 0\}$. The submodule $\boldsymbol{\mathcal{S}}_2(23;\mathbf{Z})$ has rank four and has as basis the first four of the above five symbols. Choose $\gamma_1 = \left(\begin{smallmatrix} 8 & 1 \\ 23 & 3 \end{smallmatrix}\right)$ and $\gamma_2 = \left(\begin{smallmatrix} 6 & 1 \\ 23 & 4 \end{smallmatrix}\right)$ and let $x_i = \{\infty, \gamma_i(\infty)\}$. Using the W_N-trick (see Section 3.12.3) we compute the period integrals $\langle g_i, x_j\rangle$ using 97 terms of the q-expansions of g_1 and g_2, and obtain

$$\begin{aligned} \langle g_1, x_1\rangle &\sim -1.3543 + 1.0838i, \qquad & \langle g_1, x_2\rangle &\sim -0.5915 + 1.6875i \\ \langle g_2, x_1\rangle &\sim -0.5915 - 0.4801i, \qquad & \langle g_2, x_2\rangle &\sim -0.7628 + 0.6037i \end{aligned}$$

Using 97 terms we already obtain about 14 decimal digits of accuracy, but we do not reproduce them all here. We next find that

$$\langle g_1, x_1 + x_1^*\rangle \sim 2\mathrm{Re}(-1.3543 + 1.0838i) = 2.7086,$$

and so on. Upon writing each generator of $\boldsymbol{\mathcal{S}}_2(23)$ in terms of $x_1 + x_1^*$, $x_1 - x_1^*$, $x_2 + x_2^*$ and $x_2 - x_2^*$ we discover that the period mapping with respect to the basis dual to g_1 and g_2 is (approximately)

$$\begin{aligned} \{-1/19, 0\} &\mapsto (\ \ 0.5915 - 1.6875i, \quad 0.7628 - 0.6037i) \\ \{-1/17, 0\} &\mapsto (-0.5915 - 1.6875i, \quad -0.7628 - 0.6037i) \\ \{-1/15, 0\} &\mapsto (-1.3543 - 1.0838i, \quad -0.5915 + 0.4801i) \\ \{-1/11, 0\} &\mapsto (-1.5256, \qquad\qquad\qquad 0.3425) \end{aligned}$$

Working in $\boldsymbol{\mathcal{S}}_2(23)$ we find $\boldsymbol{\mathcal{S}}_2(23)^+$ is spanned by $\{-1/19, 0\} - \{-1/17, 0\}$ and $\{-1/11, 0\}$. Using the algorithm of Section 3.12.6, we find that there is only one real component so

$$\Omega_I^+ \sim \left|\begin{array}{cc} 1.1831 & 1.5256 \\ -1.5256 & 0.3425 \end{array}\right| = 2.7327...$$

To greater precision we find that $\Omega_f^+ \sim 2.7327505324965$. This agrees with the value in [24]; since the Manin constant is an integer, it must equal 1.

28	0.000000015627	$0.0000000029272i$

Level one cusp forms

In the following two sections we consider several specific examples of tori attached to modular forms of weight greater than two.

Let $k \geq 12$ be an even integer. Associated to each Galois conjugacy class of normalized eigenforms f, there is a torus A_f over $\mathbf{R}$. The real and minus volume of the first few of these tori are displayed in Table 3.1. For weights 24 and 28 we give Ω^-/i so that the columns will line up nicely. In each case, 97 terms of the q-expansion were used.

The volumes appear to be *much* smaller than the volumes of weight two abelian varieties. The dimension of each A_f is 1, except for weights 24 and 28 when the dimension is 2.

CM elliptic curves of weight greater than two

Let f be a rational newform with “complex multiplication”, in the sense that “half” of the Fourier coefficients of f are zero. For our purposes, it is not necessary to define complex multiplication any more precisely. Experimentally, it appears that the associated elliptic A_f has rational j-invariant. As evidence for this we present Table 3.2, which includes the analytic data about every rational CM form of weight four and level $\leq$ 197. The computations of Table 3.2 were done using at least 97 terms of the q-expansion of f. The rationality of j could probably be proved by observing that the CM forces A_f to have extra automorphisms.

In these examples, the invariants c_4 and c_6 are unrecognizable to the author; in contrast, in weight 2 these invariants are (expected to be) integers (see [16, 2.14]).

Some abelian varieties of large dimension

In Table 3.3, we give the volumes of five abelian varieties of dimension greater than 1. In each case, at least 200 terms of the q-expansions were used.

Table 3.2: CM elliptic curves of weight > 2.

Chapter 4

Component groups of optimal quotients

Let A be an abelian variety over the rational numbers $\mathbf{Q}$. The Birch and Swinnerton-Dyer conjecture supplies a formula for the order of the Shafarevich-Tate group of A. A key step in computing this order is to find each of the Tamagawa numbers c_p of A. The Tamagawa numbers are defined as follows, where the definition of Néron model and component group is given below.

Definition 4.1 (Tamagawa number). Let p be a prime, let $\mathcal{A}$ be a Néron model of A over the p-adic integers $\mathbf{Z}_p$, and let $\Phi_{A,p}$ be the component group of $\mathcal{A}$ at p. Then the *Tamagawa number* c_p of A is the order of the group $\Phi_{A,p}(\mathbf{F}_p)$ of $\mathbf{F}_p$-rational points of $\Phi_{A,p}(\overline{\mathbf{F}}_p)$.

Remark 4.2. We warn the reader that the Tamagawa number is defined in a different way in some other papers. The definitions are equivalent.

In this chapter we present a method for computing the Tamagawa numbers c_p, up to a power of 2, under the hypothesis that A has purely toric reduction at p. Such A are plentiful among the modular abelian varieties; for example, if A is a new optimal quotient of $J_0(N)$ and p exactly divides N, then A is purely toric at p.

In Sections 4.1–4.5 we state and prove an explicit formula involving component groups of fairly general abelian varieties. Then in Section 4.6 we turn to quotients of modular Jacobians $J_0(N)$. We give several tables and issue a conjecture and a question.

The results of this chapter were inspired by a letter that Ribet wrote to Mestre, in which he treats the case when A is an elliptic curve.

4.1 Main results

4.1.1 Néron models and component groups

Let A be an abelian variety over a finite extension K of the p-adic numbers $\mathbf{Q}_p$. Let $\mathcal{O}$ be the ring of integers of K, let $\mathfrak{m}$ be its maximal ideal, and let $k = \mathcal{O}/\mathfrak{m}$ be the residue class field.

Definition 4.3 (Néron model). A *Néron model* of A is a smooth commutative group scheme $\mathcal{A}$ over $\mathcal{O}$ such that A is its generic fiber and $\mathcal{A}$ satisfies the Néron mapping property: the restriction map

$$\mathrm{Hom}_{\mathcal{O}}(S, \mathcal{A}) \longrightarrow \mathrm{Hom}_K(S_K, A)$$

is bijective for all *smooth* schemes S over $\mathcal{O}$.

The Néron mapping property implies that $\mathcal{A}$ is unique up to a unique isomorphism, so we will refer without hesitation to "the" Néron model of A.

The closed fiber $\mathcal{A}_k$ of $\mathcal{A}$ is a group scheme over k, which need not be connected; denote by $\mathcal{A}_k^0$ the connected component containing the identity. There is an exact sequence

$$0 \longrightarrow \mathcal{A}_k^0 \longrightarrow \mathcal{A}_k \longrightarrow \Phi_A \longrightarrow 0,$$

where Φ_A a finite étale group scheme over k. Equivalently, Φ_A may be viewed as a finite abelian group equipped with an action of $\mathrm{Gal}(\overline{k}/k)$.

Definition 4.4 (Component group). The *component group* of an abelian variety $\mathcal{A}$ over a local field K is the group scheme $\Phi_A = A_k/A_k^0$ defined above.

4.1.2 Motivating problem

This chapter is motivated by the problem of computing the groups $\Phi_{A,p}$ attached to quotients A of Jacobians of modular curves $X_0(N)$. When A has semistable reduction, Grothendieck and Mumford described the component group in terms of a monodromy pairing on certain free abelian groups. When $A = J = J_0(N)$ is the Jacobian of $X_0(N)$, this pairing can be explicitly computed, hence the component group Φ_J can also be computed; this has been done in many cases in [40] and [23].

Suppose now that $A = A_f$ is an optimal quotient of $J_0(N)$ that is attached to a newform f, so that the kernel of the map $\pi : J \to A$ is connected. There is a natural map $\pi_* : \Phi_J \to \Phi_A$. We wish to compute the image and the order of the cokernel of π_*.

4.1.3 The main result

We now state our main result more precisely, necessarily supressing some of the definitions of the terms used until later. Suppose $\pi : J \to A$ is an optimal quotient, with J a Jacobian with semistable reduction and A having purely toric reduction. We express the component group of A in terms of the monodromy pairing associated to J.

Let $m_A = \sqrt{\deg(\theta_A)}$, where $\theta_A : A^\vee \to A$ is induced by the canonical principal polarization of J arising from the θ-divisor. Let X_J be the character group of the toric part of the closed fiber of the Néron model of J. Let $\mathcal{L}$ be the saturation of the image of X_A in X_J. The monodromy pairing induces a map $\alpha : X_J \to \mathrm{Hom}(\mathcal{L}, \mathbf{Z})$. Let Φ_X be the cokernel of α and $m_X = [\alpha(X_J) : \alpha(\mathcal{L})]$ be the order of the finite group $\alpha(X_J)/\alpha(\mathcal{L})$. We obtain the equality

$$\frac{\#\Phi_A}{m_A} = \frac{\#\Phi_X}{m_X}.$$

Using the snake lemma, one see that Φ_X is isomorphic to the image of the natural map $\Phi_J \to \Phi_A$, and the above formula implies that the cokernel of the map $\Phi_J \to \Phi_A$ has order m_A/m_X.

If the optimal quotient $J \to A$ arises from a modular form on $\Gamma_0(N)$, then the quantities m_A, m_X and Φ_X can be explicitly computed, hence we can compute $\#\Phi_A$.

4.2 Optimal quotients of Jacobians

Let J be a Jacobian, and let θ_J be the canonical principal polarization arising from the θ-divisor. Recall that an *optimal quotient* of J is an abelian variety A and a surjective map $\pi : J \to A$ whose kernel is an abelian subvariety B of J. Denote by $J^\vee$ and $A^\vee$ the abelian varieties dual to J and A, respectively. Upon composing the dual of π with $\theta_J^\vee = \theta_J$, we obtain a map

$$A^\vee \xrightarrow{\pi^\vee} J^\vee \xrightarrow{\theta_J} J.$$

Proposition 4.5. *The map $A^\vee \to J$ is injective.*

Proof. Since θ_J is an isomorphism it suffices to prove that $\pi^\vee$ is injective. Since the dual of $\pi^\vee$ is $(\pi^\vee)^\vee = \pi$ and π is surjective, the map $\pi^\vee$ must have finite kernel. Thus $A^\vee \to C = \mathrm{im}(\pi^\vee)$ is an isogeny. Let G denote the kernel of this isogeny, and dualize. By [50, §11] we have the following two commutative diagrams:

$$\begin{tikzcd} G \arrow[r] & A^\vee \arrow[r, two heads] \arrow[dr, "\pi^\vee"'] & C \arrow[d] & {} \arrow[r, "\text{dualize}"] & {} & A & C^\vee \arrow[l] & G^\vee \arrow[l] \\ & & J^\vee & & & & J, \arrow[ul, "\pi"] \arrow[u, "\varphi"'] & \end{tikzcd}$$

where $G^\vee$ is the Cartier dual of G. Since $G^\vee$ is finite, $\ker(\varphi)$ is of finite index in $\ker(\pi)$. Since $\ker(\pi)$ is an abelian variety, as a group it is divisible. But a divisible group has no nontrivial finite-index subgroups (divisibility is a property inherited by quotients, and nonzero finite groups are not divisible). Thus $\ker(\varphi) = \ker(\pi)$, so $G^\vee = 0$. It follows that $G = 0$. □

Henceforth we will abuse notation and denote the injection $A^\vee \to J$ by $\pi^\vee$. The kernel of θ_A equals the intersection of $A^\vee$ and $B = \ker(\pi)$, as depicted in the following diagram:

$$\begin{tikzcd} A^\vee \cap B \arrow[r] \arrow[d] & B \arrow[d] \\ A^\vee \arrow[r, hook, "\pi^\vee"] \arrow[dr, "\theta_A"'] & J \arrow[d, "\pi"] \\ & A. \end{tikzcd}$$

Since θ_A is a polarization, the degree $\#\ker(\theta_A)$ of θ_A is a perfect square (see [50, Thm. 13.3]). Recall that the *modular degree* is the integer

$$m_A = \sqrt{\#\ker(\theta_A)}.$$

For an algorithm to compute m_A, see Section 3.9 and Corollary 4.23.

4.3 The closed fiber of the Néron model

Let K be a finite extension of $\mathbf{Q}_p$ with ring of integers $\mathcal{O}$ and residue class field k. Let A be an abelian variety over K and denote its Néron model by $\mathcal{A}$. Let Φ_A be the group of connected components of the closed fiber $\mathcal{A}_k$. This group is a finite étale group scheme over k; equivalently, it is a finite abelian group equipped with an action of $\mathrm{Gal}(\overline{k}/k)$. There is an exact sequence of group schemes

$$0 \to \mathcal{A}_k^0 \to \mathcal{A}_k \to \Phi_A \to 0.$$

The group scheme $\mathcal{A}_k^0$ is an extension of an abelian variety $\mathcal{B}$ of some dimension a by a group scheme $\mathcal{C}$; we have a diagram

$$\begin{tikzcd}
 & 0 \arrow[d] & & & \\
 & \mathcal{T} \arrow[d] & & & \\
0 \arrow[r] & \mathcal{C} \arrow[r] \arrow[d] & \mathcal{A}_k^0 \arrow[r] & \mathcal{B} \arrow[r] & 0 \\
 & \mathcal{U} \arrow[d] & & & \\
 & 0 & & &
\end{tikzcd}$$

with $\mathcal{T}$ a torus of dimension t and $\mathcal{U}$ a unipotent group of dimension u. The abelian variety A is said to have *purely toric reduction* if $t = \dim A$, and have *semistable reduction* if $u = 0$.

Definition 4.6 (Character group of torus). The *character group*

$$X_A = \mathrm{Hom}_{\overline{k}}(\mathcal{T}_{/\overline{k}}, \mathbf{G}_{m/\overline{k}})$$

is a free abelian group of rank t contravariantly associated to A.

As discussed in, e.g., [53], if A is semistable there is a *monodromy pairing* $X_A \times X_{A^\vee} \to \mathbf{Z}$ and an exact sequence

$$0 \to X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

4.4 Rigid uniformization

In this section we review the rigid analytic uniformization of a semistable abelian variety over a finite extension K of the maximal unramified extension $\mathbf{Q}_p^{\mathrm{ur}}$ of $\mathbf{Q}_p$. We use this uniformization to prove that if A has purely toric reduction, and $\phi : A^\vee \to A$ is a symmetric isogeny (as defined below), then

$$\deg(\phi) = (\#\,\mathrm{coker}(X_A \to X_{A^\vee}))^2.$$

We also prove some lemmas about character groups.

It is possible to prove the assertions we will need without recourse to rigid uniformization, as Ahmed Abbes has pointed out to the author.

4.4.1 Raynaud's uniformization

Theorem 4.7 (Raynaud). *If A is a semistable abelian variety, its universal covering (as defined in [14]) is isomorphic to an extension G of an abelian variety B with good reduction by a torus T. The covering map from G to A is a homomorphism, and its kernel is a twisted free abelian group Γ of finite rank.*

This may be summarized by the diagram

$$\begin{tikzcd}
 & \Gamma \arrow[d] & \\
T \arrow[r] & G \arrow[r] \arrow[d] & B \\
 & A, &
\end{tikzcd}$$

which we call the *uniformization cross* of A.

Remark 4.8. The group Γ can be identified with the character group $X_{A^\vee}$ of the previous and latter sections.

The uniformization cross of the dual abelian variety $A^\vee$ is

$$\begin{tikzcd}
 & \Gamma^\vee \arrow[d] & \\
T^\vee \arrow[r] & G^\vee \arrow[r] \arrow[d] & B^\vee \\
 & A^\vee, &
\end{tikzcd}$$

where $\Gamma^\vee = \mathrm{Hom}(T, \mathbf{G}_m)$, where $T^\vee = \mathrm{Hom}(\Gamma, \mathbf{G}_m)$, and the morphisms $\Gamma^\vee \to G^\vee$ and $T^\vee \to G^\vee$ are the one-motif duals of the morphisms $T \to G$ and $\Gamma \to G$, respectively. For more details see, e.g., [14].

To avoid confusion when considering the uniformization of more than one abelian variety, we will often denote the objects T, G, Γ, and B connected with A by T_A, G_A, Γ_A, and B_A, respectively.

Example 4.9 (Tate curve). If $E/\mathbf{Q}_p$ is an elliptic curve with split multiplicative reduction, then the uniformization is $E = \mathbf{G}_m/q^{\mathbf{Z}}$ where $q = q(j)$ is obtained by inverting the expression for j as a function of $q(z) = e^{2\pi i z}$.

4.4.2 Some lemmas

Let $\pi : J \to A$ be an optimal quotient, assume that J has semistable reduction, and that A has purely toric reduction.

Lemma 4.10. *The map $\Gamma_J \to \Gamma_A$ induced by π is surjective.*

Proof. Since G_J is simply connected, π induces a map $G_J \to T_A$ and a map $\Gamma_J \to \Gamma_A$. Because π is surjective and T_A is a torus, the map $G_J \to T_A$ is surjective. Upon applying the snake lemma to the following diagram, we obtain a surjective map from $B = \ker(\pi)$ to $M = \mathrm{coker}(\Gamma_J \to \Gamma_A)$:

$$\begin{tikzcd}
 & \Gamma_J \arrow[r] \arrow[d] & \Gamma_A \arrow[r] \arrow[d] & M \arrow[r] \arrow[d] & 0 \\
 & G_J \arrow[r] \arrow[d] & T_A \arrow[r] \arrow[d] & 0 & \\
B \arrow[r] & J \arrow[r, "\pi"] & A. & &
\end{tikzcd}$$

Since $\pi : J \to A$ is an optimal quotient, the kernel B is connected. Thus M must also be connected. Since M is discrete it follows that $M = 0$. □

Abelian varieties with purely toric reduction

Assume that A has purely toric reduction. Then $B = 0$, and the uniformization cross is simply

$$\begin{tikzcd}
\Gamma \arrow[d] \\
T \arrow[d] \\
A.
\end{tikzcd}$$

Definition 4.11 (Symmetric isogeny). A *symmetric isogeny* $\varphi : A^\vee \to A$ is an isogeny such that the map $\varphi^\vee : A^\vee \to (A^\vee)^\vee = A$ is equal to φ.

Let $\varphi : A^\vee \to A$ be a symmetric isogeny. Denote by $\varphi_t : T^\vee \to T$ and $\varphi_a : \Gamma^\vee \to \Gamma$ the maps induced by φ.

Proposition 4.12. *There is an exact sequence*

$$0 \to \ker(\varphi_t) \to \ker(\varphi) \to \mathrm{coker}(\varphi_a) \to 0,$$

and $\ker(\varphi_t)$ *is the Cartier dual of* $\mathrm{coker}(\varphi_a)$*.*

Proof. Since φ is an isogeny we obtain the following diagram:

$$\begin{tikzcd}
0 \arrow[r] \arrow[d] & \Gamma^\vee \arrow[r, "\varphi_a"] \arrow[d] & \Gamma \arrow[r] \arrow[d] & \mathrm{coker}(\varphi_a) \arrow[d] \\
\ker(\varphi_t) \arrow[r] \arrow[d] & T^\vee \arrow[r, "\varphi_t"] \arrow[d] & T \arrow[r] \arrow[d] & 0 \\
\ker(\varphi) \arrow[r] & A^\vee \arrow[r, "\varphi"] & A. &
\end{tikzcd}$$

The snake lemma then gives the claimed exact sequence.

For the second assertion, observe that if we take one-motif duals of every object in the diagram

$$\begin{tikzcd}
 & \Gamma^\vee \arrow[r, "\varphi_a"] \arrow[d] & \Gamma \arrow[r] \arrow[d] & \mathrm{coker}(\varphi_a) \\
\ker(\varphi_t) \arrow[r] & T^\vee \arrow[r, "\varphi_t"] & T &
\end{tikzcd}$$

we obtain the following diagram:

$$\begin{tikzcd}
 & T & T^\vee \arrow[l, "\varphi_a^\vee"'] & \mathrm{coker}(\varphi_a)^\vee \arrow[l] \\
\ker(\varphi_t)^\vee & \Gamma \arrow[l] \arrow[u] & \Gamma^\vee. \arrow[l, "\varphi_t^\vee"] \arrow[u] &
\end{tikzcd}$$

Since φ is symmetric, $\varphi_a^\vee = \varphi_t$, so

$$\ker(\varphi_t) = \mathrm{coker}(\varphi_a)^\vee.$$

□

Lemma 4.13. $\#\ker(\varphi) = \#\,\mathrm{coker}(\varphi_a)^2$

Proof. Use the exact sequence of Proposition 4.12 together with the observation that the order of a finite group scheme equals the order of its Cartier dual. □

4.5 The main theorem

Let $\pi : J \to A$ be an optimal quotient, with J a Jacobian having semistable reduction and A an abelian variety having purely toric reduction. Let X_A, $X_{A^\vee}$, and X_J denote the character groups of the toric parts of the closed fibers of the abelian varieties A, $A^\vee$, and J, respectively.

4.5.1 Description of the component group in terms of the monodromy pairing

Recall that there is a pairing $X_A \times X_{A^\vee} \to \mathbf{Z}$ called the monodromy pairing. We have an exact sequence

$$0 \to X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

If J is a Jacobian then J is canonically self-dual via the θ-polarization, so the monodromy pairing on J can be viewed as a pairing $X_J \times X_J \to \mathbf{Z}$, and there is an exact sequence

$$0 \to X_J \to \mathrm{Hom}(X_J, \mathbf{Z}) \to \Phi_J \to 0.$$

Example 4.14 (Tate curve). Suppose $E = \mathbf{G}_m/q^{\mathbf{Z}}$ is a Tate curve over $\mathbf{Q}_p^{\mathrm{ur}}$. The monodromy pairing on $X_E = q^{\mathbf{Z}}$ is

$$\langle q, q\rangle = \operatorname{ord}_p(q) = -\operatorname{ord}_p(j).$$

Thus Φ_E is cyclic of order $-\operatorname{ord}_p(j)$.

Proof of the main theorem

We now prove the main theorem. Let $\pi : J \to A$ be an optimal quotient, and let $\theta : A^\vee \to A$ denote the induced polarization. Let π_*, π^*, θ_*, and θ^* be the maps induced on character groups by the various functorialities, as indicated in the following two key diagrams:

$$\begin{tikzcd}
A^\vee \arrow[r, hook, "\pi^\vee"] \arrow[dr, "\theta"'] & J \arrow[d, two heads, "\pi"] \\
 & A
\end{tikzcd}
\qquad\qquad
\begin{tikzcd}
X_A \arrow[r, hook, "\pi^*"] \arrow[dr, "\theta^*"] & X_J \arrow[d, two heads, "\pi_*"] \\
 & X_{A^\vee}. \arrow[ul, bend left, "\theta_*"]
\end{tikzcd}$$

The surjectivity of π_* was proved in Lemma 4.10. The injectivity of π^* follows because

$$\theta_*\pi_*\pi^* = \theta_*\theta^* = \deg(\theta) \neq 0,$$

and multiplication by a nonzero integer on a free abelian group is injective.

Let

$$\alpha : X_J \to \operatorname{Hom}(\pi^* X_A, \mathbf{Z})$$

be the map defined by the monodromy pairing restricted to $X_J \times \pi^* X_A$.

Lemma 4.15. $\ker(\pi_*) = \ker(\alpha)$

Proof. Suppose $x \in \ker(\pi_*)$, and let $y = \pi^* z$ with $z \in X_A$. Then

$$\langle x, y\rangle = \langle x, \pi^* z\rangle = \langle \pi_* x, z\rangle = 0,$$

so $x \in \ker(\alpha)$. Next let $x \in \ker(\alpha)$. Then for all $z \in X_A$,

$$0 = \langle x, \pi^* z\rangle = \langle \pi_* x, z\rangle,$$

so $\pi_* x$ is in the kernel of the monodromy map

$$X_{A^\vee} \to \operatorname{Hom}(X_A, \mathbf{Z}).$$

Since $X_{A^\vee}$ and $\operatorname{Hom}(X_A, \mathbf{Z})$ are free of the same finite rank and the cokernel is torsion, the monodromy map is injective. Thus $\pi_* x = 0$ and $x \in \ker(\pi_*)$. □

Lemma 4.16. *There is an exact sequence*

$$X_J \to \operatorname{Hom}(\pi^* X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

Proof. Lemma 4.15 gives the following commutative diagram with exact rows

$$\begin{tikzcd}
0 \arrow[r] & X_J/\ker(\alpha) \arrow[r] \arrow[d, "\cong"] & \mathrm{Hom}(\pi^* X_A, \mathbf{Z}) \arrow[r] \arrow[d, "\cong"] & \mathrm{coker}(\alpha) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & X_{A^\vee} \arrow[r] & \mathrm{Hom}(X_A, \mathbf{Z}) \arrow[r] & \Phi_A \arrow[r] & 0.
\end{tikzcd}$$

By Lemma 4.15, the first vertical map is an isomorphism. The second is an isomorphism because it is induced by the isomorphism $\pi^* : X_A \to \pi^* X_A$. It follows that $\mathrm{coker}(\alpha) \cong \Phi_A$, as claimed. □

Let $\mathcal{L}$ be the *saturation* of $\pi^* X_A$ in X_J; thus $\pi^* X_A$ is a finite-index subgroup of $\mathcal{L}$ and the quotient $X_J/\mathcal{L}$ is torsion free. For L of finite index in $\mathcal{L}$, define the *modular degree* of L to be

$$m_L = [\alpha(X_J) : \alpha(L)],$$

and the *component group* of L to be

$$\Phi_L = \mathrm{coker}(X_J \to \mathrm{Hom}(L, \mathbf{Z})).$$

When $L = \mathcal{L}$ and A is fixed, we often slightly abuse notation and write $m_X = m_{\mathcal{L}}$ and $\Phi_X = \Phi_{\mathcal{L}}$. We think of m_X and Φ_X as the character group "modular degree and component group" of A.

Lemma 4.17. *Choose a subgroup L of finite index in $\mathcal{L}$. The rational number $\dfrac{\#\Phi_L}{m_L}$ is independent of the choice of L.*

Proof. Suppose L' is another finite index subgroup of $\mathcal{L}$, and let $n = [L : L']$. Here n is a rational number, the lattice index of L' in L. Since α is injective when restricted to $\mathcal{L}$, it follows that

$$m_{L'} = [\alpha(X_J) : \alpha(L')] = [\alpha(X_J) : \alpha(L)] \cdot [\alpha(L) : \alpha(L')] = m_L \cdot n.$$

Similarly, $\#\Phi_{L'} = \#\Phi_L \cdot n$. □

Recall that $m_A = \sqrt{\deg(\theta)}$ and

$$\Phi_A \cong \mathrm{coker}(X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z})),$$

where m_A is the modular degree of A and Φ_A is the component group of A.

Theorem 4.18. *For any subgroup L of finite index in $\mathcal{L}$, the following relation holds:*

$$\frac{\#\Phi_A}{m_A} = \frac{\#\Phi_L}{m_L}.$$

Proof. By Lemma 4.17 we may assume that $L = \pi^* X_A$. With this choice of L, Lemma 4.16 asserts that $\Phi_L \cong \Phi_A$. By Lemma 4.15, properties of the index, and Lemma 4.13 we have

$$\begin{aligned} m_L &= [\alpha(X_J) : \alpha(L)] \\ &= [\pi_*(X_J) : \pi_*(L)] \\ &= [X_{A^\vee} : \pi_*(\pi^* X_A)] \\ &= [X_{A^\vee} : \theta^* X_A] \\ &= \#\operatorname{coker}(\theta^*) \\ &= \sqrt{\deg(\theta)} = m_A. \end{aligned}$$

□

Proposition 4.19.

$$\operatorname{image}(\Phi_J \to \Phi_A) \cong \Phi_{\mathcal{L}}.$$

Proof. Since $\pi^* X_A \subset \mathcal{L} \subset X_J$, an application of Lemma 4.16 gives the following commutative diagram with exact rows:

$$\begin{tikzcd} X_J \arrow[r] \arrow[d, equal] & \operatorname{Hom}(X_J, \mathbf{Z}) \arrow[r] \arrow[d] & \Phi_J \arrow[r] \arrow[d] & 0 \\ X_J \arrow[r] \arrow[d, equal] & \operatorname{Hom}(\mathcal{L}, \mathbf{Z}) \arrow[r] \arrow[d] & \Phi_{\mathcal{L}} \arrow[r] \arrow[d] & 0 \\ X_J \arrow[r] & \operatorname{Hom}(\pi^* X_A, \mathbf{Z}) \arrow[r] & \Phi_A \arrow[r] & 0. \end{tikzcd}$$

The map $\operatorname{Hom}(\mathcal{L}, \mathbf{Z}) \to \operatorname{Hom}(\pi^* X_A, \mathbf{Z})$ is an isomorphism, so the map $\Phi_{\mathcal{L}} \to \Phi_A$ is injective. Thus

$$\operatorname{image}(\Phi_J \to \Phi_A) \cong \operatorname{image}(\Phi_J \to \Phi_{\mathcal{L}}).$$

The cokernel of $\operatorname{Hom}(X_J, \mathbf{Z}) \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})$ surjects onto the cokernel of $\Phi_J \to \Phi_{\mathcal{L}}$. Using the exact sequence

$$0 \to \mathcal{L} \to X_J \to X_J/\mathcal{L} \to 0,$$

we find that

$$\operatorname{coker}(\operatorname{Hom}(X_J, \mathbf{Z}) \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})) \subset \operatorname{Ext}^1(X_J/\mathcal{L}, \mathbf{Z}).$$

Because $\mathcal{L}$ is saturated, the quotient $X_J/\mathcal{L}$ is torsion free, so the indicated Ext^1 group vanishes. Thus the map $\Phi_J \to \Phi_{\mathcal{L}}$ is surjective, from which the proposition follows. □

The following corollary follows from Theorem 4.18 and Proposition 4.19.

Corollary 4.20.

$$\#\operatorname{coker}(X_J \to X_A) = \frac{m_A}{m_{\mathcal{L}}}.$$

Remark 4.21. A non-obvious consequence of this corollary is that

$$m_{\mathcal{L}} \mid m_A.$$

4.6 Optimal quotients of $J_0(N)$

We now summarize some facts about $J_0(N)$ that will be used in our numerical computations. Some of these facts were discussed in greater generality in the previous chapters of this thesis.

4.6.1 Modular curves and semistability

Let $X_0(N)$ be the modular curve associated to the subgroup $\Gamma_0(N)$ of $\mathrm{SL}_2(\mathbf{Z})$ that consists of those matrices which are upper triangular modulo N. Initially, $X_0(N)$ is constructed as a Riemann surface as the quotient

$$\Gamma_0(N)\backslash(\{z : z \in \mathbf{C}, \operatorname{Im}(z) > 0\} \cup \mathbf{P}^1(\mathbf{Q})).$$

With some work, we find that $X_0(N)$ has a canonical structure of algebraic curve over $\mathbf{Q}$.

Suppose that p is a prime divisor of N such that N/p is coprime to p. We write $p \,||\, N$. In this situation, it is well-known that the Jacobian $J_0(N)$ of $X_0(N)$ has semistable reduction at p.

4.6.2 Newforms and optimal quotients

The Hecke algebra

$$\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots] \subset \operatorname{End}(J_0(N))$$

is a commutative ring of endomorphisms of $J_0(N)$ of $\mathbf{Z}$-rank equal to the dimension $J_0(N)$. The character group $X_{J_0(N)}$ of $J_0(N)$ at p is equipped with a functorial action of $\mathbf{T}$. The Hecke algebra $\mathbf{T}$ also acts on the complex vector space $S = S_2(\Gamma_0(N), \mathbf{C})$ of cusp forms.

A newform f is an eigenform normalized so that the coefficient of q in the Fourier expansion of f at the cusp ∞ is 1, and such that f is not a modular form of any level $N' \mid N$, with N' a proper divisor of N.

Let f be a newform, and associate to f the ideal I_f of the Hecke algebra $\mathbf{T}$ of elements which annihilate f. Then $\mathcal{O}_f = \mathbf{T}/I_f$ is an order in the ring of integers of the totally real number field K_f obtained by adjoining the Fourier coefficients of f to $\mathbf{Q}$. The quotient

$$A_f = J_0(N)/I_f J_0(N)$$

is an optimal quotient of $J_0(N)$ of dimension equal to $[K_f : \mathbf{Q}]$. It is purely toric at p, since $p \,||\, N$.

4.6.3 Homology and the modular degree

Let $H = H_1(X_0(N), \mathbf{Z})$ be the integral homology of the complex algebraic curve $X_0(N)$. Integration defines a $\mathbf{T}$-equivariant nondegenerate pairing $S \times H \to \mathbf{C}$. This pairing induces a map $\alpha : H \to \operatorname{Hom}_{\mathbf{C}}(S, \mathbf{C})$.

Theorem 4.22. *We have the following commutative diagram of* $\mathbf{T}$*-modules:*

$$\begin{tikzcd}
H[I_f] \arrow[r, hook] \arrow[d, hook] & H \arrow[r, two heads] \arrow[d, hook] & \alpha(H) \arrow[d, hook] \\
\mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C})[I_f] \arrow[r, hook] \arrow[d, two heads] & \mathrm{Hom}_{\mathbf{C}}(S, \mathbf{C}) \arrow[r, two heads] \arrow[d, two heads] & \mathrm{Hom}_{\mathbf{C}}(S[I_f], \mathbf{C}) \arrow[d, two heads] \\
A_f^{\vee}(\mathbf{C}) \arrow[r, hook] \arrow[rr, bend right, "\theta_A"'] & J(\mathbf{C}) \arrow[r, two heads] & A_f(\mathbf{C})
\end{tikzcd}$$

Proof. This can be deduced from [61]. See also Section 2.7. □

Corollary 4.23. $m_A^2 = [\alpha(H) : \alpha(H[I_f])]$.

Proof. Recall that m_A is by definition equal to $\sqrt{\deg(\theta_A)}$. The kernel of an isogeny between complex tori is isomorphic to the cokernel of the induced map on lattices. The corollary now follows from the diagram of Theorem 4.22, which indicates that the index $[\alpha(H) : \alpha(H[I_f])]$ is the cokernel of the map $H[I_f] \to \alpha(H)$.

For more details, see Section 3.9. □

4.6.4 Rational points of the component group (Tamagawa numbers)

Let $\mathrm{Frob}_p : X_J \to X_J$ denote the map induced by the Frobenius automorphism. We have $\mathrm{Frob}_p = -W_p$, where W_p is the map induced by the Atkin-Lehner involution on $J_0(p)$. Let f be a newform, $A = A_f$ the corresponding optimal quotient, and w_p the sign of the eigenvalue of W_p on f.

Proposition 4.24.

$$\Phi_A(\mathbf{F}_p) = \begin{cases} \Phi_A(\overline{\mathbf{F}}_p) & \text{if } w_p = -1, \\ \Phi_A(\overline{\mathbf{F}}_p)[2] & \text{if } w_p = 1. \end{cases}$$

Proof. If $w_p = -1$, then $\mathrm{Frob}_p = 1$ and the $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$-action of $\Phi_A(\overline{\mathbf{F}}_p)$ is trivial. In this case $\Phi(\mathbf{F}_p) = \Phi(\overline{\mathbf{F}}_p)$. Next suppose $w_p = 1$. Recall that we have an exact sequence

$$0 \to X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

Since W_p acts as $+1$ on f, it also acts as $+1$ on each of the four modules A, X_A, $\mathrm{Hom}(X_A, \mathbf{Z})$, and Φ_A. Thus $\mathrm{Frob}_p = -W_p$ acts as -1 on Φ_A. Since the subgroup of 2-torsion elements of a finite abelian group equals the subgroup of elements fixed under -1, it follows that $\Phi_A(\mathbf{F}_p) = \Phi_A(\overline{\mathbf{F}}_p)[2]$. □

WARNING: When we extend this result to the whole of $J_0(N)$, it is necessary to be exceedingly careful! The action of $\mathrm{Frob}_p = T_p$ need not be by ±1, even though it must be by an involution of order 2. For example, the component group of $J_0(65)$ at 5 is cyclic of order 42. The action of Frob_5 is by multiplication by -13. Note that $(-13)^2 = 1 \pmod{42}$. The fixed points of multiplication by -13 is the order 14 subgroup of $\mathbf{Z}/42\mathbf{Z}$.

4.7 Computations

Using the algorithms of Chapter 3, we can enumerate the optimal quotients A_f of $J_0(N)$ and compute the modular degree m_A. The method of graphs (see [47]) and quaternion algebras (see [32]) can be used to compute $X = X_{J_0(N)}$ with its $\mathbf{T}$-action and the monodromy pairing. We can then compute the following three modules: the saturated submodule $\mathcal{L} = \bigcap_{t\in I_f} \ker(t)$ of X, the character group modular degree $m_X = m_{\mathcal{L}}$, and $\Phi_X = \Phi_{\mathcal{L}}$. By Theorem 4.18 we obtain

$$\#\Phi_A = \#\Phi_X \cdot \frac{m_A}{m_X}.$$

Using this method, we have computed $\#\Phi_A$ in a number of cases. We give tables that report on some of these computations in Secton 4.7.2. In the next section we discuss a conjecture and a question, which were both suggested by our numerical computations.

4.7.1 Conjectures and questions

Suppose that $N = pM$ with $(p, M) = 1$. Let

$$H_{\text{new}} = \ker\Big(H_1(X_0(N),\mathbf{Z}) \longrightarrow H_1(X_0(M),\mathbf{Z}) \oplus H_1(X_0(M),\mathbf{Z})\Big),$$

where the map is induced by the two natural degeneracy maps $X_0(N) \to X_0(M)$.

The Hecke algebra $\mathbf{T}$ acts on H_{new}, and also on the submodule $H_{\text{new}}[I_f]$ of those elements that are annihilated by I_f. Integration defines a map $\alpha : H_{\text{new}} \to \operatorname{Hom}(S[I_f], \mathbf{C})$. Define the p-new homology modular degree m_H by

$$m_H^2 = [\alpha(H_{\text{new}}) : \alpha(H_{\text{new}}[I_f])].$$

We expect that there is a very close relationship between m_X and m_H.

Question 4.25. Is m_X equal to m_H?

The following conjecture offers a refinement of some of the results of [40].

Conjecture 4.26 (Refined Eisenstein conjecture). *Let p be a prime and let $f_1, \ldots, f_n$ be a set of representatives for the Galois-conjugacy classes of newforms in $S_2(\Gamma_0(p))$. Let $A_1, \ldots, A_n$ be the optimal quotients associated to $f_1, \ldots, f_n$, respectively. Then for each i, $i = 1, \ldots, n$, we have*

$$\#A_i(\mathbf{Q})_{\text{tor}} = \#\Phi_{A_i}(\overline{\mathbf{F}}_p) = \#\Phi_{A_i}(\mathbf{F}_p).$$

Furthermore,

$$\#\Phi_{J_0(p)}(\overline{\mathbf{F}}_p) = \prod_{i=1}^{d} \#\Phi_{A_i}(\overline{\mathbf{F}}_p).$$

We have verified Conjecture 4.26 for all $p \leq 757$, and, up to a power of 2, for all $p < 2000$.

Remark 4.27. It is tempting to guess that, e.g., the natural map

$$\Phi_{J_0(113)}(\overline{\mathbf{F}}_p) \to \prod_{i=1}^{4} \Phi_{A_i}(\overline{\mathbf{F}}_p)$$

is an isomorphism. Two of the $\Phi_{A_i}(\overline{\mathbf{F}}_p)$ have order 2, so the product $\prod \Phi_{A_i}(\overline{\mathbf{F}}_p)$ can not be a cyclic group. However, the groups $\Phi_{J_0(p)}(\overline{\mathbf{F}}_p)$ are known to be cyclic for all primes p.

4.7.2 Tables

We have computed component groups of many optimal quotients A_f of $J_0(N)$. In this section we provide tables, which hint at the data we have gathered. Our notation for optimal quotients is described in Section 1.3.1. See also Table 1.6.

Table 4.1: Component groups at low level

Table 4.1 gives the component groups of the quotients A_f of $J_0(N)$ for $N \leq 106$. The column labeled d contains the dimensions of the A_f, and the column labeled $\#\Phi_{A,p}$ contains a list of the orders of the component groups of A_f, one for each divisor p of N, ordered by increasing p. An entry of "?" indicates that $p^2 \mid N$, so our algorithm does not apply. A component group order is starred if the $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$-action is nontrivial.

Table 4.2–4.3: Big component groups

Using the algorithms described in Section 3.10, we computed the rational numbers $L(A,1)/\Omega_A$ for every optimal quotient A that is attached to a newform of level ≤ 1500. There are exactly 5 optimal quotients A such that the numerator of $L(A,1)/\Omega_A$ is nonzero and divisible by a prime $> 10^9$. The Birch and Swinnerton-Dyer conjecture predicts that these large prime divisors must divide either $\#\Phi_A$ or the Shafarevich-Tate group of A. This is the case, as Table 4.3 shows.

Table 4.4: Quotients of $J_0(N)$

Table 4.4 contains all of the invariants involved in the computation of component groups for each of the newform optimal quotients of levels 65, 66, 68, and 69.

Table 4.5: Quotients of $J_0(p)^-$

We computed the quantities m_A, m_X and Φ_X for each abelian variety $A = A_f$ associated to a newform of prime level p with $p \leq 757$. The results are as follows:

1. In all cases $m_A = m_X$, so the map $\Phi_J \to \Phi_A$ is surjective.
2. $\Phi_A = 1$ whenever the sign of the Atkin-Lehner involution w_p on A is 1.
3. $\prod \#\Phi_A(\overline{\mathbf{F}}_p) = \#\Phi_J(\overline{\mathbf{F}}_p)$

Table 4.5 lists those A of level ≤ 631 for which $w_p = -1$, along with the order of the corresponding component group.

4 A Mod Five Approach To Modularity Of Icosahedral Galois Representations, with K. Buzzard

PACIFIC JOURNAL OF MATHEMATICS
Vol. 203, No. 2, 2002

A MOD FIVE APPROACH TO MODULARITY OF ICOSAHEDRAL GALOIS REPRESENTATIONS

Kevin Buzzard and William A. Stein

We give eight new examples of icosahedral Galois representations that satisfy Artin's conjecture on holomorphicity of their L-function. We give in detail one example of an icosahedral representation of conductor $1376 = 2^5 \cdot 43$ that satisfies Artin's conjecture. We briefly explain the computations behind seven additional examples of conductors $2416 = 2^4 \cdot 151$, $3184 = 2^4 \cdot 199$, $3556 = 2^2 \cdot 7 \cdot 127$, $3756 = 2^2 \cdot 3 \cdot 313$, $4108 = 2^2 \cdot 13 \cdot 79$, $4288 = 2^6 \cdot 67$, and $5373 = 3^3 \cdot 199$. We also generalize a result of Sturm on computing congruences between eigenforms.

Introduction.

Consider a continuous irreducible Galois representation

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_n(\mathbf{C})$$

with $n > 1$. Inspired by his reciprocity law, Artin conjectured in [1] that $L(\rho, s)$ has an analytic continuation to the whole complex plane. Many of the known cases of this conjecture were obtained by proving the apparently stronger assertion that ρ is *automorphic*, in the sense that the L-function of ρ is equal to the L-function of a certain automorphic representation (whose L-function is known to have analytic continuation). In the special case where $n = 2$ and ρ is in addition assumed to be odd, the automorphic representation in question should be the one associated to a classical weight 1 modular eigenform, and in fact there is conjectured to be a bijection between such ρ and the set of all weight 1 cuspidal newforms, which should preserve L-functions. It is this bijection that we are concerned with in this paper, so assume for the rest of the paper that $n = 2$ and ρ is odd.

In this special case, the construction of [7] shows how to construct a continuous irreducible odd 2-dimensional representation from a weight 1 newform, and the problem is to go the other way. Say that a representation is *modular* if it arises in this way.

If the image of ρ is solvable, then ρ is known to be modular [11, 18]; if the image is not solvable, then $\mathrm{Im}(\rho)$ in $\mathrm{PGL}_2(\mathbf{C})$ is isomorphic to the alternating group A_5, and the modularity of ρ is, in general, unknown. We call such a 2-dimensional representation an “icosahedral representation”. The published literature contains only eight examples (up to twist) of odd icosahedral Galois representations that are known to satisfy Artin’s conjecture: One of conductor $800 = 2^5 \cdot 5^2$ (see [3]), and seven of conductors: 2083, $2^2 \cdot 487$, $2^2 \cdot 751$, $2^2 \cdot 887$, $2^2 \cdot 919$, $2^5 \cdot 73$, and $2^5 \cdot 193$ (see [8]).

After the first draft of this paper was written, the preprint [4] appeared, which contains a general theorem that yields infinitely many (up to twist) modular icosahedral representations. However, we feel that our work, although much less powerful, is still of some worth, because it gives an effective computational approach to proving that certain mod 5 representations are modular, without computing any spaces of weight 1 forms or using effective versions of the Chebotarëv density theorem. We also note that the main theorem of [4] does not apply to any of the examples considered in the present paper. Very recently, the preprint [17] appeared, which gives new local conditions under which an icosahedral representation can be proved to be modular. In particular, [17] also proves that the first three examples in the present paper, of conductors 1376, 2416, 3184, are modular; these correspond to the first, third, and fourth equations at the end of [17]. However, [17] does not apply to our remaining five examples. Finally, we note that this paper also contains a result (Corollary 1.7) generalizing the main results of [16], which makes explicit computations with mod p modular forms much more practical.

Let ρ be a continuous odd icosahedral representation. We briefly summarise our approach for verifying modularity of ρ. As all the representations we consider are unramified at 5, one can use the main theorem of [5] to reduce the problem to showing that the mod 5 reduction of ρ is modular. We do this by using a computer to find a candidate mod 5 modular form at weight 5 and then, using the table of icosahedral extensions of $\mathbf{Q}$ in [8] and what we know about the 5-adic representation attached to our candidate form, we deduce that the mod 5 representation attached to our candidate form must be the reduction of ρ. In particular, this paper gives a computational method for checking the modularity of certain mod 5 representations whose conductors are not too large.

We now explain something about a problematic point in this approach, which is to verify that a given modular form which has been obtained by a computation actually gives rise to an explicit mod 5 representation which has been given by another computation. In each of our examples it is easy to compute a few Hecke operators and be morally convinced that this is the case; it is far more difficult to prove this. Effective variants of the Chebotarëv density theorem require that we check vastly more traces of Frobenius than is practical. Our approach was as follows. Let f be one of the forms that we computed. We firstly used the compatibility of the Local and Global Langlands correspondences for GL_2 and some twisting tricks to deduce that the kernel of the projective mod 5 representation associated to f must correspond to an A_5-extension of $\mathbf{Q}$. We then used the theory of companion forms and a careful local analysis of the representations associated to the forms to deduce strong local results about these A_5-extensions. Finally we used Table 2 of [8] to prove that in each case the A_5-extension was precisely the one we wanted it to be.

We carried out this program for icosahedral representations of the following conductors: $\mathbf{1376} = 2^5 \cdot 43$, $\mathbf{2416} = 2^4 \cdot 151$, $\mathbf{3184} = 2^4 \cdot 199$, $\mathbf{3556} = 2^2 \cdot 7 \cdot 127$, $\mathbf{3756} = 2^2 \cdot 3 \cdot 313$, $\mathbf{4108} = 2^2 \cdot 13 \cdot 79$, $\mathbf{4288} = 2^6 \cdot 67$, and $\mathbf{5373} = 3^3 \cdot 199$.

This paper is divided into three sections. In Section 1, we give in detail our proof that the icosahedral representation of minimal conductor 1376 satisfies Artin's conjecture. The subsections of Section 1 follow the plan outlined above. Section 2 summarizes the data necessary to deduce Artin's conjecture for all eight of our examples. Finally, Section 3 contains a brief review of modular symbols, and contains some tables of running times.

1. Modularity of an icosahedral representation of conductor $1376 = 2^5 \cdot 43$.

In this section we prove the following theorem.

Theorem 1.1. *The icosahedral representations whose corresponding icosahedral extension is the splitting field of* $x^5 + 2x^4 + 6x^3 + 8x^2 + 10x + 8$ *are modular.*

Let K be the splitting field of $h = x^5+2x^4+6x^3+8x^2+10x+8$. The Galois group of K is A_5, so we obtain a homomorphism $G_{\mathbf{Q}} \to A_5 \subset \mathrm{PGL}_2(\mathbf{C})$; let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}_2(\mathbf{C})$ be a minimal lift, minimal in the sense that the Artin conductor of ρ is minimal. By Table A_5 of [3], the conductor of ρ is $N = 1376 = 2^5 \cdot 43$. Since $h \equiv (x-1)(x^2-x+1)(x^2-x+2) \pmod 5$, and $\mathrm{disc}(h)$ is coprime to 5, any Frobenius element at 5 in $\mathrm{Gal}(K/\mathbf{Q})$ has order 2.

We use the notation of Tables 3.1 and 3.2 of [3, p. 46], which gives a complete classification of the way that ramified primes can behave in such representations. In our case the ramified primes are 2 and 43. From Table 3.2 of [3] we see that the type of ρ at 2 is 17 and the type at 43 is 2. The level N Dirichlet character $\widetilde{\varepsilon} = \det(\rho)$ factors as $\widetilde{\varepsilon} = \widetilde{\varepsilon}_2 \cdot \widetilde{\varepsilon}_{43}$ where $\widetilde{\varepsilon}_2$ is a character of conductor dividing 2^5 and $\widetilde{\varepsilon}_{43}$ is a character of conductor 43. We can work out these characters explicitly as we know the type of ρ at 2 and 43—indeed, there is a character associated to each type in Buhler's table, which unfortunately is not tabulated. An easy local computation shows that $\widetilde{\varepsilon}_{43}$ has order 3, and fortunately Buhler's level 800 example also was of type 17 at 2 (see the first line of [3, Table 3.2]), hence by [3, p. 80] $\widetilde{\varepsilon}_2$ is the unique character of conductor 4 and order 2. We think of these characters now has having values in $\mathbf{Q}(\zeta_3) \subseteq \overline{\mathbf{Q}}$, where ζ_3 is a primitive cube root of unity.

If ρ is modular, then there is a weight 1 newform $f_? \in S_1(N, \widetilde{\varepsilon}; \overline{\mathbf{Q}})$ that gives rise to ρ. Suppose for the moment that ρ is modular, so that $f_?$ exists. The Eisenstein series E_4 of level 1 and weight 4 is congruent to 1 modulo 5, so $E_4 \cdot \overline{f}_? \in S_5(N, \widetilde{\varepsilon}; \overline{\mathbf{Q}})$ reduces modulo a prime above 5 to a form which is an eigenform for all Hecke operators T_q for $q \neq 5$ prime, with the same eigenvalues mod 5 as $f_?$, and hence is a mod 5 weight 5 eigenform giving rise to the mod 5 reduction of ρ. Using a computer, we can search for such a mod 5 eigenform. In practice one computes a $\mathbf{Z}[\zeta_3]$-lattice in $S_5(N, \widetilde{\varepsilon}; \mathbf{Q}(\zeta_3))$ and then reduces the lattice modulo 5; we refer to the resulting quotient space as $S_5(N, \varepsilon; \mathbf{F}_{25})$, abusing notation slightly, where ε denotes the reduction of $\widetilde{\varepsilon}$. (Similarly we write ε_2 and ε_{43} to be the reductions of $\widetilde{\varepsilon}_2$ and $\widetilde{\varepsilon}_{43}$.) We search for an eigenform f in this mod 5 space of modular forms, whose existence is assured if we believe Artin's conjecture.

Instead of multiplying $\overline{f}_?$ by E_4, we could have multiplied it by an appropriate Eisenstein series of weight 1 and level 5. We used E_4 because the dimension of $S_5(N, \varepsilon; \overline{\mathbf{F}}_5)$ is 696 whereas the dimension of the relevant space $S_2(5 \cdot N, \varepsilon_{43})$ of weight 2 cusp forms is 1040.

1.1. Searching for the newform f. Using modular symbols we compute the space $S_5(1376, \varepsilon; \mathbf{F}_{25})$. By computing the kernels of various Hecke operators on this space, we find f. In the following computations, we represent nonzero elements of $\mathbf{F}_{25}$ as powers of a generator α of $\mathbf{F}_{25}^*$, which satisfies

$$\alpha^2 + 4\alpha + 2 = 0.$$

If 2 is the least common multiple of the degrees of the factors of the polynomial h modulo an unramified prime p, then $\mathrm{Frob}_p \in \mathrm{Gal}(K/\mathbf{Q})$ has order 2, hence trace 0. The first three such p are $19, 31, 97$. We computed the mod 5 reduction $S_5(1376, \varepsilon; \mathbf{F}_{25}) = \boldsymbol{\mathcal{S}}_5(1376, \varepsilon; \mathbf{F}_{25})^+$ of the $\mathbf{Z}_5[\zeta_3]$-lattice of modular symbols of level 1376 and character ε, where complex conjugation acts as $+1$. The intersection V of the kernels of T_{19}, T_{31}, and T_{97} inside $\boldsymbol{\mathcal{S}}_5(1376, \varepsilon; \mathbf{F}_{25})^+$ has dimension 8, and no doubt all the eigenforms in this space give rise to ρ or one of its twists. One of the eigenvalues of T_3 on this space is α^{16}, and the kernel V_1 of $T_3 - \alpha^{16}$ is 2-dimensional over $\mathbf{F}_{25}$. The Hecke operator T_5 acted as a diagonalizable matrix on V_1, with eigenvalues α^{10} and α^{22}, so the corresponding two systems of eigenvalues must correspond to mod 5 modular eigenforms, and furthermore we must have found all mod 5 modular eigenforms $\sum a_n q^n$ of this level, weight and character, such that $a_{19} = a_{31} = a_{97} = 0$ and $a_3 = \alpha^{16}$.

Remark 1.2. The careful reader might wonder how we know that the systems of mod 5 eigenvalues really do correspond to mod 5 modular forms, and not to perhaps some strange mod 5 torsion in the space of modular symbols.

Table 1. Eigenvalues of f.

2	0	59	4	137	0	227	α^{10}	313	0	419	3	509	α^{8}
3	α^{16}	61	α^{14}	139	α^{22}	229	0	317	0	421	α^{20}	521	α^{10}
5	α^{22}	67	α^{4}	149	α^{4}	233	α^{14}	331	α^{14}	431	4	523	α^{14}
7	α^{14}	71	α^{20}	151	1	239	0	337	0	433	α^{4}	541	α^{20}
11	4	73	α^{2}	157	α^{14}	241	α^{2}	347	α^{16}	439	α^{20}	547	α^{22}
13	α^{14}	79	α^{20}	163	0	251	α^{2}	349	α^{4}	443	0	557	3
17	α^{14}	83	α^{4}	167	α^{22}	257	3	353	0	449	0	563	1
19	0	89	α^{10}	173	4	263	α^{16}	359	0	457	0	569	α^{16}
23	α^{16}	97	0	179	α^{2}	269	2	367	α^{22}	461	0	571	α^{22}
29	α^{8}	101	α^{8}	181	α^{14}	271	α^{8}	373	0	463	α^{10}	577	α^{14}
31	0	103	α^{14}	191	α^{10}	277	0	379	3	467	0	587	α^{20}
37	α^{10}	107	0	193	4	281	α^{16}	383	3	479	0	593	0
41	1	109	α^{10}	197	0	283	0	389	1	487	α^{8}	599	α^{22}
43	α^{10}	113	2	199	3	293	3	397	α^{16}	491	α^{2}	601	0
47	1	127	0	211	0	307	α^{4}	401	0	499	α^{20}	607	α^{16}
53	α^{22}	131	2	223	0	311	α^{22}	409	2	503	α^{2}	613	2

However, we eliminated this possibility by computing the dimension of the full space of mod 5 modular symbols where complex conjugation acts as $+1$, and checking that it equals 696, the dimension of $S_5(1376, \widetilde{\varepsilon}, \mathbf{C})$, which we computed using the formula in [6].

Let f be the eigenform in V_1 that satisfies $a_5 = \alpha^{22}$; the q-expansion of f begins

$$f = q + \alpha^{16}q^3 + \alpha^{22}q^5 + \alpha^{14}q^7 + \alpha^{14}q^9 + 4q^{11} + \cdots .$$

Further eigenvalues are given in Table 1. The primes p in the table such that $a_p = 0$ are exactly those predicted by considering the splitting behavior of h. This is strong evidence that ρ is modular, and also that our modular symbols algorithms have been correctly implemented.

1.2. Twisting into $\mathrm{GL}(2, \mathbf{F}_5)$**.** Although there is a representation $\rho_f : G_{\mathbf{Q}} \to \mathrm{GL}(2, \mathbf{F}_{25})$ attached to the weight 5 mod 5 eigenform f, it is difficult to say anything about its image without further work. We use a trick to show that the image of ρ_f is small. Firstly, for a character $\chi : G_{\mathbf{Q}} \to \overline{\mathbf{F}}_5$, let $\widetilde{\chi}$ denote its Teichmüller lift to $\overline{\mathbf{Q}}_5$. Consider the $\mathbf{Z}$-algebra of Hecke operators acting on $S_5(N, \widetilde{\varepsilon}; \overline{\mathbf{Q}}_5)$. By choosing a minimal prime under the maximal ideal of this algebra corresponding to f, we see that there is a characteristic 0 eigenform $\widetilde{f} \in S_5(N, \widetilde{\varepsilon}; \overline{\mathbf{Q}}_5)$ lifting f.

The component ε_{43} of ε at 43 is represented by the map sending $(1, 3) \in (\mathbf{Z}/2^5\mathbf{Z})^* \times (\mathbf{Z}/43\mathbf{Z})^*$ to $2\alpha + 1$ and sending the subgroup $(\mathbf{Z}/2^5\mathbf{Z})^* \times \{1\}$

Table 2. Eigenvalues of $g = f \otimes \varepsilon_{43}$.

to 1. Note that 3 is a primitive root mod 43, and that $2\alpha+1$ has order 3. The complementary character ε_2 is defined by $\varepsilon = \varepsilon_2 \cdot \varepsilon_{43}$. The twist $\widetilde{g} = \widetilde{f} \otimes \widetilde{\varepsilon}_{43}$ is, by [14, Prop. 3.64], an eigenform in $S_5(43N, \widetilde{\varepsilon}_2; \overline{\mathbf{Q}}_5)$, and its reduction is a form $g \in S_5(43N, \varepsilon_2; \mathbf{F}_{25})$. The eigenvalues $a_p(g) = a_p(f)\varepsilon_{43}(p)$, for the first few $p \nmid 5N$, are given in Table 2.

Proposition 1.3. *Let $g = f \otimes \varepsilon_{43}$. Then $a_p(g) \in \mathbf{F}_5$ for all $p \nmid 5N$.*

Proof. Consider an eigenform $\widetilde{f} \in S_5(N, \widetilde{\varepsilon}; \overline{\mathbf{Q}}_5)$ lifting f as above. Associated to $\widetilde{f}$ there is an automorphic representation $\pi = \otimes'_v \pi_v$ of $\mathrm{GL}(2, \mathbf{A})$, where $\mathbf{A}$ is the adèle ring of $\mathbf{Q}$. Because $43 \mid\mid N$, and 43 divides the conductor of ε, we see that the local component π_{43} of π at 43 must be ramified principal series. By the compatibility of the local and global Langlands correspondence, proved by Deligne, Langlands and Carayol, we see that $\rho_{\widetilde{f}}|_{D_{43}} \sim \left(\begin{smallmatrix}\Psi_1 & 0\\ 0 & \Psi_2\end{smallmatrix}\right)$ with, without loss of generality, Ψ_2 unramified. We have $(\Psi_1 \cdot \Psi_2)|_{I_{43}} = \widetilde{\varepsilon}|_{I_{43}} = \widetilde{\varepsilon}_{43}$, therefore, $\rho_{\widetilde{f}}|_{I_{43}} \sim \left(\begin{smallmatrix}\widetilde{\varepsilon}_{43} & 0\\ 0 & 1\end{smallmatrix}\right)$.

Now twist $\widetilde{f}$ by $\widetilde{\varepsilon}_{43}^{-1}$; we find that $\rho_{\widetilde{f} \otimes \widetilde{\varepsilon}_{43}^{-1}}|_{I_{43}} \sim \left(\begin{smallmatrix}1 & 0\\ 0 & \widetilde{\varepsilon}_{43}^{-1}\end{smallmatrix}\right)$. In particular, there is an eigenform $\widetilde{f}' \in S_5(N, \widetilde{\varepsilon}_2\widetilde{\varepsilon}_{43}^{-1}; \overline{\mathbf{Q}}_5)$ whose associated Galois representation is the twist by $\widetilde{\varepsilon}_{43}^{-1}$ of that of $\widetilde{f}$ (recall that $N = 1376$ so 43 divides N exactly once). Let f' denote the mod 5 reduction of $\widetilde{f}'$. Then one checks easily that $f' \in S_5(N, \varepsilon_2\varepsilon_{43}^{-1}; \mathbf{F}_{25}) = S_5(N, \varepsilon^5; \mathbf{F}_{25})$.

For all primes $p \nmid 5N$ we have $a_p(f') = \varepsilon_{43}(p)^{-1}a_p(f)$. In particular, we have $a_p(f') = 0$ for $p = 19, 31$. Also, $\varepsilon_{43}(3) = \alpha^8$ and $\varepsilon_{43}(5) = \alpha^8$, so

$$a_3(f') = \alpha^{16}/\alpha^8 = \alpha^8 = (\alpha^{16})^5$$

$$a_5(f') = \alpha^{22}/\alpha^8 = \alpha^{14} = (\alpha^{22})^5.$$

Now if σ is the nontrivial automorphism of $\mathbf{F}_{25}$, then $\sigma(f')$ and f both lie in $S_5(1376, \varepsilon; \mathbf{F}_{25})$ and have the same a_p for $p = 3, 5, 19, 31$, so they are equal because we found f by computing the unique eigenform with given a_p for $p = 3, 5, 19, 31$. So $g = f \otimes \varepsilon_{43} = \sigma(f) \otimes \varepsilon_{43}^2$. Thus for all $p \nmid 5N$, we see that $a_p(g) = a_p(f)^5\varepsilon_{43}^2$ has fifth power $a_p(g)^5 = a_p(f)^{25}\varepsilon_{43}^{10} = a_p(f)\varepsilon_{43} = a_p(g)$. □

1.3. Proof that ρ_g is unramified at 5. We begin with a generalization of [16]. Let $M > 4$ be an integer, and let $h = \sum_{n \geq 1} c_n q^n$ be a normalized cuspidal eigenform of some weight $k \geq 1$, level M and character χ, defined over some field of characteristic not dividing M. Even though the base field might not have characteristic zero, we may still define the conductor of χ to be the smallest divisor f of M such that χ factors through $(\mathbf{Z}/f\mathbf{Z})^\times$. Let I be a set of primes, with the property that for all p in I, one of the following conditions hold:

(i) p divides M but p does not divide $M/\operatorname{cond}(\chi)$, or

(ii) p divides M exactly once, and h is p-new, in the sense that there is no eigenform h' of level M/p such that the T_n-eigenvalues of h and h' agree for all n prime to p.

Let C denote the orbit of the cusp ∞ in $X_1(M)$ under the action of the group generated by w_p for $p \in I$, and the Diamond operators $\langle d \rangle_M$. The orbit of ∞ under the Diamond operators has size $\phi(M)/2$, and each w_p increases the size of the orbit by a factor of 2. In this situation, we have:

Lemma 1.4. *The first t terms of the q-expansion of h at any cusp in C are determined by M, k, χ, c_p for p in I, and c_n for $1 \leq n \leq t$.*

Remark 1.5. Our proof is just a translation of Corollary 4.6.18 of [13] into the language of moduli problems (Miyake's argument technically is only valid over the complex numbers).

Proof. If $J \subseteq I$ is any subset, and w_J denotes the product of w_p for $p \in J$, then $h|w_J$ is an eigenform for all the Diamond operators, and this observation reduces the proof of the lemma to showing that for $p \in I$, if $h|w_p = \sum_m d_m q^m$, then d_j for $1 \leq j \leq n$ and d_q for all $q \in I$ are determined by M, k, χ, p, c_j for $1 \leq j \leq n$ and c_q for all $q \in I$.

We first deal with primes p of the form (i). Say $M = p^m R$, where R is prime to p. Thinking of h as a rule for attaching k-fold differentials to elliptic curves equipped with points of order p^m and R, we have by definition that

$$h(\mathbf{G}_m/q^{\mathbf{Z}}, \zeta, \zeta_R) = \left(\sum c_n q^n\right)(dt/t)^k,$$

where $\zeta = \zeta_{p^m}$ and ζ_R are fixed p^mth and Rth roots of unity in $\mathbf{G}_m$ which correspond to the cusp ∞, and dt/t is the canonical differential on the Tate curve $\mathbf{G}_m/q^{\mathbf{Z}}$. We normalize things such that

$$h(\mathbf{G}_m/q^{p^m\mathbf{Z}}, q, \zeta_R) = \left(\sum d_n q^n\right)(dt/t)^k,$$

and remark that because h is an eigenvector for the Diamond operators, we do not have to worry too much about whether this corresponds to the standard normalization of the w_p-operator.

We recall that the operator pU_p in this setting can be thought of as being defined by the rule:

$$(pU_p h)(E, P, Q) = \sum_C \pi^* h(E/C, \overline{P}, \overline{Q}),$$

where C runs through the subgroups of E of order p which have trivial intersection with $\langle P\rangle$, and π denotes the canonical projection $E \to E/C$. We see that

$$\begin{aligned}(pc_p)^m\left(\sum d_n q^n\right)(dt/t)^k &= (p^m U_{p^m} h)(\mathbf{G}_m/q^{p^m\mathbf{Z}}, q, \zeta_R)\\ &= \sum_{c=0}^{p^m-1} \pi^* h(\mathbf{G}_m/\langle q^{p^m}, \zeta q^c\rangle, q, \zeta_R),\end{aligned}$$

where π denotes the canonical projection from $\mathbf{G}_m/\langle q^{p^m}\rangle$ to the appropriate quotient. This last sum can be written as a double sum

$$\begin{aligned}&\sum_{c\in(\mathbf{Z}/p^m\mathbf{Z})^\times} \pi^* h(\mathbf{G}_m/\langle q^{p^m}, \zeta q^c\rangle, q, \zeta_R) + \sum_{a=0}^{p^{m-1}-1} \pi^* h(\mathbf{G}_m/\langle q^{p^m}, \zeta q^{pa}\rangle, q, \zeta_R)\\
&= \sum_{b\in(\mathbf{Z}/p^m\mathbf{Z})^\times} \pi^* h(\mathbf{G}_m/\langle q^{p^m}, \zeta^{-b} q\rangle, q, \zeta_R)\\
&\quad + p^{m-1}\pi^* U_{p^{m-1}} h(\mathbf{G}_m/\langle q^{p^m}, \zeta^{p^{m-1}}\rangle, q, \zeta_R)\\
&= \sum_{b\in(\mathbf{Z}/p^m\mathbf{Z})^\times} \pi^* h(\mathbf{G}_m/\langle \zeta^{-b} q\rangle, \zeta^b, \zeta_R)\\
&\quad + (pc_p)^{m-1}\pi^* h(\mathbf{G}_m/\langle q^{p^m}, \zeta^{p^{m-1}}\rangle, q, \zeta_R)\\
&= \sum_b \chi_p(b) \sum_{n\geq 1} c_n(\zeta^{-b}q)^n (dt/t)^k + p^k (pc_p)^{m-1}\pi^* h(\mathbf{G}_m/\langle q^{p^{m+1}}\rangle, q^p, \zeta_R^p),\end{aligned}$$

where we have written $\chi = \chi_R\chi_p$, for χ_R a character of level R and χ_p a character of level p^m. We deduce that

$$\begin{aligned}&(pc_p)^m \left(\sum d_n q^n\right)(dt/t)^k - p^k(pc_p)^{m-1}\chi_R(p)\pi^* h(\mathbf{G}_m/\langle q^{p^{m+1}}\rangle, q^p, \zeta_R)\\&= \left(\sum_n \left(\sum_b \chi_p(b)\zeta^{-bn}\right) c_n q^n\right)(dt/t)^k\\&= W(\chi_p)\left(\sum_{p\nmid n}\chi_p(-n)^{-1}c_n q^n\right)(dt/t)^k\end{aligned}$$

where $W(\chi_p) = \sum_{b\in(\mathbf{Z}/p^m\mathbf{Z})^\times}\chi_p(b)\zeta^b$ can be checked to be nonzero because the conductor of χ_p is p^m. Hence

$$\begin{aligned}&(pc_p)^m \sum_n d_n q^n - p^k(pc_p)^{m-1}\chi_R(p)\sum_n d_n q^{np}\\&= W(\chi_p)\chi_p(-1)\sum_{p\nmid n}\chi_p(n)^{-1}c_n q^n.\end{aligned}$$

Equating coefficients of q we deduce that $W(\chi_p)\chi_p(-1) = (pc_p)^m d_1$, and because $h|w_p$ is an eigenform for T_n for all n prime to p, with eigenvalues determined by χ and c_n, we deduce that we can determine d_n for n prime to p from c_n. It remains to establish what d_p is, and equating coefficients of q^p in the above equation gives us that $(pc_p)^m d_p = p^k(pc_p)^{m-1}\chi_R(p)d_1$ and hence that d_p is determined by χ and c_p. Note that as a consequence we see that $d_p/d_1 = p^{k-1}\chi_R(p)/c_p$, a classical formula if the base field is the complexes.

Now we deal with primes of the form (ii) (note that we never use this case in the rest of the paper). We think of h as a rule associating k-fold differentials to triples (E, C, Q) where C a cyclic subgroup of order p and Q a point of order $R = M/p$. Because h is p-new, the trace of h down to $X_1(M/p)$ must be zero, and hence we see that for any elliptic curve E equipped with a point Q of order R,

$$\sum_C \pi^* h(E/C, E[p]/C, \overline{Q}) = 0.$$

As before, normalize things so that

$$h(\mathbf{G}_m/q^{\mathbf{Z}}, \mu_p, \zeta_R) = \left(\sum_n c_n q^n\right)(dt/t)^k$$

and

$$h(\mathbf{G}_m/q^{p\mathbf{Z}}, \langle q\rangle, \zeta_R) = \left(\sum_n d_n q^n\right)(dt/t)^k.$$

The fact that the trace of h is zero implies that

$$(pU_p)h(\mathbf{G}_m/q^{p\mathbf{Z}},\langle q\rangle,\zeta_R)+\pi^*h(\mathbf{G}_m/q^{\mathbf{Z}},\mu_p,\zeta_R)=0,$$

and hence that

$$c_p\sum d_nq^n+p^{k-1}\sum c_nq^n=0$$

from which we deduce that the d_n can be read off from c_p and the c_n. □

Remark 1.6. The size of C is $\phi(M)\cdot 2^{|I|-1}$, and the usefulness of this lemma is that if h_1 and h_2 are two normalized eigenforms of the same level, weight and character as above, both new at all primes in I, and the coefficients of q^n in the q-expansions of h_1 and h_2 agree for $n\in I$ and $n\leq t$, then h_1-h_2 has a zero of order at least $t+1$ at all cusps in C, and in particular if $\phi(M)\cdot 2^{|I|-1}(t+1)>\frac{k}{24}[\mathrm{SL}_2(\mathbf{Z}):\Gamma_1(M)]=\deg(\omega^k)$ on $X_1(M)$ then $h_1=h_2$. Using the fact that $[\Gamma_0(M):\Gamma_1(M)]=\phi(M)$, we deduce:

Corollary 1.7. *Let h_1 and h_2 be two normalized eigenforms as above. If the coefficients of q^n in the q-expansions of h_1 and h_2 agree for all primes in I and for all $n\leq\frac{k}{12}[\mathrm{SL}_2(\mathbf{Z}):\Gamma_0(M)]/2^{|I|}$ then $h_1=h_2$.*

Remark 1.8. One can certainly do better than this corollary in many cases. For example, when $n>1$ and p^n exactly divides both the level of an eigenform and the conductor of its character, then one can compute the q-expansion of the eigenform at many "middle cusps" too, and hence increase the size of C in the result above. The general result however is rather messy to state and prove, and so for simplicity we have chosen to prove only what we needed in the cases we were interested in.

We now go back to the explicit situation we are concerned with. Although g is an eigenform of level $59168=2^5\cdot 43^2$, we can still consider the corresponding representation $\rho_g:G_{\mathbf{Q}}\to\mathrm{GL}(2,\mathbf{F}_5)$, and then directly analyze its ramification.

Proposition 1.9. *The representation ρ_g is unramified at 5.*

Proof. Continuing the modular symbols computations as above, we find that V_1 is spanned by the two eigenforms

$$\begin{aligned}f\ &=q+\alpha^{16}q^3+\alpha^{22}q^5+\alpha^{14}q^7+\alpha^{14}q^9+4q^{11}+\cdots\\ f_1&=q+\alpha^{16}q^3+\alpha^{10}q^5+\alpha^{14}q^7+\alpha^{14}q^9+4q^{11}+\cdots.\end{aligned}$$

For $p\neq 5$ and $p\leq 997$, we have $a_p(f_1)=a_p(f)$. To check that $a_p(f)=a_p(f_1)$ for all $p\neq 5$, it suffices to show that the difference $f-f_1$ has q-expansion involving only powers of q^5; for this we use the θ-operator $q\frac{d}{dq}:S_5(1376,\varepsilon;\mathbf{F}_{25})\to S_{11}(1376,\varepsilon;\mathbf{F}_{25})$. Since θ sends normalized eigenforms to normalized eigenforms, it suffices to check that the subspace of $S_{11}(1376,\varepsilon;\mathbf{F}_{25})$ generated by $\theta(f)$ and $\theta(f_1)$ has dimension 1. Corollary 1.7

implies that it suffices to verify that the coefficients $a_p(\theta(f))$ and $a_p(\theta(f_1))$ are equal for all

$$p \leq \frac{11}{12} \cdot [\mathrm{SL}_2(\mathbf{Z}) : \Gamma_0(1376)] \cdot \frac{1}{2} = 968.$$

The eigenform f must be new because we computed it by finding the intersections of the kernels of Hecke operators T_p with $p \nmid 1376$; if f were an oldform then the intersection of the kernels of these Hecke operators would necessarily have dimension greater than 1. Because it takes less than a second to compute each $a_p(\theta(f))$, we were easily able to verify that the space generated by $\theta(f)$ and $\theta(f_1)$ has dimension 1.

Remark 1.10. In this example (but not some of the other seven examples!) it is possible to avoid appealing to Corollary 1.7 by using one of the following two alternative methods:

1) Define θ directly on modular symbols and compute it. On modular symbols, the analogue of the θ operator seems to be multiplication by $X^pY - XY^p$; thus, if $p = k = 5$ then $\theta(X^3\{0,\infty\}) = (X^8Y - X^4Y^5)\{0,\infty\}$. The main point in the proof is that one can check easily from the definitions that $T_q\theta = q\theta T_q$ for q a good prime, and hence this map theta must correspond with the "classical" theta up to a constant; one should perhaps worry that this constant could be zero, but in practice given an f one can check explicitly that $\theta(f) \neq 0$ by direct computation.
2) Compute the intersection

$$\bigcap_{p \geq 2} \ker(T_p - pa_p(f)) \subset S_{11}(1376, \varepsilon; \mathbf{F}_{25}).$$

Since $\theta(f)$ and $\theta(f_1)$ both lie in the intersection, the moment the dimension of a partial intersection is 1, it follows that $\theta(f - f_1) = 0$.

We successfully carried out both alternatives. For the second, we find that after intersecting kernels for $p \leq 11$, the dimension is already 1. The first of these two methods took much less time than the second.

Next we use that $\theta(f - f_1) = 0$ to show that ρ_g is unramified, thus finishing the proof of the proposition. Since f is ordinary, Deligne's theorem (see [9, §12]) implies that

$$\rho_f|_{D_5} \sim \begin{pmatrix} \gamma & * \\ 0 & \delta \end{pmatrix} \qquad \text{over } \overline{\mathbf{F}}_5$$

with γ and δ unramified characters, $\gamma(\mathrm{Frob}_5) = \varepsilon(5)/a_5 = \alpha^8/\alpha^{22} = \alpha^{10}$, and $\delta(\mathrm{Frob}_5) = \alpha^{22}$. Since $a_p(f_1) = a_p(f)$, for $p \neq 5$, we have

$$\rho_f|_{D_5} \sim \rho_{f_1}|_{D_5} \sim \begin{pmatrix} \gamma' & * \\ 0 & \delta' \end{pmatrix}$$

with $\gamma'(\mathrm{Frob}_5) = \alpha^8/\alpha^{10} = \alpha^{22}$ and $\delta'(\mathrm{Frob}_5) = \alpha^{10}$; in particular, $\gamma' = \delta$. Thus $\rho_f|_{D_5}$ contains $\gamma \oplus \delta$, so $\rho_f|_{D_5} \sim \gamma \oplus \delta$ and hence there is a choice of basis so that $* = 0$. □

1.4. The image of $\operatorname{proj} \rho_g$.

Proposition 1.11. *The image of* $\operatorname{proj} \rho_g$ *is* A_5.

Proof. The image H of $\operatorname{proj} \rho_g$ in $\mathrm{PGL}_2(\mathbf{F}_5)$ is easily checked to lie in $\mathrm{PSL}_2(\mathbf{F}_5) \cong A_5$ because of what we know about the determinant of ρ_g. Hence H is a subgroup of A_5 that contains an element of order 2 (complex conjugation) and an element of order 3 (for example, $\rho_g(\mathrm{Frob}_7)$ has characteristic polynomial $x^2 - 2x - 1$). This proves that H is isomorphic to either S_3, A_4, or A_5. Let L be the number field cut out by H. If L were an S_3-extension, then there would be a quadratic extension contained in it which is unramified outside $2 \cdot 5 \cdot 43$; it is furthermore unramified at 5 by the previous section and unramified at 43 because I_{43} has order 3. Thus it is one of the three quadratic fields unramified outside 2. In particular, the trace of Frob_p would be zero for all primes in a certain congruence class modulo 8. However, there are primes p congruent to 3, 5, and 7 mod 8 such that $a_p(g) \neq 0$, e.g., 3, 7, and 13.

If H were isomorphic to A_4, then let M denote the cyclic extension of degree 3 over $\mathbf{Q}$ contained in L. Now M is unramified at 2 and 5, and hence is the subfield of $\mathbf{Q}(\zeta_{43})$ of degree 3. Choose $p \nmid 1376 \cdot 5$ that is inert in M, i.e., so that p is not a cube mod 43. The order of $\rho_g(\mathrm{Frob}_p)$ in $\mathrm{GL}_2(\mathbf{F}_5)$ must be divisible by 3. However, a quick check using Table 2 shows that this is not the case for $p = 3$. □

1.5. Bounding the ramification at 2 and 43.

Let L be the fixed field of $\ker(\operatorname{proj}(\rho_g))$. We have just shown that $\mathrm{Gal}(L/\mathbf{Q})$ is isomorphic to A_5. By a root field for L, we mean a non-Galois extension of $\mathbf{Q}$ of degree 5 whose Galois closure is L.

Proposition 1.12. *The discriminant of a root field for L divides* $(43\cdot 8)^2 = 344^2$*, and in particular, L must be mentioned in Table* 1 *of* [8, pg. 122].

Proof. The analysis of the local behavior of ρ_f at 43 given in Proposition 1.3 shows that the inertia group at 43 in $\mathrm{Gal}(L/\mathbf{Q})$ has order 3. Using Table 3.1 of [3], we see that if $\mathrm{Gal}(L/\mathbf{Q}) \cong A_5$ then it must be of type 2 at 43, and hence the discriminant of a root field of L, that is, of a non-Galois extension of $\mathbf{Q}$ of degree 5 whose Galois closure is L, must be 43^2 at 43.

At 2 the behavior of ρ is more subtle and we shall not analyze it fully. But we can say that, because ρ has arisen from a form of level $1376 = 2^5 \cdot 43$, we must be either of type 5 or one of types 14–17, in the notation of Table 3.2 of [3]. In particular, the discriminant at 2 of a root field for L will be at most 2^6.

Finally, L is unramified at all other primes, because ρ is. Hence the discriminant of a root field for L, assuming that $\mathrm{Gal}(L/\mathbf{Q}) \cong A_5$, divides $(43.8)^2 = 344^2$. □

We know that L is an icosahedral extension of $\mathbf{Q}$ with discriminant dividing $43^2 \cdot 2^6$. Table 1 of [8, p. 122] contains all icosahedral extensions, such that the discriminant of a root field is bounded by 2083^2. The table must contain L; there is only one icosahedral extension with discriminant dividing $43^2 \cdot 2^6$, so $L = K$.

1.6. Obtaining a classical weight one form. We have shown that a twist of the icosahedral representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \mathbf{C})$, obtained by lifting $G_{\mathbf{Q}} \to \mathrm{Gal}(K/\mathbf{Q}) \approx A_5$, has a mod 5 reduction $\rho_g : G_{\mathbf{Q}} \to \mathrm{GL}_2(\mathbf{F}_5)$ that is modular. Since ρ ramifies at only finitely many primes, and ρ is unramified at 5 with distinct eigenvalues, [5] implies that ρ arises from a classical weight 1 newform.

2. More examples.

The data necessary to deduce modularity of each of our eight icosahedral examples is summarized in Tables 3–6.

Table 3. Data on icosahedral representations mod 5.

N	h	$\mathrm{ord}(\mathrm{Frob}_5)$	p with $a_p = 0$	ε	$\dim S_5(N, \varepsilon)$
1376	$[2, 6, 8, 10, 8]$	2	$19, 31, 97$	$[2, 1, 3]$	696
2416	$[0, -2, 2, 5, 6]$	2	$53, 97, 127$	$[2, 1, 3]$	1210
3184	$[5, 8, -20, -21, -5]$	2	$31, 89, 97$	$[2, 1, 3]$	1594
3556	$[3, 9, -6, -4, -40]$	3	$19, 29, 89$	$[1, 2, 3]$	2042
3756	$[0, -3, 10, 30, -18]$	3	$17, 61, 67$	$[1, 2, 3]$	2506
4108	$[4, 3, 9, 4, 5]$	3	$17, 23, 31, 89$	$[1, 3, 2]$	2234
4288	$[4, 5, 8, 3, 2]$	3	$19, 23, 47$	$[1, 2, 3]$	2164
5373	$[2, 1, 7, 23, -11]$	2	$7, 23, 37, 79, 89$	$[2, 3]$	2394

The notation in Table 3 is as follows. The first column contains the conductor. The second column contains a 5-tuple $[a_4, a_3, a_2, a_1, a_0]$ such that the A_5-extension is the splitting field of the polynomial $h = x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0$. The column labeled $\mathrm{ord}(\mathrm{Frob}_5)$ contains the order of the image of Frob_5 in A_5. The next column, which is labeled "p with $a_p = 0$", contains the first few p such that a_p is easily seen to equal 0 by considering the splitting of h mod p. The ε column contains the character of the representation, where the notation is as follows. Write $(\mathbf{Z}/N\mathbf{Z})^*$ as a product of cyclic groups corresponding to the prime divisors of N in ascending order, and then the tuples give the orders of the images of these

Table 4. The newform f and the companion form bound.

1376	$q+\alpha^{16}q^3+\alpha^{22}q^5+\alpha^{14}q^7+\alpha^{14}q^9+4q^{11}+\alpha^{14}q^{13}+\cdots$	968
2416	$q+3q^3+\alpha^{22}q^5+\alpha^{16}q^7+\alpha^{4}q^{11}+\alpha^{2}q^{13}+\alpha^{16}q^{15}+\cdots$	1672
3184	$q+\alpha^{16}q^3+3q^5+\alpha^{22}q^7+\alpha^{14}q^9+3q^{11}+\alpha^{22}q^{13}+\cdots$	2200
3556	$q+\alpha^{16}q^3+\alpha^{14}q^5+\alpha^{10}q^7+\alpha^{14}q^9+\alpha^{2}q^{11}+\alpha^{22}q^{13}+\cdots$	1408
3756	$q+\alpha^{14}q^3+\alpha^{14}q^5+3q^7+\alpha^{4}q^9+\alpha^{16}q^{11}+\alpha^{10}q^{13}+\cdots$	1727
4108	$q+\alpha^{16}q^3+\alpha^{11}q^5+\alpha^{20}q^7+\alpha^{14}q^9+\alpha^{10}q^{11}+4q^{13}+\cdots$	1540
4288	$q+3q^3+\alpha^{14}q^5+\alpha^{20}q^7+3q^9+\alpha^{20}q^{11}+\alpha^{16}q^{13}+\cdots$	2992
5373	$q+\alpha^{16}q^2+\alpha^{14}q^4+4q^5+3q^8+\alpha^{4}q^{10}+2q^{11}+\cdots$	3300

cyclic factors; when $8 \mid N$, there are two cyclic factors corresponding to the prime 2. Finally, the last column records the dimension of $S_5(\Gamma_1(N),\varepsilon)$.

The notation in Table 4 is as follows. The first column contains the conductor. The second column contains an eigenform that was found by first intersecting the kernels of the Hecke operators T_p with p as in Table 3, and then locating an eigenform. In each case, a companion form was found, by computing $a_p(f)$ for $p \leq$ bound, where bound is the bound from Corollary 1.7.

Table 5 shows that the fixed field of the image of each $\operatorname{proj}(\rho_g)$ is icosahedral. The first column contains the conductor N. The second column contains a twist g of f such that $a_p(g) \in \mathbf{F}_5$ for all $p \nmid 5N$. The third column contains a Frob_p such that $\operatorname{proj}(\rho_g(\mathrm{Frob}_p))$ has order 3, along with the characteristic polynomial of $\rho_g(\mathrm{Frob}_p)$. As in the proof of Proposition 1.11, the other two boxes give data that allows us to deduce that the fixed field of the image of $\operatorname{proj}(\rho_g)$ is icosahedral. The case 5373 must be treated separately, because there are three possibilities M_1, M_2, and M_3 for the cubic field M of the analogue of Proposition 1.11. For M_1 we find a prime p such that

$$(p^2 \mod 9,\;\; p^{66} \mod 199) \notin \{(1,1),(4,1),(7,1)\}$$

with $\rho_g(\mathrm{Frob}_p)$ of order not divisible by 3; for this, $p=2$ suffices, since the characteristic polynomial of $\rho_g(\mathrm{Frob}_2)$ is $(x+2)^2$ and $(p^2 \bmod 9,\; p^{66} \bmod 199) = (4,106)$. For M_2 we find a prime p such that

$$(p^2 \mod 9,\;\; p^{66} \mod 199) \notin \{(1,1),(4,92),(7,106)\}$$

with $\rho_g(\mathrm{Frob}_p)$ of order not divisible by 3; again, $p=2$ suffices. For M_3 we find a prime p such that

$$(p^2 \mod 9,\;\; p^{66} \mod 199) \notin \{(1,1),(4,106),(7,92)\}$$

with $\rho_g(\mathrm{Frob}_p)$ of order not divisible by 3; here, $p=13$ suffices, as the characteristic polynomial of $\rho_g(\mathrm{Frob}_p)$ is $(x+4)^2$ and $(p^2 \bmod 9,\;\; p^{66} \bmod 199) = (7,106)$.

Table 6 gives upper bounds on the ramification of the fixed field of the image of $\mathrm{proj}(\rho_g)$. These bounds were deduced using Table 3.1 of [3] by restricting the possible "types" using information about the character ε. Note that though the bounds are not sharp, e.g., the discriminant of the

representation of conductor 2416 is $2^4 \cdot 151^2$, they are all less than 2083^2, so the corresponding field must appear in Table 2 of [8].

3. Computing mod p modular forms.

3.1. Higher weight modular symbols. The second author developed software that computes the space of weight k modular symbols $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$, for $k \geq 2$ and arbitrary ε. See [12] for the standard facts about higher weight modular symbols, and [15] for a description of how to compute with them.

Let $K = \mathbf{Q}(\varepsilon)$ be the field generated by the values of ε. The cuspidal modular symbols $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$ are a finite dimensional vector space over K, which is generated by all linear combinations of higher weight modular symbols

$$X^i Y^{k-2-i}\{\alpha, \beta\}$$

that lie in the kernel of an appropriate boundary map. There is an involution $*$ that acts on $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)$, and $\boldsymbol{\mathcal{S}}_k(N, \varepsilon)^+ \otimes_K \mathbf{C}$ is isomorphic, as a module over the Hecke algebra, to the space $S_k(N, \varepsilon; \mathbf{C})$ of cusp forms.

Fix $k = 5$. In each case considered in this paper, there is a prime ideal λ of the ring of integers $\mathcal{O}$ of K such that $\mathcal{O}/\lambda \cong \mathbf{F}_{25}$. Let $\mathcal{L}$ be the $\mathcal{O}$-module generated by all modular symbols of the form $X^i Y^{3-i}\{\alpha, \beta\}$, and let

$$\boldsymbol{\mathcal{S}}_5(N, \varepsilon; \mathbf{F}_{25}) = (\mathcal{L} \cap \boldsymbol{\mathcal{S}}_5(N, \varepsilon)) \otimes_{\mathcal{O}} \mathbf{F}_{25}.$$

This is the space that we computed. The Hecke algebra acts on $\boldsymbol{\mathcal{S}}_5(N,\varepsilon; \mathbf{F}_{25})$, so when we find an eigenform we find a maximal ideal of the Hecke algebra.

As an extra check on our computation of $\boldsymbol{\mathcal{S}}_5(N, \varepsilon; \mathbf{F}_{25})$, we computed the dimension of $S_5(N, \varepsilon; \mathbf{C})$ using both the formula of [6] and the Hijikata trace formula (see [10]) applied to the identity Hecke operator.

3.2. Complexity. We implemented the modular symbols algorithms mentioned above in Magma (see [2]) because of its robust support for linear algebra over small finite fields.

The following table gives a flavor of the complexity of the machine computations appearing in this paper. The table indicates how much CPU time on a Sun Ultra E450 was required to compute all data for the given level, including the matrices T_p on the 2-dimensional spaces, for $p < 2000$. For example, the total time for level $N = 1376$ was 6 minutes and 58 seconds.

N	time (minutes)
1376	6:58
2416	10:42
3184	14:16
3556	19:55
3756	27:47
4108	23:11
4288	15:18
5376	24:49

Acknowledgment. Some of the computing equipment was purchased by the second author using a UC Berkeley Vice Chancellor Research Grant. Additional computer runs were made on the Sun Ultra E450 of the Computational Algebra Group at the University of Sydney. Allan Steel was very helpful in optimizing our code.

There are genus one curves over $\mathbb{Q}$ of every odd index

By *William A. Stein*[*] at Harvard University

Abstract. The index of a genus one curve X over a field K is the smallest degree of an extension L of K such that $X(L)$ is nonempty. Let K be a number field. We prove that for every integer r not divisible by 8, there is a genus one curve X over K of index r. Our proof involves an analysis of Kolyvagin's Euler system of Heegner points combined with explicit computations on the modular curve $X_0(17)$.

1. Introduction

How complicated are curves of genus one? One possible measure of the complexity of a curve is the smallest degree of an extension of the base field in which the curve has a point. Consider a curve X of positive genus g over a number field K. The canonical divisor class on X contains a K-rational effective divisor of degree $2g-2$, so the greatest common divisor of the degrees of the extension fields in which X has a rational point divides $2g-2$. When $g = 1$ this is no condition at all!

In the 1950s, S. Lang and J. Tate asked in [11] whether, given a positive integer r, there exists a genus one curve X such that r is the smallest of all degrees of extensions of K over which X has a point. Using Kolyvagin's Euler system of Heegner points, we answer their question in the affirmative, under the hypothesis that r is odd. The curves we produce are torsors for the elliptic curve $X_0(17)$, though our methods apply to a more general class of genus one curves. The following theorem is proved in Section 5.4.

Theorem 1.1. *Let K be a number field and let r be an integer not divisible by* 8. *Then there are infinitely many genus one curves over K of index r.*

In Section 2 we recall standard facts about indexes of genus one curves. Section 3 contains a brief discussion of Heegner points, and summarizes the relevant results about Kolyvagin's Euler system from [18]. In Section 4, which forms the heart of our paper, we prove a nonvanishing result for Kolyvagin's cohomology classes. Finally, in Section 5, we

[*] Supported by an NSF Mathematical Sciences Postdoctoral Research Fellowship.

prove Theorem 1.1 by combining a general result about Galois representations with explicit computations on $X_0(17)$.

Acknowledgement. The author would like to thank H. Lenstra for introducing him to this problem, K. Buzzard for teaching him about Kolyvagin's Euler system, K. Rubin and M. Flach for extensive comments, D. Y. Logachev, C. O'Neil, and K. Ribet for inspiring conversations, and N. Elkies and G. Grigorov for useful comments.

2. Indexes of genus one curves

Let E be an elliptic curve over an arbitrary field k. The Galois cohomology group $H^1(k,E) = H^1\big(\mathrm{Gal}(k^{\mathrm{sep}}/k), E(k^{\mathrm{sep}})\big)$ classifies the isomorphism classes of torsors (principal homogeneous spaces) for E over k.

Definition 2.1 (Index of cohomology class). The *index* of $c \in H^1(k,E)$, denoted $\mathrm{ind}(c)$, is the greatest common divisor of the degrees of the separable extensions K of k for which $\mathrm{res}_K(c) = 0$.

The torsor X corresponding to c is a genus one curve over k equipped with an action of E. Furthermore, $X(K) \neq \emptyset$ exactly when $\mathrm{res}_K(c) = 0$, so

$$\mathrm{ind}(c) = \gcd\{[K:k] \colon X(K) \neq \emptyset\}.$$

Thus $\mathrm{ind}(c)$ generates the image of the degree map $\deg\colon \mathrm{Div}_k(X) \to \mathbb{Z}$. We now define $\mathrm{ind}(X)$ so that $\mathrm{ind}(X) = \mathrm{ind}(c)$.

Definition 2.2 (Index of curve). The *index* of an algebraic curve over k is the cardinality of the cokernel of the degree map.

Any canonical divisor is an element of $\mathrm{Div}_k(X)$ of degree $2g-2$, where g is the genus of X, so $\mathrm{ind}(X)$ divides $2g-2$. As mentioned in the introduction, when $g = 1$ this is no condition; in fact, E. Artin conjectured, and Lang and Tate proved in [11], pg. 670, that for every integer r there is some genus one curve X over some field L such that $\mathrm{ind}(X) = r$. The construction of [11] requires the existence of an L-rational point of order r on the elliptic curve $E = \mathrm{Jac}(X)$. The torsion subgroups of elliptic curves are "uniformly bounded", so for K a fixed number field and for almost all r, the results of [11] do not imply the existence of genus one curves over K of index r.

Let E be an elliptic curve over a number field K, and let r be a positive integer. Is there an element of $H^1(K,E)$ of index r? In [21], Shafarevich proved that $H^1(K,E)$ contains infinitely many elements of every *order* (see also [5], §27 where Cassels sketches an alternative approach to proving Shafarevich's theorem). However, this does not answer the question of Artin, because the order need not equal the index as Cassels remarked in [4], where he found an elliptic curve E and a class $c \in H^1(\mathbb{Q},E)$ such that c has order 2 and index 4.

2.1. Elementary facts about the index. We pause to state some basic facts about the order and index, which we will use later. Fix an elliptic curve E over a number field K, and let c and c' be elements of $H^1(K,E)$.

Proposition 2.3. $\mathrm{ord}(c) \mid \mathrm{ind}(c)$, *and they have the same prime factors.*

Proof. See [11], §2, Prop. 5. □

Lemma 2.4. *There is an extension L of K such that* $[L:K] = \mathrm{ind}(c)$ *and* $\mathrm{res}_L(c) = 0$.

Proof. See the paragraph before the corollary in [11], §2. □

Proposition 2.5. *Suppose* c' *has order coprime to* c. *Then* $\mathrm{ind}(c + c') = \mathrm{ind}(c) \cdot \mathrm{ind}(c')$.

Proof. If M is a field that splits $c + c'$, then M also splits $\mathrm{ord}(c')(c + c') = \mathrm{ord}(c')c$, so M splits c. Likewise, M splits c', so $\mathrm{ind}(c) \cdot \mathrm{ind}(c') \mid \mathrm{ind}(c + c')$. For the other divisibility, note that by Lemma 2.4, there are extensions L and L' such that $[L:K] = \mathrm{ind}(c)$, $[L':K] = \mathrm{ind}(c')$, and $\mathrm{res}_L(c) = \mathrm{res}_{L'}(c') = 0$. Then the compositum $L.L'$ splits $c + c'$ and $[L.L':K] = \mathrm{ind}(c) \cdot \mathrm{ind}(c')$. Thus $\mathrm{ind}(c + c')$ divides $\mathrm{ind}(c) \cdot \mathrm{ind}(c')$. □

Remark 2.6. In [12], Lichtenbaum proved that $\mathrm{ind}(c) \mid \mathrm{ord}(c)^2$ for any $c \in H^1(K, E)$, and Cassels proved in [3] that if $c \in Ш(E/K)$, then $\mathrm{ord}(c) = \mathrm{ind}(c)$.

If E is an elliptic curve over $\mathbb{Q}$ such that $\# Ш(E/\mathbb{Q}) = \# E(\mathbb{Q})_{\mathrm{tor}} = 1$, then the results mentioned above do not rule out the possibility that every element of $H^1(\mathbb{Q}, E)$ has index a perfect square. We prove, under the assumption that $L(E, 1) \neq 0$, that there is an integer B such that $H^1(\mathbb{Q}, E)$ contains infinitely many elements of index n, for every integer n that is coprime to B (see Theorem 3.1). For example, in Section 5 we prove that one can take $B = 2$ for the elliptic curve $X_0(17)$.

3. Kolyvagin's Euler system

In this section, we recall the definition of Heegner points and several basic results about the system of cohomology classes Kolyvagin attaches to these points. We also state the main theorem of this paper.

3.1. Kolyvagin classes. Let E be an elliptic curve over $\mathbb{Q}$ of conductor N, and denote by $X_0(N)$ the modular curve that classifies cyclic isogenies of degree N. By [1], there is a surjective map $\pi: X_0(N) \to E$. (Note that for the proof of Theorem 1.1 we do not need any modularity theorems, because we take $E = X_0(17)$.) Let K be a quadratic imaginary extension of $\mathbb{Q}$ in which all primes dividing N split, and let D_K be the discriminant and $\mathcal{O}$ the ring of integers of K. Since all primes dividing N split, there is an ideal $\mathfrak{a} \subset \mathcal{O}$ such that $\mathcal{O}/\mathfrak{a}$ is cyclic of order N. Let H be the Hilbert class field of K, and $x_H \in X_0(N)(H)$ be the Heegner points corresponding to $(\mathbb{C}/\mathcal{O}, \mathfrak{a}^{-1}/\mathcal{O})$. Set $y_H = \pi(x_H) \in E(H)$, $y_K = \mathrm{tr}_{H/K}(y_H) \in E(K)$, and $y = y_K - y_K^{\tau} \in E(K)^{-}$, where τ denotes complex conjugation. Assume that $L(E, 1) \neq 0$, so by [2] and [15] there are infinitely many ways in which to choose K as above so that y has infinite order. Under this nonvanishing hypothesis on $L(E, 1)$, Kolyvagin proves in [10] that the groups $E(\mathbb{Q})$ and $Ш(E/\mathbb{Q})$ are both finite.

In the course of his proof, Kolyvagin considers more general Heegner points $y_\ell \in E(\bar{\mathbb{Q}})$, for appropriate primes ℓ, and from these constructs cohomology classes $c_{\ell, p^n} \in H^1(\mathbb{Q}, E)[p^n]$ that are used to bound the orders of certain Selmer groups associated to E. We will study Kolyvagin's classes further and prove that for each prime p not in an explicit finite set and each positive integer n, there are infinitely many primes ℓ such that

$$\operatorname{ord}(c_{\ell,p^n}) = \operatorname{ind}(c_{\ell,p^n}) = p^n.$$

We thus obtain the following theorem, which will be proved in Section 4.2.

Theorem 3.1. *Let E be an elliptic curve over $\mathbb{Q}$ such that $L(E,1) \neq 0$. Then there is an integer B such that, for all integers r coprime to B, there are infinitely many $c \in H^1(\mathbb{Q},E)$ such that* $\operatorname{ord}(c) = \operatorname{ind}(c) = r$.

Remark 3.2. Cathy O'Neil [16] has investigated the obstruction to $\operatorname{ord}(c) = \operatorname{ind}(c)$. We show that when E has analytic rank 0, this obstruction vanishes for infinitely many c.

3.2. Basic properties of Kolyvagin's Euler system. In [18], Rubin gives a concise account of Kolyvagin's proof of finiteness of $\text{Ш}(E/\mathbb{Q})[p^\infty]$, under the simplifying assumption that p is odd. Though Kolyvagin's argument works even when $p = 2$, for simplicity, we rely exclusively on Rubin's paper.

Let K be a quadratic imaginary field as above, chosen in such a way that the associated Heegner point y_K has infinite order. Fix embeddings of $\bar{\mathbb{Q}}$ into $\mathbb{C}$ and into each p-adic field $\bar{\mathbb{Q}}_p$. Let τ denote complex conjugation, and for any $\mathbb{Z}[\tau]$-module A, let A^+ and A^- denote the kernel of $\tau - 1$ and $\tau + 1$, respectively. For the remainder of this section, we assume that p is an odd prime, and if $K = \mathbb{Q}(\sqrt{-3})$ that $p \geqq 5$. If ℓ is a prime that is inert in K, let K_ℓ denote the completion of K at the unique prime lying over ℓ. If L is a finite Galois extension of $\mathbb{Q}$, let $\operatorname{Frob}_\ell(L/\mathbb{Q})$ denote the conjugacy class of some Frobenius element of a prime lying over ℓ. For each prime $\ell \nmid N$, let $a_\ell = \ell + 1 - \#E(\mathbb{F}_\ell)$ be the ℓth Fourier coefficient of the newform attached to E.

Definition 3.3. For each place v of $\mathbb{Q}$, let

$$m_v = \#H^1\big(\mathbb{Q}_v^{\text{unr}}/\mathbb{Q}_v, E(\mathbb{Q}_v^{\text{unr}})\big).$$

By [14], I.3.8, each m_v is finite and $m_v = 1$ for all but finitely many v, so

$$m(p) = \sup\{\operatorname{ord}_p(m_v)\colon \text{all places } v \text{ of } \mathbb{Q}\}$$

is well defined, and $m(p) = 0$ for almost all p.

Let n be a positive integer.

Proposition 3.4. *Let p be a prime that does not divide the class number of K and for which $m(p) = 0$. Suppose $\ell \nmid pD_KN$ and* $\operatorname{Frob}_\ell\big(K(E[p^n])/\mathbb{Q}\big) = [\tau]$. *Then there is an element $c_{\ell,p^n} \in H^1(\mathbb{Q},E)[p^n]$ such that the order of* $\operatorname{res}_\ell(c_{\ell,p^n})$ *in $H^1(\mathbb{Q}_\ell,E)[p^n]$ is equal to the order of the image of y in $E(K_\ell)/p^nE(K_\ell)$, and the index of c_{ℓ,p^n} divides p^n.*

Proof. The existence of c_{ℓ,p^n} and statement about its order is proved in [18], Prop. 5, where c_{ℓ,p^n} is constructed from Heegner points on $X_0(N)$. For the index bound, note that in the proof of [18], Prop. 5, when $p \nmid [H : K]$, Rubin constructs a class

$$c' \in H^1\big(K'/K, E(K')\big)[p^r]^+,$$

where $r = n + m(p)$ and K' is the unique extension of K of degree p^r in a certain class field of K. Since p is odd, the restriction map res: $H^1(\mathbb{Q}, E)[p^r] \to H^1(K, E)[p^r]^+$ is an isomorphism. Rubin takes $c_{\ell,p^n} = \mathrm{res}^{-1}(c')$. Since c_{ℓ,p^n} splits over the degree $2p^r$ extension K' of $\mathbb{Q}$, the index of c_{ℓ,p^n} divides $2p^r$. But c_{ℓ,p^n} has odd order and, by Proposition 2.3, $\mathrm{ind}(c_{\ell,p^n})$ has the same prime factors as $\mathrm{ord}(c_{\ell,p^n})$, so $\mathrm{ind}(c_{\ell,p^n})$ divides p^r. □

Remark 3.5. The author does not know whether or not the proposition is true if p is allowed to divide the class number of K.

4. Nonvanishing of cohomology classes

In this section, we prove a nonvanishing result about the cohomology classes c_{ℓ,p^n} of Proposition 3.4, then use it to deduce Theorem 3.1.

4.1. Local nonvanishing. Let E be as above. For any point $x \in E(K)$, let $K([p^n]^{-1}x)$ denote the field obtained by adjoining the coordinates of all p^nth roots of x to K. Without imposing further hypothesis, this field need not be Galois over $\mathbb{Q}$.

Lemma 4.1. *If $x \in E(K)^+ \cup E(K)^-$, then $K([p^n]^{-1}x)$ is Galois over $\mathbb{Q}$.*

Proof. Since $G_{\mathbb{Q}}$ acts on x by ± 1, the subgroup $\mathbb{Z}x$ is $G_{\mathbb{Q}}$-invariant. Since $[p^n]: E \to E$ is a $\mathbb{Q}$-rational isogeny the inverse image $[p^n]^{-1}\mathbb{Z}x$ is also $G_{\mathbb{Q}}$-invariant, so $K([p^n]^{-1}x) = K([p^n]^{-1}\mathbb{Z}x)$ is Galois over $\mathbb{Q}$. □

Definition 4.2. An odd prime p is *firm* for E if $m(p) = 0$, there are no nontrivial $\mathbb{Q}$-rational cyclic subgroups of $E[p^\infty]$, and $H^1\big(K(E[p^n])/K, E[p^n]\big) = 0$ for all $n \geqq 1$.

Remark 4.3. The set of primes that are not firm is finite, by Serre's theorem [19] and the theory of complex multiplication.

Let p be an odd prime that is firm for E. The following proposition produces infinitely many primes ℓ such that we have control over the orders of the image in $E(K_\ell)/p^nE(K_\ell)$ of a global point. It will be used as input to Proposition 3.4 to produce cohomology classes of known index. The proof, which involves an application of the Chebotarëv density theorem, follows a strategy similar to that used in the proof of Kolyvagin's theorem on page 135 of [18].

Proposition 4.4. *Let p be a prime that is firm for E, and let $x \in E(K)^{\pm}$. Then there is a set of primes ℓ of positive Dirichlet density such that* $\mathrm{Frob}_\ell\big(K(E[p^n])/\mathbb{Q}\big) = [\tau]$ *and the orders of the images of x in $E(K)/p^nE(K)$ and in $E(K_\ell)/p^nE(K_\ell)$ are the same.*

Proof. Let p^a be the order of the image of x in $E(K)/p^nE(K)$. If $a = 0$, then there is nothing to prove, so assume that $a > 0$. If ℓ is a prime such that the orders of the images of $p^{a-1}x$ in $E(K)/p^nE(K)$ and $E(K_\ell)/p^nE(K_\ell)$ both equal p, then the images of x in $E(K)/p^nE(K)$ and $E(K_\ell)/p^nE(K_\ell)$ both have order p^a. It thus suffices to prove the proposition in the case when the order of the image of x in $E(K)/p^nE(K)$ is p.

Let $L = K(E[p^n])$, suppose ℓ is a prime such that $\mathrm{Frob}_\ell(L/\mathbb{Q}) = [\tau]$, and let λ be one of the prime ideals of L that lies over ℓ. We have a diagram

$$\begin{tikzcd}
E(K)/p^nE(K) \arrow[r, hook] \arrow[d] & H^1(K, E[p^n]) \arrow[r, hook] \arrow[d] & \mathrm{Hom}(G_L, E[p^n]) \arrow[d] \\
E(K_\ell)/p^nE(K_\ell) \arrow[r] & H^1(K_\ell, E[p^n]) \arrow[r] & \mathrm{Hom}(G_{L_\lambda}, E[p^n]).
\end{tikzcd}$$

Let $\varphi\colon G_L \to E[p^n]$ be the element of $\mathrm{Hom}(G_L, E[p^n])$ that x maps to. The top row is injective, because p is firm, so it suffices to show that the image φ_ℓ of φ in $\mathrm{Hom}(G_{L_\lambda}, E[p^n])$ is nonzero.

Let M be the fixed field of the kernel of φ. Since M is the compositum of the two Galois extensions $K([p^n]^{-1}x)$ and $\mathbb{Q}(E[p^n])$ of $\mathbb{Q}$, it is also Galois (see Lemma 4.1). Because $\mathrm{Frob}_\ell(M/\mathbb{Q})|_L = [\tau]$, there is an element $\sigma \in \mathrm{Gal}(M/L)$ such that

$$\mathrm{Frob}_\ell(M/\mathbb{Q}) = [\sigma\tau].$$

The order of $\sigma\tau$ equals the degree of $M_{\lambda'}$ over $\mathbb{Q}_\ell$, where λ' is a prime of M lying over ℓ. If $\varphi_\ell = 0$, then $M_{\lambda'} = L_\lambda = K_\ell$, so $\sigma\tau$ would have order 2.

The image of φ is a nonzero subgroup H of $E[p^n]$, which is defined over $\mathbb{Q}$ since $x \in E(K)^{\pm}$. If every $\sigma \in \mathrm{Gal}(M/L)$ has the property that $\sigma\tau$ has order 2, then $H \subset E[p^n]^-$. This contradicts our assumption that p is firm, since H is a nontrivial cyclic subgroup of $E[p^\infty]$. Thus there exists $\sigma \in \mathrm{Gal}(M/L)$ such that $\sigma\tau$ has order different than 2. For this σ and for any prime ℓ such that $\mathrm{Frob}_\ell(M/\mathbb{Q}) = [\sigma\tau]$, we see that $\varphi_\ell \neq 0$. The Chebotarëv density theorem provides a positive density of such ℓ. □

4.2. Proof of Theorem 3.1. Let E be an elliptic curve over $\mathbb{Q}$ such that $L(E,1) \neq 0$. Let K be one of the infinitely many imaginary quadratic fields such that the associated Heegner point y has infinite order. Let B_K be an integer that is divisible by 2 and

- the primes p such that $y \in pE(K)$,
- the primes p that are not firm,
- the order $\#E(K)_{\mathrm{tor}}$, and
- the class number of K.

If $K = \mathbb{Q}(\sqrt{-3})$, assume in addition that 3 divides B_K.

Fix a prime $p \nmid B_K$. Since $E(K)$ has rank 1 (see, e.g., [9], Thm. 1.3) and $p \nmid \#E(K)_{\mathrm{tor}}$, the image of y in $E(K)/p^nE(K)$ has order p^n. By Proposition 4.4 there are infinitely many primes ℓ such that $\mathrm{Frob}_\ell\big(K(E[p^n])/\mathbb{Q}\big) = [\tau]$ and the image of y in $E(K_\ell)/p^nE(K_\ell)$ has order p^n. For these ℓ, Proposition 4.4 produces infinitely many cohomology classes c_{ℓ,p^n} having order and index both equal to p^n. (Note that if $\ell \neq \ell'$ then $c_{\ell,p^n} \neq c_{\ell',p^n}$.)

Let B be the greatest common divisor of the set of integers B_K, as K varies over all quadratic imaginary extensions such that the associated Heegner point has infinite order. For each prime power p^n that does not divide B, we have produced infinitely many $c \in H^1(\mathbb{Q}, E)$ having order and index both equal to p^n. If the orders of c and c' are coprime, then $\operatorname{ord}(c + c') = \operatorname{ord}(c) \cdot \operatorname{ord}(c')$ and, by Proposition 2.5,

$$\operatorname{ind}(c + c') = \operatorname{ind}(c) \cdot \operatorname{ind}(c').$$

This proves the theorem. □

5. Computing the bound B_K

In this section we compute, in some cases, the the bound B_K that appears in Section 4.2. First we prove a general theorem about semistable elliptic curves. Next we compute the index of a Heegner point, and finally in Section 5.4 we prove Theorem 1.1.

5.1. Galois representations attached to isolated curves. The following proposition sometimes permits us to compute the integer B_K, which appears in Section 4.2.

Proposition 5.1. *Let E be a semistable elliptic curve over $\mathbb{Q}$ of conductor N, let p be an odd prime, and let K be a quadratic imaginary field such that* $\gcd(D_K, pN) = 1$. *Assume that $p \nmid \operatorname{ord}_\ell(j(E))$, for each prime $\ell | N$, and that E admits no isogenies of degree p. Then $p \nmid \# E(K)_{\text{tor}}$ and p is firm for E.*

Before giving the proof, we summarize its main ingredients. First, we observe that the assertion that $m(p) = 0$ (see Definition 3.3) uses a standard result that relates unramified Galois cohomology to component groups. Next, we use the semistability and isogeny hypotheses to deduce that $\rho_{E,p}$ is surjective. Then we use standard group cohomology to deduce that p is firm.

Proof. Let ℓ be a prime. By [14], I.3.8,

$$H^1(\mathbb{Q}_\ell^{\text{unr}}/\mathbb{Q}_\ell, E(\mathbb{Q}_\ell^{\text{unr}})) \cong H^1(\overline{\mathbb{F}}_\ell/\mathbb{F}_\ell, \Phi_{E,\ell}(\overline{\mathbb{F}}_\ell)),$$

where $\Phi_{E,\ell}$ is the component group of E at ℓ. If $\ell \nmid N$, there is nothing further to prove, so assume $\ell | N$. Since E is semistable, $\# \Phi_{E,\ell}(\overline{\mathbb{F}}_\ell) = -\operatorname{ord}_\ell(j)$. By hypothesis, $p \nmid \operatorname{ord}_\ell(j)$. Thus $m(p) = 0$.

Since E admits no isogenies of degree p, the Galois representation

$$\rho_{E,p}: G_{\mathbb{Q}} \to \mathrm{GL}(2, E[p])$$

is irreducible, and there are no nontrivial $\mathbb{Q}$-rational cyclic subgroups of $E[p^\infty]$. Since E is semistable, work of Serre [19], Prop. 21 and [20], §3.1 implies that $\rho_{E,p}$ is surjective. Thus $p \nmid \# E(K)_{\text{tor}}$ because a point in $E(\overline{\mathbb{Q}})$ of order p must generate an extension of $\mathbb{Q}$ of degree at least $p^2 - 1 \geqq 3$.

The field K and $\mathbb{Q}(E[p])$ are linearly disjoint, since $\gcd(D_K, pN) = 1$, so

$$H^1\big(K(E[p])/K, E[p]\big) \cong H^1\big(\mathbb{Q}(E[p])/\mathbb{Q}, E[p]\big) \approx H^1\big(\mathrm{GL}(2, \mathbb{F}_p), \mathbb{F}_p^2\big).$$

The group $H = H^1\big(K(E[p^n])/K, E[p^n]\big)$ has exponent a power of p. If an element α in $\mathrm{Gal}\big(K(E[p^n])/K\big) \subset \mathrm{GL}_2(\mathbb{Z}/p^n\mathbb{Z})$ is scalar, then every element of H has order dividing $\alpha - 1$. This is because the scalar is central, so the morphism of pairs it induces is both the identity and multiplication by α. It is necessary only to choose α such that $\gcd(\alpha - 1, p) = 1$. Since p is odd, -1 is a nonidentity element of

$$\mathrm{Aut}(E[p]) = \mathrm{Gal}\big(K(E[p])/K\big).$$

Every automorphism lifts, so -1 lifts to some g in $\mathrm{Gal}\big(K(E[p^n])/K\big) \subset \mathrm{Aut}(E[p^n])$. Then $g^{p^{n-1}} = -1$ in $\mathrm{Aut}(E[p^n])$, so $-1 \in \mathrm{Gal}\big(K(E[p^n])/K\big)$ and every element of H has order dividing 2. (To show that $g^{p^{n-1}} = -1$, we use that $\mathrm{ord}_p\begin{pmatrix} p^n \\ k \end{pmatrix} = n + \mathrm{ord}_p\left(\frac{1}{k}\right)$.) □

5.2. The number B_K for $X_0(17)$. In this section, we show that for $E = X_0(17)$ and $K = \mathbb{Q}(\sqrt{-2})$, we have $B_K = 2$. This is accomplished by showing that the index $[E(K) : \mathbb{Z}y]$ is a power of 2. The elliptic curve $E = X_0(17)$ given by the Weierstrass equation

$$y^2 + xy + y = x^3 - x^2 - x - 14$$

satisfies the hypothesis of Proposition 5.1 for each odd prime p. Since the j-invariant of E is $3^3 \cdot 11^3/17^4$, every odd prime p is firm for E and $\# E(K)_{\mathrm{tor}}$ is a power of 2.

The conductor 17 of E splits in K, and the quadratic twist E' of E by K is the curve $y^2 = x^3 - 44x + 7120$, which is labeled **1088K4** in [7]. Using MAGMA (or `mwrank`), one finds that $E'(\mathbb{Q}) \cong \mathbb{Z}P \times \mathbb{Z}/2$, where $P = (-3, 85) \in E'(\mathbb{Q})$ has infinite order. Since the rank of E' is 1, we set $K = \mathbb{Q}(\sqrt{-2})$ in Section 4.2. Then B_K is divisible only by 2 and the index $[E(K) : \mathbb{Z}y]$. This index can only change by a power of 2 if y is replaced by y_K, so we instead consider the index $[E(K) : \mathbb{Z}y_K]$. The cokernel of the natural map $E(\mathbb{Q}) \oplus E'(\mathbb{Q}) \to E(K)$ is a 2-group and $E(\mathbb{Q}) \cong \mathbb{Z}/4\mathbb{Z}$, so $[E(K) : \mathbb{Z}y_K]$ is a power of 2 times $h(y_K)/h(P)$, where h is the Néron-Tate canonical height on E_K. By the Gross-Zagier formula (see [8], Thm. 6.3),

$$h(y_K) = \frac{u^2|D|^{\frac{1}{2}}}{\|\omega_f\|} L'_{E'}(1) L_E(1),$$

where $D = -8$ is the discriminant of K, $u = 1$ is half the number of units, and $\|\omega_f\|$ is the Peterson norm of the newform f corresponding to E. Generators for the period lattice of E are $\omega_1 \sim 1.547079$ and $\omega_2 \sim 0.773539 + 1.372869i$; taking the determinant gives $\|\omega_f\| \sim 2.123938$. Furthermore, again from [7], we find that $L_E(1) \sim 0.386769$ and $L'_{E'}(1) \sim 2.525026$, so $h(y_K) \sim 1.300533$. Using a computer, we find that $h(P) \sim 1.300533$ as well, so $[E(K) : \mathbb{Z}y_K]$ is a power of two.

5.3. Elements of index 2 and 4. The torsion subgroup of $E = X_0(17)$ is isomorphic to $\mathbb{Z}/4\mathbb{Z}$, so [11], pg. 670 implies that there are infinitely many elements of $H^1(\mathbb{Q}, E)$ having order and index equal to 2, and also infinitely many having order and index equal to 4.

5.4. Proof of Theorem 1.1. To prove Theorem 1.1, we combine the above computations with Theorem 3.1, and an observation about the local properties of Kolyvagin's classes c_{ℓ, p^n}.

Proof of Theorem 1.1. Let $E = X_0(17)$ as above, and let K be an arbitrary number field. Let p^n be either an odd prime power, or 2, or 4. The computations of the previous section combined with Theorem 3.1 prove that there are infinitely many elements c_{ℓ,p^n} of $H^1(\mathbb{Q}, E)$ whose index and order both equal p^n. Let A be the subgroup of $H^1(\mathbb{Q}, E)$ generated by these classes. The kernel B of $\mathrm{res}_K\colon A \to H^1(K, E)$ is finite, so the set $\mathscr{S}$ of primes ℓ such that $\mathrm{res}_\ell(c) \neq 0$ for some $c \in B$ is finite. By Proposition 3.4, we have $\mathrm{res}_v(c_{\ell,p^n}) = 0$ for all places $v \neq \ell$, so the subgroup A' of A generated by all c_{ℓ,p^n} with $\ell \notin \mathscr{S}$ has trivial intersection with B. Thus $\mathrm{res}_K(A')$ consists of infinitely many classes in $H^1(K, E)$ having order and index both equal to p^n, and the theorem now follows from Proposition 2.3. □

London Mathematical Society ISSN 1461–1570

CUSPIDAL MODULAR SYMBOLS ARE TRANSPORTABLE

WILLIAM A. STEIN AND HELENA A. VERRILL

Abstract

Modular symbols of weight 2 for a congruence subgroup Γ satisfy the identity $\{\alpha, \gamma(\alpha)\} = \{\beta, \gamma(\beta)\}$ for all α, β in the extended upper half plane and $\gamma \in \Gamma$. The analogue of this identity is false for modular symbols of weight greater than 2. This paper provides a definition of transportable modular symbols, which are symbols for which an analogue of the above identity holds, and proves that every cuspidal symbol can be written as a transportable symbol. As a corollary, an algorithm is obtained for computing periods of cuspforms.

Introduction

It is well known that modular symbols of weight 2 for a congruence subgroup Γ satisfy the identity $\{\alpha, \gamma(\alpha)\} = \{\beta, \gamma(\beta)\}$ for all α, β in the extended upper half plane and $\gamma \in \Gamma$. The analogue of this identity is, in general, false for modular symbols of weight greater than 2. To investigate further, we define transportable modular symbols, which are symbols that can be expressed in such a way that an analogue of the above identity holds. We then prove that every cuspidal symbol is transportable. As a corollary, we obtain an algorithm for computing periods of cuspforms.

In Section 1 we review the definition of modular symbols. In Section 2 we define transportable modular symbols, and prove our main theorem. Section 3 contains an application of our transportability result to the computation of periods of modular forms. Finally, Section 4 contains two examples in which we verify the assertion of Theorem 2.4 and apply the period computation algorithm.

1. *Modular symbols*

In Section 1.1 we recall the definition of modular symbols given in [**5**]; then in Section 1.2 we introduce a slight generalization of the definition. Let N and k be positive integers with $k \geqslant 2$, and let $\varepsilon : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}$ be a Dirichlet character modulo N.

1.1. *Definition*

Let $\mathcal{M}$ be the abelian group generated by all symbols $\{\alpha, \beta\}$ with $\alpha, \beta \in \mathbb{P}^1(\mathbb{Q})$, modulo the relations $\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0$, and modulo any torsion. Let V_{k-2} denote the group of homogeneous polynomials in $\mathbb{Z}[X, Y]$ of degree $k - 2$.

Each element $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}(2, \mathbb{Z})$ acts on the left on V_{k-2} by

$$\gamma(P(X, Y)) = P(dX - bY, -cX + aY),$$

and on $\mathcal{M}_k = V_{k-2} \otimes \mathcal{M}$ by

$$\gamma(P \otimes \{\alpha, \beta\}) = \gamma(P) \otimes \{\gamma(\alpha), \gamma(\beta)\}.$$

Fix a Dirichlet character $\varepsilon : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}$, and denote by $\mathbb{Z}[\varepsilon]$ the ring generated by the image of ε. We also view ε as a homomorphism $\Gamma_0(N) \to \mathbb{C}^*$ by setting $\varepsilon \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) = \varepsilon(d)$.

The space $\mathcal{M}_k(N, \varepsilon)$ of *modular symbols* of level N and character ε is the quotient of the $\mathbb{Z}[\varepsilon]$-module $\mathcal{M}_k \otimes \mathbb{Z}[\varepsilon]$ by the $\mathbb{Z}[\varepsilon]$-submodule generated by $\gamma(x) - \varepsilon(\gamma)x$ for all $x \in \mathcal{M}_k$, for all $\gamma \in \Gamma_0(N)$, and by any torsion. Denote by $P\{\alpha, \beta\}$ the image of $P \otimes \{\alpha, \beta\}$ in $\mathcal{M}_k(N, \varepsilon)$. The $\mathbb{Q}[\varepsilon]$-vector space

$$\mathcal{M}_k(N, \varepsilon; \mathbb{Q}) = \mathcal{M}_k(N, \varepsilon) \otimes_{\mathbb{Z}} \mathbb{Q}$$

contains $\mathcal{M}_k(N, \varepsilon)$.

Let $\mathcal{B}$ be the free abelian group generated by all symbols $\{\alpha\}$, for $\alpha \in \mathbb{P}^1(\mathbb{Q})$. Define a left action of $\mathrm{SL}(2, \mathbb{Z})$ on $\mathcal{B}_k = V_{k-2} \otimes \mathcal{B}$ by

$$\gamma(P \otimes \{\alpha\}) = \gamma(P) \otimes \{\gamma\alpha\}.$$

The space $\mathcal{B}_k(N, \varepsilon)$ of *boundary symbols* is the quotient of $\mathcal{B}_k \otimes \mathbb{Z}[\varepsilon]$ by the $\mathbb{Z}[\varepsilon]$-submodule generated by $\gamma(x) - \varepsilon(\gamma)x$ for all $x \in \mathcal{B}_k$, for all $\gamma \in \Gamma_0(N)$, and by any torsion. The subspace $\mathcal{S}_k(N, \varepsilon)$ of *cuspidal symbols* is the kernel of the map $\delta : \mathcal{M}_k(N, \varepsilon) \to \mathcal{B}_k(N, \varepsilon)$ given by $\delta(P\{\alpha, \beta\}) = P\{\beta\} - P\{\alpha\}$.

When $\varepsilon = 1$ is the trivial character, we shall also write $\mathcal{M}_k(\Gamma_0(N))$ for $\mathcal{M}_k(N, 1)$, and similarly for $\mathcal{S}_k$ and $\mathcal{B}_k$.

1.2. *Extended modular symbols*

It is useful to extend the notion of modular symbols to allow symbols of the form $P\{z, w\}$ where z and w are arbitrary elements of $\mathfrak{h}^* = \mathfrak{h} \cup \mathbb{P}^1(\mathbb{Q})$.

Definition 1 (Extended modular symbols). The group $\overline{\mathcal{M}}_k$ of *extended modular symbols* is the free abelian group with basis the set of all symbols $P\{z, w\}$ with $z, w \in \mathfrak{h}^*$, subject to the relations $P\{u, v\} + P\{v, w\} + P\{w, u\} = 0$.

Note that $\overline{\mathcal{M}}_k$ is of uncountable rank over $\mathbb{Z}$. It is equipped with an action of $\Gamma_0(N)$; we let $\overline{\mathcal{M}}_k(N, \varepsilon)$ be the largest torsion-free quotient of $\overline{\mathcal{M}}_k$ by the relations $\gamma x = \varepsilon(\gamma)x$ for $\gamma \in \Gamma_0(N)$.

2. *Transportable modular symbols*

In Section 2.1 we define transportable modular symbols, and we prove an elementary proposition that motivates the definition. Section 2.2, which is the heart of this paper, contains a proof that every cuspidal modular symbol is transportable.

2.1. *Definition*

Definition 2 (Transportable). A modular symbol is *transportable* if it can be written in the form

$$\sum_{i=1}^{m} P_i\{\infty, \gamma_i(\infty)\},$$

for $\gamma_i \in \Gamma_0(N)$ and $P_i \in V_{k-2}$ with

$$\sum_{i=1}^{m} P_i\{\infty, \gamma_i(\infty)\} = \sum_{i=1}^{m} P_i\{\alpha, \gamma_i(\alpha)\}$$

for all $\alpha \in \mathfrak{h}^*$, where the equality takes place in $\overline{\mathcal{M}}_k(N, \varepsilon)$.

When $k = 2$, the identity $\{\infty, \gamma(\infty)\} = \{\alpha, \gamma(\alpha)\}$ holds for any $\alpha \in \mathfrak{h}^*$, so in weight 2 there is a plentiful supply of transportable modular symbols.

Proposition 2.1. *For any $\gamma \in \Gamma_0(N)$, $P \in V_{k-2}$ and $\alpha \in \mathfrak{h}^*$,*

$$\begin{aligned} P\{\infty, \gamma(\infty)\} &= P\{\alpha, \gamma(\alpha)\} + \big(P - \varepsilon(\gamma)\gamma^{-1}P\big)\{\infty, \alpha\} \\ &= \varepsilon(\gamma)\big(\gamma^{-1}P\big)\{\alpha, \infty\} - P\{\gamma(\alpha), \infty\}. \end{aligned} \tag{1}$$

In particular,

$$P\{\infty, \gamma(\infty)\} = P\{\alpha, \gamma(\alpha)\} \Leftrightarrow P = \varepsilon(\gamma)\gamma^{-1}P. \tag{2}$$

Proof. If $x \in \mathcal{M}_k(N, \varepsilon)$ is a modular symbol and $\gamma \in \Gamma_0(N)$, then $\gamma x = \varepsilon(\gamma)x$, where, as usual, ε is viewed as a homomorphism $\Gamma_0(N) \to \mathbb{C}^*$ via $\varepsilon\big(\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)\big) = \varepsilon(d)$. In particular, $\varepsilon(\gamma)\gamma^{-1}x = x$, so

$$\begin{aligned} P\{\infty, \gamma(\infty)\} &= P\{\infty, \alpha\} + P\{\alpha, \gamma(\alpha)\} + P\{\gamma(\alpha), \gamma(\infty)\} \\ &= P\{\infty, \alpha\} + P\{\alpha, \gamma(\alpha)\} + \varepsilon(\gamma)\gamma^{-1}(P\{\gamma(\alpha), \gamma(\infty)\}) \\ &= P\{\infty, \alpha\} + P\{\alpha, \gamma(\alpha)\} + \varepsilon(\gamma)\big(\gamma^{-1}P\big)\{\alpha, \infty\} \\ &= P\{\alpha, \gamma(\alpha)\} + P\{\infty, \alpha\} - \varepsilon(\gamma)\big(\gamma^{-1}P\big)\{\infty, \alpha\} \\ &= P\{\alpha, \gamma(\alpha)\} + \big(P - \varepsilon(\gamma)\gamma^{-1}P\big)\{\infty, \alpha\}. \end{aligned}$$

The remaining statements of the proposition now follow easily. □

Example 2.2. In some cases it is easy to give a formula for symbols that are obviously transportable. Suppose that $k \geqslant 2$ is an even integer. If P is a polynomial such that $\gamma(P) = P$ for some $\gamma \in \Gamma_0(N)$, then $P\{\infty, \gamma(\infty)\}$ is transportable. Given $\gamma \in \Gamma_0(N)$, an example of such a P is

$$P(X, Y) = \big(cX^2 + (d-a)XY - bY^2\big)^{(k-2)/2}.$$

We found this polynomial by viewing V_{k-2} as the $(k-2)$th symmetric product of the 2-dimensional space on which $\Gamma_0(N)$ acts naturally. If γ, which has determinant 1, has eigenvalues α and α^{-1}, then the eigenvalues of the $(k-2)$-fold symmetric product of γ are given by α^{k-2-2j} for $0 \leqslant j \leqslant k-2$. Although we have not been able to find a counterexample, the authors see no reason to believe that transportable symbols of the form given in this example always span $\mathcal{S}_k(N; \mathbb{Q})$.

More generally, given any sequence of matrices $\gamma_1, \ldots, \gamma_n$ in $\Gamma_0(N)$, it is a simple matter of linear algebra to give transportable symbols of the form $\sum_{i=1}^{n} P_i\{\infty, \gamma_i\infty\}$. This follows from Lemma 2.3, which shows that this symbol is transportable exactly when $(P_1, \ldots, P_n)$ is in the kernel of the map $\bigoplus_{i=1}^{n}(1 - \gamma_i^{-1})$ from $\bigoplus_{i=1}^{n} V_{k-2}$ to V_{k-2}.

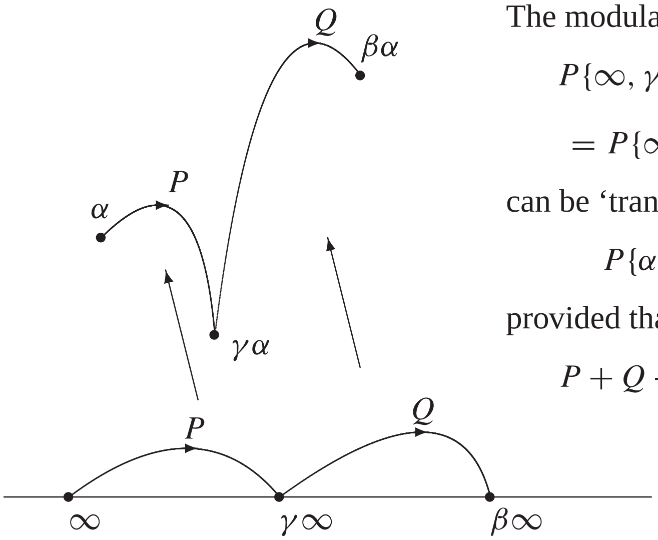
2.2. *Characterization of transportable modular symbols*

Lemma 2.3. *A modular symbol in $\mathcal{M}_k(N, \varepsilon; \mathbb{Q})$ is transportable if and only if it can be written in the form $\sum_{i=1}^m P_i\{\infty, \gamma_i(\infty)\}$ with*

$$\sum P_i = \sum \varepsilon(\gamma_i)\gamma_i^{-1}P_i.$$

Proof. This follows from Proposition 2.1. □

Figure 1 illustrates Lemma 2.3 with a trivial-character example.



The modular symbol

$$P\{\infty, \gamma\infty\} + Q\{\gamma\infty, \beta\infty\}$$

$$= P\{\infty, \gamma\infty\}+Q\{\infty, \beta\infty\}-Q\{\infty, \gamma\infty\}$$

can be 'transported' to

$$P\{\alpha, \gamma\alpha\} + Q\{\gamma\alpha, \beta\alpha\},$$

provided that

$$P + Q - Q = \gamma^{-1}P + \beta^{-1}Q - \gamma^{-1}Q.$$

Figure 1: 'Transporting' a transportable modular symbol.

Theorem 2.4. *A modular symbol is transportable if and only if it is cuspidal.*

Proof. By Lemma 2.3, every transportable modular symbols is cuspidal, so we must prove that every cuspidal symbol is transportable.

Let $I = I_{N,\varepsilon}$ be the ideal in the group ring of $\Gamma_0(N)$ generated by all elements of the form $\varepsilon(\gamma) - \gamma$ for $\gamma \in \Gamma_0(N)$. Suppose that $v \in \mathcal{S}_k(N, \varepsilon)$. Use the relation $\{\alpha, \beta\} = \{\infty, \beta\} - \{\infty, \alpha\} \in \mathcal{M}$ to see that any v is the image of an element $\tilde{v} \in \mathcal{M}_k$ of the form

$$\tilde{v} = \sum_{\beta\in\mathbb{Q}} P_\beta \otimes \{\infty, \beta\} \in \mathcal{M}_k$$

with only finitely many P_β nonzero. For later convenience, we set $P_\infty = 0$, and take sums over all $\beta \in P^1(\mathbb{Q})$. The boundary map δ lifts in a natural way to $\mathcal{M}_k = V_{k-2} \otimes \mathcal{M}$, as illustrated.

$$\begin{tikzcd}
 & I(V_{k-2} \otimes \mathcal{M}) \arrow[r] \arrow[d] & I(V_{k-2} \otimes \mathcal{B}) \arrow[d] \\
 & V_{k-2} \otimes \mathcal{M} \arrow[r, "\tilde{\delta}"] \arrow[d] & V_{k-2} \otimes \mathcal{B} \arrow[d] \\
\mathcal{S}_k(N, \varepsilon) \arrow[r, hook] & \mathcal{M}_k(N, \varepsilon) \arrow[r, "\delta"] & \mathcal{B}_k(N, \varepsilon)
\end{tikzcd}$$

Bearing in mind torsion, our assumption that $\delta(v) = 0$ implies that for some nonzero $M \in \mathbb{Z}$, we have $M\tilde{\delta}(\tilde{v}) \in I(V_{k-2} \otimes \mathcal{B})$. So there are $Q_{\gamma,\beta} \in V_{k-2}$, for $\gamma \in \Gamma_0(N)$ and $\beta \in \mathbb{P}^1(\mathbb{Q})$, only finitely β many nonzero, such that

$$M\tilde{\delta}(\tilde{v}) = \sum_{\gamma,\beta} \big(\varepsilon(\gamma) - \gamma\big)\big(Q_{\gamma,\beta} \otimes \{\beta\}\big).$$

We now use a summation trick.

$$\begin{aligned} M\tilde{\delta}(\tilde{v}) &= M\sum_{\beta}\big(P_\beta \otimes \{\beta\} - P_\beta \otimes \{\infty\}\big) \\ &= \sum_{\gamma,\beta}\big(\varepsilon(\gamma)Q_{\gamma,\beta} \otimes \{\beta\} - (\gamma Q_{\gamma,\beta}) \otimes \{\gamma\beta\}\big) \\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta} \otimes \{\beta\} - (\gamma Q_{\gamma,\gamma^{-1}\beta}) \otimes \{\beta\} \\ &= \sum_{\gamma,\beta}\big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\big) \otimes \{\beta\}. \end{aligned}$$

This shows that

$$M\sum_{\beta}\big(P_\beta \otimes \{\beta\} - P_\beta \otimes \{\infty\}\big) = \sum_{\gamma,\beta}\big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\big) \otimes \{\beta\}. \tag{3}$$

Equating terms, we deduce that for $\beta \neq \infty$,

$$MP_\beta = \sum_{\gamma}\big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\big). \tag{4}$$

Using this expression for P_β, as well as the fact that $\varepsilon(\gamma)\gamma^{-1}$ acts trivially on $\mathcal{M}_k(N,\varepsilon)$, we find that

$$\begin{aligned} Mv = M\sum_{\beta}P_\beta\{\infty,\beta\} &= \sum_{\gamma,\beta}\big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\big)\{\infty,\beta\} \\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta} - \varepsilon(\gamma)\gamma^{-1}\big((\gamma Q_{\gamma,\gamma^{-1}\beta})\{\infty,\beta\}\big) \\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty,\beta\} - \varepsilon(\gamma)Q_{\gamma,\gamma^{-1}\beta}\big\{\gamma^{-1}\infty,\gamma^{-1}\beta\big\} \\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty,\beta\} - \varepsilon(\gamma)Q_{\gamma,\beta}\big\{\gamma^{-1}\infty,\beta\big\} \\ &= \sum_{\gamma,\beta}\varepsilon(\gamma)Q_{\gamma,\beta}\big\{\infty,\gamma^{-1}\infty\big\}. \end{aligned} \tag{5}$$

Equating coefficients of $\{\infty\}$ in Equation 3, we have

$$-M\sum_{\beta}P_\beta = \sum_{\gamma}\big(\varepsilon(\gamma)Q_{\gamma,\infty} - \gamma Q_{\gamma,\gamma^{-1}\infty}\big),$$

which, combining with Equation 4, and recalling that $P_\infty = 0$, means that

$$-\sum_{\gamma,\beta\neq\infty}\big(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\gamma^{-1}\beta}\big) = \sum_{\gamma}\big(\varepsilon(\gamma)Q_{\gamma,\infty} - \gamma Q_{\gamma,\gamma^{-1}\infty}\big),$$

and hence

$$\sum_{\gamma,\beta}\bigl(\varepsilon(\gamma)Q_{\gamma,\beta} - \gamma Q_{\gamma,\beta}\bigr) = 0.$$

Using the expression

$$v = -\tfrac{1}{M}\sum_{\beta,\gamma}\varepsilon(\gamma)Q_{\gamma,\beta}\{\infty, \gamma^{-1}\infty\}$$

obtained from Equation 5, we see that this is the condition for v to be transportable. □

Corollary 2.5. *Fix $\alpha \in \mathfrak{h}^*$. Every element of $\mathcal{S}_k(N,\varepsilon)$ is a sum of modular symbols of the form $P\{\alpha, \gamma(\alpha)\}$.*

Proof. Let $x \in \mathcal{S}_k(N,\varepsilon)$. Proposition 2.1 implies that x is transportable, so there exist P_i and γ_i such that

$$x = \sum P_i\{\infty, \gamma_i(\infty)\} = \sum P_i\{\beta, \gamma_i(\beta)\}$$

for any $\beta \in \mathfrak{h}^*$. Taking $\beta = \alpha$ proves the corollary. □

Remark 2.6.

1. When $k = 2$, the corollary follows from [4, Section 1], which asserts that map $\Gamma_0(N) \to \mathcal{S}_2(\Gamma_0(N)) = H_1(X_0(N),\mathbb{Z})$ sending γ to $\{\alpha, \gamma(\alpha)\}$ is a surjective group homomorphism.
2. In Proposition 2.7 below, we shall prove more generally that every element of $\mathcal{M}_k(N,\varepsilon)$ is a sum of modular symbols of the form $P\{\alpha, \gamma(\alpha)\}$, as long as we allow α to vary over $\mathbb{P}^1(\mathbb{Q})$.

2.3. *What space do the symbols $P\{\infty, \gamma(\infty)\}$ span?*

Suppose that N and k are positive integers, with k even.

Definition 3. For any $\alpha \in \mathbb{P}^1(\mathbb{Q})$, let $\mathcal{W}_\alpha$ denote the subspace of $\mathcal{M}_k(\Gamma_0(N);\mathbb{Q})$ spanned by symbols of the form $P\{\alpha, \gamma(\alpha)\}$, for $P \in V_{k-2}$ and $\gamma \in \Gamma_0(N)$.

Corollary 2.5 draws our attention to $\mathcal{W}_\infty$. Since $\mathcal{W}_\infty$ contains $\mathcal{S}_k(\Gamma_0(N))$, it is natural to ask how much bigger it is. As mentioned in Remark 2.6, when $k = 2$, Manin proved that for any $\alpha \in \mathbb{P}^1(\mathbb{Q})$, we have $\mathcal{W}_\alpha = \mathcal{W}_\infty = \mathcal{S}_2(\Gamma_0(N);\mathbb{Q})$. We now compute $\mathcal{W}_\alpha$ for any weight $k > 2$.

Proposition 2.7. *Suppose that $k > 2$. Then the space $\mathcal{W}_\alpha$ is equal to the inverse image under the boundary map δ of the one-dimensional subspace $V_{k-2}\{\alpha\} \subset \mathcal{B}_k(\Gamma_0(N);\mathbb{Q})$. Hence* $\dim \mathcal{W}_\alpha = \dim \mathcal{S}_k(\Gamma_0(N);\mathbb{Q}) + 1$ *and* $\mathcal{M}_k(\Gamma_0(N);\mathbb{Q}) = \sum_{\alpha\in\mathbb{P}^1(\mathbb{Q})}\mathcal{W}_\alpha$.

Proof. In [5, Section 1.4], Merel shows that $V_{k-2}\{\alpha\}$ has dimension 1 (see the proof of [5, Section 1.4, Proposition 4]), and that $P(X,Y)\{u/v\}$ is nonzero if $P(u,v) \neq 0$.

Corollary 2.5 implies that $\mathcal{W}_\alpha$ contains the kernel $\mathcal{S}_k(\Gamma_0(N))$ of the boundary map δ. It thus suffices to show that $\delta(\mathcal{W}_\alpha) = V_{k-2}\{\alpha\}$. For $P \in V_{k-2}$ and $\gamma \in \Gamma_0(N)$, we have

$$\delta(P\{\alpha, \gamma(\alpha)\}) = P\{\gamma(\alpha)\} - P\{\alpha\} = (\gamma^{-1}P - P)\{\alpha\} \in V_{k-2}\{\alpha\},$$

so $\delta(\mathcal{W}_\alpha) \subset V_{k-2}\{\alpha\}$.

For $\gamma = \left(\begin{smallmatrix} 1 & 0 \\ N & 1 \end{smallmatrix}\right) \in \Gamma_0(N)$, we have

$$\begin{aligned}\delta\big(X^{k-3}Y\{\alpha, \gamma(\alpha)\}\big) &= \big(\gamma^{-1}(X^{k-3}Y) - X^{k-3}Y\big)\{\alpha\} \\ &= \big(X^{k-3}(NX+Y) - X^{k-3}Y\big)\{\alpha\} \\ &= NX^{k-2}\{\alpha\}.\end{aligned}$$

If $\alpha \neq 0$, then, as mentioned above, $X^{k-2}\{\alpha\} \neq 0$. (If $\alpha = 0$, use XY^{k-3} and $\gamma = \left(\begin{smallmatrix} 1 & N \\ 0 & 1 \end{smallmatrix}\right)$ instead.) Because there is a nonzero element in $\delta(\mathcal{W}_\alpha)$ and $V_{k-2}\{\alpha\}$ has dimension 1, it follows that $\delta(\mathcal{W}_\alpha) = V_{k-2}\{\alpha\}$. The final claim of the proposition is true because $\mathcal{B}_k(\Gamma_0(N);\mathbb{Q}) = \sum_{\alpha\in\mathbb{P}^1(\mathbb{Q})} V_{k-2}\{\alpha\}$. □

Corollary 2.8. *Fix $\alpha \in \mathbb{P}^1(\mathbb{Q})$. Then $\mathcal{W}_\alpha = \mathcal{M}_k(\Gamma_0(N);\mathbb{Q})$ if and only if $N = 1$.*

Proof. When $N = 1$, γ can be any element of $\mathrm{SL}_2(\mathbb{Z})$, so the assertion is clear. Next, suppose that $\mathcal{W}_\alpha = \mathcal{M}_k(\Gamma_0(N);\mathbb{Q})$. If $k = 2$, then by [**4**, Section 1], $\mathcal{W}_\alpha = \mathcal{S}_k(\Gamma_0(N);\mathbb{Q})$, so $N = 1$ since there is always a weight 2 Eisenstein series when $N > 1$. Next, suppose that $k > 2$. By [**5**, Section 1.4, Proposition 5], δ is surjective and by [**5**, Section1.4, Proposition 5] the dimension of the image of δ equals $\#\Gamma_0(N)\backslash\mathbb{P}^1(\mathbb{Q})$. Combining Proposition 2.7 with our assumption that $\mathcal{W}_\alpha = \mathcal{M}_k(\Gamma_0(N);\mathbb{Q})$ implies that $\#\Gamma_0(N)\backslash\mathbb{P}^1(\mathbb{Q}) = 1$, so $N = 1$, as claimed. □

3. *Application to computing periods of newforms*

The authors were led to introduce transportable modular symbols in order to study the error term $(P - \varepsilon(\gamma)\gamma^{-1}P)\{\infty,\alpha\}$ of equation 1 of Proposition 2.1 in the context of computing periods of newforms. There are many ways to compute periods of newforms, but we hope that the method given below will be of value in some contexts.

Section 3.1 contains an algorithm for computing periods that relies on Theorem 2.4. We present a potentially more efficient method in Section 3.2.

3.1. *An algorithm for computing periods*

Let $f = \sum a_n q^n \in S_k(N,\varepsilon)$ be a cuspform, and let $x \in \mathcal{M}_k(N,\varepsilon)$ be a modular symbol. Then $\langle f, x\rangle$ is a linear combination of integrals of the form

$$\big\langle f, X^mY^{k-2-m}\{\alpha,\infty\}\big\rangle = 2\pi i\int_\alpha^{i\infty} f(z)z^m dz, \tag{6}$$

(see [**5**, Section 1.5]), where $\alpha \in \mathfrak{h}^*$ and the integer m satisfies $0 \leqslant m \leqslant k-2$. If $\alpha \in \mathfrak{h}$, then the imaginary part of α is positive, so

$$2\pi i\int_\alpha^{i\infty} f(z)z^m dz = \sum_{n\geqslant 1} a_n c_n,$$

where

$$c_n = 2\pi i\int_\alpha^{i\infty} z^m e^{2\pi i n z} dz.$$

The reversal of summation and integration is justified because the sum converges absolutely. We compute the c_n using the following formula, which we obtain using repeated integration by parts.

Lemma 3.1.

$$\int_{\alpha}^{i\infty} e^{2\pi inz} z^m dz = e^{2\pi in\alpha} \sum_{s=0}^{m} \left\{ \frac{(-1)^s \alpha^{m-s}}{(2\pi in)^{s+1}} \cdot \prod_{j=(m+1)-s}^{m} j \right\}.$$

If α has large imaginary part, the c_n will rapidly converge to 0 as $n \to \infty$. However, the reversal of summation and integration above need not be valid when α is a real number, so for computational purposes we are led to express periods in terms of integrals with end points that are in $\mathfrak{h}$. When $k = 2$, this is easy because of the identity $\{\infty, \gamma(\infty)\} = \{\alpha, \gamma(\alpha)\}$, which is valid for any $\alpha \in \mathfrak{h}^*$. However, this identity can fail when $k > 2$; the failure is made precise in Proposition 2.1.

Since we can take the real part of α to be greater than 0, each of the terms on the right-hand side of Equation 1 can be computed using the sum given by Lemma 3.1.

We showed in Section 2 that every cuspidal modular symbol can be expressed as a sum of symbols of the form $P\{\infty, \gamma(\infty)\}$. Periods of modular symbols of this form can then be computed using the following algorithm.

Algorithm 3.2. Given a triple $\gamma \in \Gamma_0(N)$, $P \in V_{k-2}$ and $g \in S_k(N, \varepsilon)$, this algorithm computes the period integral $\langle g,\ P\{\infty, \gamma(\infty)\}\rangle$.

Express γ as $\left(\begin{smallmatrix} a & b \\ cN & d \end{smallmatrix}\right) \in \Gamma_0(N)$, and set $\alpha = (-d + i)/cN$ in Proposition 2.1.

Replacing γ by $-\gamma$ if necessary, we find that the imaginary parts of α and $\gamma(\alpha) = (a + i)/cN$ are both equal to the positive number $1/cN$.

Equation 6 and Lemma 3.1 can now be used to compute the period integrals provided by Proposition 2.1.

3.2. *The W_N-trick*

In this section, in order to obtain a potentially more efficient way of computing periods than Algorithm 3.2, we generalize the method of Cremona [3] to even integer weight $k \geqslant 2$. In Algorithm 3.2, with $\gamma = \left(\begin{smallmatrix} a & b \\ cN & d \end{smallmatrix}\right)$, the endpoints of the corresponding integrals have imaginary part $1/cN$. However, using the following trick, one can increase the imaginary part of all the endpoints involved to at least $1/d\sqrt{N}$, which is sometimes a significant improvement.

Recall that the Atkin–Lehner involution $W = W_N$ is induced by the matrix $\left(\begin{smallmatrix} 0 & -1 \\ N & 0 \end{smallmatrix}\right)$; it acts on modular forms by sending a cuspform $f \in S_k(N, \varepsilon)$ to the form

$$f|_W(z) = N^{-k/2} z^{-k} f(-1/(Nz)) \in S_k\big(N, \varepsilon^{-1}\big).$$

If f is an eigenvector for W, then necessarily $\varepsilon = \varepsilon^{-1}$. For the rest of this section, we assume that $\varepsilon^2 = 1$. Then W acts on $\mathcal{M}_k(N, \varepsilon)$ by

$$W\Big(P(X, Y)\{\alpha, \beta\}\Big) = \frac{P(Y, -NX)}{N^{k/2-1}} \left\{-\frac{1}{N\alpha}, -\frac{1}{N\beta}\right\},$$

and this action is compatible with the integration pairing.

Proposition 3.3. *Let $g \in S_k(N, \varepsilon)$ be a cuspform that is an eigenform for the Atkin–Lehner involution W having eigenvalue w. Then for any transportable modular symbol $\sum_{j=1}^{m} P_j\{\infty, \gamma_j(\infty)\}$ with $\gamma_j \in \Gamma_0(N)$ and $P_j \in V_{k-2}$, we have for any $\alpha \in \mathfrak{h}$ the following formula:*

$$\left\langle g, \sum_{j=1}^{m} P_j\{\infty, \gamma_j(\infty)\}\right\rangle = \left\langle g, \sum_{j=1}^{m} w\frac{P_j(Y, -NX)}{N^{k/2-1}}\{W(\alpha), \infty\} + \sum_{j=1}^{m}\left(P_j - w\frac{P_j(Y, -NX)}{N^{k/2-1}}\right)\left\{\frac{i}{\sqrt{N}}, \infty\right\} - \sum_{j=1}^{m} P_j\left\{\gamma_j(\alpha), \infty\right\}\right\rangle.$$

Here $W(\alpha) = -1/(N\alpha)$.

If $\gamma_j = \left(\begin{smallmatrix} a_j & b_j \\ c & d \end{smallmatrix}\right)$, where c and d are fixed integers that do not depend on j, then

$$\left\langle g, \sum_{j=1}^{m} P_j\{\infty, \gamma_j(\infty)\}\right\rangle = \left\langle g, \sum_{j=1}^{m} w\frac{P_j(Y, -NX)}{N^{k/2-1}}\left\{\frac{c}{d} + \frac{i}{d\sqrt{N}}, \infty\right\} + \sum_{j=1}^{m}\left(P_j - w\frac{P_j(Y, -NX)}{N^{k/2-1}}\right)\left\{\frac{i}{\sqrt{N}}, \infty\right\} - \sum_{j=1}^{m} P_j\left\{\frac{b_j}{d} + \frac{i}{d\sqrt{N}}, \infty\right\}\right\rangle.$$

Proof. By Proposition 2.1, our condition of transportability implies that we have

$$\sum_{j=1}^{m} P_j\{\infty, \gamma_j(\infty)\} = \sum_{j=1}^{m} P_j\{\alpha, \gamma_j(\alpha)\}.$$

The steps of the following computation are described below.

$$\begin{aligned}
&\langle g, P_j\{\alpha, \gamma_j(\alpha)\}\rangle \\
&\quad = \left\langle g, P_j\left\{\alpha, \frac{i}{\sqrt{N}}\right\} + P_j\left\{\frac{i}{\sqrt{N}}, W(\alpha)\right\} + P_j\{W(\alpha), \gamma_j(\alpha)\}\right\rangle \\
&\quad = \left\langle g, w\frac{W(P_j)}{N^{k/2-1}}\left\{W(\alpha), \frac{i}{\sqrt{N}}\right\} + P_j\left\{\frac{i}{\sqrt{N}}, W(\alpha)\right\} + P_j\{W(\alpha), \gamma_j(\alpha)\}\right\rangle \\
&\quad = \left\langle g, \left(w\frac{W(P_j)}{N^{k/2-1}} - P_j\right)\left\{W(\alpha), \frac{i}{\sqrt{N}}\right\} + P_j\{W(\alpha), \infty\} - P_j\{\gamma_j(\alpha), \infty\}\right\rangle \\
&\quad = \left\langle g, w\frac{W(P_j)}{N^{k/2-1}}\{W(\alpha), \infty\} + \left(P_j - w\frac{W(P_j)}{N^{k/2-1}}\right)\left\{\frac{i}{\sqrt{N}}, \infty\right\} - P_j\{\gamma_j(\alpha), \infty\}\right\rangle.
\end{aligned}$$

In the first step, we break the path from α to $\gamma_j(\alpha)$ into three paths. In the second step, we apply the W-involution to the first term, and use the fact that the action of W is compatible with the pairing $\langle\,,\,\rangle$. The third step involves combining the first two terms, and breaking up the third. In the final step, we replace $\{W(\alpha), i/\sqrt{N}\}$ by $\{W(\alpha), \infty\} + \{\infty, i/\sqrt{N}\}$, and regroup. Taking the sum of both sides of the expression over j from 1 to m gives the first result of the proposition.

Now, following Cremona [2, Section 2.10.8], in order to simultaneously maximize the imaginary parts of $\gamma_j(\alpha)$ and $W(\alpha)$, we take

$$\alpha = \gamma_1^{-1}\left(\frac{b_1}{d} + \frac{i}{d\sqrt{N}}\right).$$

In this case we have

$$W(\alpha) = \frac{c}{d} + \frac{i}{d\sqrt{N}}$$

and

$$\gamma_j(\alpha) = \frac{b_j}{d} + \frac{i}{d\sqrt{N}}.$$

The second formula then follows. □

Remark 3.4. Let $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$. Since the imaginary parts of the terms $i/\sqrt{N}$, $\gamma_j(\alpha)$ and $W(\alpha)$ in the second part of the proposition are all relatively large, the sums appearing in Equation 6 converge relatively quickly if d is small. However, we emphasize that *it is extremely important to choose γ_j in Proposition 3.3 with d small; otherwise, the series will converge very slowly.*

4. *Examples*

The example of Section 4.1 illustrates some of the results of this paper for the weight-12 modular form Δ, and Section 4.2 concerns a nonrational form of level 11 and weight 4. The computations below were done using the first author's implementation of the algorithms of [6] in Magma [1].

4.1. *The weight*-12 *form* Δ

Let $f = \Delta = q \cdot \prod(1-q^n)^{24}$ be the unique normalized eignform in $S_{12}(1)$. The space $\mathcal{M}_{12}(1;\mathbb{Q})$ of modular symbols has dimension 3, and is spanned by $a_1 = X^{10}\{0,\infty\}$, $a_2 = X^8Y^2\{0,\infty\}$, and $a_3 = X^9Y\{0,\infty\}$, and the cuspidal subspace $\mathcal{S}_{12}(1;\mathbb{Q})$ has dimension 2, and is spanned by a_2 and a_3.

As explained in Example 2.2, there is a transportable modular symbol associated to each nonidentity element $\gamma \in \mathrm{SL}_2(\mathbb{Z})$. The transportable symbol

$$\left(2X^2 + 2XY - Y^2\right)^5\left\{\infty, \tfrac{1}{2}\right\} = -300X^9Y\{0,\infty\}$$

is attached to $\left(\begin{smallmatrix} 1 & 1 \\ 2 & 3 \end{smallmatrix}\right)$, and

$$-4665600X^8Y^2\{0,\infty\} - 87300X^9Y\{0,\infty\}$$

is attached to $\left(\begin{smallmatrix} -8 & 5 \\ 19 & -12 \end{smallmatrix}\right)$. Together, these two transportable symbols span $\mathcal{S}_{12}(1;\mathbb{Q})$.

The period map Φ_f sends $X^iY^{10-i}\{0,\infty\}$ to $2\pi i\int_0^\infty z^i f(z)\,\mathrm{dz}$. These integrals are, up to scalars, special values of $L(f,s)$ at critical integers, so they could be computed using any of the standard methods. In any case, we obtain an approximation for the period map:

$$\begin{aligned} \Phi_f(a_1) &\sim 0.0374412812, \\ \Phi_f(a_2) &\sim -0.0159703242, \\ \Phi_f(a_3) &\sim -0.0232962319i. \end{aligned}$$

The period lattice Λ of f is spanned by $\Phi_f((1/14)a_2)$ and $\Phi_f((1/48)a_3)$. (The fractions appear because $\mathcal{S}_{12}(1;\mathbb{Z})$ has basis $(1/14)a_2$ and $(1/48)a_3$.) Since $\mathbb{C}/\Lambda$ is a one-dimensional torus, it makes sense to consider the corresponding elliptic curve over $\mathbb{C}$. This is the elliptic curve $y^2 = x^3 - 27c_4x - 54c_6$, where $c_4 \sim 28091951348793344.58$ and $c_6 \sim -4.70682548 \times 10^{24}$. The j-invariant of this curve is approximately 2592849.394270. Is j a transcendental number?

4.2. *Level* 11, *weight* 4

The unique normalized eigenform in $S_4(\Gamma_0(11))$ is

$$f = q + \alpha q^2 + (-4\alpha + 3)q^3 + (2\alpha - 6)q^4 + (8\alpha - 7)q^5 + \cdots,$$

where $\alpha^2 - 2\alpha - 2 = 0$. The space $\mathcal{M}_4(\Gamma_0(11);\mathbb{Q})$ has basis

$$\begin{aligned}
a_1 &= X^2\{0,\infty\},\\
a_2 &= \left(64X^2 + 16XY + Y^2\right)\left\{-\tfrac{1}{8}, 0\right\},\\
a_3 &= \left(49X^2 + 14XY + Y^2\right)\left\{-\tfrac{1}{7}, 0\right\},\\
a_4 &= \left(25X^2 + 10XY + Y^2\right)\left\{-\tfrac{1}{5}, 0\right\},\\
a_5 &= \left(100X^2 + 20XY + Y^2\right)\left\{-\tfrac{1}{10}, 0\right\},\\
a_6 &= Y^2\{\infty, 0\}.
\end{aligned}$$

The subspace $\mathcal{S}_4(\Gamma_0(11);\mathbb{Q})$ has basis $b_1 = a_2 - a_6$, $b_2 = a_3 - a_6$, $b_3 = a_4 - a_6$, $b_4 = a_5 - a_6$.

As explained in Example 2.2, there is a transportable modular symbol associated to each nonidentity element $\gamma \in \Gamma_0(11)$. For example the transportable symbol

$$\left(11X^2 - 11XY + Y^2\right)\left\{\infty, \tfrac{10}{11}\right\} = 11(a_5 - a_6)$$

is associated to $\gamma = \left(\begin{smallmatrix} 10 & -1 \\ 11 & -1 \end{smallmatrix}\right)$. The symbol

$$-\tfrac{5}{4}b_1 + \tfrac{5}{4}b_2 - \tfrac{1}{4}b_3 + \tfrac{1}{4}b_4$$

is the transportable symbol associated to $\left(\begin{smallmatrix} 5 & -1 \\ 11 & -2 \end{smallmatrix}\right)$. The symbol

$$-\tfrac{9}{8}b_1 - \tfrac{19}{8}b_2 + \tfrac{19}{8}b_3 + \tfrac{99}{8}b_4$$

is associated to $\left(\begin{smallmatrix} 4 & 1 \\ 11 & 3 \end{smallmatrix}\right)$, and

$$-\tfrac{27}{8}b_1 + \tfrac{11}{8}b_2 + \tfrac{9}{8}b_3 + \tfrac{49}{8}b_4$$

is associated to $\left(\begin{smallmatrix} 3 & -2 \\ 11 & -7 \end{smallmatrix}\right)$. Together, these four transportable symbols span $\mathcal{S}_4(\Gamma_0(11);\mathbb{Q})$.

In order to illustrate Section 2.3, we remark that symbols of the form $P\{\infty, \gamma(\infty)\}$ do not span all of $\mathcal{M}_4(\Gamma_0(11);\mathbb{Q})$, but they do span a space bigger than $\mathcal{S}_4(\Gamma_0(11);\mathbb{Q})$. Corollary 2.5 implies that their span contains $\mathcal{S}_4(\Gamma_0(11);\mathbb{Q})$; however, the symbol $Y^2\{\infty, 1/11\}$ does not lie in $\mathcal{S}_4(\Gamma_0(11);\mathbb{Q})$.

Acknowledgements. The authors would like to thank L. Merel and J. Cremona for helpful advice, I. Kiming for improving the proof of Theorem 2.4, and the referee for several helpful remarks.

Preface

We shall begin by discussing some examples of mod ℓ representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. We'll try to motivate Serre's conjectures by referring first to the case of representations that are unramified outside ℓ; these should come from cusp forms on the full modular group $\mathrm{SL}(2,\mathbf{Z})$. In another direction, one might think about representations coming from ℓ-division points on elliptic curves, or more generally from ℓ-division points on abelian varieties of "GL_2-type." Amazingly, Serre's conjectures imply that all odd irreducible two-dimensional mod ℓ representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ may be realized in spaces of ℓ-division points on such abelian varieties. The weak Serre conjecture states that all such representations come from modular forms, and then it takes only a bit of technique to show that one can take the modular forms to have weight two (if one allows powers of ℓ in the level).

Since little work has been done toward proving the weak Serre conjecture, these notes will focus on the bridge between the weak and the strong conjectures. The latter states that each ρ as above comes from the space of cusp forms of a specific weight and level, with these invariants between determined by the local behavior of ρ at ℓ and at primes other than ℓ (respectively). To motivate the strong conjecture, and to begin constructing the bridge, we discuss the local behavior of those ρ that do come from modular forms. For the most part, we look only at forms of weight $k \geq 2$ whose levels N are prime to ℓ. For these forms, the behavior of ρ at ℓ is described in detail in [**32**], where theorems of P. Deligne and Fontaine are recalled. (In [**32**, §6], B. Edixhoven presents a proof of Fontaine's theorem.) Further, the behavior of ρ at primes $p \neq \ell$ may be deduced from H. Carayol's theorems [**11, 12**], which relate the behavior at p of the ℓ-adic representations attached to f with the p-adic component of the automorphic representation of $\mathrm{GL}(2)$ that one associates with f. (The behavior of ρ at ℓ in the case where ℓ divides N is analyzed in [**89**].)

In [**102**], Serre associates to each ρ a level $N(\rho)$ and a weight $k(\rho)$. These invariants are defined so that $N(\rho)$ is prime to ℓ and so that $k(\rho)$ is an integer greater than 1. As Serre anticipated, if ρ arises from a modular form of weight k and level N, and if k is at least 2 and N is prime to ℓ, then one has $k(\rho) \leq k$ and $N(\rho) \mid N$. To find an f for which $N = N(\rho)$ and $k = k(\rho)$ is to "optimize" the level and weight of a form giving ρ. As Edixhoven explains in his article [**32**], weight optimization follows in a somewhat straightforward manner from the theorems of Deligne and Fontaine alluded to above, Tate's theory of θ-cycles, and Gross's theorem on companion forms [**46**] (see also [**17**]). Moreover, it is largely the case that weight and level optimization can be performed independently.

In [**12**], Carayol analyzes the level optimization problem. He shows, in particular, that the problem breaks down into a series of sub-problems, all but one of which he treats by appealing to a single lemma, the lemma of [**12**, §3]. The remaining sub-problem is the one that intervenes in establishing the implication "Shimura-Taniyama $\Longrightarrow$ Fermat." This problem has been discussed repeatedly [**83, 84, 86, 87**]. In Section 3.10, we will explain the principle of [**86**].

The case $\ell = 2$ is the only remaining case for which the level optimization problem has not been resolved. The proof in [**26, 87**] of level optimization for $\ell \geq 3$ does not fully exploit multiplicity one results, but appears to completely break down when $\ell = 2$. In the recent paper [**9**], Kevin Buzzard observed that many new cases of multiplicity one are known and that this can be used to obtain new level optimization results when $\ell = 2$.

In view of these remarks it might be appropriate for us to summarize in a few sentence what is known about the implication "weak Serre conjecture $\Longrightarrow$ strong Serre conjecture." As explained in [**26**], for $\ell \geq 5$ the weak conjecture of Serre implies the strong conjecture about the optimal weight, level, and character. For $\ell = 3$, the weak conjecture implies the strong conjecture, except in a few well-understood situations, where the order of the character must be divisible by ℓ when the level is optimal. The difficulty disappears if one works instead with Katz's definition of a mod ℓ modular form, where the character is naturally defined only mod ℓ. The situation is less complete when $\ell = 2$, but quite favorable. When $\ell = 2$ the situation concerning the weight is explained by Edixhoven in [**32**]: the results of [**17**] do not apply and those of [**46**] rely on unchecked compatibilities.

A certain amount of work has been done on the Hilbert modular case, i.e., the case where $\mathbf{Q}$ is replaced by a totally real number field F. For this work, the reader may consult articles of Frazer Jarvis [**52, 53, 54**], Kazuhiro Fujiwara [**45**], and Ali Rajaei [**79**]. The authors are especially grateful to Fujiwara for sending them a preliminary version of his manuscript, "Level optimization in the totally real case." However, these notes will treat only the classical case $F = \mathbf{Q}$.

This paper emerged out of a series of lectures that were delivered by the first author at the 1999 IAS/Park City Mathematics Institute. The second author created the text based on the lectures and added examples, diagrams, an exercise section, and the index. Brian Conrad contributed the appendix, which describes a construction of Shimura.

For other expository accounts of Serre's conjectures, the reader may consult the articles of Edixhoven [**33, 34, 35**], H. Darmon [**22**], and R. Coleman [**15**].

The authors would like to thank K. Buzzard and Serre for many useful comments on various drafts of this paper, B. Conrad for providing the appendix, M. Emerton for his enlightening lecture on Katz's definition of modular forms, N. Jochnowitz for suggestions that improved the exposition in Section 2.2, and L. Kilford for help in finding examples of mod 2 representations in Section 3.7.

CHAPTER 1

Introduction to Serre's conjecture

1.1. Introduction

Let's start with an elliptic curve $E/\mathbf{Q}$. Nowadays, it's a familiar activity to consider the Galois representations defined by groups of division points of E. Namely, let n be a positive integer, and let $E[n]$ be the kernel of multiplication by n on $E(\overline{\mathbf{Q}})$. The group $E[n]$ is free of rank two over $\mathbf{Z}/n\mathbf{Z}$. After a choice of basis, the action of $\operatorname{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ on $E[n]$ is given by a homomorphism

$$\rho_n : \operatorname{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \operatorname{Aut}(E[n]) \approx \operatorname{GL}(2, \mathbf{Z}/n\mathbf{Z}).$$

This homomorphism is unramified at each prime p that is prime to the product of n with the conductor of E (see Exercise 15). For each such p, the element $\rho_n(\operatorname{Frob}_p)$ is a 2×2 matrix that is well defined up to conjugation. Its determinant is $p \bmod n$; its trace is $a_p \bmod n$, where a_p is the usual "trace of Frobenius" attached to E and p, i.e., the quantity $1 + p - \#E(\mathbf{F}_p)$. In his 1966 article [**107**], G. Shimura studied these representations and the number fields that they cut out for the curve $E = J_0(11)$. (This curve was also studied by Serre [**91**, pg. 254].) He noticed that for prime values $n = \ell$, the representations ρ_n tended to have large images. In [**93**], J-P. Serre proved that for any fixed elliptic curve E, not having complex multiplication, the indices

$$[\operatorname{GL}(2, \mathbf{Z}/n\mathbf{Z}) : \rho_n(\operatorname{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}))]$$

are bounded independently of n. In Shimura's example, Serre proved that

$$[\operatorname{GL}(2, \mathbf{Z}/\ell\mathbf{Z}) : \rho_\ell(\operatorname{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}))] = 1$$

for all $\ell \neq 5$ (see [**93**, §5.5.1]).

In this article, we will be concerned mainly with two-dimensional representations over finite fields. To that end, we restrict attention to the case where $n = \ell$ is prime. The representation ρ_ℓ is "modular" in the familiar sense that it's a representation of a group over a field in positive characteristic. The theme of this course is that it's modular in a different and deeper sense: it comes from a modular form! Indeed, according to a recent preprint of Breuil, Conrad, Diamond and Taylor (see [**7, 19, 114, 117**]), the Shimura-Taniyama conjecture is now a theorem—all elliptic curves over $\mathbf{Q}$ are modular!! Thus if N is the conductor of E, there is a weight-two newform $f = \sum_{n=1}^{\infty} c_n q^n$ ($q = e^{2\pi i z}$) on $\Gamma_0(N)$ with the property that $a_p = c_p$ for all p prime to N. Accordingly, ρ_ℓ is connected up with modular forms via the relation $\operatorname{tr}(\rho_\ell(\operatorname{Frob}_p)) \equiv c_p \pmod{\ell}$, valid for all but finitely many primes p.

The Shimura-Taniyama conjecture asserts that for each positive integer N there is a bijection between isogeny classes of elliptic curves A over $\mathbf{Q}$ of conductor N and rational newforms f on $\Gamma_0(N)$ of weight two. Given A, the Shimura-Taniyama conjecture produces a modular form $f = \sum_{n=1}^{\infty} c_n q^n$ whose Dirichlet series is equal to the L-series of A:

$$\sum_{n=1}^{\infty} \frac{c_n}{n^s} = L(f,s) =\!=\!=\!=\!=\!=\!= L(A,s) = \sum_{n=1}^{\infty} \frac{a_n}{n^s}\ .$$

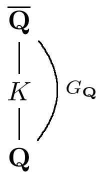
The integers a_n encode information about the number of points on A over various finite fields $\mathbf{F}_p$. If p is a prime not dividing N, then $a_p = p + 1 - \#A(\mathbf{F}_p)$; if $p \mid N$,

$$a_p = \begin{cases} -1 & \text{if } A \text{ has non-split multiplicative reduction at } p \\ 1 & \text{if } A \text{ has split multiplicative reduction at } p \\ 0 & \text{if } A \text{ has additive reduction at } p. \end{cases}$$

The integers a_n are obtained recursively from the a_p as follows:

- $a_{p^r} = \begin{cases} a_{p^{r-1}} a_p - p a_{p^{r-2}} & \text{if } p \nmid N \\ a_p^r & \text{if } p \mid N \end{cases}$
- $a_{nm} = a_n a_m, \qquad$ if $(n,m) = 1$.

The conjectures made by Serre in [**102**], which are the subject of this paper, concern representations $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$. We always require (usually tacitly) that our representations are continuous. The continuity condition just means that the kernel of ρ is open, so that it corresponds to a finite Galois extension K of $\mathbf{Q}$. The representation ρ then embeds $\mathrm{Gal}(K/\mathbf{Q})$ into $\mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$. Since K is a finite extension of $\mathbf{Q}$, the image of ρ is contained in $\mathrm{GL}(2, \mathbf{F})$ for some finite subfield $\mathbf{F}$ of $\overline{\mathbf{F}}_\ell$.



$$\begin{tikzcd} G_{\mathbf{Q}} \arrow[d, two heads] \arrow[dr, "\rho"] & \\ \mathrm{Gal}(K/\mathbf{Q}) \arrow[r, hook] & \mathrm{GL}(2, \overline{\mathbf{F}}_\ell) \end{tikzcd}$$

For various technical reasons, the original conjectures of Serre insist that ρ be irreducible. It is nevertheless fruitful to consider the reducible case as well (see [**111**]).

The conjectures state (in particular) that each continuous irreducible ρ that satisfies a necessary parity condition "arises from" (or is associated with) a suitable modular form mod ℓ. To explain what's going on, let's start with

$$\Delta := \sum_{n=1}^{\infty} \tau(n) q^n = q \prod_{i=1}^{\infty} (1 - q^i)^{24},$$

the unique (normalized) cusp form of weight 12 on $\mathrm{SL}(2, \mathbf{Z})$. In [**92**], Serre conjectured the existence of a "strictly compatible" family of ℓ-adic representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ whose L-function is the L-function of Δ, namely

$$L(\Delta, s) = \sum_{n=1}^{\infty} \tau(n) n^{-s} = \prod_p (1 - \tau(p) p^{-s} + p^{11-2s})^{-1},$$

where the product is taken over all prime numbers p. The conjectured ℓ-adic representations were constructed soon after by Deligne [**24**]. Specifically, Deligne constructed, for each prime ℓ, a representation

$$\rho_{\ell^\infty} : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \mathbf{Z}_\ell),$$

unramified outside ℓ, such that for all primes $p \neq \ell$,

$$\operatorname{tr}(\rho_{\ell^\infty}(\mathrm{Frob}_p)) = \tau(p), \qquad \det(\rho_{\ell^\infty}(\mathrm{Frob}_p)) = p^{11}.$$

On reducing ρ_{ℓ^∞} mod ℓ, we obtain a representation

$$\rho_\ell : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \mathbf{F}_\ell)$$

with analogous properties. (Equalities are replaced by congruences mod ℓ.) In other words, the ρ_ℓ for Δ are just like the ρ_ℓ for an elliptic curve E, except that the integers a_p are replaced by the corresponding values of the τ-function. The determinant of ρ_ℓ is the 11th power of the mod ℓ cyclotomic character $\chi : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathbf{F}_\ell^*$, i.e., the character giving the action of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ on the group of ℓth roots of unity in $\overline{\mathbf{Q}}$ (see Section 1.5).

More generally, take a weight $k \geq 12$ and suppose that $f = \sum_n c_n q^n$ is a nonzero weight-k cusp form for $\mathrm{SL}(2, \mathbf{Z})$ that satisfies $f|T_n = c_n f$ for all $n \geq 1$, T_n being the nth Hecke operator on the space of cusp forms of weight k for $\mathrm{SL}(2, \mathbf{Z})$ (see Section 1.5). Then the complex numbers c_n ($n \geq 1$) are algebraic integers. Moreover, the field $E := \mathbf{Q}(\ldots c_n \ldots)$ generated by the c_n is a totally real number field (of finite degree over $\mathbf{Q}$). Thus the c_n all lie in the integer ring $\mathcal{O}_E$ of E. For each ring homomorphism $\varphi : \mathcal{O}_E \to \overline{\mathbf{F}}_\ell$, one finds a representation

$$\rho = \rho_\varphi : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell),$$

unramified outside ℓ, such that

$$\operatorname{tr}(\rho(\mathrm{Frob}_p)) = \varphi(c_p), \qquad \det(\rho(\mathrm{Frob}_p)) = p^{k-1}$$

for all $p \neq \ell$. We have $\det \rho = \chi^{k-1}$. Of course, there is no guarantee that ρ is irreducible. We can (and do) suppose that ρ is semisimple by replacing it by its semisimplification. Then ρ is determined up to isomorphism by the displayed trace and determinant conditions; this follows from the Cebotarev density theorem and the Brauer-Nesbitt theorem [**21**], which states that semisimple representations are determined by their characteristic polynomials.

It is important to note that k is necessarily an even integer; otherwise the space $S_k(\mathrm{SL}(2, \mathbf{Z}))$ of weight-k cusp forms on $\mathrm{SL}(2, \mathbf{Z})$ is easily seen to be 0. Thus the determinant χ^{k-1} of ρ is an odd power of χ. In particular, $\det \rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathbf{F}_\ell^*$ is unramified outside ℓ and takes the value -1 on complex conjugations $c \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. It's a nice exercise to check that, conversely, all continuous homomorphisms with these properties are odd powers of χ (see Exercise 1).

In the early 1970s, Serre conjectured that all homomorphisms that are "like ρ" come from cusp forms of some weight on $\mathrm{SL}(2, \mathbf{Z})$. Namely, let

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$$

be a continuous, irreducible representation that is (1) unramified outside ℓ and (2) of odd determinant, in the sense that $\det \rho(c) = -1 \in \overline{\mathbf{F}}_\ell$ for complex conjugations $c \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. In a May, 1973 letter to Tate, Serre conjectured that ρ is of the form ρ_φ. This means that there is a weight $k \geq 12$, an eigenform $f \in S_k(\mathrm{SL}(2, \mathbf{Z}))$, and a homomorphism $\varphi : \mathcal{O}_E \to \overline{\mathbf{F}}_\ell$ (where $\mathcal{O}_E$ is the ring of integers of the field generated by the coefficients of f) so that ρ_φ and ρ are isomorphic.

To investigate Serre's conjecture, it is fruitful to consider the operation $\rho \mapsto \rho \otimes \chi$ on representations. This "twisting" operation preserves the set of representations that come from modular forms. Indeed, let $\theta = q\frac{d}{dq}$ be the classical differential operator $\sum a_n q^n \mapsto \sum n a_n q^n$. According to Serre and Swinnerton-Dyer [**61, 94, 112**], if f is a mod ℓ form of weight k, then θf is a mod ℓ form of weight $k+\ell+1$. Then if ρ is associated to f, $\rho \otimes \chi$ is associated with θf. According to a result of Atkin, Serre and Tate (see [**97**, Th. 3] and Section 2.1), if ρ comes from an eigenform in some space $S_k(\mathrm{SL}(2,\mathbf{Z}))$, then a suitable twist $\rho \otimes \chi^i$ of f comes from a form of weight $\leq \ell+1$.

Serre's conjecture thus has the following consequence: each two-dimensional irreducible odd representation of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ over $\overline{\mathbf{F}}_\ell$ that is unramified outside ℓ has a twist (by a power of χ) coming from an eigenform on $\mathrm{SL}(2,\mathbf{Z})$ of weight at most $\ell+1$. In particular, suppose that $\ell < 11$. Then the spaces $S_k(\mathrm{SL}(2,\mathbf{Z}))$ with $k \leq \ell+1$ are all 0; as a result, they contain no nonzero eigenforms! The conjecture that all ρ are modular (of level 1) thus predicts that there are *no* representations of the type contemplated if ℓ is 2, 3, 5 or 7. In support of the conjecture, the non-existence statement was proved for $\ell = 2$ by J. Tate in a July, 1973 letter to Serre [**113**]. Soon after, Serre treated the case $\ell = 3$ by methods similar to those of Tate. (See [**113**, p. 155] for a discussion and a reference to a note in Serre's Œuvres.) Quite recently, Sharon Brueggeman considered the case $\ell = 5$; she proved that the conjectured result follows from the Generalized Riemann Hypothesis (see [**8**]). In another direction, Hyunsuk Moon generalized Tate's result and proved that there are only finitely many isomorphism classes of continuous semisimple Galois representations $\rho : G_{\mathbf{Q}} \to \mathrm{GL}_4(\overline{\mathbf{F}}_2)$ unramified outside 2 such that field $K/\mathbf{Q}$ corresponding to the kernel of ρ is totally real (see [**76**]). Similar work in this direction has been carried out by Joshi [**58**], under additional local hypothesis.

Serre discussed his conjecture with Deligne, who pointed out a number of surprising consequences. In particular, suppose that one takes a ρ coming from an eigenform f' of some weight and of level $N > 1$. On general grounds, ρ has the right to be ramified at primes p dividing N as well as at the prime ℓ. Suppose that, by accident as it were, ρ turned out to be unramified at all primes $p \mid N$. Then the conjecture would predict the existence of a level-1 form f' (presumably of the same weight as f) whose mod ℓ representation was isomorphic to ρ. For example, if $N = \ell^\alpha$ is a power of ℓ, then the conjecture predicts that ρ arises from a form f' of level 1. How could one manufacture the f'?

The passage $f \rightsquigarrow f'$ comes under the rubric of "level optimization". When you take a representation ρ that comes from high level N, and it seems as though that representation comes from a lower level N', then to "optimize the level" is to cough up a form of level N' that gives ρ.

Deligne pointed out also that Serre's conjecture implies that representations ρ over $\overline{\mathbf{F}}_\ell$ are required to "lift" to λ-adic representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. In the recent articles [**80**] and [**81**], R. Ramakrishna used purely Galois cohomological techniques to prove results in this direction.

1.2. The weak conjecture of Serre

In the mid 1980s, Gerhard Frey began lecturing on a link between Fermat's Last Theorem and elliptic curves (see [**42, 43**]). (Earlier, Hellegouarch had also considered links between Fermat's Last Theorem and elliptic curves; see the MathSciNet review and Appendix of [**48**].) As is now well known, Frey proposed that if $a^\ell + b^\ell$ was a perfect ℓth power, then the elliptic curve $y^2 = x(x-a^\ell)(x+b^\ell)$ could be proved to be non-modular. Soon after, Serre pointed out that the non-modularity contemplated by Frey would follow from suitable level-optimization results concerning modular forms [**101**]. To formulate such optimization results, Serre went back to the tentative conjecture that he had made 15 years earlier and decided to study representations $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ that are not necessarily unramified at ℓ. The results, of course, were the conjectures of [**102**].

An important consequence of these conjectures is the so-called "weak conjecture of Serre." As background, we recall that Hecke eigenforms on congruence subgroups of $\mathrm{SL}(2, \mathbf{Z})$ give rise to two-dimensional representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. If we set things up correctly, we get representations over $\overline{\mathbf{F}}_\ell$. More specifically, take integers $k \geq 2$ and $N \geq 1$; these are the weight and level, respectively. Let $f = \sum a_n q^n$ be a normalized Hecke eigenform in the space $S_k(\Gamma_1(N))$ of complex weight-k cusp forms on the subgroup $\Gamma_1(N)$ of $\mathrm{SL}(2, \mathbf{Z})$. Thus f is nonzero and it satisfies $f|T_n = a_n f$ for all $n \geq 1$. Further, there is a character $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ so that $f|\langle d\rangle = \varepsilon(d)f$ for all $d \in (\mathbf{Z}/N\mathbf{Z})^*$, where $\langle d\rangle$ is the diamond-bracket operator. Again, let $\mathcal{O}$ be the ring of integers of the field $\mathbf{Q}(\ldots a_n \ldots)$ generated by the a_n; this field is a number field that is either totally real or a CM field. Consider a ring homomorphism $\varphi : \mathcal{O} \to \overline{\mathbf{F}}_\ell$ as before. Associated to this set-up is a representation $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ with properties that connect it up with f (and φ). First, the representation is unramified at all p not dividing ℓN. Next, for all such p, we have

$$\mathrm{tr}(\rho(\mathrm{Frob}_p)) = a_p, \qquad \det(\rho(\mathrm{Frob}_p)) = p^{k-1}\varepsilon(p);$$

the numbers a_p and $p^{k-1}\varepsilon(p)$, literally in $\mathcal{O}$, are mapped tacitly into $\overline{\mathbf{F}}_\ell$ by φ. The representation ρ is determined up to isomorphism by the trace and determinant identities that are displayed, plus the supplemental requirement that it be semisimple. We are interested mainly in the (generic) case in which ρ is irreducible; in that case, it is of course semisimple.

The construction of ρ from f, k and φ was described in [**24**]. In this article, Deligne sketches a method that manufactures for each non-archimedean prime λ of E a representation $\tilde{\rho}_\lambda : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, E_\lambda)$, where E_λ denotes the completion of E at λ. Given φ, we let $\lambda = \ker\varphi$ and find a model of $\tilde{\rho}_\lambda$ over the ring of integers $\mathcal{O}_\lambda$ of E_λ. Reducing $\tilde{\rho}_\lambda$ modulo λ, we obtain a representation over the finite field $\mathcal{O}_\lambda/\lambda\mathcal{O}_\lambda$, and φ embeds this field into $\overline{\mathbf{F}}_\ell$.

In fact, as Shimura has pointed out, the machinery of [**24**] can be avoided if one seeks only the mod λ representation attached to f (as opposed to the full λ-adic representation $\tilde{\rho}_\lambda$). As the first author pointed out in [**87**], one can use congruences among modular forms to find a form of weight two and level $N\ell^2$ that gives rise to ρ. Accordingly, one can find ρ concretely by looking within the group of ℓ-division points of a suitable abelian variety over $\mathbf{Q}$: the variety $J_1(\ell^2 N)$, which is defined in Section 2.3 and in Conrad's Appendix.

Which representations of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ arise in this way (as k, N, f and φ all vary)? As in the case $N = 1$ (i.e., that where $\Gamma_1(N) = \mathrm{SL}(2, \mathbf{Z})$), any ρ that comes from modular forms is an odd representation: we have $\det(\rho(c)) = -1$ when $c \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ is a complex conjugation. To see this, we begin with the fact that $\varepsilon(-1) = (-1)^k$, which generalizes (1.4); this follows from the functional equation that relates $f(\frac{az+b}{cz+d})$ to $f(z)$ when $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ is an element of $\Gamma_0(N)$ (see Exercise 7). On the other hand, using the Cebotarev density theorem, we find that $\det\rho = \chi^{k-1}\varepsilon$, where χ is again the mod ℓ cyclotomic character and where ε is regarded now as a map $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \overline{\mathbf{F}}_\ell^*$ in the obvious way, namely by composing $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \overline{\mathbf{F}}_\ell^*$

with the mod N cyclotomic character. The value on c of the latter incarnation of ε is the number $\varepsilon(-1) = (-1)^k$. Since $\chi(c) = -1$, we deduce that $(\det \rho)(c) = -1$, as was claimed.

Serre's weak conjecture states that, conversely, every irreducible odd representation $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ is modular in the sense that it arises from some f and φ.

A concrete consequence of the conjecture is that all odd irreducible 2-dimensional Galois representations ρ come from abelian varieties over $\mathbf{Q}$. Given ρ, one should be able to find a totally real or CM number field E, an abelian variety A over $\mathbf{Q}$ of dimension $[E : \mathbf{Q}]$ that comes equipped with an action of the ring of integers $\mathcal{O}$ of E, and a ring homomorphism $\varphi : \mathcal{O} \to \overline{\mathbf{F}}_\ell$ with the following property: Let $\lambda = \ker \varphi$. *Then the representation* $A[\lambda] \otimes_{\mathcal{O}/\lambda} \overline{\mathbf{F}}_\ell$ *is isomorphic to* ρ. (In comparing $A[\lambda]$ and ρ, we use $\varphi : \mathcal{O}/\lambda \hookrightarrow \overline{\mathbf{F}}_\ell$ to promote the 2-dimensional $A[\lambda]$ into a representation over $\overline{\mathbf{F}}_\ell$.)

Much of the evidence for the weak conjecture concerns representations taking values in $\mathrm{GL}(2, \mathbf{F}_q)$ where the finite field $\mathbf{F}_q$ has small cardinality. In his original article [**102**, §5], Serre's discusses a large number of examples of such representations. Serre uses theorems of Langlands [**68**] and Tunnell [**115**] to establish his weak conjecture for odd irreducible representations with values in $\mathrm{GL}(2, \mathbf{F}_2)$ and $\mathrm{GL}(2, \mathbf{F}_3)$. Further, he reports on numerical computations of J.-F. Mestre that pertain to representations over $\mathbf{F}_4$ (and trivial determinant). Additionally, Serre remarks [**102**, p. 219] that the weak conjecture is true for those representations with values in $\mathrm{GL}(2, \overline{\mathbf{F}}_p)$ that are dihedral in the sense that their projective images (in $\mathrm{PGL}(2, \overline{\mathbf{F}}_p)$) are dihedral groups. (See also [**29**, §5] for a related argument.) This section of Serre's paper concludes with examples over $\mathbf{F}_9$ and $\mathbf{F}_7$.

More recently, representations over the fields $\mathbf{F}_4$ and $\mathbf{F}_5$ were treated, under somewhat mild hypotheses, by Shepherd-Barron and Taylor [**105**]. For example, Shepherd-Barron and Taylor show that $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \mathbf{F}_5)$ is isomorphic to the 5-torsion representaton of an elliptic curve over $\mathbf{Q}$ provided that $\det \rho$ is the mod 5 cyclotomic character. Because elliptic curves over $\mathbf{Q}$ are modular, it follows that ρ is modular.

1.3. The strong conjecture

Fix an odd irreducible Galois representation

$$\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell).$$

As discussed above, the weak conjecture asserts that ρ is modular, in the sense that there exists integers N and k such that ρ comes from some $f \in S_k(\Gamma_1(N))$. The *strong conjecture* goes further and gives a recipe for integers $N(\rho)$ and $k(\rho)$, then asserts that ρ comes from $S_{k(\rho)}(\Gamma_1(N(\rho)))$. In any particular instance, the strong conjecture is, a priori, easier to verify or disprove than the weak conjecture because $S_{k(\rho)}(\Gamma_1(N(\rho)))$ is a finite-dimensional vector space that can be computed (using, e.g., the algorithm in [**73**]). The relation between the weak and strong conjectures is analogous to the relation between the assertion that an elliptic curve is modular of some level and the assertion that an elliptic curve A is modular of a specific level, the conductor of A.

For each prime p, let $I_p \subset G_{\mathbf{Q}}$ denote an inertia group at p. The optimal level is a product

$$N(\rho) = \prod_{p \neq \ell} p^{n(p)},$$

where $n(p)$ depends only on $\rho|_{I_p}$. The optimal weight $k(\rho)$ depends only on $\rho|_{I_\ell}$. The integer $n(p)$ is a conductor in additive notation. In particular, $n(p) = 0$ if and only if ρ is unramified at p.

View ρ as a homomorphism $G_{\mathbf{Q}} \to \operatorname{Aut}(V)$, where V is a two-dimensional vector space over $\overline{\mathbf{F}}_\ell$. It is natural to consider the subspace of inertia invariants:

$$V^{I_p} := \{v \in V : \rho(\sigma)v = v, \text{ all } \sigma \in I_p\}.$$

For example, $V^{I_p} = V$ if and only if ρ is unramified at p. Define

$$n(p) := \dim(V/V^{I_p}) + \operatorname{Swan}(V),$$

where the wild term $\operatorname{Swan}(V)$ is the Swan conductor

$$\operatorname{Swan}(V) := \sum_{i=1}^{\infty} \frac{1}{[G_0 : G_i]} \dim(V/V^{G_i}) \geq 0.$$

Here $G_0 = I_p$ and the $G_i \subset G_0$ are the higher ramification groups.

Suppose that ρ arises from a newform $f \in S_k(\Gamma_1(N))$. A theorem of Carayol [**12**], which was proved independently by Livné [**70**, Prop. 0.1], implies that $N(\rho) \mid N$. It is productive to study the quotient $N/N(\rho)$. Let $\mathcal{O}$ be the ring of integers of the field generated by the Fourier coefficients of f and let $\varphi : \mathcal{O} \to \overline{\mathbf{F}}_\ell$ be the map such that $\varphi(a_p) = \operatorname{tr}(\rho(\operatorname{Frob}_p))$. Let λ be a prime of $\mathcal{O}$ lying over ℓ and E_λ be the completion of $\operatorname{Frac}(\mathcal{O})$ at λ. Deligne [**24**] attached to the pair f, λ a representation

$$\rho_\lambda : G_{\mathbf{Q}} \to \operatorname{GL}(2, E_\lambda) = \operatorname{Aut}(\tilde{V})$$

where $\tilde{V}$ is a two-dimensional vector space over E_λ. The representation ρ_λ can be conjugated so that its images lies inside $\operatorname{GL}(2, \mathcal{O}_\lambda)$; the reduction of ρ_λ modulo λ is then ρ. The following diagram summarizes the set up:

$$\begin{tikzcd}
 & & \operatorname{GL}(2, E_\lambda) = \operatorname{Aut}(\tilde{V}) \\
G_{\mathbf{Q}} \arrow[r] \arrow[urr, bend left, "\rho_\lambda"] \arrow[drr, bend right, "\rho"'] & \operatorname{GL}(2, \mathcal{O}_\lambda) \arrow[ur, hook] \arrow[dr, "\varphi"] & \\
 & & \operatorname{GL}(2, \overline{\mathbf{F}}_\ell) = \operatorname{Aut}(V)
\end{tikzcd}$$

Let $m(p)$ be the power of p dividing the conductor of ρ_λ. In [**12**], Carayol proves that $m(p) = \operatorname{ord}_p N$. As above, $m(p) = \dim(\tilde{V}/\tilde{V}^{I_p}) + (\text{wild term})$, and the wild term is the same as for ρ. The power of p dividing $N/N(\rho)$ is $\dim(\tilde{V}/\tilde{V}^{I_p}) - \dim(V/V^{I_p}) = \dim V^{I_p} - \dim \tilde{V}^{I_p}$. Though $\tilde{V}$ and V are vector spaces over different fields, we can compare the dimensions of their inertia invariant subspaces. The formula

$$\operatorname{ord}_p(N) = n(p) + (\dim V^{I_p} - \dim \tilde{V}^{I_p}) \tag{1.1}$$

indicates how this difference is the deviation of N from the optimal level locally at p. This is the description of $n(p)$ that is used in proving that if ρ is modular at all, then it is possible to refine N and k to eventually discover that ρ arises from a newform in $S_{k(\rho)}(\Gamma_1(N(\rho)))$. After much work (see [**26, 87**]) it has been shown that *for $\ell > 2$ the weak and strong conjectures are equivalent.* See [**9**] for equivalence in many cases when $\ell = 2$.

Rearranging (1.1) into

$$n(p) = \mathrm{ord}_p(N) - (\dim V^{I_p} - \dim \tilde{V}^{I_p})$$

provides us with a way to read off $N(\rho)$ from $\mathrm{ord}_p(N)$, $\dim V^{I_p}$, and $\dim \tilde{V}^{I_p}$. If $f \in S_k(\Gamma_1(N))$ gives rise to ρ and $\ell \nmid N$, then $k(\rho) \leq k$. In contrast, if we allow powers of ℓ in the level then the weight k can always be made equal to 2.

1.4. Representations arising from an elliptic curve

Equations for elliptic curves can be found in the Antwerp tables [**4**] and the tables of Cremona [**20**]. For example, consider the elliptic curve B given by the equation $y^2+y = x^3+x^2-12x+2$. This is the curve labeled **141A1** in [**20**]; it has conductor $N = 3 \cdot 47$ and discriminant $\Delta = 3^7 \cdot 47$. There is a newform $f \in S_2(\Gamma_0(141))$ attached to B. Because N is square free, the elliptic curve B is *semistable*, in the sense that B has multiplicative reduction at each prime.

The curve B is isolated in its isogeny class; equivalently, for every ℓ the representation

$$\rho_\ell : G_{\mathbf{Q}} \to \mathrm{Aut}(B[\ell]) \approx \mathrm{GL}(2, \mathbf{F}_\ell)$$

is irreducible (see Exercise 4 and Exercise 5). We will frequently consider the representations ρ_ℓ attached to B. The following proposition shows that because B is semistable, each ρ_ℓ is surjective [**93**].

Proposition 1.1. *If A is a semistable elliptic curve over $\mathbf{Q}$ and ℓ is a prime such that ρ_ℓ is irreducible, then ρ_ℓ is surjective.*

Proof. Serre proved this when ℓ is odd; see [**93**, Prop. 21], [**103**, §3.1]. If ρ_2 isn't surjective, then by [**93**, Prop. 21(b)] and Theorem 2.10 it's unramified outside 2. This contradicts [**113**]. □

To give a flavor of Serre's invariants, we describe $N(\rho_\ell)$ and $k(\rho_\ell)$ for the representations ρ_ℓ attached to B. (Note that we still have not defined $k(\rho)$.) At primes p of bad reduction, after a possible unramified quadratic extension of $\mathbf{Q}_p$, the elliptic curve B is a Tate curve. This implies that for $p \neq \ell$, the representation ρ_ℓ is unramified at p if and only if $\mathrm{ord}_p(\Delta) \equiv 0 \pmod{\ell}$; for more details, see Section 2.4.

The optimal level $N(\rho_\ell)$ is a divisor of $3 \cdot 47$; it is divisible only by primes for which ρ_ℓ is ramified, and is not divisible by ℓ. The representation ρ_ℓ is unramified at 3 if and only if $\ell \mid \mathrm{ord}_3(\Delta) = 7$, i.e., when $\ell = 7$. Furthermore, ρ_ℓ is always ramified at 47. First suppose $\ell \notin \{3, 47\}$. If in addition $\ell \neq 7$ then $N(\rho_\ell) = 3 \cdot 47$, and $k(\rho_\ell) = 2$ since $\ell \nmid 3 \cdot 47$. If $\ell = 7$ then $N(\rho_\ell) = 47$, and again $k(\rho_\ell) = 2$. The remaining cases are $\ell = 3$ and $\ell = 47$. If $\ell = 47$ then $N(\rho_\ell) = 3$, and because $\ell - 1$ is the order of the cyclotomic character, $k(\rho_\ell) \equiv 2 \pmod{47-1}$; Serre's recipe then gives $k(\rho_\ell) = 2 + (47 - 1) = 48$. Similarly, when $\ell = 3$, we have $N(\rho_\ell) = 47$ and $k(\rho_\ell) = 2 + (3 - 1) = 4$. The following table summarizes the Serre invariants:

Table 1.4. The Serre invariants of ρ_ℓ

ℓ	$N(\rho_\ell)$	$k(\rho_\ell)$
3	47	4
7	47	2
47	3	48
all other ℓ	141	2

To verify the strong conjecture of Serre for $\ell = 3, 47$, we use a standard tradeoff of level and weight, which relates eigenforms in $S_2(\Gamma_0(141); \mathbf{F}_\ell)$ to eigenforms in $S_{2+\ell-1}(\Gamma_0(141/\ell); \mathbf{F}_\ell)$ (see Section 3.1). The only exceptional prime is $\ell = 7$, for which the minimal weight $k(\rho)$ is 2. The strong conjecture of Serre predicts the existence of an eigenform $g \in S_2(\Gamma_0(47))$ that gives rise to ρ_ℓ. Our initial instinct is to look for an elliptic curve A of conductor 47 such that $A[\ell] \cong B[\ell]$, as $G_{\mathbf{Q}}$-modules. In fact, there are no elliptic curves of conductor 47. This is because $S_2(\Gamma_0(47))$ is four dimensional, having basis the Galois conjugates of a single eigenform $g = \sum c_n q^n$. The Fourier coefficients c_n of g generate the full ring of integers in the field K obtained from $\mathbf{Q}$ by adjoining a root of $h = x^4 - x^3 - 5x^2 + 5x - 1$. The discriminant $1957 = 19 \cdot 103$ of K equals the discriminant of h, so a root of h generates the full ring of integers. The eigenvalue c_2 satisfies $h(c_2) = 0$. Since $h \equiv (x+2)(x^3 + 4x^2 + x + 3) \pmod 7$, there is a prime λ lying over 7 such that $\mathcal{O}/\lambda \cong \mathbf{F}_7$; the isomorphism is given by $c_2 \mapsto -2 \bmod 7$. As a check, note that $\#B(\mathbf{F}_2) = 5$ so $a_2 = 3 - 5 = -2 = \varphi(c_2)$. More generally, for $p \nmid 7 \cdot 141$, we have $\varphi(c_p) \equiv a_p \bmod 7$. This equality of traces implies that the representation $\rho_{g,\lambda}$ is isomorphic to $\rho = \rho_{A,7}$, so A is modular of level 47.

1.5. Background material

In this section, we review the cyclotomic character, Frobenius elements, modular forms, and Tate curves. We frequently write $G_{\mathbf{Q}}$ for $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. Many of these basics facts are also summarized in [**23**].

1.5.1. The cyclotomic character

The mod ℓ *cyclotomic character* is defined by considering the group $\boldsymbol{\mu}_\ell$ of ℓth roots of unity in $\overline{\mathbf{Q}}$; the action of the Galois group $G_{\mathbf{Q}}$ on the cyclic group $\boldsymbol{\mu}_\ell$ gives rise to a continuous homomorphism

$$\chi_\ell : G_{\mathbf{Q}} \to \mathrm{Aut}(\boldsymbol{\mu}_\ell). \tag{1.2}$$

Since $\boldsymbol{\mu}_\ell$ is a cyclic group of order ℓ, its group of automorphisms is canonically the group $(\mathbf{Z}/\ell\mathbf{Z})^* = \mathbf{F}_\ell^*$. We emerge with a map $G_{\mathbf{Q}} \to \mathbf{F}_\ell^*$, which is the character in question.

Let A be an elliptic curve and ℓ be a prime number. The Weil pairing e_ℓ (see [**109**, III.8]) sets up an isomorphism of $G_{\mathbf{Q}}$-modules

$$e_\ell : \bigwedge^2 A[\ell] \xrightarrow{\cong} \boldsymbol{\mu}_\ell. \tag{1.3}$$

The determinant of the representation $\rho_{A,\ell}$ is the mod ℓ cyclotomic character χ_ℓ.

Suppose now that $c \in G_{\mathbf{Q}}$ is the automorphism "complex conjugation." Then the determinant of $\rho_{A,\ell}(c)$ is $\chi_\ell(c)$. Now c operates on roots of unity by the map

$\zeta \mapsto \zeta^{-1}$, since roots of unity have absolute value 1. Accordingly,

$$\det \rho_{A,\ell}(c) = -1; \tag{1.4}$$

one says that $\rho_{A,\ell}$ is *odd*. If $\ell \neq 2$, then $\rho_{A,\ell}(c)$ is conjugate over $\overline{\mathbf{F}}_\ell$ to $\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ (Exercise 7). If $\ell = 2$ then the characteristic polynomial of $\rho_{A,\ell}(c)$ is $(x+1)^2$ so $\rho_{A,\ell}(c)$ is conjugate over $\overline{\mathbf{F}}_\ell$ to either the identity matrix or $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$.

1.5.2. Frobenius elements

Let K be a number field. The Galois group $\mathrm{Gal}(K/\mathbf{Q})$ leaves the ring $\mathcal{O}_K$ of integers of K invariant, so that one obtains an induced action on the ideals of $\mathcal{O}_K$. The set of prime ideals $\mathfrak{p}$ of $\mathcal{O}_K$ lying over p (i.e., that contain p) is permuted under this action. For each $\mathfrak{p}$, the subgroup $D_\mathfrak{p}$ of $\mathrm{Gal}(K/\mathbf{Q})$ fixing $\mathfrak{p}$ is called the *decomposition group* of $\mathfrak{p}$. Meanwhile, $\mathbf{F}_\mathfrak{p} := \mathcal{O}_K/\mathfrak{p}$ is a finite extension of $\mathbf{F}_p$. The extension $\mathbf{F}_\mathfrak{p}/\mathbf{F}_p$ is necessarily Galois; its Galois group is cyclic, generated by the Frobenius automorphism $\varphi_p : x \mapsto x^p$ of $\mathbf{F}_\mathfrak{p}$. There is a natural surjective map $D_\mathfrak{p} \to \mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p)$; its injectivity is equivalent to the assertion that p is unramified in $K/\mathbf{Q}$. Therefore, whenever this assertion is true, there is a unique $\sigma_\mathfrak{p} \in D_\mathfrak{p}$ whose image in $\mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p)$ is φ_p. The automorphism $\sigma_\mathfrak{p}$ is then a well-defined element of $\mathrm{Gal}(K/\mathbf{Q})$, the Frobenius automorphism for $\mathfrak{p}$. The various $\mathfrak{p}$ are all conjugate under $\mathrm{Gal}(K/\mathbf{Q})$ and that the Frobenius automorphism for the conjugate of $\mathfrak{p}$ by g is $g\sigma_\mathfrak{p}g^{-1}$. In particular, the various $\sigma_\mathfrak{p}$ are all conjugate; this justifies the practice of writing σ_p for any one of them and stating that σ_p is well defined up to conjugation.

We next introduce the concept of Frobenius elements in $G_\mathbf{Q} = \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. Let p again be a prime and let $\mathfrak{p}$ now be a prime of the ring of integers of $\overline{\mathbf{Q}}$ lying over p. To $\mathfrak{p}$ we associate: (1) its residue field $\mathbf{F}_\mathfrak{p}$, which is an algebraic closure of $\mathbf{F}_p$, and (2) a decomposition subgroup $D_\mathfrak{p}$ of $G_\mathbf{Q}$. There is again a surjective map $D_\mathfrak{p} \to \mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p)$. The Frobenius automorphism φ_p topologically generates the target group. We shall use the symbol Frob_p to denote any preimage of φ_p in any $D_\mathfrak{p}$ corresponding to a prime lying over p, and refer to Frob_p as a Frobenius element for p in $G_\mathbf{Q}$. This element is doubly ill defined. The ambiguity in Frob_p results from the circumstance that $\mathfrak{p}$ needs to be chosen and from the fact that $D_\mathfrak{p} \to \mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p)$ has a large kernel, the inertia subgroup $I_\mathfrak{p}$ of $D_\mathfrak{p}$. The usefulness of $\mathrm{Frob}_\mathfrak{p}$ stems from the fact that the various $\mathfrak{p}$ are all conjugate, so that likewise the subgroups $D_\mathfrak{p}$ and $I_\mathfrak{p}$ are conjugate. Thus if ρ is a homomorphism mapping $G_\mathbf{Q}$ to some other group, the kernel of ρ contains one $I_\mathfrak{p}$ if and only if it contains all $I_\mathfrak{p}$. In this case, one says that ρ is *unramified* at p; the image of Frob_p is then an element of the target that is well defined up to conjugation.

Consider an elliptic curve A over $\mathbf{Q}$ and let ℓ be a prime number. The fixed field of $\rho_{A,\ell}$ is a finite Galois extension $K_\ell/\mathbf{Q}$ whose Galois group G_ℓ is a subgroup of $\mathrm{GL}(2, \mathbf{F}_\ell)$. A key piece of information about the extension $K_\ell/\mathbf{Q}$ is that its discriminant is divisible at most by ℓ and primes dividing the conductor of A. In other words, if $p \neq \ell$ is a prime number at which A has good reduction, then $K_\ell/\mathbf{Q}$ is unramified at ℓ (see Exercise 15); one says that the representation $\rho_{A,\ell}$ is unramified at p. Whenever this occurs, the construction described above produces a Frobenius element σ_p in G_ℓ that is well defined up to conjugation.

Fix again an elliptic curve A and a prime number ℓ, and let $\rho_{A,\ell} : G_\mathbf{Q} \to \mathrm{GL}(2, \mathbf{F}_\ell)$ be the associated representation. For each prime p not dividing ℓ at which A has good reduction the Frobenius $\sigma_p = \rho_{A,\ell}(\mathrm{Frob}_p)$ is well defined only up to conjugation. Nevertheless, the trace and determinant of σ_p are well defined. The determinant of $\rho_{A,\ell}$ is the mod ℓ cyclotomic character χ, so $\sigma_p = \chi(\mathrm{Frob}_p) = p \in \mathbf{F}_\ell$. On the other hand, one has the striking congruence

$$\mathrm{tr}(\rho_{A,\ell}(\mathrm{Frob}_p)) = p + 1 - \#\tilde{A}(\mathbf{F}_p) \pmod{\ell}.$$

1.5.3. Modular forms

We now summarize some background material concerning modular forms. Serre's book [**96**] is an excellent introduction (it treats only $N = 1$). One might also read the survey article [**27**] or consult any of the standard references [**65, 66, 75, 108**].

The *modular group* $\mathrm{SL}(2, \mathbf{Z})$ is the group of 2×2 invertible integer matrices. For each positive integer N, consider the subgroup

$$\Gamma_1(N) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbf{Z}) \ : \ N \mid c \quad \text{and} \quad a \equiv d \equiv 1 \pmod{N} \right\}.$$

Let $\mathfrak{h}$ be the complex upper half plane. A *cusp form* of integer weight $k \geq 1$ and level N is a holomorphic function $f(z)$ on $\mathfrak{h}$ such that

$$f\left(\frac{az+b}{cz+d}\right) = (cz+d)^k f(z) \quad \text{for all } \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_1(N); \tag{1.5}$$

we also require that $f(z)$ vanishes at the cusps (see [**108**, §2.1]). We denote by $S_k(\Gamma_1(N))$ the space of weight-k cusp forms of level N. It is a finite dimensional complex vector space. When $k \geq 2$ a formula for the dimension can be found in [**108**, §2.6].

Modular forms are usually presented as convergent Fourier series

$$f(z) = \sum_{n=1}^{\infty} a_n q^n$$

where $q := e^{2\pi i z}$. This is possible because the matrices $\left(\begin{smallmatrix} 1 & b \\ 0 & 1 \end{smallmatrix}\right)$ lie in $\Gamma_1(N)$ so that $f(z+b) = f(z)$ for all integers b. For the forms that most interest us, the complex numbers a_n are algebraic integers.

The space $S_k(\Gamma_1(N))$ is equipped with an action of $(\mathbf{Z}/N\mathbf{Z})^*$; this action is given by

$$f(z) \mapsto f|\langle \overline{d} \rangle(z) := (cz+d)^{-k} f\left(\frac{az+b}{cz+d}\right)$$

where $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}(2, \mathbf{Z})$ is any matrix such that $d \equiv \overline{d} \pmod{N}$. The operator $\langle d \rangle = \langle \overline{d} \rangle$ is referred to as a "diamond-bracket" operator.

For each integer $n \geq 1$, the nth *Hecke operator* on $S_k(\Gamma_1(N))$ is an endomorphism T_n of $S_k(\Gamma_1(N))$. The action is generally written on the right: $f \mapsto f|T_n$. The various T_n commute with each other and are interrelated by identities that express a given T_n in terms of the Hecke operators indexed by the prime factors of n. If $p \nmid N$ is a prime define the operator T_p on $S_k(\Gamma_1(N))$ by

$$f|T_p(z) = \sum_{n=1}^{\infty} a_{np} q^n + p^{k-1} \sum_{n=1}^{\infty} a_n (f|\langle p \rangle) q^{np}.$$

For $p \mid N$ prime, define T_p by

$$f|T_p(z) = \sum_{n=1}^{\infty} a_{np} q^n.$$

The *Hecke algebra* associated to cusp forms of weight k on $\Gamma_1(N)$ is the subring

$$\mathbf{T} := \mathbf{Z}[\ldots T_n \ldots \langle d \rangle \ldots] \subset \mathrm{End}(S_k(\Gamma_1(N)))$$

generated by all of the T_n and $\langle d \rangle$. It is finite as a module over $\mathbf{Z}$ (see Exercise 20). The diamond-bracket operators are really Hecke operators, in the sense that they lie in the ring generated by the T_n; thus $\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots]$.

An *eigenform* is a nonzero element $f \in S_k(\Gamma_1(N))$ that is a simultaneous eigenvector for every element of the Hecke algebra $\mathbf{T}$. Writing $f = \sum a_n q^n$ we find that $a_n = a_1 c_n$ where c_n is the eigenvalue of T_n on f. Since f is nonzero, a_1 is also nonzero, so it is possible to multiply f by a_1^{-1}. The resulting *normalized eigenform* wears its eigenvalues on its sleeve: $f = \sum c_n q^n$. Because f is an eigenform, the action of the diamond bracket operators defines a character $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$; we call ε the *character* of f.

Associated to an eigenform $f \in S_k(\Gamma_1(N))$ we have a system $(\ldots a_p \ldots)$, $p \nmid N$, of eigenvalues. We say that f is a *newform* if this system of eigenvalues is not the system of eigenvalues associated to an eigenform $g \in S_k(\Gamma_1(M))$ for some level $M \mid N$ with $M \neq N$. Newforms have been extensively studied (see [**2, 13, 69, 75**]); the idea is to understand where systems of eigenvalues first arise, and then reconstruct the full space $S_k(\Gamma_1(N))$ from newforms of various levels.

1.5.4. Tate curves

The Tate curve is a p-adic analogue of the exponentiation of the representation $\mathbf{C}/\Lambda$ of the group of an elliptic curve over $\mathbf{C}$. In this section we recall a few facts about Tate curves; for further details, see [**110**, V.3].

Let K be a finite extension of $\mathbf{Q}_p$; consider an elliptic curve E/K with *split multiplicative* reduction, and let j denote the j-invariant of E. By formally inverting the well-known relation

$$j(q(z)) = \frac{1}{q(z)} + 744 + 196884 q(z) + \cdots$$

between the complex functions $q(z) = e^{2\pi i z}$ and $j(z)$, we find an element $q \in K^*$ with $j = j(q)$ and $|q| < 1$. There is a $\mathrm{Gal}(\overline{\mathbf{Q}}_p/K)$-equivariant isomorphism $E(\overline{\mathbf{Q}}_p) \cong \overline{\mathbf{Q}}_p^*/q^{\mathbf{Z}}$. The Tate curve, which we suggestively denote by $\mathbf{G}_m/q^{\mathbf{Z}}$, is a scheme whose $\overline{\mathbf{Q}}_p$ points equal $\overline{\mathbf{Q}}_p^*/q^{\mathbf{Z}}$.

As a consequence, the group of n-torsion points on the Tate curve is identified with the $\mathrm{Gal}(\overline{\mathbf{Q}}_p/K)$-module $\{\zeta_n^a (q^{1/n})^b : 0 \leq a, b \leq n-1\}$; here ζ_n is a primitive nth root of unity and $q^{1/n}$ is a fixed nth root of q in $\overline{\mathbf{Q}}_p$. In particular, the subgroup generated by ζ_n is invariant under $\mathrm{Gal}(\overline{\mathbf{Q}}_p/K)$, so the local Galois representation on $E[n]$ is reducible. It is also known that the group of connected component of the reduction of the Néron model of E over $\overline{\mathbf{F}}_p$ is a cyclic group whose order is $\mathrm{ord}_p(q)$. The situation is summarized by the following table (taken from [**88**]):

Complex case	p-adic case
$\mathbf{C}/\Lambda$	no p-adic analogue
$\Big\downarrow$ exponential map $e^{2\pi i z}$	no exponential available
$\mathbf{C}^*/q^{\mathbf{Z}}$	$K^*/q^{\mathbf{Z}}$.

Remark 1.2. When E has non-split multiplicative reduction over K, there is an unramified extension L over which E aquires split multiplicative reduction.

1.5.5. Mod ℓ modular forms

There are several excellent papers to consult when learning about mod ℓ modular forms. The papers of Serre [**95**] and Swinnerton-Dyer [**112**] approach the subject from the point of view of Galois representations. Katz's paper [**59**] is very geometric. Edixhoven's paper [**32**] contains a clear description of the basic facts. See also Jochnowitz's paper [**56**].

CHAPTER 2

Optimizing the weight

In [**102**, §2] Serre associated to an odd irreducible Galois representation

$$\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$$

two integers $N(\rho)$ and $k(\rho)$, which are meant to be the minimal level and weight of a form giving rise to ρ.

Conjecture 2.1 (Strong conjecture of Serre)**.** Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be an odd irreducible Galois representation arising from a modular form. Then ρ arises from a modular form of level $N(\rho)$ and weight $k(\rho)$.

In this chapter, we are concerned with $k(\rho)$. We consider a mod ℓ representation ρ that arises from an eigenform of level N not divisible by ℓ. Using results of Fontaine and Deligne, we motivate Serre's recipe for $k(\rho)$. In [**32**], Edixhoven also defines an "optimal" weight, which sometimes differs from Serre's $k(\rho)$. Our definition is an "average" of the two; for example, we introduce a tiny modification of $k(\rho)$ when $\ell = 2$. We appologize for any confusion this may cause the reader.

Using various arguments involving the Eichler-Shimura correspondence and Tate's θ-cycles, Edixhoven showed in [**31**] that there must exist another form of weight at most $k(\rho)$, also of level N, which gives rise to ρ. Some of Edixhoven's result rely on unchecked compatibilities that are assumed in [**46**]; however, when $\ell \neq 2$ these results were obtained unconditionally by Coleman and Voloch in [**17**]. We sketch some of Edixhoven's arguments to convey the flavor of the subject.

Remark 2.2 (Notation)**.** We pause to describe a notational shorthand which we will employ extensively in this chapter. If $\rho : G \to \mathrm{Aut}(V)$ is a two-dimensional representation over a field $\mathbf{F}$, we will frequently write

$$\rho \sim \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$$

to mean that there is a basis for V with respect to which

$$\rho(x) = \begin{pmatrix} \alpha(x) & \beta(x) \\ \gamma(x) & \delta(x) \end{pmatrix} \in \mathrm{GL}_2(\mathbf{F})$$

for all $x \in G$. If we do not wish to specify one of the entries we will simply write $*$. Thus "$\rho \sim \left(\begin{smallmatrix} * & * \\ 0 & 1 \end{smallmatrix}\right)$" means that ρ possesses a one-dimensional invariant subspace, and the action on the quotient is trivial.

2.1. Representations arising from forms of low weight

We first consider irreducible Galois representations associated to newforms of low weight. Fix a prime ℓ and suppose $f = \sum a_n q^n$ is a newform of weight k and level N, such that $\ell \nmid N$ and $2 \leq k \leq \ell+1$. Let $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ denote the character of f. Fix a homomorphism φ from the ring of integers $\mathcal{O}$ of $\mathbf{Q}(\ldots a_n \ldots)$ to $\overline{\mathbf{F}}_\ell$. To abbreviate, we often write a_n for $\varphi(a_n)$; thereby thinking of a_n as an element $\overline{\mathbf{F}}_\ell$. Let $\rho = \rho_{f,\varphi} : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be the two-dimensional semisimple odd Galois representation attached to f and φ, and assume that ρ is irreducible.

The recipe for $N(\rho)$ depends on the local behavior of ρ at primes p other than ℓ; the recipe for $k(\rho)$ depends on the restriction $\rho|_{I_\ell}$ of ρ to the inertia group at ℓ. Motivated by questions of Serre, Fontaine and Deligne described $\rho|_{I_\ell}$ in many situations. We distinguish two cases: the ordinary case and the non-ordinary case, which we call the *"supersingular case."*

2.1.1. The ordinary case

Deligne (see [**46**, Prop. 12.1]) considered the *ordinary case*, in which ρ arises from a weight-k newform f with $a_\ell(f) \neq 0 \in \overline{\mathbf{F}}_\ell$. He showed that ρ has a one-dimensional unramified quotient β, so $\rho|_{D_\ell} \sim \begin{pmatrix} \alpha & * \\ 0 & \beta \end{pmatrix}$ with $\beta(I_\ell) = 1$ and $\alpha\beta = \chi^{k-1}\varepsilon$. The mod N character ε is also unramified at ℓ because $\ell \nmid N$. Since the mod ℓ cyclotomic character χ has order $\ell - 1$ and $\rho|_{I_\ell} \sim \begin{pmatrix} \chi^{k-1} & * \\ 0 & 1 \end{pmatrix}$, the value of k modulo $\ell - 1$ is determined by $\rho|_{I_\ell}$. In the case when k is not congruent to 2 modulo $\ell - 1$, the restriction $\rho|_{I_\ell}$ determines the minimal weight $k(\rho)$. We will discuss the remaining case in Section 2.2.

2.1.2. The supersingular case and fundamental characters

Fontaine (see [**32**, §6]) investigated the supersingular case, in which ρ arises from a newform f with $a_\ell(f) = 0 \in \overline{\mathbf{F}}_\ell$. We call such a newform f *supersingular.* To describe the restriction $\rho|_{I_\ell}$ of ρ to the inertia group at ℓ, we introduce the fundamental characters of the tame inertia group. Fix an algebraic closure $\overline{\mathbf{Q}}_\ell$ of the field $\mathbf{Q}_\ell$ of ℓ-adic numbers; let $\mathbf{Q}_\ell^{\mathrm{nr}} \subset \overline{\mathbf{Q}}_\ell$ denote the maximal unramified extension of $\mathbf{Q}_\ell$, and $\mathbf{Q}_\ell^{\mathrm{tm}} \subset \overline{\mathbf{Q}}_\ell$ the maximal tamely ramified extension of $\mathbf{Q}_\ell^{\mathrm{nr}}$. The extension $\mathbf{Q}_\ell^{\mathrm{tm}}$ is the compositum of all finite extensions of $\mathbf{Q}_\ell^{\mathrm{nr}}$ in $\overline{\mathbf{Q}}_\ell$ of degree prime to ℓ. Letting D_ℓ denote the decomposition group, I_ℓ the inertia group, I_t the tame inertia group, and I_w the wild inertia group, we have the following diagram:

$$\begin{tikzcd}
\overline{\mathbf{Q}}_\ell \arrow[d, dash, "I_w"] \arrow[ddd, dash, bend right=40, "D_\ell"'] \arrow[dd, dash, bend left=60, "I_\ell"] \\
\mathbf{Q}_\ell^{\mathrm{tm}} \arrow[d, dash, "I_t"] \\
\mathbf{Q}_\ell^{\mathrm{nr}} \arrow[d, dash, "\widehat{\mathbf{Z}}"] \\
\mathbf{Q}_\ell
\end{tikzcd}$$

It is a standard fact (see, e.g., [**44**, §8]) that the extensions $\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell})$, for all n not divisible by ℓ, generate $\mathbf{Q}_\ell^{\mathrm{tm}}$. For n not divisible by ℓ, the nth roots of unity $\boldsymbol{\mu}_n$ are contained in $\mathbf{Q}_\ell^{\mathrm{nr}}$. Kummer theory (see [**3**]) gives, for each n, a canonical isomorphism

$$\mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell})/\mathbf{Q}_\ell^{\mathrm{nr}}) \xrightarrow{\sim} \boldsymbol{\mu}_n, \qquad \sigma \mapsto \frac{\sigma(\sqrt[n]{\ell})}{\sqrt[n]{\ell}}.$$

Each isomorphism lifts to a map $I_\ell \to \boldsymbol{\mu}_n$ that factors through the tame quotient I_t of I_ℓ. The groups $\boldsymbol{\mu}_n = \boldsymbol{\mu}_n(\overline{\mathbf{Q}}_\ell)$ lie in the ring of integers $\overline{\mathbf{Z}}_\ell$ of $\overline{\mathbf{Q}}_\ell$. Composing any of the maps $I_t \to \boldsymbol{\mu}_n$ with reduction modulo the maximal ideal of $\overline{\mathbf{Z}}_\ell$ gives a mod ℓ character $I_t \to \overline{\mathbf{F}}_\ell^*$, as illustrated:

$$\begin{tikzcd}
I_t \arrow[rrr] \arrow[dr] & & & \overline{\mathbf{F}}_\ell^* \\
& \boldsymbol{\mu}_n(\overline{\mathbf{Q}}_\ell) \arrow[r, "\cong"] & \boldsymbol{\mu}_n(\overline{\mathbf{F}}_\ell). \arrow[ur, hook] &
\end{tikzcd}$$

Let $n = \ell^\nu - 1$ with $\nu > 0$. The map $I_t \to \boldsymbol{\mu}_n$ defines a character $\varepsilon : I_\ell \to \mathbf{F}_{\ell^\nu}^*$. Composing with each of the ν field embeddings $\mathbf{F}_{\ell^\nu} \to \overline{\mathbf{F}}_\ell$ gives the ν *fundamental characters* of level ν:

$$\begin{tikzcd}
I_t \arrow[dr] & & \overline{\mathbf{F}}_\ell. \\
& \mathbf{F}_{\ell^\nu}^* \subset \mathbf{F}_{\ell^\nu} \arrow[ur, shift left=2] \arrow[ur] \arrow[ur, shift right=2, "\nu \text{ maps}"'] &
\end{tikzcd}$$

For example, the unique fundamental character of level 1 is the mod ℓ cyclotomic character (see Exercise 16). When $\nu = 2$, there are two fundamental characters, denoted Ψ and Ψ'; these satisfy $\Psi^\ell = \Psi'$ and $(\Psi')^\ell = \Psi$.

Let A be an elliptic curve over $\mathbf{Q}_\ell$ with good supersingular reduction. In [**93**], Serre proved that the representation

$$I_t \to \mathrm{Aut}(A[\ell]) \subset \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$$

is the direct sum of the two fundamental characters Ψ and Ψ'. One of the characters is

$$I_t \to \mathbf{F}_{\ell^2}^* \subset \mathrm{GL}(2, \mathbf{F}_\ell)$$

where $\mathbf{F}_{\ell^2}^*$ is contained in $\mathrm{GL}(2, \mathbf{F}_\ell)$ as a non-split Cartan subgroup of $\mathrm{GL}(2, \mathbf{F}_\ell)$. More precisely, $\mathbf{F}_{\ell^2}^*$ is embedded in $\mathrm{GL}(2, \mathbf{F}_\ell)$ via the action of the multiplicative group of a field on itself after a choice of basis. More generally, in unpublished joint work, Fontaine and Serre proved in 1979 that if f is a supersingular eigenform of weight $k \leq \ell$, then $\rho|_{I_\ell} : I_\ell \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ factors through I_t and is a direct sum of the two character Ψ^{k-1} and $(\Psi')^{k-1}$. Note that k is determined by this representation, because it is determined modulo $\ell^2 - 1$.

2.2. Representations of high weight

Let D_ℓ be a decomposition group at ℓ and consider a representation $\rho : D_\ell \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ that arises from a newform f of possibly large weight k. Let ρ^{ss} denote the *semisimplification* of ρ; so $\rho^{\mathrm{ss}} = \rho$ if ρ is irreducible, otherwise ρ^{ss} is a direct sum of two characters α and β. The following lemma of Serre (see [**93**, Prop. 4]) asserts that ρ^{ss} is tamely ramified.

Lemma 2.3. *Any semisimple representation ρ is tame, in the sense that $\rho(I_w) = 0$.*

Proof. Since the direct sum of tame representations is tame, we may assume that ρ is simple.

The wild inertia group I_w is the profinite Sylow ℓ-subgroup of I_ℓ: it is a Sylow ℓ-subgroup because each finite Galois extension of $\mathbf{Q}_\ell^{\mathrm{tm}}$ has degree a power of ℓ, and the order of I_t is prime to ℓ; it is unique, because it is the kernel of $\mathrm{Gal}(\overline{\mathbf{Q}}_\ell/\mathbf{Q}_\ell) \to \mathrm{Gal}(\overline{\mathbf{Q}}_\ell/\mathbf{Q}_\ell^{\mathrm{tm}})$, hence normal.

Because ρ is continuous, the image of D_ℓ is finite and we view ρ as a representation on a vector space W over a finite extension of $\mathbf{F}_\ell$. The subspace

$$W^{I_w} = \{w \in W : \sigma(\tau)w = w \text{ for all } \tau \in I_w\}$$

is invariant under D_ℓ. It is nonzero, as can be seen by writing the finite set W as a disjoint union of its orbits under I_w: since I_w is a pro-ℓ-group, each orbit has size either 1 or a positive power of ℓ. The orbit $\{0\}$ has size 1, and $\#W$ is a power of ℓ, so there must be at least $\ell - 1$ other singleton orbits $\{w\}$; for each of these, $w \in W^{I_w}$.

Since ρ is simple and W^{I_w} is a nonzero D_ℓ-submodule, it follows that $W^{I_w} = W$, as claimed. □

The restriction $\rho^{\mathrm{ss}}|_{I_\ell}$ is abelian and semisimple, so it is given by a pair of characters $\alpha, \beta : I_\ell \to \overline{\mathbf{F}}_\ell^*$. Let n be an integer not divisible by ℓ, and consider the tower of fields

$$\begin{tikzcd}
\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell}) \arrow[d, dash, "\boldsymbol{\mu}_n"] \arrow[dd, dash, bend right, "G"'] \\
\mathbf{Q}_\ell^{\mathrm{nr}} \arrow[d, dash, "\widehat{\mathbf{Z}}=\langle \mathrm{Frob}_\ell \rangle"] \\
\mathbf{Q}_\ell
\end{tikzcd}$$

in which $G = \mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell})/\mathbf{Q}_\ell)$, $\boldsymbol{\mu}_n \cong \mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell})/\mathbf{Q}_\ell^{\mathrm{nr}})$, and $\mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}/\mathbf{Q}_\ell)$ is topologically generated by a Frobenius element at ℓ. Choose a lift $g \in G$ of Frob_ℓ, and consider an element $h \in \boldsymbol{\mu}_n$ corresponding to an element $\sigma \in \mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[n]{\ell})/\mathbf{Q}_\ell^{\mathrm{nr}})$. Then since g acts as the ℓth powering map on roots of unity,

$$\frac{g\sigma g^{-1}(\sqrt[n]{\ell})}{\sqrt[n]{\ell}} = \frac{g\sigma(\zeta_{g^{-1}}\sqrt[n]{\ell})}{\sqrt[n]{\ell}} = \frac{g(\zeta_{g^{-1}}h\sqrt[n]{\ell})}{\sqrt[n]{\ell}} = \frac{g(h)\sqrt[n]{\ell}}{\sqrt[n]{\ell}} = h^\ell.$$

Applying the conjugation formula $ghg^{-1} = h^\ell$ to ρ^{ss} gives $\rho^{\mathrm{ss}}(ghg^{-1}) = \rho^{\mathrm{ss}}(h^\ell) = \rho^{\mathrm{ss}}(h)^\ell$. The two representations $h \mapsto \rho^{\mathrm{ss}}(h)^\ell$ and $h \mapsto \rho^{\mathrm{ss}}(h)$ of I_t are thus equivalent via conjugation by $\rho^{\mathrm{ss}}(g)$; we have $\rho^{\mathrm{ss}}(g)\rho^{\mathrm{ss}}(h)\rho^{\mathrm{ss}}(g^{-1}) = \rho^{\mathrm{ss}}(ghg^{-1}) = \rho^{\mathrm{ss}}(h)^\ell$. Consequently, the pair of characters $\{\alpha, \beta\}$ is stable under the ℓth power map, so as a set $\{\alpha, \beta\} = \{\alpha^\ell, \beta^\ell\}$. There are two possibilities:

— The *ordinary case*: $\alpha^\ell = \alpha$ and $\beta^\ell = \beta$.

— The *supersingular case*: $\alpha^\ell = \beta \neq \alpha$ and $\beta^\ell = \alpha \neq \beta$.

In the first case α and β take values in $\mathbf{F}_\ell^*$ and in the second case they take values in $\mathbf{F}_{\ell^2}^*$ but not in $\mathbf{F}_\ell^*$. By the results discussed in Section 2.1, this terminology is consistent with the terminology introduced above.

We first consider the supersingular case. Let Ψ denote one of the fundamental characters of level 2, and write $\alpha = \Psi^n$, $\beta = \Psi^{n\ell}$, with n an integer modulo ℓ^2-1. Next write the smallest non-negative representative for n in base ℓ: $n = a + \ell b$ with $0 \leq a, b \leq \ell - 1$. Then $\ell n \equiv b + \ell a \pmod{\ell^2-1}$. Switching α and β permutes a and b so, relabeling if necessary, we may assume that $a \leq b$. If $a = b$, then $\alpha = \Psi^a(\Psi')^a = \chi^a$, so α takes values in $\mathbf{F}_\ell^*$, which is not the supersingular case; thus we may assume that $0 \leq a < b \leq \ell - 1$. We now factor out by a power of the cyclotomic character:

$$\begin{aligned}\alpha &= \Psi^n = \Psi^a(\Psi')^b = \Psi^a(\Psi')^a(\Psi')^{b-a} = \chi^a(\Psi')^{b-a}\\ \beta &= \chi^a\Psi^{b-a}.\end{aligned}$$

Put another way,

$$\rho^{\mathrm{ss}} \sim \chi^a \otimes \begin{pmatrix}\Psi^{b-a} & 0\\ 0 & (\Psi')^{b-a}\end{pmatrix}.$$

The untwisted representation is $\left(\begin{smallmatrix}\Psi^{k-1} & 0\\ 0 & (\Psi')^{k-1}\end{smallmatrix}\right)$, where $k = 1 + b - a$. Since $2 \leq 1+b-a \leq \ell-1$, the weight of the untwisted representation is in the range considered above. Thus we are in good shape to define $k(\rho)$.

Before giving $k(\rho)$ it is necessary to understand how the weight changes upon twisting by a power of the cyclotomic character χ. This problem is addressed by the theory of mod ℓ modular forms, first developed by Serre [**95**] and Swinnerton-Dyer [**112**], then generalized by Katz [**59**]. A brief review of the geometric theory, which gives an excellent definition of mod ℓ modular forms, can be found in [**32**, §2], [**35**, §1], or [**46**, §2].

In [**61**], Katz defined spaces of mod ℓ modular forms, and a q-expansion map

$$\alpha : \bigoplus_{k\geq 0} M_k(\Gamma_1(N); \mathbf{F}_\ell) \to \mathbf{F}_\ell[[q]].$$

This map is not injective, because both the Hasse invariant of weight $\ell - 1$ and the constant 1 have the same q-expansion.

Definition 2.4. The *minimal weight filtration* $w(f) \in \mathbf{Z}$ of an element f of the *ring* of mod ℓ modular forms is the smallest integer k such that the q-expansion of f comes from a modular form of weight k; if no such k exists, do not define $w(f)$.

Definition 2.5. Define the operator $\theta = q\frac{d}{dq}$ on q-expansions by $\theta(\sum a_n q^n) = \sum n a_n q^n$.

For example, if f is an eigenform of weight k, then there is a mod ℓ eigenform θf of weight $k + \ell + 1$, still of level N, whose q-expansion is $\theta(\sum a_n q^n)$.

Theorem 2.6. *Let f be a mod ℓ modular form. Then $w(\theta f) = w(f) + \ell + 1$ if and only if $\ell \nmid w(f)$. In addition, if $\ell \mid w(f)$ then $w(\theta f) < w(f) + \ell + 1$.*

2.2.1. The supersingular case

We now give Serre's recipe for $k(\rho)$ in the supersingular case. The minimal weight before twisting is $1+b-a$, which is a positive integer that is not divisible by ℓ. Each twist by χ adds $\ell+1$ to the weight, so in the supersingular case we are motivated to define

$$k(\rho) := (1+b-a) + a(\ell+1) = 1 + \ell a + b.$$

We have to check that *at each step* the weight is prime to ℓ, so the minimal weight does not drop during any of the a twists by χ. Since $1 < 1+b-a < \ell$ and

$$(1+b-a) + a(\ell+1) \leq (\ell-1) + (\ell-2)(\ell+1) < \ell^2,$$

the weight can only drop if there exists c with $1 \leq c < a$ such that

$$(1+b-a) + c(\ell+1) \equiv 0 \pmod{\ell}.$$

If this occurred, then $c \equiv a-b-1 \pmod{\ell}$. But $1 \leq c < a \leq \ell-2$, so either $c = a-b-1$, which implies $c \leq 0$ since $a < b$, or $c = \ell+a-b-1 = a+\ell-1-b \geq a$, which would be a contradiction.

Assume that $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ arises from an eigenform f such that $a_\ell(f) = 0 \in \overline{\mathbf{F}}_\ell$. Now we sketch Edixhoven's proof that ρ arises from a mod ℓ eigenform of weight $k(\rho)$.

Let ρ^{ss} denote the semisimplification of the restriction of ρ to a decomposition group at ℓ. The restriction of ρ^{ss} to the inertia group at ℓ is

$$\rho^{\mathrm{ss}}|_{I_\ell} \sim \begin{pmatrix} \Psi^n & 0 \\ 0 & (\Psi')^n \end{pmatrix},$$

where Ψ and $\Psi' = \Psi^\ell$ are the two fundamental characters of level 2. If necessary, reorder Ψ and Ψ' so that $n = a + b\ell$ with $0 \leq a < b \leq \ell-1$. Then

$$\Psi^n = \Psi^{a+b\ell} = \Psi^a(\Psi')^b = \Psi^a(\Psi')^a(\Psi')^{b-a} = \chi^a(\Psi')^{b-a},$$

and

$$\rho^{\mathrm{ss}}|_{I_\ell} \sim \chi^a \otimes \begin{pmatrix} (\Psi')^{b-a} & 0 \\ 0 & \Psi^{b-a} \end{pmatrix}.$$

Recall that, motivated by Fontaine's theorem on Galois representations arising from supersingular eigenforms, we defined

$$k(\rho) = a(\ell+1) + (b-a+1) = 1 + \ell a + b.$$

The first step in showing that ρ arises from a form of weight $k(\rho)$, is to recall the well known result that, up to twist, all systems of mod ℓ eigenvalues occur in weight at most $\ell+1$. This is the subject of the next section.

2.2.2. Systems of mod ℓ eigenvalues

Theorem 2.7. *Suppose ρ is modular of level N and some weight k, and that $\ell \nmid N$. Then some twist $\rho \otimes \chi^{-\alpha}$ is modular of weight $\leq \ell+1$ and level N.*

This is a general theorem, applying to both the ordinary and supersingular cases. See Serre [**97**, Th. 3] when $N = 1$; significant further work was carried out by Jochnowitz [**55**] and Ash-Stevens [**1**, Thm. 3.5] when $\ell \geq 5$. Two proofs are given in [**32**, Thm. 3.4 and §7]. The original method of Serre, Tate, and Koike for treating questions like this is to use the Eichler-Selberg trace formula. As Serre has pointed out to us, the weight appears in that formula simply as an exponent; this makes more or less clear that a congruence modulo ℓ^2-1 gives information on modular forms mod ℓ.

As a digression, we pause to single out some of the tools involved in one possible proof of Theorem 2.7. Note that by twisting we may assume without loss of generality that $k \geq 2$. The group $\Gamma_1(N)$ acts by matrix multiplication on the real vector space $\mathbf{R}^2$. The Eichler-Shimura correspondence (see [**108**, §8.2]) is an isomorphism of real vector spaces

$$S_k(\Gamma_1(N)) \xrightarrow{\cong} H^1_P(\Gamma_1(N), \mathrm{Sym}^{k-2}(\mathbf{R}^2)).$$

The *parabolic* (or cuspidal) cohomology group H^1_P is the intersection, over all cusps $\alpha \in \mathbf{P}^1(\mathbf{Q})$, of the kernels of the restriction maps

$$\mathrm{res}_\alpha : H^1(\Gamma_1(N), \mathrm{Sym}^{k-2}(\mathbf{R}^2)) \to H^1(\Gamma_\alpha, \mathrm{Sym}^{k-2}(\mathbf{R}^2)),$$

where Γ_α denotes the stabilizer of α. For fixed z_0 in the upper half plane, the Eichler-Shimura isomorphism sends a cusp form f to the class of the cocycle $c : \Gamma_1(N) \to \mathrm{Sym}^{k-2}(\mathbf{R}^2)$ induced by

$$\gamma \mapsto \int_{z_0}^{\gamma(z_0)} \mathrm{Re}\left(f(z) \begin{pmatrix} z \\ 1 \end{pmatrix}^{k-2} dz \right),$$

where $\begin{pmatrix} z \\ 1 \end{pmatrix}^{k-2}$ denotes the image of $\begin{pmatrix} z \\ 1 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} z \\ 1 \end{pmatrix} \in \mathrm{Sym}^{k-2}(\mathbf{C}^2)$, and integration is coordinate wise. There is an action of the Hecke algebra $\mathbf{T}$ on

$$H^1_P(\Gamma_1(N), \mathrm{Sym}^{k-2}(\mathbf{R}^2)),$$

such that the Eichler-Shimura correspondence is an isomorphism of $\mathbf{T}$-modules.

The forms whose periods are integral form a lattice $H^1_P(\Gamma_1(N), \mathrm{Sym}^{k-2}(\mathbf{Z}^2))$ inside $H^1_P(\Gamma_1(N), \mathrm{Sym}^{k-2}(\mathbf{R}^2))$. Reducing this lattice modulo ℓ suggests that there is a relationship between mod ℓ modular forms and the cohomology group

$$H^1_P(\tilde{\Gamma}_1(N), \mathrm{Sym}^{k-2}(\mathbf{F}_\ell^2)),$$

where $\tilde{\Gamma}_1(N)$ is the image of $\Gamma_1(N)$ in $\mathrm{SL}(2, \mathbf{F}_\ell)$. Serre and Hida observed that for $k - 2 \geq \ell$ the $\tilde{\Gamma}_1(N)$ representations $\mathrm{Sym}^{k-2}(\mathbf{F}_\ell^2)$ are sums of representations arising in $\mathrm{Sym}^{k'-2}(\mathbf{F}_\ell^2)$ for $k' < k$. This essential idea is used in proving that all systems of eigenvalues occur in weight at most $\ell + 1$.

2.2.3. The supersingular case revisited

Let ρ be a supersingular mod ℓ representation that arises from some modular form. By Theorem 2.7 there is a form f of weight $k \leq \ell + 1$ such that $\chi^{-\alpha} \otimes \rho \sim \rho_f$. In fact, we may assume that $2 \leq k \leq \ell$; when $k = \ell + 1$ a theorem of Mazur (see [**32**, Thm. 2.8]) implies that there is a form of weight 2 giving rise to ρ_f, and when $k = 1$ we multiply f by the weight $\ell - 1$ Hasse invariant. To show that $w(\theta^\alpha f) = k(\rho)$ we investigate how application of the θ-operator changes the minimal weight. We have $(\rho_f \otimes \chi^\alpha)|_{I_\ell} \sim \left(\begin{smallmatrix} \Psi^n & 0 \\ 0 & (\Psi')^n \end{smallmatrix}\right)$ with $n = a + b\ell$ and $a < b$. Fontaine's theory (see Section 2.1) identifies the characters corresponding to $\rho_f|_{I_\ell}$ as powers Ψ^{k-1} and $(\Psi')^{k-1}$ of the fundamental characters. This gives an equality of unordered sets

$$\{\Psi^{k-1}\chi^\alpha, (\Psi')^{k-1}\chi^\alpha\} = \{\Psi^n, (\Psi')^n\}.$$

It is now possible to compute $w(\theta^\alpha f)$ by considering two cases, corresponding to the ways in which equality of unordered pairs can occur.

Case 1. Suppose that $\Psi^{k-1}\chi^{\alpha} = (\Psi')^n$. Since $\chi = \Psi^{\ell+1}$, we have

$$\Psi^{k-1+\alpha(\ell+1)} = \Psi^{k-1}\chi^{\alpha} = (\Psi')^n = (\Psi')^{a+b\ell} = \Psi^{b+a\ell}.$$

Comparing exponents of Ψ gives

$$k - 1 + \alpha(\ell+1) \equiv b + a\ell \pmod{\ell^2 - 1}, \tag{2.1}$$

which reduces modulo $\ell + 1$ to $k - 1 \equiv b - a \pmod{\ell+1}$; because $2 \leq k \leq \ell$, this implies that $k = 1 + b - a$. Reducing (2.1) modulo $\ell - 1$ and substituting $k = 1 + b - a$ gives $b - a + 2\alpha \equiv b + a \pmod{\ell - 1}$; we find the possible solutions $\alpha = a + m(\ell-1)/2$ with m an integer. No solution $\alpha = a + m(\ell-1)/2$, with m odd, satisfies (2.1), so $\alpha = a$ as an integer mod $\ell - 1$. Finally, we apply Theorem 2.6 and argue as in the end of Section 2.2, to show that

$$w(\theta^a f) = w(f) + a(\ell+1) = 1 + b - a + a\ell + a = 1 + b + a\ell = k(\rho).$$

Case 2. Suppose that $\Psi^{k-1}\chi^{\alpha} = \Psi^n$. Then

$$\Psi^{k-1+\alpha(\ell+1)} = \Psi^{k-1}\chi^{\alpha} = \Psi^n = \Psi^{a+b\ell}.$$

Comparing powers of Ψ, we obtain

$$k - 1 + \alpha(\ell+1) \equiv a + b\ell \pmod{\ell^2 - 1}, \tag{2.2}$$

which reduces modulo $\ell+1$ to $k - 1 \equiv a - b \pmod{\ell+1}$; thus $k = \ell + 2 - (b - a)$. The difference $b - a$ must be greater than 1; otherwise $k = \ell + 1$, contrary to our assumption that $2 \leq k \leq \ell$. Reducing (2.2) modulo $\ell - 1$ gives

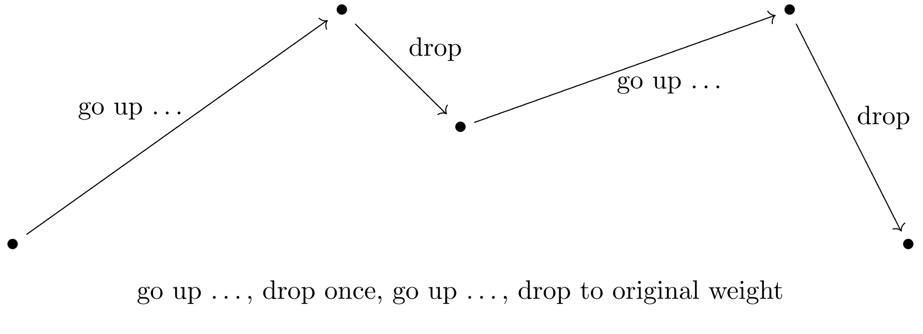
$$k - 1 + 2\alpha \equiv a + b \pmod{\ell - 1};$$

substituting $k = \ell + 2 - (b - a)$ we find that $\alpha = b - 1 + m(\ell - 1)/2$ with m an integer. If m is odd, then α does not satisfy (2.2), so $\alpha = b - 1$ as an integer modulo $\ell - 1$. It remains to verify the equality $w(\theta^{b-1}f) = w(\rho)$. Unfortunately, $k = \ell + 2 - (b - a)$ is not especially telling. The argument of Case 1 does not apply to compute $w(\theta^{\alpha}f)$; instead we use θ-cycles.

Because f is supersingular, Fermat's Little Theorem implies that $\theta^{\ell-1}f = f$. We use Tate's theory of θ-cycles (see [**32**, §7] and [**55**]) to compute $w(\theta^{b-1}f)$. The θ-cycle associated to f is the sequence of integers

$$w(f), w(\theta f), w(\theta^2 f), \ldots, w(\theta^{\ell-2}f), w(f).$$

The θ-cycle for any supersingular eigenform must behave as follows (see Theorem 2.6):



go up ..., drop once, go up ..., drop to original weight

Knowing this, we can deduce the exact θ-cycle. List ℓ numbers starting and ending with k:

$$\begin{aligned}&k,\ k+(\ell+1),\ k+2(\ell+1),\ \ldots,\ k+(\ell-k)(\ell+1),\\ &\ell+3-k,\ (\ell+3-k)+(\ell+1),\ \ldots,\ (\ell+3-k)+(k-3)(\ell+1),\\ &k\end{aligned}$$

The first and second lines contain $\ell+1-k$ and $k-2$ numbers, respectively. All told, ℓ numbers are listed; this must be the θ-cycle.

It is now possible to compute $w(\theta^{b-1}f)$. If

$$b-1 \le \ell-k = \ell-(\ell+2-b+a) = -2+b-a,$$

then $a \le -1$, a contradiction; thus $b-1 > \ell-k$. It follows that

$$w(\theta^{b-1}f) = \ell+3-k+(\ell+1)(b-2-(\ell-k)) = 1+b+a\ell = k(\rho),$$

verifying Serre's conjecture in this case.

2.2.4. The ordinary case

We next turn to the ordinary case, in which

$$\rho|_{I_\ell} \sim \begin{pmatrix}\alpha & * \\ 0 & \beta\end{pmatrix}$$

with $\alpha,\beta : I_\ell \to \mathbf{F}_\ell^*$ powers of the cyclotomic character. View $\rho|_{I_\ell}$ as the twist of a representation in which the lower right entry is 1:

$$\begin{pmatrix}\alpha & * \\ 0 & \beta\end{pmatrix} \sim \beta \otimes \begin{pmatrix}\alpha\beta^{-1} & * \\ 0 & 1\end{pmatrix}.$$

To determine the minimal weight of a form giving rise to $\rho|_{I_\ell}$, it is necessary to develop an ordinary version of θ-cycles. In general this is complicated, so we make the simplifying assumption that $\beta = 1$; then $\rho|_{I_\ell} \sim \begin{pmatrix}\chi^i & * \\ 0 & 1\end{pmatrix}$ with $1 \le i \le \ell-1$. Deligne showed that if f is of weight k and $\beta = 1$, then the associated representation is $\left(\begin{smallmatrix}\chi^{k-1} & * \\ 0 & 1\end{smallmatrix}\right)$ with $2 \le k \le \ell+1$. Motivated by this, our first reaction is to define $k(\rho)$ to be $i+1$. This definition does not distinguish between the extreme weights 2 and $\ell+1$ because they are congruent modulo $\ell-1$. Given a representation ρ arising from a form of weight either 2 or $\ell+1$, we cannot, in general, set $k(\rho) = 2$. For example, suppose $f = \Delta$ is the level 1 cusp form of weight 12 and ρ is the associated mod 11 representation. It would be wrong to set $k(\rho) = 2$, because there is no cusp form of weight 2 and level 1.

Warning: When $\ell = 2$ and our $k(\rho)$ is 3, Serre replaced $k(\rho)$ by 4 because there are no weight-3 modular forms whose character is of degree coprime to $\ell = 2$.

2.3. Distinguishing between weights 2 and $\ell+1$

We continue to motivate the definition of $k(\rho)$. Consider a representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ that arises from a newform f of the optimal level $N = N(\rho)$ and weight k satisfying $2 \le k \le \ell+1$. Assume that f is ordinary in the sense that $a_\ell(f) \ne 0 \in \overline{\mathbf{F}}_\ell$. Then, as discussed in Section 2.1,

$$\rho|_{I_\ell} \sim \left(\begin{smallmatrix}\chi^{k-1} & * \\ 0 & 1\end{smallmatrix}\right),$$

so $\rho|_{I_\ell}$ determines k modulo $\ell - 1$. This suggests a way to define $k(\rho)$ purely in terms of the Galois representation ρ, at least when $k \not\in \{2,\ \ell+1\}$.

The key to defining $k(\rho)$ when $k = 2$ or $k = \ell + 1$ is good reduction. To understand why this is so, we briefly summarize Shimura's geometric construction of Galois representations associated to newforms of weight 2.

2.3.1. Geometric construction of Galois representations

Shimura attached mod ℓ representations to a weight-2 newform $f = \sum a_n q^n$ of level N. Let E be the totally real or CM field $\mathbf{Q}(\ldots a_n \ldots)$. In [**108**, Thm. 7.14], Shimura described how to associate to f an abelian variety $A = A_f$ over $\mathbf{Q}$ of dimension $[E : \mathbf{Q}]$ furnished with an embedding $E \hookrightarrow \operatorname{End}_{\mathbf{Q}} A$ (see also Conrad's appendix). The mod ℓ representations attached to f are then found in the ℓ-torsion of A.

Over the complex numbers, the abelian variety A is found as a quotient of the Jacobian of the Riemann surface

$$X_1(N) := \overline{\Gamma_1(N)\backslash\mathfrak{h}} = \Gamma_1(N)\backslash\mathfrak{h} \cup \{\text{cusps}\}.$$

The Riemann surface $X_1(N)$ has a structure of algebraic curve over $\mathbf{Q}$; it is called the *modular curve* of level N. Its Jacobian $J_1(N)$ is an abelian variety over $\mathbf{Q}$ which, by work of Igusa, has good reduction at all primes $\ell \nmid N$. The dimension of $J_1(N)$ equals the genus of $X_1(N)$; for example, when $N = 1$, the curve $X_1(1)$ is isomorphic over $\mathbf{Q}$ to the projective line and $J_1(1) = 0$. There are (at least) two functorial actions of the Hecke algebra $\mathbf{T}$ on $J_1(N)$, and (at least) two definitions of $J_1(N)$. In the next section we will fix choices, and then construct A as the quotient of $J_1(N)$ by the image of the annihilator in $\mathbf{T}$ of f.

2.3.1.1. *Hecke operators on $J_1(N)$.* We pause to formulate a careful definition of $X_1(N)$ and of our preferred functorial action of the Hecke operators T_p on $J_1(N)$. For simplicity, we assume that $N > 4$ and $p \nmid N$. Following [**46**, Prop. 2.1] there is a smooth, proper, geometrically connected algebraic curve $X_1(N)$ over $\mathbf{Z}[1/N]$ that represents the functor assigning to each $\mathbf{Z}[1/N]$-scheme S the set of isomorphism classes of pairs (E, α), where E is a generalized elliptic curve over S and $\alpha : (\boldsymbol{\mu}_N)_S \hookrightarrow E^{\mathrm{sm}}[N]$ an embedding of group schemes over S whose image meets every irreducible component in each geometric fiber. Let $X_1(N, p)$ be the fine moduli scheme over $\mathbf{Z}[1/N]$ that represents the functor assigning to each $\mathbf{Z}[1/N]$-scheme S the set of isomorphism classes of triples (E, α, C), where E is a generalized elliptic curve over S, $\alpha : (\boldsymbol{\mu}_N)_S \hookrightarrow E^{\mathrm{sm}}[N]$ an embedding of group schemes over S, and C a locally free subgroup scheme of rank p in $E^{\mathrm{sm}}[p]$, such that $\mathrm{im}(\alpha) \times C$ meets every irreducible component in each geometric fiber of E. Let $\pi_1, \pi_2 : X_1(N, p) \to X_1(N)$ over $\mathbf{Z}[1/N]$ be the two standard degeneracy maps, which are defined on genuine elliptic curves by $\pi_1(E, \alpha, C) = (E, \alpha)$ and $\pi_2(E, \alpha, C) = (E', \alpha' = \varphi\alpha)$, where $E' = E/C$ and $\varphi : E \to E'$ is the associated p-isogeny. The Hecke operator $T_p = (T_p)^*$ acts on divisors D on $X_1(N)_{/\mathbf{Q}}$ by

$$T_p(D) = (\pi_1)_* \circ \pi_2^* D.$$

For example, if (E, α) is a non-cuspidal $\overline{\mathbf{Q}}$-point, then

$$T_p(E, \alpha) = \sum (E', \varphi \circ \alpha \circ [p]^{-1}),$$

The Hecke operatorThe Hecke operator $T_p = (T_p)^*$ acts on divisors D on $X_1(N)_{/\mathbf{Q}}$ by

$$T_p(D) = (\pi_1)_* \circ \pi_2^* D.$$

For example, if (E, α) is a non-cuspidal $\overline{\mathbf{Q}}$-point, then

$$T_p(E, \alpha) = \sum (E', \varphi \circ \alpha \circ [p]^{-1}),$$

where the sum is over all isogenies $\varphi : E \to E'$ of degree p, and $T_p = (T_p)^*$ acts on divisors D on $X_1(N)_{/\mathbf{Q}}$ by

$$T_p(D) = (\pi_1)_* \circ \pi_2^* D.$$

For example, if (E, α) is a non-cuspidal $\overline{\mathbf{Q}}$-point, then

$$T_p(E, \alpha) = \sum (E', \varphi \circ \alpha \circ [p]^{-1}),$$

where the sum is over all isogenies $\varphi : E \to E'$ of degree p, and where the sum is over all isogenies $\varphi : E \to E'$ of degree p, and $[p]^{-1}$ is the inverse of pth powering on $\boldsymbol{\mu}_N$. This map on divisors defines an endomorphism T_p of the Jacobian $J_1(N)$ associated to $X_1(N)$ via Picard functoriality.

For each prime p there is an involution $\langle p \rangle$ of $X_1(N)$ called a *diamond bracket operator*, defined functorially by

$$\langle p \rangle (E, \alpha) = (E, \alpha \circ [p]).$$

The diamond bracket operator defines a correspondence, such that the induced map $(\langle p \rangle)^*$ on $J_1(N)$ is

$$(\langle p \rangle)^* (E, \alpha) = (E, \alpha \circ [p^{-1}]).$$

If $(T_p)_*$ denotes the pth Hecke operator as defined in [**46**, §3], then

$$(T_p)_* = T_p \circ (\langle p^{-1} \rangle)^*,$$

Thus our T_p differs from Gross's $(T_p)_*$. Furthermore, upon embedding $X_1(N)$ into $J_1(N)$ and identifying weight-2 cusp forms with differentials on $J_1(N)$, Gross's $(T_p)_*$ induces, via Albanese functoriality, the usual Hecke action on cusp forms, whereas ours does not. In addition, we could have defined $X_1(N)$ by replacing the group scheme $\boldsymbol{\mu}_N$ by $(\mathbf{Z}/N\mathbf{Z})$. In this connection, see the discussion at the end of Section 5 of [**26**] and [**35**, §2.1].

2.3.1.2. *The representations attached to a newform.* Again let $\mathcal{O}$ be the ring of integers of $E = \mathbf{Q}(\ldots a_n \ldots)$, where $f = \sum a_n q^n$ is a weight-2 modular forms on $\Gamma_1(N)$. Recall that $A = A_f$ is the quotient of $J_1(N)$ by the image of the annihilator in $\mathbf{T}$ of f. In general, $\mathcal{O}$ need not be contained in $\operatorname{End} A$. However, by replacing A by an abelian variety $\mathbf{Q}$-isogenous to A, we may assume that $\mathcal{O}$ is contained in $\operatorname{End} A$ (see [**108**, pg. 199]). Let λ be a maximal ideal of $\mathcal{O}$ and set

$$A[\lambda] := \{P \in A(\overline{\mathbf{Q}}) : xP = 0 \text{ all } x \in \lambda\}.$$

By [**108**, Prop. 7.20, pg 190], $\dim_{\mathcal{O}/\lambda} A[\lambda] = 2$, so $A[\lambda]$ affords a 2-dimensional Galois representation, which is well-defined up to semisimplification. Let $\rho_{f,\lambda} : G_{\mathbf{Q}} \to A[\lambda]^{\mathrm{ss}}$ be the semisimplification of $A[\lambda]$.

2.3.1.3. *Good reduction.*

Definition 2.8. A finite group scheme G over $\mathbf{Q}_\ell^{\mathrm{nr}}$ is said to have *good reduction*, or to be *finite flat*, if it extends to a finite flat group scheme over the ring of integers $\mathcal{O}_{\mathbf{Q}_\ell^{\mathrm{nr}}}$ of $\mathbf{Q}_\ell^{\mathrm{nr}}$.

Proposition 2.9. *The representation $\rho_{f,\lambda}$ is finite flat at each prime $p \nmid N$.*

Proof. The finite flat group scheme extending $A[\lambda]$ is the scheme theoretic closure of $A[\lambda]$ in a good model $\mathcal{A}/\mathcal{O}_{\mathbf{Q}_\ell^{\mathrm{nr}}}$ of A. Such a model exists because A has good reduction at p. □

Consider again a Galois representation ρ as in the beginning of Section 2.3 such that $\rho|_{I_\ell} \sim \left(\begin{smallmatrix} \chi^{k-1} & * \\ 0 & 1 \end{smallmatrix}\right)$. If $k \not\equiv 2 \pmod{\ell - 1}$ then $k(\rho)$ is defined to equal k. If $k \equiv 2$ $(\mathrm{mod}\ \ell - 1)$, then

$$k(\rho) := \begin{cases} 2 & \text{if } \rho \text{ is finite flat,} \\ \ell + 1 & \text{otherwise.} \end{cases}$$

2.4. Representations arising from elliptic curves

Theorem 2.10. *Suppose $A/\mathbf{Q}$ is a semistable elliptic curve and that $\rho_{A,\ell}$ is irreducible. Let Δ_A denote the minimal discriminant of A. The representation $\rho_{A,\ell}$ is finite flat at ℓ if and only if $\ell \mid \mathrm{ord}_\ell \Delta_A$. If $p \neq \ell$, then $\rho_{A,\ell}$ is unramified at p if and only if $\ell \mid \mathrm{ord}_p \Delta_A$.*

Proof. The first statement is Proposition 5 of [**102**].

When A has good reduction at p, the second statement holds (see Exercise 15). Suppose A has multiplicative reduction at p. There is an unramified extension K of $\mathbf{Q}_p$ such that A has split multiplicative reduction at p. Consider the Tate curve $\mathbf{G}_m/q^{\mathbf{Z}}$ over K associated to A. Thus $\overline{\mathbf{Q}}_p^*/q^{\mathbf{Z}} \cong A(\overline{\mathbf{Q}}_p)$ as $\mathrm{Gal}(\overline{\mathbf{Q}}_p/K)$-modules. The ℓ-torsion points $A[\ell]$ correspond to the points $\{\zeta_\ell^a (q^{1/\ell})^b : 0 \leq a, b < \ell\}$ in the Tate curve. The extension $K(\zeta_\ell, q^{1/\ell})$ of K is unramified because $\ell \neq p$ and $\mathrm{ord}_p(q) = \mathrm{ord}_p(\Delta_A)$ is divisible by ℓ. Since an unramified extension of an unramified extension is unramified, the extension $K(\zeta_\ell, q^{1/\ell})$ of $\mathbf{Q}_p$ is unramified, which proves the second part of the theorem. □

2.4.1. Frey curves

Using Theorem 2.10 we see that the Shimura-Taniyama conjecture together with Serre's conjecture implies Fermat's Last Theorem. Suppose (a, b, c) is a solution to the Fermat equation $a^\ell + b^\ell = c^\ell$ with $\ell \geq 11$ and $abc \neq 0$. Consider the Frey curve A given by the equation $y^2 = x(x - a^\ell)(x + b^\ell)$; it is an elliptic curve with discriminant $\Delta_A = \frac{((abc)^2)^\ell}{2^8}$. By [**93**, §4.1, Prop. 6] the representation $A[\ell]$ is irreducible. Theorem 2.10 implies that $\rho_{A,\ell}$ is unramified, except possibly at 2 and ℓ. Thus $N(\rho) \mid 2$, and $k(\rho) = 2$ since $\ell \mid \mathrm{ord}_\ell(\Delta_A)$. But there are no cusp forms of level 2 and weight 2. The modularity of A (proved in [**114, 117**]), together with the weak conjecture of Serre (enough of which is proved in [**84**]), leads to a contradiction.

2.4.2. Examples

Using Theorem 2.10 we can frequently determine the Serre invariants $N(\rho)$ and $k(\rho)$ of a representation ρ attached to an elliptic curve. When $N(\rho) < N$, it is illustrative to verify directly that there is a newform of level $N(\rho)$ that also gives rise to ρ. For example, there is a unique weight-2 normalized newform

$$f = q + q^2 - q^3 - q^4 - 2q^5 - q^6 + 4q^7 - 3q^8 + q^9 + \cdots$$

on $\Gamma_0(33)$. One of the elliptic curves associated to f is the curve A given by the equation

$$y^2 + xy = x^3 + x^2 - 11x.$$

The discriminant of A is $\Delta = 3^6 \cdot 11^2$ and the conductor is $N = 3 \cdot 11$. Because A is semistable and there are no elliptic curves 3-isogenous to A, the associated mod 3 representation $\rho = \rho_{A,3} : G_{\mathbf{Q}} \to \mathrm{Aut}(A[3])$ is surjective (see Section 1.4). Since $3 \mid \mathrm{ord}_3 \Delta_A$, the Serre weight and level are $k(\rho) = 2$ and $N(\rho) = 11$. As predicted by Serre's conjecture, there is a weight-2 newform on $\Gamma_0(11)$ such that if B is one of the three elliptic curves of conductor 11 (it does not matter which), then $B[3] \approx A[3]$ as representations of $G_{\mathbf{Q}}$. Placing the eigenforms corresponding to A and B next to each other, we observe that their Fourier coefficients are congruent modulo 3:

$$\begin{array}{lcccccccccccc} f_A & = & q & +q^2 & -q^3 & -q^4 & -2q^5 & -q^6 & +4q^7 & -3q^8 & +q^9 & + & \cdots \\ f_B & = & q & -2q^2 & -q^3 & +2q^4 & +q^5 & +2q^6 & -2q^7 & & -2q^9 & + & \cdots . \end{array}$$

Next consider the elliptic curve A cut out by the equation

$$y^2 + y = x^3 + x^2 - 12x + 2.$$

It has conductor $N = 141 = 3 \cdot 47$ and discriminant $\Delta = 3^7 \cdot 47$. Since $\mathrm{ord}_3(\Delta)$ is divisible by 7, the mod 7 representation $\rho_{A,7}$ has Serre invariants $k(\rho_{A,7}) = 2$ and $N(\rho_{A,7}) = 47$. In confirmation of Serre's conjecture, we find a form $f \in S_2(\Gamma_0(47))$ that gives rise to $\rho_{A,7}$. The Fourier coefficients of f generate a quartic field.

Next consider $\rho_{A,3}$, whose Serre invariants are $N(\rho_{A,3}) = 47$ and, since 3 does not divide $\mathrm{ord}_3(\Delta)$, $k(\rho_{A,3}) = \ell + 1 = 4$. In $S_4(\Gamma_0(47))$ there are two conjugacy classes of eigenforms, which are defined over fields of degree 3 and 8, respectively. The one that gives rise to $\rho_{A,3}$ is

$$g = q + aq^2 + (-1/2a^2 - 5/2a - 1)q^3 + (a^2 - 8)q^4 + (a^2 + a - 10)q^5 + \cdots,$$

where $a^3 + 5a^2 - 2a - 12 = 0$.

2.5. Companion forms

Suppose f is a newform of weight k with $2 \leq k \leq \ell + 1$. Let ℓ be an ordinary prime, so $a_\ell(f)$ is not congruent to 0 modulo a prime λ lying over ℓ and

$$\rho_{f,\lambda}|_{I_\ell} \sim \begin{pmatrix} \chi^{k-1} & * \\ 0 & 1 \end{pmatrix}.$$

Is this representation split or not? Put another way, can $*$ be taken equal to 0, after an appropriate choice of basis? For how many ℓ do these representations split? We suspect that the ordinary split primes ℓ are in the minority, among all primes. How can we quantify the number of split primes?

If $* = 0$, then

$$\rho|_{I_\ell} \sim \begin{pmatrix} 1 & 0 \\ 0 & \chi^{k-1} \end{pmatrix},$$

so

$$\rho|_{I_\ell} \otimes \chi^{\ell-k} \sim \begin{pmatrix} \chi^{\ell-k} & 0 \\ 0 & 1 \end{pmatrix}.$$

Assume that $2 \leq 1+\ell-k \leq \ell+1$, so $k(\rho\otimes\chi^{\ell-k}) = 1+\ell-k$. Using the θ-operator we see that $\rho\otimes\chi^{\ell-k}$ is modular, of *some* weight and level. To say that it is modular of Serre's conjectured weight $k(\rho)$ is to make a much strong statement. If $\rho\otimes\chi^{\ell-k}$ is indeed modular of weight $1+\ell-k$, then by definition there exists an eigenform g of weight $1+\ell-k$ with $\rho_g \sim \rho_f \otimes \chi^{\ell-k}$. Such an eigenform g, if it exists, is called a *companion* of f. The existence of g is far from obvious.

We can extend the notion of companion form to the case when $k(\rho) = \ell$. In this case the companion has weight 1. If ρ is unramified at ℓ, then we expect ρ to also arise from a weight-1 eigenform.

The existence of a companion form was proved (assuming unchecked compatibilities) in most cases in which $k < \ell$ by Gross in [**46**] and in a few cases when $k = \ell$. Using new methods, Coleman and Voloch [**17**] proved all cases except $k = \ell = 2$. The arguments of Coleman and Voloch do not require verification of Gross's unchecked compatibilities.

CHAPTER 3

Optimizing the level

Consider an irreducible Galois representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ that arises from a newform of weight k and level N. Serre defined integers $k(\rho)$ and $N(\rho)$, and conjectured that ρ arises from a newform of weight $k(\rho)$ and level $N(\rho)$. In Chapter 2 we sketched Edixhoven's proof that if $\ell \nmid N$ then ρ arises from an newform of weight $k(\rho)$ and level N. In this chapter, we introduce some of the techniques used in proving that ρ arises from a newform level $N(\rho)$. For more details, see [**84, 87**].

In [**102**, §1.2] Serre defined the *optimal level* $N(\rho)$ as the prime-to-ℓ part of the Artin conductor of ρ. Recall that $N(\rho)$ is a product $\prod p^{n(p)}$ over prime numbers $p \neq \ell$. The integer $n(p)$ is defined by restricting ρ to a decomposition group D_p at p. Consider the sequence of ramification groups $G_0 \supset G_1 \supset \cdots \supset G_i \supset \cdots$ where G_0 is the inertia subgroup I_p of D_p. Let V be a vector space over $\overline{\mathbf{F}}_\ell$ affording the representation ρ, and for each $i \geq 0$ let V_i be the subspace of V consisting of those $v \in V$ that are fixed by G_i. Then

$$n(p) := \sum_{i=0}^{\infty} \frac{1}{(G_0 : G_i)} \dim V/V_i.$$

3.1. Reduction to weight 2

The optimal level $N(\rho)$ is not divisible by ℓ. The first step in level optimization is to strip the power of ℓ from N. When ℓ is odd, this is done explicitly in [**87**, §2]; for the case $\ell = 2$ see [**9**, §1]. Many of the arguments and key ideas are due to Serre [**94**]. This proof that ℓ can be stripped from the level uses concrete techniques of Serre [**95**, §3], [**98**, Thm. 5.4], and Queen [**78**, §3]; it involves multiplying f by suitable Eisenstein series and taking traces. Katz's theory of ℓ-adic modular forms suggests an alternative method. A classical form of weight 2 and level $M\ell^m$ is an ℓ-adic form of level M; the mod ℓ reduction of this form is classical of level M and some weight, and is congruent to f. See the appendices of [**60**] and the discussions in [**49**, §1] and [**50**, §1].

The next step is to replace f by a newform of weight between 2 and $\ell + 1$ that gives rise to a twist of ρ. Twisting ρ by the mod ℓ cyclotomic character χ preserves N; this is because $\rho \otimes \chi$ arises from $\theta(f) = q\frac{d}{dq}(f)$, which also has level N. Theorem 2.7 asserts that some twist $\rho \otimes \chi^i$ of ρ arises from a form g of weight between 2 and $\ell + 1$. If $\rho \otimes \chi^i$ arises from a newform of level N, then ρ also arises from a newform of the same level, so we can replace f by g and k by the weight of g. By results discussed in Chapter 2, we may assume that $k = k(\rho \otimes \chi^i)$. For the case $\ell = 2$ see [**9**, Prop. 1.3(a)].

We have reduced to considering a representation ρ that arises from a newform f of weight $k(\rho)$ and level N not divisible by ℓ. The weight satisfies $2 \leq k(\rho) \leq \ell+1$, but N need not equal $N(\rho)$. That N is a multiple of $N(\rho)$ is a theorem proved by both Carayol [**12**] and Livné [**70**, Prop. 0.1].

In order to lower N it is convenient to work systematically with form of weight 2. Paradoxically, even though we have just taken all powers of ℓ out of N, we are now going to allow one power of ℓ back into N. This allows us to reduce to weight 2 and realize ρ as a group of torsion points on an abelian variety. An alternative approach (see [**41, 57**]) is to avoid this crutch and work directly with representations coming from arbitrary weights between 2 and $\ell+1$; these are realized in étale cohomology groups. This later approach has the advantage that $X_0(N)$ has good reduction at ℓ.

Reduction to weight 2 is accomplished using a general relationship that originates with ideas of Koike and Shimura. In characteristic ℓ, eigenforms of level N whose weights satisfy $2 < k \leq \ell+1$ correspond to eigenforms of weight 2 and level ℓN (see [**87**, Thm. 2.2]):

$$\left\{ \ 2 < k \leq \ell+1, \text{ level } N \ \right\} \leftrightsquigarrow \left\{ \ k = 2, \text{ level } \ell N \ \right\}.$$

Thus we can and do work with weight 2 and level

$$N^* := \begin{cases} N & \text{if } k = 2, \\ N\ell & \text{if } k > 2. \end{cases}$$

3.2. Geometric realization of Galois representations

To understand representations arising from modular forms, it is helpful to realize these representations inside of geometric objects such as $J := J_1(N^*)$. These representations are constructed geometrically with the help of the Hecke algebra

$$\mathbf{T} := \mathbf{Z}[\ldots T_n \ldots],$$

which was defined in Section 2.3. Recall that $\mathbf{T}$ is a commutative subring of $\operatorname{End}_{\mathbf{Q}} J$ that is free as a module over $\mathbf{Z}$, and that its rank is equal to the dimension of J. When N is cube free, $\mathbf{T}$ is an order in a product of integer rings of number fields; this is a result of Coleman and Edixhoven (see [**16**, Thm. 4.1]). In contrast, the Hecke operators T_p, for $p^3 \mid N$, are usually not semisimple (see Exercise 3).

It is fruitful to view a newform f as a homomorphism

$$\mathbf{T} \to \mathcal{O} = \mathbf{Z}[\ldots a_n \ldots], \qquad T_n \mapsto a_n.$$

Letting $\varphi : \mathcal{O} \to \overline{\mathbf{F}}_\ell$ be the map sending a_p to $\operatorname{tr}(\rho(\operatorname{Frob}_p)) \in \overline{\mathbf{F}}_\ell$, we obtain an exact sequence $0 \to \mathfrak{m} \to \mathbf{T} \to \overline{\mathbf{F}}_\ell$ with $\mathfrak{m}$ a maximal ideal.

Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be an irreducible Galois representation that arises from a weight-2 newform f. The next step, after having attached a maximal ideal $\mathfrak{m}$ to f and φ, is to find a $\mathbf{T}/\mathfrak{m}$-vector space affording ρ inside of the group of ℓ-torsion points of J. Following [**71**, §II.7], we consider the $\mathbf{T}/\mathfrak{m}$-vector space

$$J[\mathfrak{m}] := \{P \in J(\overline{\mathbf{Q}}) : tP = 0 \text{ all } t \in \mathfrak{m}\} \subset J(\overline{\mathbf{Q}})[\ell] \approx (\mathbf{Z}/\ell\mathbf{Z})^{2g}.$$

Since the endomorphisms in $\mathbf{T}$ are $\mathbf{Q}$-rational, $J[\mathfrak{m}]$ comes equipped with a linear action of $G_{\mathbf{Q}}$.

That $\mathrm{tr}(\rho(\mathrm{Frob}_p))$ and $\det(\rho(\mathrm{Frob}_p))$ both lie in the subfield $\mathbf{T}/\mathfrak{m}$ of $\overline{\mathbf{F}}_\ell$ suggests that ρ has a model over $\mathbf{T}/\mathfrak{m}$, in the sense that ρ is equivalent to a representation taking values in $\mathrm{GL}(2, \mathbf{T}/\mathfrak{m}) \subset \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$.

Lemma 3.1. *The representation ρ has a model $\rho_\mathfrak{m}$ over the finite field $\mathbf{T}/\mathfrak{m}$.*

Proof. This is a classical result of I. Schur. Brauer groups of finite fields are trivial (see e.g., [**100**, X.7, Ex. a]), so the argument of [**99**, §12.2] proves the lemma.

Alternatively, when the residue characteristic ℓ of $\mathbf{T}/\mathfrak{m}$ is odd, the following more direct proof can be used. Complex conjugation acts through ρ as a matrix with distinct $\mathbf{F}_\ell$-rational eigenvalues; another well known theorem of Schur [**90**, IX a] (cf. [**116**, Lemme I.1]) then implies that ρ can be conjugated into a representation with values in $\mathrm{GL}(2, \mathbf{T}/\mathfrak{m})$. □

3.3. Multiplicity one

Let $V_\mathfrak{m}$ be a vector space affording $\rho_\mathfrak{m}$. Under the assumption that $\rho_\mathfrak{m}$ is absolutely irreducible, Boston, Lenstra, and Ribet (see [**6**]) proved that $J[\mathfrak{m}]$ is isomorphic as a $G_\mathbf{Q}$-module to a sum of copies of $V_\mathfrak{m}$:

$$J[\mathfrak{m}] \approx \bigoplus_{i=1}^{t} V_\mathfrak{m}.$$

The number of copies of $V_\mathfrak{m}$ is called the *multiplicity* of $\mathfrak{m}$. When ℓ is odd, the hypothesis of irreducibility of $\rho_\mathfrak{m}$ is equivalent to absolute irreducibility (see Exercise 3).

Proposition 3.2. *The multiplicity t is at least* 1.

Proof. Let $\mathbf{T} \subset \mathrm{End}(J)$ be the Hecke algebra associated to J. Because $\mathbf{T} \otimes \mathbf{Z}_\ell$ is an algebra of finite rank over the local ring $\mathbf{Z}_\ell$, we have a decomposition

$$\mathbf{T} \otimes \mathbf{Z}_\ell = \bigoplus_{\lambda | \ell} \mathbf{T}_\lambda,$$

where λ runs through the maximal ideals of $\mathbf{T}$ lying over ℓ, and $\mathbf{T}_\lambda$ denotes the completion of $\mathbf{T}$ at λ (see, e.g., [**37**, Cor. 7.6]). The Tate module

$$\mathrm{Tate}_\ell\, J := \mathrm{Hom}(\mathbf{Q}_\ell/\mathbf{Z}_\ell, \cup_{n\geq 1} J[\ell^n]) \cong \varprojlim J[\ell^n]$$

is a free $\mathbf{Z}_\ell$-module of rank equal to twice the dimension of J. For each maximal ideal λ of $\mathbf{T}$ lying over ℓ, let $e_\lambda \in \mathbf{T} \otimes \mathbf{Z}_\ell$ denote the corresponding idempotent; thus $e_\lambda^2 = e_\lambda$ and $\sum_{\lambda|\ell} e_\lambda = 1$. The map $x \mapsto \sum_\lambda e_\lambda x$ gives a decomposition

$$\mathrm{Tate}_\ell\, J \xrightarrow{\cong} \bigoplus_{\lambda|\ell} e_\lambda \,\mathrm{Tate}_\ell\, J.$$

The ring $\mathrm{End}(J) \otimes \mathbf{Z}_\ell$ operates faithfully on $\mathrm{Tate}_\ell\, J$ (see, e.g., [**74**, Lem. 12.2]), so each summand $e_\lambda \,\mathrm{Tate}_\ell\, J$ is nonzero. Set

$$\mathrm{Tate}_\lambda\, J := \mathrm{Hom}(\mathbf{Q}_\ell/\mathbf{Z}_\ell, \cup_{n\geq 1} J[\lambda^n]).$$

We claim that $\mathrm{Tate}_\lambda\, J$ is identified with $e_\lambda \,\mathrm{Tate}_\ell\, J$ under the natural inclusion $\mathrm{Tate}_\lambda\, J \subset \mathrm{Tate}_\ell\, J$. Denote by $\tilde{\lambda}$ the maximal ideal in $\mathbf{T} \otimes \mathbf{Z}_\ell$ generated by λ. Let n be a positive integer, and let I be the ideal in $\mathbf{T}_\lambda$ generated by ℓ^n. Because $\mathbf{T}_\lambda$ is a local ring with maximal ideal $\tilde{\lambda}$, there is an integer m such that $\tilde{\lambda}^m \subset I$. Since I is principal and generated by ℓ^n, and $\mathbf{T}$ acts on $e_\lambda J[\ell^n]$ through $\mathbf{T}_\lambda$, we have

$$e_\lambda J[\ell^n] = (e_\lambda J[\ell^n])[I] \subset (e_\lambda J[\ell^n])[\tilde{\lambda}^m] \subset (e_\lambda J[\ell^n])[\lambda^m] \subset J[\lambda^m].$$

This shows that $e_\lambda \operatorname{Tate}_\ell J \subset \operatorname{Tate}_\lambda J$. Next suppose $\lambda' \neq \lambda$ and let n be a positive integer. Since $\mathbf{T}_\lambda$ acts on $J[\lambda^n]$ through $\mathbf{T}/\lambda^n = \mathbf{T}_\lambda/\tilde{\lambda}^n$, we have $e_{\lambda'} J[\lambda^n] = 0$, so

$$J[\lambda^n] = \sum_{\text{all } \lambda'} e_{\lambda'} J[\lambda^n] = e_\lambda J[\lambda^n].$$

The other inclusion $\operatorname{Tate}_\lambda J = e_\lambda \operatorname{Tate}_\lambda J \subset e_\lambda \operatorname{Tate}_\ell J$, which we need to prove equality, then follows.

We apply the above conclusion with $\lambda = \mathfrak{m}$. Since $\operatorname{Tate}_\mathfrak{m} J \neq 0$, some $J[\mathfrak{m}^r]$ is nonzero; let r be the smallest such integer. Following [**71**, p. 112], observe that for each generating set of elements $a_1, \ldots, a_t$ of the $\mathbf{T}/\mathfrak{m}$-vector space $\mathfrak{m}^{r-1}/\mathfrak{m}^r$, the map $x \mapsto a_1 x \oplus \cdots \oplus a_t x$ is an injection of the module $J[\mathfrak{m}^r]/J[\mathfrak{m}^{r-1}]$ into the direct sum of t copies of $J[\mathfrak{m}]$. Thus $J[\mathfrak{m}]$ is nonzero. □

The special case $t = 1$, in which the multiplicity is one, plays a central role in the development of the theory. A detailed summary of multiplicity one results can be found in [**32**, §9], and some supplementary results are contained in [**117**, Thm. 2.1]. In general, the multiplicity can be greater than one (see [**72**, §13] and [**63**]).

3.3.1. Multiplicity one representations

Let $\rho : G_\mathbf{Q} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be an irreducible modular Galois representation such that

$$2 \leq k(\rho) \leq \ell + 1.$$

Consider pairs (N, α) where $N \geq 1$ is an integer with the property that $\ell \nmid N$ if $k(\rho) = 2$ and $\ell \mid\mid N$ if $k(\rho) > 2$, together with maps $\alpha : \mathbf{T}_N \to \overline{\mathbf{F}}_\ell$, such that $\alpha(T_p) = \operatorname{tr}(\rho(\operatorname{Frob}_p))$ and $\alpha(p\langle p\rangle) = \det(\rho(\operatorname{Frob}_p))$ for almost all p. Here $\mathbf{T}_N$ is the Hecke algebra associated to $S_2(\Gamma_1(N))$. Note that if (N, α) is such a pair and $\mathfrak{m} = \ker(\alpha)$, then

$$\rho \approx \rho_\mathfrak{m} \otimes_{\mathbf{T}/\mathfrak{m}} \overline{\mathbf{F}}_\ell,$$

where $\alpha : \mathbf{T}/\mathfrak{m} \hookrightarrow \overline{\mathbf{F}}_\ell$ and $\rho_\mathfrak{m}$ is the unique (up to isomorphism) semisimple representation over $\overline{\mathbf{F}}_\ell$ such that

$$\operatorname{tr}(\rho_\mathfrak{m}(\operatorname{Frob}_p)) = \alpha(T_p) \qquad \det(\rho_\mathfrak{m}(\operatorname{Frob}_p)) = \alpha(p\langle p\rangle)$$

for almost all p.

Definition 3.3. ρ is a multiplicity one representation if $J_1(N)[\ker\alpha]$ has dimension 2 for all pairs (N, α) as above.

Remark 3.4.
1. If $J_1(N)[\ker\alpha]$ has dimension 2 then $\rho_\mathfrak{m} = J_1(N)[\ker\alpha]$ by Eichler-Shimura, see [**6**].
2. The definition extends to arbitrary modular Galois representations ρ as follows. As explained in Section 2.2, every ρ has a twist $\rho \otimes \chi^i$ by some power of the cyclotomic character such that $k(\rho \otimes \chi^i) \leq \ell + 1$. We say that ρ is a *multiplicity one representation* if $\rho \otimes \chi^i$ is a multiplicity one representation.

3.3.2. Multiplicity one theorems

Techniques for proving multiplicity one results were pioneered by Mazur in [**71**] who considered $J_0(p)$ with p prime. Let f be an eigenform and fix a nonzero prime λ of the ring generated by the Fourier coefficients of f such that $\rho_{f,\lambda}$ is absolutely irreducible. View the Hecke algebra $\mathbf{T}$ as a subring of $\mathrm{End}(J_0(p))$, and let $\mathfrak{m}$ be the maximal ideal associated to f and λ. Let $V_{\mathfrak{m}}$ again be a two-dimensional $\mathbf{T}/\mathfrak{m}$-vector space that affords $\rho_{\mathfrak{m}} : G_{\mathbf{Q}} \to \mathrm{GL}(2, \mathbf{T}/\mathfrak{m})$. Mazur proved (see Prop. 14.2, ibid.) that $J[\mathfrak{m}] \approx V_{\mathfrak{m}}$, except perhaps when $\mathfrak{m}$ is ordinary of residue characteristic $\ell = 2$. The missing ordinary case can be treated under suitable hypothesis. If $\rho_{\mathfrak{m}}$ restricted to a decomposition group at 2 is not contained in the scalar matrices, then $J[\mathfrak{m}] \approx V_{\mathfrak{m}}$ (see, e.g., [**9**, Prop. 2.4]). The results of Mazur are extended in [**72**] and [**84**, §5].

Theorem 3.5. *An irreducible modular Galois representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}_2(\overline{\mathbf{F}}_\ell)$ is a multiplicity one representation, except perhaps when all of the following hypothesis on ρ are simultaneously satisfied:*

— *$k(\rho) = \ell$;*
— *ρ is unramified at ℓ;*
— *ρ is ordinary at ℓ;*
— *$\rho|_{D_\ell} \sim \left(\begin{smallmatrix} \alpha & * \\ 0 & \beta \end{smallmatrix}\right)$ with $\alpha = \beta$.*

Proof. See [**32**, §9], [**117**, Thm. 2.1], and [**9**, Prop. 2.4] for the case $\ell = 2$. □

In [**46**, §12] Gross proves multiplicity one when $\alpha \neq \beta$, $k(\rho) \leq \ell$, and ρ is ordinary; he uses this result in his proof of the existence of companion forms. In contrast, Coleman and Voloch [**17**] prove the existence of companion forms when $\alpha = \beta$ and $\ell > 2$ using a method that avoids the need for multiplicity one.

Remark 3.6. L. Kilford of London, England has recently discovered an example at prime level 503 in which multiplicity one fails. Let E_1, E_2, and E_3 be the three elliptic curves of conductor 503, and for each $i = 1, 2, 3$, let $\mathfrak{m}_i$ be the maximal ideal of $\mathbf{T} \subset \mathrm{End}(J_0(503))$ generated by 2 and all $T_p - a_p(E_i)$, with p prime. Each of the Galois representations $E_i[2]$ is irreducible, and one can check that $\mathfrak{m}_1 = \mathfrak{m}_2 = \mathfrak{m}_3$. If multiplicity one holds, then $E_1[2] = E_2[2] = E_3[2]$ inside of $J_0(503)$. However, this is not the case, as a modular symbols computation in the integral homology $H_1(X_0(N), \mathbf{Z})$ reveals that $E_1 \cap E_2 = \{0\}$.

3.3.3. Multiplicity one for mod 2 representations

For future reference, we now wish to consider multiplicity one in the following rather extreme situation. Suppose that $\ell = 2$, and let ρ be a mod ℓ representation arising from a form of weight either 2 or 3. If the weight is 3 then ρ is not finite at 2; this can be used to deduce multiplicity one by adapting the arguments of [**72**] (see the proof of [**9**, Prop. 2.4]). When the weight is 2, we have the following proposition.

Proposition 3.7. *Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}_2(\overline{\mathbf{F}}_2)$ be an irreducible Galois representation that arises from a weight-2 form $f = \sum a_n q^n$ on $\Gamma = \Gamma_1(N) \cap \Gamma_0(2)$ with N odd, and let ε be the character of f. If $\overline{a}_2^2 \not\equiv \overline{\varepsilon}(2) \in \overline{\mathbf{F}}_2$, then ρ is a multiplicity one representation.*

Proof. Let $\mathfrak{m}$ be the maximal ideal associated to f in the Hecke algebra $\mathbf{T}$ attached to Γ. Because the weight of f is 2, the representation ρ is finite at 2. If ρ is supersingular then the inertia group I_2 operates through the two fundamental characters of level 2. These both have order $\ell^2 - 1 = 3 \neq 1$, so ρ is ramified and this can be used to deduce multiplicity one. If ρ is ordinary then $\rho|_{D_2} \sim \left(\begin{smallmatrix} \alpha & * \\ 0 & \beta \end{smallmatrix}\right)$ with β unramified and $\beta(\mathrm{Frob}_2) \equiv T_2 \bmod \mathfrak{m}$. The determinant $\alpha\beta$ of $\rho|_{D_2}$ is $\chi \cdot \varepsilon$ where χ is the mod 2 cyclotomic character and ε is unramified at 2. Since χ, ε, and β are unramified, α is also unramified. Since $\chi(\mathrm{Frob}_2) = 1$ and $\alpha\beta = \chi\varepsilon$, we have $\alpha(\mathrm{Frob}_2) = \beta^{-1}(\mathrm{Frob}_2)\varepsilon(2) = a_2^{-1}\varepsilon(2) \pmod{\mathfrak{m}}$. The further condition, under which we might not know multiplicity one, is $\alpha|_{D_2} = \beta|_{D_2}$; expressed in terms of the image of Frobenius, this becomes $a_2^{-1}\varepsilon(2) \equiv a_2 \pmod{\mathfrak{m}}$, or equivalently, $a_2^2 \equiv \varepsilon(2) \pmod{\mathfrak{m}}$. By hypothesis, this latter condition does not hold. □

3.4. The key case

We have set our problem up so that level optimization pertains to weight-2 forms of appropriate level, and takes place on Jacobians of modular curves. This level optimization problem was described, and partially treated, in a paper of Carayol [**12**]. In this paper, Carayol reduced the problem to the following key case.

Key case: Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be a Galois representation that arises from a weight-2 newform f of level pM, with $p \nmid \ell M$, and character $\varepsilon : (\mathbf{Z}/pM\mathbf{Z})^* \to \mathbf{C}^*$. Assume that ρ is unramified at p, and that ε factors through the natural map $(\mathbf{Z}/pM\mathbf{Z})^* \to (\mathbf{Z}/M\mathbf{Z})^*$. Show that ρ arises from a form of level M.

In the key case, the character ε of f is unramified at p. Thus f, a priori on $\Gamma_1(pM)$, is also on the bigger group $\Gamma_1(M) \cap \Gamma_0(p)$; that is, f lies in $S_2(\Gamma_1(M) \cap \Gamma_0(p))$.

Example 3.8. Consider the representation ρ arising from the 7-division points of the modular elliptic curve A of conductor $N_A = 3 \cdot 47$ and minimal discriminant $\Delta_A = 3^7 \cdot 47$. (The curve A is labeled **141A** in Cremona's notation [**20**].) The newform f corresponding to A is on $\Gamma_0(3{\cdot}47)$. As in Section 1.4, since $\mathrm{ord}_3(\Delta_A) = 7$, the representation ρ is unramified at 3 and $N(\rho) = 47$. To optimize the level means to find a form g on $\Gamma_0(47)$ that gives rise to ρ.

Example 3.9 (Frey curves)**.** The elliptic curves that Frey associated in [**42**] to hypothetical solutions of the Fermat equation $x^\ell + y^\ell = z^\ell$ give rise to mod ℓ Galois representations. According to Wiles's theorem [**117**], there is a weight-2 form f of level $2L$, with L big and square free, that gives rise to ρ. At the same time, $N(\rho) = 2$. Taking p to be any odd prime dividing L, we are put in the key case. If we can optimize the level, then we eventually reach a contradiction and thus deduce Fermat's Last Theorem.

The key case divides into two subcases; the more difficult one occurs when the following conditions are both satisfied:

— $p \equiv 1 \pmod{\ell}$;
— $\rho(\mathrm{Frob}_p)$ is a scalar matrix.

The second condition makes sense because $p \nmid N(\rho)$; since $\det(\rho(\mathrm{Frob}_p)) = \chi^{k-1}\varepsilon$, we know the scalar up to ± 1. The complementary case is easier; it can be treated using "Mazur's principle" (see Section 3.9). Though Example 3.8 falls into the easier case because $3 \not\equiv 1 \pmod 7$, the proof of Fermat's Last Theorem requires level optimization in both cases.

Consider a modular representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ that arises from a newform of level N and weight $k = k(\rho)$, and assume that $\ell \nmid N$. The goal of level optimization is to show that there is a newform of Serre's optimal level $N(\rho)$ that gives rise to ρ.

As discussed in Section 3.1, ρ arises from a newform $f = \sum a_n q^n$ on $\Gamma_1(N^*)$ of weight 2 and some character ε. Thus there is a homomorphism φ from $\mathcal{O} = \mathbf{Z}[\ldots a_n \ldots]$ to $\overline{\mathbf{F}}_\ell$ such that $\varphi(a_p) = \mathrm{tr}(\rho(\mathrm{Frob}_p))$ for all $p \nmid \ell N^*$. Let $\mathbf{T}$ be the Hecke algebra associated to $S_2(\Gamma_1(N^*))$. The maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ associated to ρ is the kernel of the map sending T_n to $\varphi(a_n)$. As was discussed in the previous chapter, the representation ρ is realized geometrically inside the subspace $J[\mathfrak{m}] \subset J[\ell]$ of the ℓ-torsion of the Jacobian J of $X_1(N^*)$.

Problem. Fix a divisor p of $N^*/N(\rho)$. Find a newform whose level is a divisor of N^*/p that also gives rise to ρ.

Lemma 3.10. *Let ρ be as above, and suppose p is a prime such that $p \mid N^*$ but $p \nmid \ell N(\rho)$, so ρ is unramified at p. Let ε_p denote the p part of ε. Then either $\varepsilon_p = 1$ or $p \equiv 1 \pmod \ell$.*

Proof. The character ε is initially defined as a homomorphism $(\mathbf{Z}/N^*\mathbf{Z})^* \to \mathcal{O}^*$; the reduction $\overline{\varepsilon}$ is obtained by composing ε with $\varphi : \mathcal{O} \to \overline{\mathbf{F}}_\ell$. Since ρ is unramified at p, the determinant $\det(\rho) = \chi_\ell^{k-1}\overline{\varepsilon} = \chi_\ell \overline{\varepsilon}$ is also unramified at p. Because χ_ℓ is ramified only at ℓ, the character $\overline{\varepsilon}$ is unramified at p. Let $M = N^*/p^r$ where $r = \mathrm{ord}_p(N^*)$, and write $(\mathbf{Z}/N^*\mathbf{Z})^* \cong (\mathbf{Z}/p^r\mathbf{Z})^* \times (\mathbf{Z}/M\mathbf{Z})^*$. By restricting ε to each factor, we write ε as a product of two characters: $\varepsilon = \varepsilon_p \cdot \varepsilon^{(p)}$ where ε_p is a character of $(\mathbf{Z}/p^r\mathbf{Z})^*$ and $\varepsilon^{(p)}$ is a character of $(\mathbf{Z}/M\mathbf{Z})^*$. The character $\varepsilon^{(p)}$ has conductor dividing M, so it is unramified at p. By class field theory, ε_p is totally ramified at p, so the reduction $\overline{\varepsilon}$ is unramified at p precisely when $\overline{\varepsilon}_p = 1$; equivalently, $\overline{\varepsilon}$ is unramified at p exactly when ε_p has order a power of ℓ. If ε_p is non-trivial, then, since the order of ε_p divides the order $p^{r-1}(p-1)$ of a generator of $(\mathbf{Z}/p^r\mathbf{Z})^*$, a power of ℓ divides $p^{r-1}(p-1)$, so $p \equiv 1 \pmod \ell$ since $\ell \neq p$. □

In addition to his conjectures about the optimal weight and level, Serre also made a conjecture about the optimal character of a form giving rise to ρ. Let p be a prime not dividing $\ell N(\rho)$. Serre's optimal character conjecture implies that ρ, which we know to arise from a form on $\Gamma_1(M) \cap \Gamma_1(p^r)$, arises from a form on $\Gamma_1(M) \cap \Gamma_0(p^r)$, and this has been proved in most cases.

3.5. Approaches to level optimization in the key case

As discussed in Section 3.4, results of Carayol and Livné (see [**12, 70**]) reduce the level optimization problem to the following key case. The weight-2 newform f, a priori on $\Gamma_1(N^*)$, is in fact on the bigger group $\Gamma_1(M) \cap \Gamma_0(p)$, where $Mp = N^*$, $p \nmid M$, and ρ is unramified at p. The goal is to show that ρ arises from a newform on $\Gamma_1(M)$. This has been achieved when ℓ is odd, and in many cases when $\ell = 2$, using several level optimization techniques.

I. **Mazur's principle**
If either $\rho(\mathrm{Frob}_p)$ is not a scalar matrix or $p \not\equiv 1 \pmod{\ell}$, then an argument of Mazur, explained in Section 3.9, can be used to optimize the level.

II. **Multiplicity one**
It is possible to optimize the level if ρ is a multiplicity one representation, as explained in [**84, 9**] and Section 3.11. The cases in which multiplicity one is known were reviewed in Section 3.3. In particular, we do not know multiplicity one in some cases when $k(\rho) = \ell$ and the eigenvalues of Frob_p are not distinct.

III. **Using a pivot**
Suppose that M can be written as a product $M = qK$ with q a prime not dividing pK, that ρ arises from a form on $\Gamma_1(K) \cap \Gamma_0(pq)$, and that ρ is ramified at q and unramified at p. Then q can be used as a "pivot" to remove p from the level. This approach grew out of [**83**], and was introduced in the short paper [**86**]. In Section 3.10 we describe the approach and discuss the terminology.

IV. **Without multiplicity one**
When ℓ is odd and $\varepsilon = 1$, the level optimization theorem was proved in [**87**] using an argument that does not require ρ to have multiplicity one. The hypothesis $\ell \neq 2$ is used in the proof of Proposition 7.8 of [**87**] to force splitting of a short exact sequence. In [**26**], Diamond extended the results of [**87**] to cover the case of arbitrary character, still under the assumption that ℓ is odd. One encounters seemingly insurmountable difficulties in trying to push this argument through when $\ell = 2$.

3.6. Some commutative algebra

In this section we set up some of the commutative algebra that is required in order to lower levels. There are two injective maps

$$\begin{tikzcd} S_2(\Gamma_1(M)) \arrow[r, hook, shift left] \arrow[r, hook, shift right] & S_2(\Gamma_1(M) \cap \Gamma_0(p)) . \end{tikzcd}$$

One is the inclusion $f(q) \mapsto f(q)$ and the other is $f(q) \mapsto f(q^p)$ (see Exercise 18). The *p-new subspace* $S_2(\Gamma_1(M) \cap \Gamma_0(p))^{p\text{-new}}$ is the complement, with respect to the Petersson inner product, of the subspace $\mathcal{S}$ generated by the two images of $S_2(\Gamma_1(M))$. The p-new subspace can also be defined algebraically as the kernel of the natural map from $S_2(\Gamma_1(M) \cap \Gamma_0(p))$ to the direct sum of two copies of $S_2(\Gamma_1(M))$.

Let $\mathbf{T}$ denote the Hecke algebra acting on $S_2(\Gamma_1(M) \cap \Gamma_0(p))$. If $p \nmid M$, then T_p acts on $\mathcal{S}$ as a direct sum of two copies of its action on $S_2(\Gamma_1(M))$; otherwise, T_p usually does not act diagonally (see Exercise 19). The image of $\mathbf{T}$ in $\mathrm{End}(\mathcal{S})$ is a quotient $\overline{\mathbf{T}}$ called the *p-new quotient.* A representation ρ associated to a maximal ideal $\mathfrak{m}$ of $\mathbf{T}$ arises from level M if and only if $\mathfrak{m}$ arises by pullback from a maximal ideal of $\overline{\mathbf{T}}$. Because the map $\mathbf{T} \to \overline{\mathbf{T}}$ is surjective, $\mathfrak{m}$ arises from level M if and only if the image of $\mathfrak{m}$ in$\overline{\mathbf{T}}$ is not the unit ideal (see Exercise 21).

3.7. Aside: Examples in characteristic two

Sections 3.7 and 3.8 can be safely skipped on a first reading.

To orient the reader, we focus for the moment on mod 2 representations that arise from elliptic curves. We give examples in which one of the level optimizations methods applies but the others do not. We do not consider method **IV** because it is not applicable to mod 2 representations. The hypothesis of the "multiplicity one" method **II** when $\ell = 2$ are discussed after the statement of Theorem 3.19 in Section 3.11. We were unable to find an example in which none of the level optimization theorems applies.

We will repeatedly refer to the following theorem, which first appeared in [**85**].

Theorem 3.11. *Suppose ρ arises from a newform in $S_2(\Gamma_0(N))$. Let $p \nmid \ell N$ be a prime satisfying one or both of the identities*

$$\operatorname{tr}\rho(\mathrm{Frob}_p) = \pm(p+1) \pmod{\ell}.$$

Then ρ arises from a newform of level pN.

3.7.1. III applies but I and II do not

In this section we give a mod 2 representations in which the pivot hypothesis of **III** is satisfied, but the hypotheses of **I** and **II** are not. Our example is obtained by applying Theorem 3.11 to the mod 2 representation attached to a well-chosen elliptic curve.

We will find an elliptic curve E of conductor $M = qR$ such that $\rho = E[2]$ is absolutely irreducible, ramified at q, unramified at 2, and $\rho(\mathrm{Frob}_2) = \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$. Because of the last condition, [**9**, Prop. 2.4] does not imply that ρ is a multiplicity one representation, so **II** does not apply. (In fact, following Remark 3.6, one sees that ρ is not a multiplicity one representation.) Likewise, **I** does not apply because $\rho(\mathrm{Frob}_2)$ is a scalar and the p we will chose will satisfy $p \equiv 1 \pmod 2$. Next we choose a prime $p \nmid 2qR$ such that $\rho_{E,2}(\mathrm{Frob}_p) = \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$. Let f be the newform associated to E. By Theorem 3.11 there is a newform g of level pqR such that

$$\rho_{g,\lambda} \approx \rho_{E,2}.$$

In particular,

$$\rho_{g,\lambda}(\mathrm{Frob}_p) = \rho_{E,2}(\mathrm{Frob}_p) = \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$$

is scalar and $p \equiv 1 \pmod 2$, so **I** does not apply. However, method **III** does apply with q used as a pivot.

For example, consider the elliptic curve E defined by the equation

$$y^2 + xy = x^3 - x^2 + 19x - 32.$$

The conductor of E is $N = 19 \cdot 109$, and the discriminant of the field $K = \mathbf{Q}(E[2])$ is $-19^3 \cdot 109^3$. We select $q = 19$ as our pivot. The prime $p = 73$ splits completely in K, so

$$\rho_{E,2}(\mathrm{Frob}_p) = \begin{pmatrix}1&0\\0&1\end{pmatrix}.$$

By Theorem 3.11 there is a form g of level $109 \cdot 19 \cdot 73$ that is congruent to the newform f attached to E modulo a prime lying over 2. Method **III** can be used to optimize the level, but neither method **I** nor **II** applies.

3.7.2. II applies but I and III do not

We exhibit a mod 2 representation for which method **II** can be used to optimize

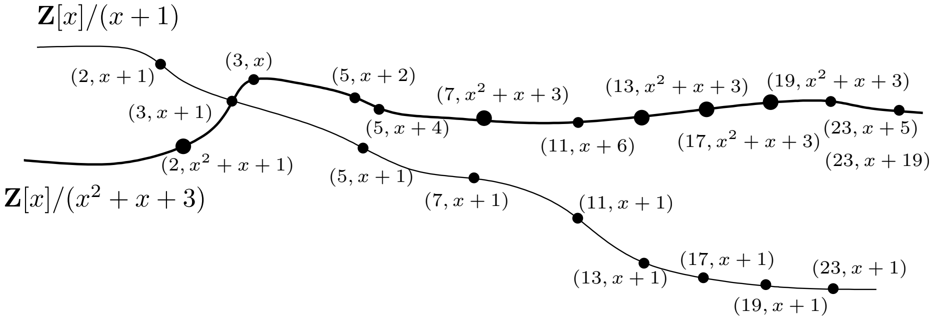


Figure 1. The spectrum of $\mathbf{T} \subset \mathrm{End}(S_2(\Gamma_0(33)))$, with $x = T_3$

the level, but neither method **I** nor **III** applies. Let K be the $\mathrm{GL}_2(\mathbf{F}_2)$-extension of $\mathbf{Q}$ obtained by adjoining all cube roots of 2. Then $K = \mathbf{Q}(E[2])$, where E is the elliptic curve $X_0(27)$ given by the equation $y^2 + y = x^3 - 7$. The prime $p = 31$ splits completely in K, so by Theorem 3.11 there is a newform f of level $31 \cdot 27$ and a maximal ideal λ of the appropriate Hecke algebra such that $\rho_{f,\lambda} \approx E[2]$. Neither method **I** nor **III** can be used to optimize the level of $\rho_{f,\lambda}$. Method **I** doesn't apply because 31 is odd and $\rho_{f,\lambda}(\mathrm{Frob}_{31}) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$; method **III** doesn't apply because the only odd prime that is ramified in K is 3, which does not exactly divide $31 \cdot 27$. If D_2 is a decomposition group at 2 then D_2 has image in $\mathrm{GL}_2(\mathbf{F}_2)$ of order 2, so it is not contained in the scalar matrices and **II** can be used to optimize the level of $\rho_{f,\lambda}$.

3.8. Aside: Sketching the spectrum of the Hecke algebra

It is helpful to understand the Hecke algebra geometrically using the language of schemes (see, e.g., [**38**]). The topological space underlying the scheme $\mathrm{Spec}(\mathbf{T})$ is the set of prime ideals of $\mathbf{T}$ endowed with the Zariski topology, in which the closed sets are the set of prime ideals containing a fixed ideal.

We can draw $\mathrm{Spec}(\mathbf{T})$ by sketching a diagram whose irreducible components correspond to the Galois conjugacy classes of eigenforms, and whose intersections correspond to congruences between eigenforms. When the level is not cube free, $\mathbf{T}$ can contain nilpotent elements, and then one might wish to include additional information. If $\sum a_n q^n$ is an eigenform, then the failure of $\mathbf{Z}[\ldots a_n \ldots]$ to be integrally closed can be illustrated by drawing singular points on the corresponding irreducible component; however, we do not do this below.

Example 3.12. The spectrum of the Hecke algebra associated to $\Gamma_0(33)$ is illustrated in Figure 1. The Hecke algebra $\mathbf{T} \subset S_2(\Gamma_0(33))$ has discriminant -99, as does the characteristic polynomial of T_3, so

$$\mathbf{T} = \mathbf{Z}[T_3]/((T_3+1)(T_3^2+T_3+3)) \cong \mathbf{Z}[x]/((x+1)(x^2+x+3)).$$

We sketch a curve corresponding to each of the two irreducible components. Some of the closed points (maximal) ideals are represented as dots. One component corresponds to the unique newform on $\Gamma_0(33)$, and the other corresponds to the two images of the newform on $\Gamma_0(11)$.

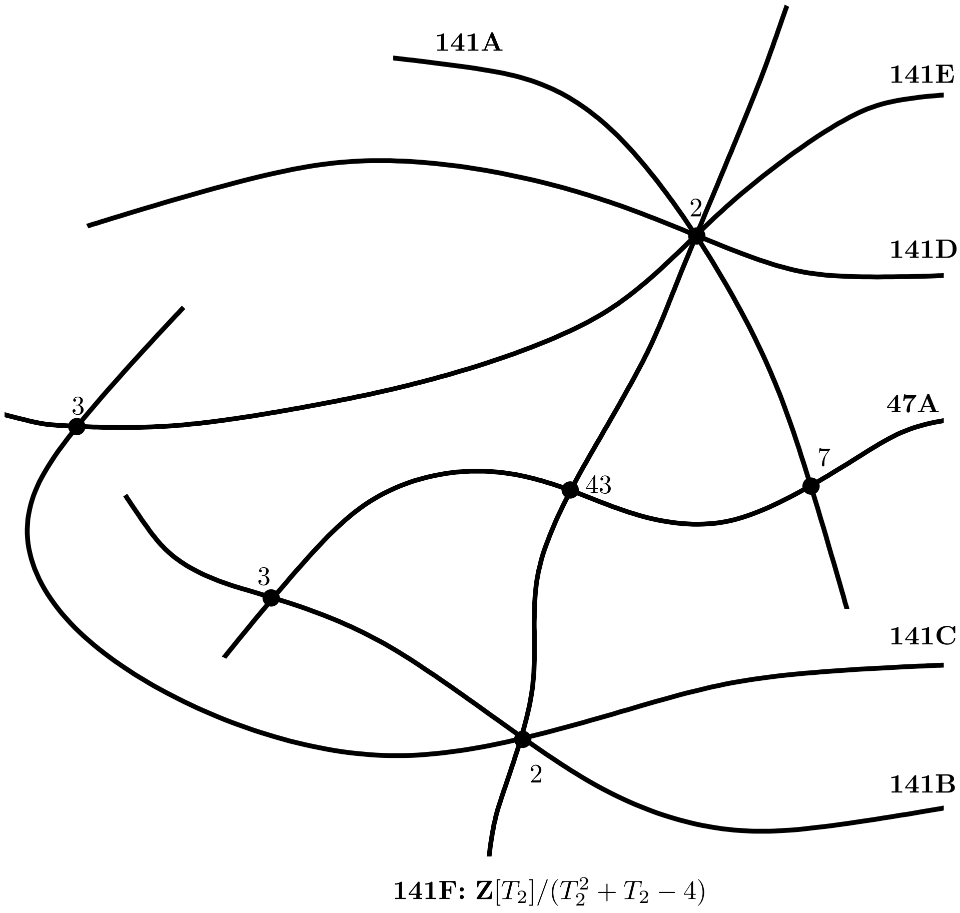

Figure 2. The spectrum of $\mathbf{T} \subset \mathrm{End}(S_2(\Gamma_0(141)))$

Example 3.13. Figure 2 is a diagram of the Hecke algebra associated to $S_2(\Gamma_0(3 \cdot 47))$. We have labeled fewer closed points than in Figure 1. The components are labeled by their isogeny class and the level at which they are new (the notation extends that of [**20**]). The component labeled **141F** corresponds to an eigenform whose Fourier coefficients generate a quadratic extension of $\mathbf{Q}$.

The newform corresponding to the elliptic curve A from Example 3.8 is labeled **141A**. Geometrically, the assertion that the level of $\rho_{A,7}$ can be optimized is represented by the characteristic-7 intersection between the component labeled **141A** and the old component **47A** coming from the unique Galois conjugacy class of newforms on $\Gamma_0(47)$.

3.9. Mazur's principle

A principle due to Mazur can be used to optimize the level in the key case, provided that a mild hypothesis is satisfied. The principle applies whenever $p \not\equiv 1 \pmod{\ell}$ and also in the case when $p \equiv 1 \pmod{\ell}$ but $\rho(\mathrm{Frob}_p)$ is not a scalar. This principle first appeared in [**84**, §6], then in [**26**, §4], and most recently when $\ell = 2$ in [**9**, pg. 7].

Theorem 3.14 (Mazur's Principle). *Suppose that $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ arises from a newform f of weight 2 and level Mp, with $p \nmid M$, and character ε of conductor dividing M. Assume that ρ is unramified at p and that either $\rho(\mathrm{Frob}_p)$ is not a scalar matrix or $p \not\equiv 1 \pmod{\ell}$. Then ρ arises from a modular of level dividing M.*

We will require the following basic fact later in the proof.

Lemma 3.15 (Li). *Let $f = \sum a_n q^n$ be a newform on $\Gamma_1(M) \cap \Gamma_0(p)$ of weight k. Then $a_p^2 = \varepsilon(p) p^{k-2}$.*

Proof. Li's proof is an easy application of her generalization to Γ_1 of the Atkin-Lehner theory of newforms [**69**, Thm. 3(iii)]. The newform f is an eigenvector for the operator W_p which is defined on $S_k(\Gamma_1(M) \cap \Gamma_0(p))$ by

$$W_p(f) = p^{k/2} f\left(\frac{apz + b}{Mpz + p}\right),$$

where a and b are integers such that $ap^2 - bMp = p$. By [**69**, Lem. 3],

$$g := T_p(f) + p^{k/2-1} W_p(f)$$

lies in $S_k(\Gamma_1(M))$. For all primes $q \nmid Mp$, the eigenvalue of T_q on the oldform g is the same as the eigenvalue of T_q on the newform f, so $g = 0$. By [**69**, Lem. 2] ${W_p}^2(f) = \varepsilon(p) f$, so $a_p^2 = \varepsilon(p) p^{k-2}$. □

Remark 3.16. The case of Lemma 3.15 that we will need can also be understood in terms of the local representation $\rho|_{G_p}$, which resembles the mod ℓ representation attached to a Tate curve, in the sense that $\rho|_{G_p} \sim \left(\begin{smallmatrix} \alpha\chi & * \\ 0 & \alpha \end{smallmatrix}\right)$. Our hypothesis include the assumption that ρ is unramified at p, so the two characters $\alpha\chi$ and α are unramified at p. Thus $\alpha(\mathrm{Frob}_p)$ makes sense; we have $\alpha(\mathrm{Frob}_p) = \overline{a}_p(f)$ and $\alpha\chi(\mathrm{Frob}_p) = \overline{a}_p(f)p$. Since $\det(\rho|_{G_p}) = \alpha^2\chi = \overline{\varepsilon}\chi$, we see that

$$\overline{a}_p^2 = \overline{\varepsilon}(p).$$

This local analysis of ρ was vastly generalized by Langlands in [**67**], which extends the analysis to include many ℓ-adic representations of possibly higher weight. See also [**13**].

Let $\mathbf{T}$ be the Hecke algebra associated to $\Gamma_1(M) \cap \Gamma_0(p)$, and let $\mathfrak{m}$ be the kernel of the following map $\mathbf{T} \to \overline{\mathbf{F}}_\ell$:

$$0 \longrightarrow \mathfrak{m} \longrightarrow \mathbf{T} \xrightarrow{T_n \mapsto \overline{a}_n,\ \langle d \rangle \mapsto \overline{\varepsilon}(d)} \overline{\mathbf{F}}_\ell.$$

As in Lemma 3.1, the determinants and traces of elements in the image of $\rho = \rho_{\mathfrak{m}}$ lie in $\mathbf{T}/\mathfrak{m} \subset \overline{\mathbf{F}}_\ell$, so there is a vector space $V \approx (\mathbf{T}/\mathfrak{m})^{\oplus 2}$ that affords $\rho_{\mathfrak{m}}$.

Next we realize $\rho_{\mathfrak{m}}$ as a group of division points in a Jacobian. The curve $X_1(Mp)$ corresponding to $\Gamma_1(Mp)$ covers the curve $X_1(M,p)$ corresponding to $\Gamma_1(M) \cap \Gamma_0(p)$. The induced map $J = \mathrm{Jac}(X_1(M,p)) \to J_1(Mp) = \mathrm{Jac}(X_1(Mp))$ has a finite kernel on which the Galois action is abelian.

Just as in Section 2.3.1.1, the Hecke algebra associated to $\Gamma_1(M) \cap \Gamma_0(p)$, can be constructed as a ring of correspondences on $X_1(M,p)$, then viewed as a subring $\mathbf{T} \subset \mathrm{End}_{\mathbf{Q}}(J)$. Inside of J we find the nonzero $G_{\mathbf{Q}}$-module $J[\mathfrak{m}] \approx \oplus_{i=1}^t V$. For the purposes of this discussion, we do not need to know that $J[\mathfrak{m}]$ is a direct sum

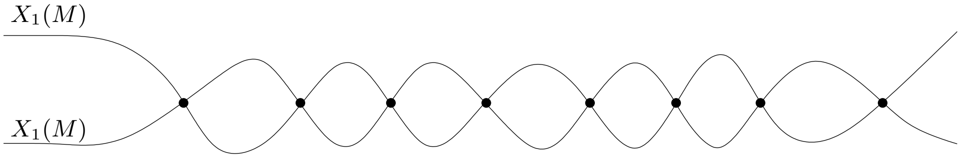

Figure 3. The reduction mod p of the Deligne-Rapoport model of $X_1(M,p)$

of copies of V. The following weaker assertion, known long ago to Mazur [**71**, §14, pg. 112], will suffice: $J[\mathfrak{m}]$ *is a successive extension of copies of* V. In particular, $V \subset J[\mathfrak{m}]$. A weaker conclusion, true since $\ell \in \mathfrak{m}$, is that $V \subset J[\ell]$,

Our hypothesis that ρ is unramified at p translates into the inclusion $V \subset J[\ell]^{I_p}$, where I_p is an inertia group at p. By [**104**, Lem. 2], if A is an abelian variety over $\mathbf{Q}$ with good reduction at p, then $A[\ell]^{I_p} \cong A_{\mathbf{F}_p}[\ell]$. However, the modular curve $X_1(M,p)$ has bad reduction at p, so J is likely to have bad reduction at p—in this case it does. We are led to consider the Néron model $\mathcal{J}$ of J (see, e.g., [**5**]), which is a smooth commutative group scheme over $\mathbf{Z}$ satisfying the following property: the restriction map $\mathrm{Hom}_{\mathbf{Z}}(\mathcal{S},\mathcal{J}) \longrightarrow \mathrm{Hom}_{\mathbf{Q}}(\mathcal{S}_{\mathbf{Q}},J)$ is bijective for all smooth schemes $\mathcal{S}$ over $\mathbf{Z}$. Passing to the scheme-theoretic closure, we have, inside of $\mathcal{J}$, a two-dimensional $\mathbf{T}/\mathfrak{m}$-vector space scheme $\mathcal{V}$.

In Section 2.3.1.1 we only defined $X_1(M,p)$ as a scheme over $\mathbf{Z}[1/Mp]$. Deligne and Rapoport [**25**] extended $X_1(M,p)$ to a scheme over $\mathbf{Z}[1/M]$ and computed the reduction modulo p. The introduction to [**62**] contains a beautiful historical discussion of the difficulties involved in extending modular curves over $\mathbf{Z}$.

We know a great deal about the reduction of $X_1(M,p)$ at p, which is frequently illustrated by the squiggly diagram in Figure 3. This reduction is the union of 2 copies of $X_1(M)_{\mathbf{F}_p}$ intersecting transversely at the supersingular points.

The subspace $S_2(\Gamma_1(M)) \oplus S_2(\Gamma_1(M))$ of $S_2(\Gamma_1(M) \cap \Gamma_0(p))$ is stable under the Hecke algebra $\mathbf{T}$, so there is a map $\mathbf{T} \to \mathrm{End}(S_2(\Gamma_1(M)) \oplus S_2(\Gamma_1(M)))$. The *p-old quotient* of $\mathbf{T}$ is the image $\overline{\mathbf{T}}$. Since the map $\mathbf{T} \to \overline{\mathbf{T}}$ is surjective, the image of $\mathfrak{m}$ in $\overline{\mathbf{T}}$ is an ideal $\overline{\mathfrak{m}}$. To optimize the level in the key case amounts to showing that $\overline{\mathfrak{m}}$ is not the unit ideal.

As is well known (cf. [**71**, Appendix, Prop 1.4]), the results of M. Raynaud [**82**] and Deligne-Rapoport [**25**] combine to produce an exact sequence

$$0 \longrightarrow \mathcal{T} \longrightarrow \mathcal{J}^0_{\mathbf{F}_p} \longrightarrow J_1(M)_{\mathbf{F}_p} \times J_1(M)_{\mathbf{F}_p} \longrightarrow 0, \tag{3.1}$$

where $\mathcal{T}$ is a torus, i.e., $\mathcal{T}_{\overline{\mathbf{F}}_p} \approx \mathbf{G}_m \times \cdots \times \mathbf{G}_m$, and $\mathcal{J}^0_{\mathbf{F}_p}$ is the identity component of $\mathcal{J}_{\mathbf{F}_p}$. There is a concrete description of $\mathcal{T}$ and of the maps in the exact sequence. Each object in the sequence is equipped with a functorial action of the Hecke algebra $\mathbf{T}$, and the sequence is $\mathbf{T}$-invariant. The p-old quotient $\overline{\mathbf{T}}$ can be viewed as coming from the action of $\mathbf{T}$ on $J_1(M)_{\mathbf{F}_p} \times J_1(M)_{\mathbf{F}_p}$.

By a generalization of [**104**, Lem. 2], the reduction map $J(\overline{\mathbf{Q}}_p)[\ell]^{I_p} \to \mathcal{J}_{\mathbf{F}_p}(\overline{\mathbf{F}}_p)$ is injective. Thus $V = \mathcal{V}_{\mathbf{F}_p}(\overline{\mathbf{F}}_p) \subset \mathcal{J}_{\mathbf{F}_p}(\overline{\mathbf{F}}_p)$. The component group $\Phi = \mathcal{J}_{\mathbf{F}_p}/\mathcal{J}^0_{\mathbf{F}_p}$ is *Eisenstein*, in the sense that it does not contain irreducible representations arising from eigenforms. Since V is irreducible, as a Galois module Φ does not contain an isomorphic copy of V, so $\mathcal{V}_{\mathbf{F}_p} \subset \mathcal{J}^0_{\mathbf{F}_p}$ and we have the following diagram:

$$\begin{tikzcd}
0 \arrow[r] & \mathcal{T} \arrow[r] & \mathcal{J}^0_{\mathbf{F}_p} \arrow[r] & J_1(M)_{\mathbf{F}_p} \times J_1(M)_{\mathbf{F}_p} \arrow[r] & 0. \\
& & \mathcal{V}_{\mathbf{F}_p} \arrow[u, hook] \arrow[ul, dotted] \arrow[ur] & &
\end{tikzcd}$$

Since $\mathfrak{m}$ acts as 0 on V, the image $\overline{\mathfrak{m}}$ of $\mathfrak{m}$ acts as 0 on the image of V in $J_1(M)_{\mathbf{F}_p} \times J_1(M)_{\mathbf{F}_p}$. If $\overline{\mathfrak{m}} \neq (1)$ then we can optimize the level, so assume $\overline{\mathfrak{m}} = (1)$. Then the image of V in $J_1(M)_{\mathbf{F}_p} \times J_1(M)_{\mathbf{F}_p}$ is 0, so $V_{\mathbf{F}_p} \hookrightarrow \mathcal{T}$.

Let $\mathcal{X}_p(J) := \mathrm{Hom}(\mathcal{T}, \mathbf{G}_m)$ be the *character group* of $\mathcal{T}$. The action of $\mathbf{T}$ on $\mathcal{T}$ induces an action of $\mathbf{T}$ on $\mathcal{X}_p(J)$. Furthermore, $\mathcal{X}_p(J)$ supports an action of $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$ which, because tori split over a quadratic extension, factors through the Galois group of $\mathbf{F}_{p^2}$. View the Galois action as an action of $\mathrm{Frob}_p \in D_p = \mathrm{Gal}(\overline{\mathbf{Q}}_p/\mathbf{Q}_p)$. With our conventions, the action of Frobenius on the torus is as follows (cf. [**26**, pg. 31]).

Lemma 3.17. *The Frobenius* Frob_p *acts as* pT_p *on* $\mathcal{T}(\overline{\mathbf{F}}_p)$.

Make the identification $\mathcal{T} \cong \mathrm{Hom}_{\mathbf{Z}}(\mathcal{X}_p(J), \mathbf{G}_m)$, so that

$$V \subset \mathcal{T}(\overline{\mathbf{F}}_p)[\ell] = \mathrm{Hom}_{\mathbf{Z}}(\mathcal{X}_p(J), \boldsymbol{\mu}_\ell).$$

By Lemma 3.17, Frob_p acts on $V \subset \mathcal{T}(\overline{\mathbf{F}}_p)$ as $pa_p \in \mathbf{T}/\mathfrak{m}$, i.e., as a *scalar*. The determinant of ρ is $\chi\varepsilon$, so we have simulatenously

$$\det(\rho(\mathrm{Frob}_p)) = \begin{cases} p\varepsilon(p) & \text{and} \\ (pa_p)^2. \end{cases}$$

By Lemma 3.15, $a_p^2 = \varepsilon(p)$, so $p^2 \equiv p \pmod{\ell}$. Since $p \neq \ell$, this can only happen if $p \equiv 1 \pmod{\ell}$, which completes the proof.

3.10. Level optimization using a pivot

In this section we discuss an approach to level optimization that does not rely on multiplicity one results. In this approach, we eliminate a prime p from the level by making use of the rational quaternion algebra that is ramified precisely at p and at a second prime q. The latter prime is, in the simplest case, an appropriate prime number at which ρ ramifies; in more complicated cases, it is an "auxiliary" prime at which ρ is unramified. The central role of q in the argument, and the fact that q stays fixed in the level while p is removed, leads us to refer to q as a "pivot."

The following theorem first appeared in [**86**].

Theorem 3.18. *Let* $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ *be an irreducible continuous representation that arises from an eigenform* f *on* $\Gamma_1(K) \cap \Gamma_0(pq)$ *with* p *and* q *distinct primes that do not divide* ℓK. *Make the* ***key assumption*** *that the representation* ρ *is ramified at* q *and unramified at* p. *Then* ρ *arises from a weight-*2 *eigenform on* $\Gamma_1(K) \cap \Gamma_0(q)$.

The case $\ell = 2$ is not excluded from consideration.

Before sketching the proof, we describe a famous application. Edixhoven suggested to the first author that such an approach might be possible in the context of

Fermat's Last Theorem. We associate to a (hypothetical) solution $a^\ell + b^\ell + c^\ell = 0$ of the Fermat equation with $\ell > 3$ a Galois representation $E[\ell]$ attached to an elliptic curve E. A theorem of Mazur implies that this representation is irreducible; a theorem of Wiles implies that it arises from a modular form. Using Tate's algorithm, we finds that the discriminant of E is $\Delta_E = \frac{(abc)^{2\ell}}{2^8}$, which is a perfect ℓth power away from 2, and that the conductor of E is $N_E = \mathrm{rad}(abc) = \prod_{p \mid abc} p$. Let $q = 2$; then $E[\ell]$ is ramified at q because $\ell \nmid \mathrm{ord}_2(\Delta_E) = -8$ (see Theorem 2.10), but $E[\ell]$ is unramified at all other primes p, again by Theorem 2.10. To complete the proof of Fermat Last Theorem, we use $q = 2$ as a pivot and inductively remove each odd factor from N. One complication that may arise (the second case of Fermat Last Theorem) is that $\ell \mid N$. Upon removing ℓ from the level (using Section 3.1), the weight may initially go up to $\ell + 1$. If this occurs, since $k(\rho) = 2$ we can use [**32**] to optimize the weight back to 2.

As demonstrated by the application to Fermat, in problems of genuine interest the setup of Theorem 3.18 occurs. There are, however, situations in which it does not apply such as the recent applications of level optimization as a key ingredient to a proof of Artin's conjecture for certain icosahedral Galois representations (see [**10**]).

3.10.1. Shimura curves

We cannot avoid considering Shimura curves. Denote by $X(K, pq)$ the modular curve associated to $\Gamma_1(K) \cap \Gamma_0(pq)$ and let $J := \mathrm{Jac}(X(K, pq))$ be its Jacobian. Likewise, denote by $X^{pq}(K)$ the Shimura curve associated to the quaternion algebra of discriminant pq. The curve $X^{pq}(K)$ is constructed as follows. Let B be an indefinite quaternion algebra over $\mathbf{Q}$ of discriminant pq. (Up to isomorphism, B is unique.) Let $\mathcal{O}$ be an Eichler order (i.e., intersection of two maximal orders) of level K (i.e., reduced discriminant Kpq) in B. Let Γ_∞ be the group of elements of $\mathcal{O}$ with (reduced) norm 1. After fixing an embedding $B \to M(2, \mathbf{R})$ (an embedding exists because B is indefinite), we obtain in particular an embedding $\Gamma_\infty \hookrightarrow \mathrm{SL}(2, \mathbf{R})$ and therefore an action of Γ_∞ on the upper half-plane $\mathfrak{h}$. Let $X^{pq}(K)$ be the standard canonical model, over $\mathbf{Q}$, of the compact Riemann surface $\Gamma_\infty \backslash \mathfrak{h}$, and let $J' = \mathrm{Jac}(X^{pq}(K))$ denote its Jacobian. The curve $X^{pq}(K)$ is furnished with Hecke correspondences T_n for $n \geq 1$. We write T_n for the endomorphism of J induced by the T_n on $X^{pq}(K)$ via Pic functoriality.

Set $J' := \mathrm{Jac}(X^{pq}(K))$ and $J := \mathrm{Jac}(X(K, pq))$. Work of Eichler, Jacquet-Langlands, and Shimura (see [**36, 51, 106**]) has uncovered a deep correspondence between certain automorphic forms and certain cusp forms. Combining their work with the isogeny theorem of Faltings [**40**], we find (noncanonically!) a map $J' \to J$ with finite kernel.

The pq-new part of J is $J_{pq\text{-new}} := \ker(J(K, pq) \longrightarrow J(K, p)^2 \oplus J(K, q)^2)$ where the map is induced by Albanese functoriality from the four maps

$$X(K, pq) \rightrightarrows X(K, p) \qquad \text{and} \qquad X(K, pq) \rightrightarrows X(K, q).$$

The image of $J' \to J$ is the pq-new part of J.

3.10.2. Character groups

Amazingly, there seems to be no canonical map $J' \to J$ between the Shimura and classical Jacobians described in the previous section. Surprisingly, there is a canonical relationship between the character groups of J' and J. The Čerednik-Drinfeld theory gives a description of $X^{pq}(K)$ in characteristic p (see [**14, 30**]). Using this we find a canonical $\mathbf{T}$-equivariant exact sequence

$$0 \to \mathcal{X}_p(J') \to \mathcal{X}_q(J) \to \mathcal{X}_q(J'') \to 0 \tag{3.2}$$

where $J'' = \mathrm{Jac}(X(K, q))^2$. This exact sequence relates a character group "in characteristic p" to two character groups "in characteristic q". We are now prepared to prove the theorem.

3.10.3. Proof

Proof of Theorem 3.18. By our key assumption, the representation ρ is ramified at q, so $\mathfrak{m} \subset \mathbf{T}$ is not q-old. We may as well suppose we are in a situation where we can not optimize the level, so we assume that $\mathfrak{m}$ is not p-old either and hope for a contradiction.

Localization is an exact functor, so the localization

$$0 \longrightarrow \mathcal{X}_p(J')_{\mathfrak{m}} \longrightarrow \mathcal{X}_q(J)_{\mathfrak{m}} \longrightarrow \mathcal{X}_q(J'')_{\mathfrak{m}} \longrightarrow 0 \tag{3.3}$$

of (3.2) is also exact. The Hecke algebra $\mathbf{T}$ acts on $\mathcal{X}_q(J'')$ through a quotient $\overline{\mathbf{T}}$. Since $\mathfrak{m}$ is not q-old, the image of $\mathfrak{m}$ in $\overline{\mathbf{T}}$ generates the unit ideal. Therefore $\mathcal{X}_q(J'')_{\mathfrak{m}} = 0$ and we obtain an isomorphism $\mathcal{X}_p(J')_{\mathfrak{m}} \approx \mathcal{X}_q(J)_{\mathfrak{m}}$. If R is a $\mathbf{T}$-module then $R/\mathfrak{m}R = R_{\mathfrak{m}}/\mathfrak{m}R_{\mathfrak{m}}$ so

$$\mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J) \approx \mathcal{X}_p(J')/\mathfrak{m}\mathcal{X}_p(J'). \tag{3.4}$$

Switching p and q and applying the same argument shows that

$$\mathcal{X}_p(J)/\mathfrak{m}\mathcal{X}_p(J) \approx \mathcal{X}_q(J')/\mathfrak{m}\mathcal{X}_q(J'). \tag{3.5}$$

Both (3.4) and (3.5) are isomorphisms of $\mathbf{T}/\mathfrak{m}$-vector spaces.

By [**6**] we have an isomorphism $J[\mathfrak{m}] \approx \bigoplus_{i=1}^{\lambda} V$, with $\lambda > 0$ and $J'[\mathfrak{m}] \approx \bigoplus_{i=1}^{\nu} V$. (It follows from [**51**] that $\nu > 0$, but we will not use this here.) Our hypothesis that V is unramified automatically propagates to all of $J[\mathfrak{m}] \approx \bigoplus_{i=1}^{\lambda} V$. Since V is irreducible and we are assuming that $\mathfrak{m}$ is not p-old, the same argument as in Section 3.9 shows that $J[\mathfrak{m}] \subset \mathcal{T}[\mathfrak{m}]$ where $\mathcal{T}$ is the toric part of $\mathcal{J}_{\mathbf{F}_p}$. This means that $\dim(\mathcal{X}_p(J)/\mathfrak{m}\mathcal{X}_p(J)) \geq 2\lambda$. Using the same argument with J replaced by J' gives that $\dim(\mathcal{X}_p(J')/\mathfrak{m}\mathcal{X}_p(J')) \geq 2\mu$.

As an I_q-module V is an extension of two copies of the trivial character. This follows from results of Langlands [**67**], since ρ is a mod ℓ representation of $G_{\mathbf{Q}}$ associated to some newform f whose level divides pqK and is divisible by q. (The admissible representation of $\mathrm{GL}(2, \mathbf{Q}_q)$ which is associated to f is a special representation.) Because V is ramified at q and there is an unramified line, we see that $\dim(V^{I_q}) = 1$. Thus $\dim J[\mathfrak{m}]^{I_q} = \lambda$; since $q \neq \ell$ and the action of inertia on character groups is trivial, we see that

$$\mathrm{Hom}(\mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J), \boldsymbol{\mu}_\ell) \subset J[\mathfrak{m}]^{I_q},$$

so $\dim \mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J) \leq \lambda$. A similar argument bounds $\dim \mathcal{X}_q(J')/\mathfrak{m}\mathcal{X}_q(J')$. We obtain the following quadruple of inequalities:

$$\begin{aligned}
\dim \mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J) &\leq \lambda,\\
\dim \mathcal{X}_q(J')/\mathfrak{m}\mathcal{X}_q(J') &\leq \mu,\\
\dim \mathcal{X}_p(J)/\mathfrak{m}\mathcal{X}_p(J) &\geq 2\lambda,\\
\dim \mathcal{X}_p(J')/\mathfrak{m}\mathcal{X}_p(J') &\geq 2\mu.
\end{aligned}$$

Combining these with (3.4, 3.5), we find that

$$\begin{aligned}
2\lambda &\leq \dim \mathcal{X}_p(J)/\mathfrak{m}\mathcal{X}_p(J)\\
&= \dim \mathcal{X}_q(J')/\mathfrak{m}\mathcal{X}_q(J')\\
&\leq \mu
\end{aligned}$$

and simulatenously that $2\mu \leq \lambda$. Together these imply that $4\lambda \leq \lambda$ so $\lambda = 0$. But Proposition 3.2 implies that the multiplicity of ρ in $J[\mathfrak{m}]$ is strictly positive. This contradiction implies that our assumption that $\mathfrak{m}$ is not p-old is false, hence $\mathfrak{m}$ is p-old and ρ arises from an eigenform on $\Gamma_1(K) \cap \Gamma_0(q)$. □

3.11. Level optimization with multiplicity one

Theorem 3.19. *Suppose $\rho : G_{\mathbf{Q}} \to \mathrm{GL}_2(\overline{\mathbf{F}}_\ell)$ is an irreducible multiplicity one representation that arises from a weight-2 newform f on $\Gamma_1(M) \cap \Gamma_0(p)$ and that p is unramified. Then there is a newform on $\Gamma_1(M)$ that also gives rise to ρ.*

We sketch a proof, under the assumption that $\ell > 2$. Buzzard [**9**] has given a proof when $\ell = 2$; his result has been combined with the results of [**28**] to prove a Wiles-like lifting theorem valid for many representations when $\ell = 2$, and hence (thanks to Taylor) to establish new examples of Artin's conjecture (see [**10**]).

The following diagram illustrates the multiplicity one argument:

$$\begin{tikzcd}
& Mpq \arrow[rr, rightsquigarrow, "\text{pivot}"] & & Mq \arrow[dr, rightsquigarrow, "\text{easy}"] & \\
Mp \arrow[ur, rightsquigarrow, "\text{level addition}"] & & & & M.
\end{tikzcd}$$

The pivot step is potentially the hardest; though it resembles the pivot step of Section 3.10, but the symmetry is broken. In Section 3.10 we knew that q could not be removed from the level, but here q can be.

We manufacture q as follows. Pick q to be one of the (infinitely many) primes not dividing $Mp\ell$ such that the following conditions both hold:

$$(1)\quad \begin{cases} \rho(\mathrm{Frob}_q) \text{ is not a scalar, } \textit{or} \\ q \not\equiv 1 \pmod{\ell}. \end{cases}$$

$$(2)\quad \begin{cases} \text{the ratio of the eigenvalues of} \\ \rho(\mathrm{Frob}_q) \text{ is either } q \text{ or } 1/q. \end{cases}$$

The second condition means that the characteristic polynomial of $\rho(\mathrm{Frob}_q)$ is of the form $(x - a)(x - qa)$ for some $a \in \overline{\mathbf{F}}_\ell^*$.

Lemma 3.20. *There are infinitely many primes q that simultaneously satisfy both of the two conditions listed above.*

Proof. First assume that $\ell > 2$. Using the Cebotarev density theorem, find infinitely many primes q such $\rho(\mathrm{Frob}_q) = \rho(c)$ where c denotes complex conjugation. The eigenvalues of $\rho(c)$ are 1 and -1 (Exercise 8), so their ratio is -1. This ratio is equal to q because

$$-1 = \chi(c) = \det(\rho(\mathrm{Frob}_q)) = \chi(\mathrm{Frob}_q) \equiv q \pmod{\ell},$$

and $q \not\equiv 1 \pmod{\ell}$ because ℓ is odd.

Next assume that $\ell = 2$. Because ρ is irreducible, the image $\rho(G_{\mathbf{Q}}) \subset \mathrm{GL}(2, \overline{\mathbf{F}}_2)$ has even order. After a possible change of basis we find $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) \in \rho(G_{\mathbf{Q}})$. Using Cebotarev density, we find infinitely many q with $\rho(\mathrm{Frob}_q)$ conjugate to $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. For such q, condition (1) is satisfied. Condition (2) is also satisfied because the ratio of the eigenvalues is 1 which, because q is an odd prime, is congruent to q modulo $\ell = 2$. □

Sketch of proof of Theorem 3.19. Choose q as in Lemma 3.20. With q thus chosen, we can raise the level. More precisely, there exists a pq-new form on $\Gamma_1(M) \cap \Gamma_0(pq)$. We illustrate this as follows.

$$\begin{tikzcd}
& (M,\underline{pq}) \arrow[dr, mapsto, "\text{goal}"] & & \\
(M,p) \arrow[ur, mapsto, "\text{raise}"] & & (M,q) \arrow[rr, mapsto, "\text{Mazur (condition 1)}"] & & M
\end{tikzcd}$$

We underline pq to emphasize that the situation at level (M, pq) is symmetrical in p and q.

Let $J = J(M, pq)$; there is a maximal ideal $\mathfrak{m}$ in $\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots] \subset \operatorname{End} J$ attached to the pq-newform f that gives rise to ρ. Applying the multiplicity one hypothesis at level Mpq, we have $J[\mathfrak{m}] = V$ where V is a $\mathbf{T}/\mathfrak{m}$-vector space that supports ρ. In everything so far, M can be divisible by 2; the distinction between whether or not 2 divides M arises mainly in verifying the multiplicity one hypothesis.

Let $J' = J^{pq}(M)$ be the Shimura curve analogue of $J_1(M)$. As described in Section 3.10, J' is constructed in a similar manner as $J_1(M)$, but with $M_2(\mathbf{Q})$ replaced by a quaternion algebra. Of primary importance is that $J'[\mathfrak{m}] \approx \bigoplus_{i=1}^{\nu} V$, for some $\nu \geq 1$. This follows *morally* because ρ arises from a pq-new form, though the actual argument is quite involved.

Assume that we cannot optimize the level. We have an exact sequence of character groups

$$0 \longrightarrow \mathcal{X}_p(J') \longrightarrow \mathcal{X}_q(J) \longrightarrow \mathcal{X}_q(J(M,q)^2) \longrightarrow 0.$$

After localizing at $\mathfrak{m}$ as in (3.3), we discover that

$$\dim_{\mathbf{T}/\mathfrak{m}} \mathcal{X}_p(J')/\mathfrak{m}\mathcal{X}_p(J') = \dim_{\mathbf{T}/\mathfrak{m}} \mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J). \tag{3.6}$$

Furthermore, since the component group of J' at p is a quotient of $\mathcal{X}_q(J(M,q)^2)$, we find that $V \hookrightarrow (J'[\mathfrak{m}]^{I_p})^{\mathrm{toric}}$. Thus $\dim \mathcal{X}_p(J')/\mathfrak{m}\mathcal{X}_p(J') \geq 2$, so (3.6) implies that $\dim \mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J) \geq 2$. The endomorphism Frob_q acts as a scalar (cf. Lemma 3.17) on

$$J[\mathfrak{m}]^{\mathrm{toric}} = \mathrm{Hom}(\mathcal{X}_q(J)/\mathfrak{m}\mathcal{X}_q(J), \mu_\ell).$$

Furthermore, $J[\mathfrak{m}]^{\mathrm{toric}} \subset J[\mathfrak{m}]$ and both $J[\mathfrak{m}]^{\mathrm{toric}}$ and $J[\mathfrak{m}]$ have dimension 2, so Frob_q acts as a scalar on $J[\mathfrak{m}]$. If $q \not\equiv 1 \pmod{\ell}$ then we could use Mazur's principle to optimize the level, so by condition 1 we may assume that $\rho(\mathrm{Frob}_q)$ is not a scalar. This contradiction completes the sketch of the proof. $\square$

CHAPTER 4

Exercises

The following exercises were used in the Park City problem sessions. D. Savitt, K. Kedlaya, and B. Conrad contributed some of the problems. In Section 4.2, we provide several solutions, many of which were suggested by students in the problem sessions. The solution of some of the problems in this section requires facts beyond those stated explicitly in this paper.

4.1. Exercises

Exercise 1. Suppose $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathbf{F}_\ell^*$ is a one-dimensional continuous odd Galois representation.

(1) Give an example to show that ρ need not be a power of the mod ℓ cyclotomic character.

(2) Assume that ρ is unramified outside ℓ. Deduce that ρ is a power of the mod ℓ cyclotomic character.

Exercise 2. The principal congruence subgroup $\Gamma(N)$ of level N is the kernel of the reduction map $\mathrm{SL}(2, \mathbf{Z}) \to \mathrm{SL}(2, \mathbf{Z}/N\mathbf{Z})$. The subgroup $\Gamma_1(N)$ consists of matrices of the form $\left(\begin{smallmatrix} 1 & * \\ 0 & 1 \end{smallmatrix}\right)$ modulo N. Let $\Gamma \subset \mathrm{SL}(2, \mathbf{Z})$ be a subgroup that contains $\Gamma(N)$ for some N. Show that there exists $g \in \mathrm{GL}(2, \mathbf{Q})$ such that the conjugate $g^{-1}\Gamma g$, which is a subgroup of $\mathrm{GL}(2, \mathbf{Q})$, contains $\Gamma_1(N^2)$.

Exercise 3. Let k be a finite field of characteristic greater than 2, and consider an odd representation $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, k)$. Prove that ρ is irreducible if and only if ρ is absolutely irreducible. (A representation is absolutely irreducible if it remains irreducible after composing with the embedding $\mathrm{GL}(2, \mathbf{F}_\ell) \hookrightarrow \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$.) Give an example to show that this assertion is false when k has characteristic 2.

Exercise 4. Let $A/\mathbf{Q}$ be an elliptic curve. Show that the group of $\mathbf{Q}$-rational endomorphisms $\mathrm{End}(A)$ of A is equal to $\mathbf{Z}$; that is, integer multiplications are the only $\mathbf{Q}$-rational endomorphisms of A. Assume further that A is isolated in its isogeny class, in the sense that if B is an elliptic curve that is isogenous to A over $\mathbf{Q}$, then A and B are isomorphic over $\mathbf{Q}$. Show that, for every prime number ℓ, the representation

$$\rho_\ell : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{Aut}(A[\ell]) \approx \mathrm{GL}(2, \mathbf{F}_\ell)$$

is irreducible. Must ρ_ℓ be absolutely irreducible?

Exercise 5. Let $A/\mathbf{Q}$ be an elliptic curve and assume that for all ℓ the representation $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{Aut}(A[\ell])$ is irreducible. Deduce that A is isolated in its isogeny class. This is the converse of Exercise 4.

Exercise 6. Suppose $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}(2, \mathbf{F}_\ell)$ arises from the ℓ-torsion of an elliptic curve. Verify, using standard properties of the Weil pairing, that $\det(\rho)$ is the mod ℓ cyclotomic character.

Exercise 7. Let $f \in S_k(\Gamma_1(N))$ be a modular form that is an eigenform for all the Hecke operators T_p and for the diamond bracket operators $\langle d \rangle$. Let

$$\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$$

be the character of f, so $\langle d \rangle f = \varepsilon(d) f$ for all $d \in (\mathbf{Z}/N\mathbf{Z})^*$.

1. Show that f satisfies the following equation:
   for any $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$,
   $$f(z) = \varepsilon(d)(cz+d)^{-k} f\Big(\frac{az+b}{cz+d}\Big).$$
2. Conclude that $\varepsilon(-1) = (-1)^k$.
3. Choose a prime ℓ and let ρ be one of the mod ℓ Galois representations associated to f. We have $\det(\rho) = \varepsilon \cdot \chi^{k-1}$ where χ is the mod ℓ cyclotomic character. Deduce that ρ is odd, in the sense that $\det(\rho(c)) = -1$ for c complex conjugation.

Exercise 8. Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \overline{\mathbf{F}}_\ell)$ be an odd Galois representation, and let $c \in G_{\mathbf{Q}}$ denote complex conjugation.

1. Prove that if $\ell \neq 2$ then $\rho(c)$ is conjugate over $\overline{\mathbf{F}}_\ell$ to the matrix $\left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$.
2. Give an example to show that when $\ell = 2$, the matrix $\rho(c)$ need not be conjugate to $\left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

Exercise 9. Show that there exists a *non-continuous* homomorphism

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \{\pm 1\}$$

where $\{\pm 1\}$ has the discrete topology; equivalently, that there is a non-closed subgroup of index two in $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. To accomplish this, you must produce a map $\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \{\pm 1\}$ such that

1. ρ is a homomorphism, and
2. ρ does not factor through $\mathrm{Gal}(K/\mathbf{Q})$ for any *finite* Galois extension $K/\mathbf{Q}$.

Exercise 10. A potential difficulty is that a representation ρ arising from a modular form sometimes takes values in a slightly smaller field than $\mathcal{O}/\lambda$. For example, let f be one of the two conjugate normalized eigenforms in $S_2(\Gamma_0(23))$. Then

$$f = q + \alpha q^2 + (-2\alpha - 1)q^3 + (-\alpha - 1)q^4 + 2\alpha q^5 + \cdots$$

with $\alpha^2 + \alpha - 1 = 0$. The coefficients of f lie in $\mathcal{O} = \mathbf{Z}[\alpha] = \mathbf{Z}[\frac{1+\sqrt{5}}{2}]$. Take λ to be the unique prime of $\mathcal{O}$ lying over 2; then $\mathcal{O}/\lambda \cong \mathbf{F}_4$, so $\overline{\rho}_{f,\lambda}$ is a homomorphism into $\mathrm{GL}(2, \mathbf{F}_4)$. Show that if $p \neq 2$ then $a_p \in \mathbf{Z}[\sqrt{5}]$, so that $\overline{\rho}_{f,\lambda}$ possesses a model over $\mathrm{GL}(2, \mathbf{F}_2)$.

Exercise 11. Let $A/\mathbf{Q}$ be an elliptic curve and $\ell \neq 2$ be a prime.

1. Prove that the field $\mathbf{Q}(A[\ell])$ generated by the coordinates of the points in $A[\ell]$ is strictly larger than $\mathbf{Q}$.
2. Given an example of an elliptic curve A such that $\mathbf{Q}(A[2]) = \mathbf{Q}$.

Exercise 12. Let A be an elliptic curve over $\mathbf{Q}$ defined by a Weierstrass equation $y^2 = x^3 + ax + b$ with $a, b \in \mathbf{Q}$.

(1) Describe the Galois representation

$$\rho = \rho_{A,2} : G_{\mathbf{Q}} \to \mathrm{GL}(2, \mathbf{F}_2).$$

(2) Give necessary and sufficient conditions for ρ to be reducible.

(3) Choose a prime p, and give an example in which ρ is ramified only at p.

Exercise 13. Let ε and ρ be a pair of continuous homomorphisms from $G_{\mathbf{Q}}$ to $\mathbf{F}_\ell^*$. Suppose that for all primes p at which both ε and ρ are unramified we have

$$\rho(\mathrm{Frob}_p) = \varepsilon(\mathrm{Frob}_p)p^i \in \mathbf{F}_\ell.$$

Deduce that $\rho = \varepsilon \cdot \chi^i$ where χ is the mod ℓ cyclotomic character.

Exercise 14. Let $A/\mathbf{Q}$ be an elliptic curve of conductor N, and let p be a prime number not dividing N. Denote by $\tilde{A}$ the mod p reduction of A. The Frobenius endomorphism $\Phi = \Phi_p : \tilde{A} \to \tilde{A}$ sends an affine point (x, y) to (x^p, y^p) and fixes ∞. The characteristic polynomial of the endomorphism induced by Φ on the Tate module of $\tilde{A}$ at some (any) prime $\ell \neq p$ is $X^2 - \mathrm{tr}(\Phi)X + \deg(\Phi)$.

(1) Show that $\deg(\Phi) = p$.

(2) Show that $\mathrm{tr}(\Phi) = p + 1 - \#A(\mathbf{F}_p)$, that is, "$\mathrm{tr}(\Phi) = a_p$."

(3) Choose a prime $\ell \nmid pN$. Then $\tilde{A}[\ell]$ is a vector space of dimension two over $\mathbf{F}_\ell$, and Φ induces a map $\tilde{A}[\ell] \to \tilde{A}[\ell]$. Show that this is the same as the map induced by some choice of $\mathrm{Frob}_p \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$.

(4) Conclude that

$$\mathrm{tr}(\rho_{A,\ell}(\mathrm{Frob}_p)) = p + 1 - \#A(F_p) \pmod{\ell}.$$

Exercise 15. Let $A/\mathbf{Q}$ be an elliptic curve of conductor N, and let ℓ be a prime. Show that any prime p not dividing ℓN is unramified in $\mathbf{Q}(A[\ell])$. You may use the following fact which is proved using formal groups (see, e.g., [**109**, Prop. 3.1]): **Fact:** The map $A[\ell] \to \tilde{A}(\overline{\mathbf{F}}_p)$ is injective, where $\tilde{A}$ is the reduction of A modulo p.

Exercise 16. Show that the fundamental character of level 1 is the cyclotomic character $\chi|_{I_t}$. (Hint: This is trickier than it first appears, and requires Wilson's theorem from elementary number theory.)

Exercise 17. For each of the following semistable elliptic curves A, and each ℓ at which $\rho_{A,\ell}$ is *irreducible*, use Theorem 2.10 to compute Serre's minimal weight $k(\rho_{A,\ell})$ and level $N(\rho_{A,\ell})$.

N	$\lvert\Delta\rvert$	reducible ℓ	A
30	$2^4 \cdot 3^5 \cdot 5$	$2, 3$	$y^2 + xy + y = x^3 + x + 2$
210	$2^{12} \cdot 3^3 \cdot 5 \cdot 7$	$2, 3$	$y^2 + xy = x^3 - 41x - 39$
330	$2^4 \cdot 3^2 \cdot 5^4 \cdot 11^2$	2	$y^2 + xy = x^3 + x^2 - 102x + 324$
455	$5^3 \cdot 7^4 \cdot 13$	2	$y^2 + xy = x^3 - x^2 - 50x + 111$
2926	$2^8 \cdot 7^3 \cdot 11^4 \cdot 19^2$	2	$y^2 + xy + y = x^3 - x^2 + 1934x - 1935$

Attempt to verify Serre's conjecture directly in some of these cases.

Exercise 18. Let M be a positive integer and let p be a prime. Show that there is an injective linear map

$$S_2(\Gamma_1(M)) \hookrightarrow S_2(\Gamma_1(pM))$$

sending $f(q)$ to $f(q^p)$.

Exercise 19. Let M be an integer such that $S_2(\Gamma_1(M))$ has positive dimension, and let p be a prime (thus $M = 11$ or $M \geq 13$).

(1) Let $f \in S_2(\Gamma_1(M))$ be an eigenvector for T_p with eigenvalue λ. Show that T_p acting on $S_2(\Gamma_1(Mp))$ preserves the two-dimensional subspace generated by f and $f(pz)$ (see Section 1.5 for the definition of T_p when p divides the level). Show furthermore that if $\lambda^2 \neq 4p$ then T_p is diagonalizable on this 2-dimensional space. What are the eigenvalues of T_p on this space? In fact, one never has $\lambda^2 = 4p$; see [**16**] for more details.
(2) Show that for any $r > 2$, the Hecke operator T_p on $S_2(\Gamma_1(Mp^r))$ is not diagonalizable.
(3) Deduce that for $r > 2$ the Hecke algebra $\mathbf{T}$ associated to $S_2(\Gamma_1(Mp^r))$ has nilpotent elements, so it is not an order in a product of rings of integers of number fields.

Exercise 20. Let N be a positive integer. Show that the Hecke algebra $\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots] \subset \mathrm{End}(J_1(N))$ is of finite rank as a $\mathbf{Z}$-module.

Exercise 21. Suppose $N = pM$ with $(p, M) = 1$. There is an injection

$$S_2(\Gamma_1(M)) \oplus S_2(\Gamma_1(M)) \hookrightarrow S_2(\Gamma_1(M) \cap \Gamma_0(p))$$

given by $(f, g) \mapsto f(q) + g(q^p)$. The Hecke algebra $\mathbf{T} = \mathbf{T}_N$ acts through a quotient $\overline{\mathbf{T}}$ on the image of $S_2(\Gamma_1(M)) \oplus S_2(\Gamma_1(M))$. Suppose $\mathfrak{m} \subset \mathbf{T}$ is a maximal ideal that arises by pullback from a maximal ideal in $\overline{\mathbf{T}}$. Show that $\rho_{\mathfrak{m}}$ arises from a modular form of level M.

4.2. Solutions

Solution 1. 1. Let p be a prime different from ℓ and let

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{Gal}(\mathbf{Q}(\sqrt{p})/\mathbf{Q}) \approx \{\pm 1\} \hookrightarrow \mathbf{F}_\ell^*.$$

2. Let $K = \overline{\mathbf{Q}}^{\ker(\rho)}$. Then $K/\mathbf{Q}$ is abelian and ramified only at ℓ, so $K \subset \mathbf{Q}(\zeta_{\ell^\infty})$. But $[K : \mathbf{Q}] \mid \ell - 1$ so $K \subset \mathbf{Q}(\zeta_\ell)$.

Solution 2. Conjugate using $g = \left(\begin{smallmatrix} N & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

Solution 3. If ρ is absolutely irreducible then it is irreducible, so assume that ρ is irreducible. If ρ is reducible over the algebraic closure $\overline{k}$ of k, then there is a vector $v \in \overline{k}^{\oplus 2}$ that generates a one-dimensional subspace stable under ρ. In particular, v is stable under complex conjugation, which has characteristic polynomial $x^2 - 1 = (x-1)(x+1)$. Since $-1 \neq 1$, this means that v must lie in one of the two 1-dimensional eigenspaces of complex conjugation, so v is a scalar multiple of an element w of $k^{\oplus 2}$. Then ρ leaves the subspace of $k^{\oplus 2}$ spanned by w invariant, so ρ is reducible, which contradicts our assumption.

Let $\rho : G_{\mathbf{Q}} \to \mathrm{GL}(2, \mathbf{F}_2)$ be any continuous representation whose image is the subgroup generated by $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. Then ρ is irreducible because it has no one-dimensional invariant subspaces over $\mathbf{F}_2$. However, the matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ is diagonalizable over $\mathbf{F}_4$.

Solution 4. Suppose $\varphi \in \mathrm{End}(E)$ is a nonzero endomorphism. The induced map $d\varphi$ on the differentials $H^0(A, \Omega) \approx \mathbf{Q}$ is multiplication by an integer n, so $d(\varphi - n) = 0$ which implies that $\varphi = n$.

Suppose that ρ_ℓ is reducible, so that there is a one-dimensional Galois stable subspace $V \subset A[\ell]$. The quotient $B = A/V$ is then an elliptic curve over $\mathbf{Q}$ and there is an isogeny $\pi : A \to B$ of degree ℓ. Because A is isolated in its isogeny class we have that $B = A$, so there is an endomorphism of A of degree ℓ. But all $\mathbf{Q}$-rational endomorphisms are multiplication by an integer, and multiplication by an integer has degree a perfect square.

The elliptic curve E given by the equation $y^2 = x^3 - 7x - 7$ has the property that $E[2]$ is irreducible but not absolutely irreducible. To see this, note that the splitting field of $x^3 - 7x - 7$ has Galois group cyclic of order 3.

Solution 5. Suppose all $\rho_{A,\ell}$ are irreducible, yet there exists an isogeny $\varphi : A \to B$ with $B \not\approx A$. Choose φ to have minimal possible degree and let $d = \deg(\varphi) > 1$. Let ℓ be the smallest prime divisor of d and choose a point $x \in \ker(\varphi)$ of exact order ℓ. If the order-ℓ cyclic subgroup generated by x is Galois stable, then $\rho_{A,\ell}$ is reducible, which is contrary to our assumption. Thus $\ker(\varphi)$ contains the full ℓ-torsion subgroup $A[\ell]$ of A. In particular, φ factors as illustrated below:

$$\begin{tikzcd}
A \arrow[rr, "\varphi"] \arrow[dr, "\ell"'] & & B. \\
& A/A[\ell] \arrow[ur] &
\end{tikzcd}$$

Since $A/A[\ell] \cong A$, there is an isogeny from A to B of degree equal to d/ℓ^2, which contradicts our assumption that d is minimal.

Solution 6. The Weil pairing $(\,,\,) : A[\ell] \times A[\ell] \to \boldsymbol{\mu}_\ell$ can be viewed as a map

$$\bigwedge^2 A[\ell] \xrightarrow{\cong} \boldsymbol{\mu}_\ell$$

sending $P \wedge Q$ to (P, Q). For any $\sigma \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$, we have $(P^\sigma, Q^\sigma) = (P, Q)^\sigma$. With the action $(P \wedge Q)^\sigma = P^\sigma \wedge Q^\sigma$, the map $\bigwedge^2 A[\ell] \to \boldsymbol{\mu}_\ell$ is a map of Galois modules. To compute $\det(\rho(\sigma))$ observe that if e_1, e_2 is a basis for $A[\ell]$, and $\rho(\sigma) = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then

$$\begin{aligned}
\sigma(e_1 \wedge e_2) &= (ae_1 + ce_2) \wedge (be_1 + de_2) \\
&= (ad - bc) e_1 \wedge e_2 = \det(\rho(\sigma)) e_1 \wedge e_2
\end{aligned}$$

Thus $\bigwedge^2 A[\ell]$ gives the one-dimensional representation $\det(\rho)$. Since $\bigwedge^2 A[\ell]$ is isomorphic to $\boldsymbol{\mu}_\ell$ it follows that $\det(\rho) = \chi$.

Solution 7. The definition of $\langle d \rangle$ is as follows: choose any matrix $\sigma_d \in \Gamma_0(N)$ such that $\sigma_d \equiv \left(\begin{smallmatrix} d & 0 \\ 0 & d^{-1} \end{smallmatrix}\right) \pmod N$; then $\langle d \rangle f = f|_{\sigma_d}$. Observe that $\Gamma_1(N)$ is a normal subgroup of $\Gamma_0(N)$ and the matrices σ_d with $(d, N) = 1$ and $d < N$ are a system of coset representatives. Thus any $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$ can be written in the form $\sigma_d \cdot g$ for some $g \in \Gamma_1(N)$. We have

$$f = f|_{\sigma_d g} = (f|_{\sigma_d})|_g = (\varepsilon(d) f)|_g = \varepsilon(d) f|_g = \varepsilon(d)(cz + d)^{-k} f\left(\frac{az + b}{cz + d}\right).$$

Solution 8.

(1) Since $c^2 = 1$, the minimal polynomial f of $\rho(c)$ divides $x^2 - 1$. Thus f is either $x + 1$, $x - 1$, or $x^2 - 1$. If $f = x + 1$ then $\rho(c) = -1 = \left(\begin{smallmatrix}-1 & 0\\ 0 & -1\end{smallmatrix}\right)$. This implies that $\det(\rho(c)) = (-1)^2 = 1$, which is a contradiction since $\det(\rho(c)) = -1$ and the characteristic of the base field is odd. If $f = x - 1$, then $\rho(c) = 1$; again a contradiction. Thus the minimal polynomial of $\rho(c)$ is $x^2 - 1 = (x - 1)(x + 1)$. Since $-1 \neq 1$ there is a basis of eigenvectors for $\rho(c)$ such that the matrix of $\rho(c)$ with respect to this basis is $\left(\begin{smallmatrix}-1 & 0\\ 0 & 1\end{smallmatrix}\right)$.

(2) The following example shows that when $\ell = 2$ the matrix of $\rho_{A,\ell}$ need not be conjugate to $\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. Let A be the elliptic curve over $\mathbf{Q}$ defined by $y^2 = x(x^2 - a)$ with $a \in \mathbf{Q}$ not square. Then

$$A[2] = \{\infty, (0, 0), (\sqrt{a}, 0), (-\sqrt{a}, 0)\}.$$

The action of c on the basis $(0, 0), (-\sqrt{a}, 0)$ is represented by the matrix $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$, since $c(-\sqrt{a}, 0) = (\sqrt{a}, 0) = (0, 0) + (-\sqrt{a}, 0)$.

Solution 9. The extension $\mathbf{Q}(\sqrt{d}, d \in \mathbf{Q}^*/(\mathbf{Q}^*)^2)$ is an extension of $\mathbf{Q}$ with Galois group $X \approx \prod \mathbf{F}_2$. The index-two open subgroups of X correspond to the quadratic extensions of $\mathbf{Q}$. However, Zorn's lemma implies that X contains many more index-two subgroups, which can be seen more precisely as follows.

(1) Choose a sequence $p_1, p_2, p_3, \ldots$ of distinct prime numbers. Define $\rho_1 : G_{\mathbf{Q}} \to \prod \mathbf{F}_2$ by

$$\rho_1(\sigma)_i = \begin{cases} 0 & \text{if } \sigma \text{ acts trivially on } \mathbf{Q}(\sqrt{p_i}),\\ 1 & \text{otherwise}\end{cases}$$

Thus ρ_1 is just

$$G_{\mathbf{Q}} \to \mathrm{Gal}(\mathbf{Q}(\sqrt{p_1}, \sqrt{p_2}, \ldots)/\mathbf{Q}) \approx \prod \mathbf{F}_2.$$

(2) Let $\oplus\mathbf{F}_2 \subset \prod \mathbf{F}_2$ be the subgroup of elements having only finitely many nonzero coordinates. Then $\prod \mathbf{F}_2/\oplus\mathbf{F}_2$ is a vector space over $\mathbf{F}_2$ of dimension > 0. By Zorn's lemma, there is a basis $\mathcal{B}$ of $\prod \mathbf{F}_2/\oplus\mathbf{F}_2$. Let $b \in \mathcal{B}$ and let W be the subspace spanned by $\mathcal{B} - \{b\}$. Then $V = (\prod \mathbf{F}_2/\oplus\mathbf{F}_2)/W$ is an $\mathbf{F}_2$-vector space of dimensional 1.

(3) Let ρ be the composite map

$$\begin{tikzcd}
\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \arrow[d] \arrow[drr, "\rho"] & & \\
\prod \mathbf{F}_2 \arrow[r] & V \arrow[r, "\cong"'] & \{\pm 1\}
\end{tikzcd}$$

(4) Let $H = \ker(\rho) \subset \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. If $\sigma(\sqrt{p_i}) = -\sqrt{p_i}$ and $\sigma(\sqrt{p_j}) = \sqrt{p_j}$ for $i \neq j$, then $\sigma \in H$. Thus H does not fix any $\mathbf{Q}(\sqrt{p_i})$, so the fixed field of H equals $\mathbf{Q}$. The largest finite Galois group quotient through which ρ factors is then $\mathrm{Gal}(\mathbf{Q}/\mathbf{Q}) = \{1\}$. Since $\rho \neq 1$, we conclude that ρ does not factor through any finite Galois group quotient, which proves that ρ is not continuous.

Solution 10. We have $f = f_1 + \alpha f_2$ with $f_1, f_2 \in S_2(\Gamma_0(23))$ and

$$\begin{aligned} f_1 &= q - q^3 - q^4 + \cdots \\ f_2 &= q^2 - 2q^3 - q^4 + 2q^5 + \cdots . \end{aligned}$$

Because $S_2(\Gamma_0(23))$ has dimension 2, it is spanned by f_1 and f_2. Let $\eta(q) = q^{\frac{1}{24}} \prod_{n \geq 1}(1 - q^n)$. Then $g = (\eta(q)\eta(q^{23}))^2 \in S_2(\Gamma_0(23))$. Expanding we find that $g = q^2 - 2q^3 + \cdots$, so $g = f_2$. Next observe that g is a power series in q^2 modulo 2:

$$\begin{aligned} g &= q^2 \prod (1 - q^n)^2 (1 - q^{23n})^2 \\ &\equiv q^2 \prod (1 - q^{2n})(1 - q^{46n}) \pmod 2 \\ &\equiv q^2 \prod (1 + q^{2n} + q^{46n} + q^{48n}) \pmod 2 \end{aligned}$$

Thus the coefficient in f_2 of q^p with $p \neq 2$ prime is even, and the proposition follows.

Solution 11.

(1) Let $\zeta \in \boldsymbol{\mu}_\ell$ be a primitive ℓth root of unity. Since $\bigwedge^2 A[\ell] \cong \boldsymbol{\mu}_\ell$, there exists $P, Q \in A[\ell]$ such that $P \wedge Q = \zeta$. Since $\ell > 2$ there exists σ such that $\zeta^\sigma \neq \zeta$, hence $P^\sigma \wedge Q^\sigma \neq P \wedge Q$. This is impossible if all ℓ-torsion is rational, since then $P^\sigma = P$ and $Q^\sigma = Q$.

(2) Consider the elliptic curve defined by $y^2 = (x - a)(x - b)(x - c)$ where a, b, c are distinct rational numbers.

Solution 12.

(1) Let K be the splitting field of $x^3 + ax + b$. Then ρ embeds $\text{Gal}(K/\mathbf{Q})$ in $\text{GL}(2, \mathbf{F}_2)$:

$$\begin{tikzcd}
\text{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \arrow[rr, "\rho"] \arrow[dr] & & \text{GL}(2, \mathbf{F}_2) \\
& \text{Gal}(K/\mathbf{Q}) \arrow[ur, hook] &
\end{tikzcd}$$

(2) The representation ρ is reducible exactly when the polynomial $x^3 + ax + b$ has a rational root.

(3) Examples: $y^2 = x(x^2 - 23)$, $y^2 = x^3 + x - 1$.

Solution 13. Consider the character $\tau = \varepsilon\chi/\rho$. By assumption, $\tau(\text{Frob}_p) = 1$ for all unramified p. Let K be an extension of $\mathbf{Q}$ such that τ factors through $\text{Gal}(K/\mathbf{Q})$. For any $\sigma \in \text{Gal}(K/\mathbf{Q})$, the Cebotarev density theorem implies that there are infinitely many primes p such that $\text{Frob}_p = \sigma$. Thus for any σ, $\tau(\sigma) = \tau(\text{Frob}_p) = 1$, so $\tau = 1$ and hence $\rho = \varepsilon\chi$.

Solution 14.

(1) See, e.g., [**109**, 2.11].

(2) By [**109**, 5.5], $\Phi - 1$ is separable, so $\#A(\mathbf{F}_p) = \deg(\Phi - 1)$. Since Φ has degree p, there exists an isogeny $\overline{\Phi}$ (the dual isogeny, see [**109**, III.6]),

such that $\Phi\overline{\Phi} = p$. Letting bars denote the dual isogeny, we have

$$\begin{aligned}\#A(\mathbf{F}_p) = \deg(\Phi - 1) &= (\Phi - 1)\overline{(\Phi - 1)}\\ &= \Phi\overline{\Phi} - \Phi - \overline{\Phi} + 1\\ &= p - \mathrm{tr}(\Phi) + 1\end{aligned}$$

(3) Both maps are pth powering on coordinates.

Solution 15. Since $\ell \neq p$ and A has good reduction at p, the natural map $A[\ell] \to \tilde{A}[\ell]$ is an isomorphism. We have the following commutative diagram

$$\begin{tikzcd}
\mathrm{Gal}(\mathbf{Q}_p(A[\ell])/\mathbf{Q}_p) \arrow[r, hook] \arrow[d] & \mathrm{Aut}(A[\ell]) \arrow[d, "\cong"] \\
\mathrm{Gal}((\mathcal{O}/\lambda)_{\mathbf{F}_p}) \arrow[r] & \mathrm{Aut}(\tilde{A}[\ell])
\end{tikzcd}$$

It follows that the first vertical map must be injective, which is the same as $\mathbf{Q}_p(A[\ell])$ being unramified over $\mathbf{Q}_p$.

Solution 16. The fundamental character Ψ of level one is the composition

$$\mathrm{Gal}(\mathbf{Q}_\ell^{\mathrm{nr}}(\sqrt[\ell-1]{\ell})/\mathbf{Q}_\ell^{\mathrm{nr}}) \to \boldsymbol{\mu}_{\ell-1}(\overline{\mathbf{Q}}_\ell) \to \boldsymbol{\mu}_{\ell-1}(\overline{\mathbf{F}}_\ell^*) = \mathbf{F}_\ell^*.$$

Let π be such that $\pi^{\ell-1} = \ell$. Then $\Psi(\sigma) = \frac{\sigma(\pi)}{\pi} \pmod{\pi}$. Let $\zeta \in \overline{\mathbf{Q}}_\ell$ be a primitive ℓth root of unity. Now

$$\prod_{a=1}^{\ell-1}(\zeta^a - 1) = \ell,$$

so

$$(\zeta - 1)^{\ell-1}\prod_{a=1}^{\ell-1},\frac{\zeta^a - 1}{\zeta - 1} = \ell$$

and (this is where Wilson's theorem is used),

$$\prod_{a=1}^{\ell-1}\frac{\zeta_\ell^a - 1}{\zeta - 1} \equiv 1 \pmod{\zeta - 1}.$$

Since the polynomial $x^{\ell-1} - 1$ has roots over $\mathbf{F}_\ell$, by Hensel's lemma there is a unit $u \in \mathbf{Q}_\ell(\pi)$ such that

$$u^{\ell-1} = \prod_{a=1}^{\ell-1}\frac{\zeta^a - 1}{\zeta - 1}.$$

We can take $\pi = (\zeta - 1)u$. Then

$$\begin{aligned}\frac{\sigma(\pi)}{\pi} &= \frac{(\zeta^{\chi(\sigma)} - 1)\sigma(u)}{(\zeta - 1)u}\\ &= \frac{(\zeta - 1)(\zeta^{\chi(\sigma)-1} + \cdots + 1)\sigma(u)}{(\zeta - 1)u}\\ &= (\zeta^{\chi(\sigma)-1} + \cdots + 1)\sigma(u)/u\\ &\equiv \chi(\sigma) \pmod{\zeta - 1}.\end{aligned}$$

Solution 17. We write $N = N(\rho)$ and $k = k(\rho)$ to save space. The essential tool is Theorem 2.10.

(1) $\ell = 5$: $N = 6$, $k = 6$, $\ell > 5$, $N = 30$, $k = 2$.
(2) $\ell = 5$: $N = 2 \cdot 3 \cdot 7$, $k = 6$; $\ell = 7$: $N = 2 \cdot 3 \cdot 5$, $k = 8$; $\ell > 7$: $N = 2 \cdot 3 \cdot 5 \cdot 7$, $k = 2$.
(3) $\ell = 3$: $N = 2 \cdot 5 \cdot 11$, $k = 4$; $\ell = 5$: $N = 2 \cdot 3 \cdot 11$, $k = 6$; $\ell = 7$: $N = 2 \cdot 3 \cdot 5 \cdot 11$, $k = 2$; $\ell = 11$: $N = 2 \cdot 3 \cdot 5$, $k = 12$; $\ell > 11$: $N = 2 \cdot 3 \cdot 5 \cdot 11$, $k = 2$.
(4) $\ell = 3$: $N = 7 \cdot 13$, $k = 2$; $\ell = 5$: $N = 7 \cdot 13$, $k = 6$; $\ell = 7$: $N = 5 \cdot 13$, $k = 8$; $\ell = 13$: $N = 5 \cdot 7$, $k = 14$; $\ell = 11, \ell > 13$: $N = 5 \cdot 7 \cdot 13$, $k = 2$.
(5) $\ell = 3$: $N = 2 \cdot 11 \cdot 19$, $k = 2$; $\ell = 7$: $N = 2 \cdot 11 \cdot 19$, $k = 8$; $\ell = 11$: $N = 2 \cdot 7 \cdot 19$, $k = 12$; $\ell = 19$: $N = 2 \cdot 7 \cdot 11$, $k = 20$; ℓ other: $N = 2 \cdot 7 \cdot 11 \cdot 19$, $k = 2$.

Solution 20. One approach is to view $J_1(N)$ as a complex torus, and note that the endomorphism ring is the set of automorphism of a complex vector space that fix a lattice. Another approach is to use the deeper finiteness theorems that are valid in arbitrary characteristic, see, e.g., [**74**, Thm. 12.5].

CHAPTER 5

Appendix by Brian Conrad: The Shimura construction in weight 2

The purpose of this appendix is to explain the ideas of Eichler-Shimura for constructing the two-dimensional ℓ-adic representations attached to classical weight-2 Hecke eigenforms. We assume familiarity with the theory of schemes and the theory of newforms, but the essential arithmetic ideas are due to Eichler and Shimura. We warn the reader that a complete proof along the lines indicated below requires the verification of a number of compatibilities between algebraic geometry, algebraic topology, and the classical theory of modular forms. As the aim of this appendix is to explain the key arithmetic ideas of the proof, we must pass over in silence the verification of many such compatibilities. However, we at least make explicit what compatibilities we need. To prove them all here would require a serious digression from our expository goal; see [**18**, Ch. 3] for details. It is also worth noting that the form of the arguments we present is *exactly* the weight-2 version of Deligne's more general proof of related results in weight > 1, up to the canonical isomorphism

$$\mathbf{Q}_\ell \otimes_{\mathbf{Z}_\ell} \varprojlim \mathrm{Pic}^0_{X/k}[\ell^n](k) \cong H^1_{\text{ét}}(X, \mathbf{Q}_\ell(1)) \cong H^1_{\text{ét,c}}(Y, \mathbf{Q}_\ell(1))$$

for a proper smooth connected curve X over a separably closed field k of characteristic prime to ℓ, and Y a dense open in X. Using ℓ-adic Tate modules allows us to bypass the general theory of étale cohomology which arises in the case of higher weight.

5.1. Analytic preparations

Fix $i = \sqrt{-1} \in \mathbf{C}$ for all time. Fix an integer $N \geq 5$ and let $X_1(N)^{\mathrm{an}}$ denote the classical analytic modular curve, the "canonical" compactification of $Y_1(N)^{\mathrm{an}} = \Gamma_1(N)\backslash\mathfrak{h}$, where $\mathfrak{h} = \{z \in \mathbf{C} : \mathrm{Im}\, z > 0\}$ and $\Gamma_1(N) \subset \mathrm{SL}_2(\mathbf{Z})$ acts on the left via linear fractional transformations. The classical theory identifies the $\mathbf{C}$-vector space $H^0(X_1(N)^{\mathrm{an}}, \Omega^1_{X_1(N)^{\mathrm{an}}})$ with $S_2(\Gamma_1(N), \mathbf{C})$, the space of weight-2 cusp forms. Note that the classical Riemann surface $X_1(N)^{\mathrm{an}}$ has genus 0 if we consider $N < 5$, while $S_2(\Gamma_1(N), \mathbf{C}) = 0$ if $N < 5$. Thus, assuming $N \geq 5$ is harmless for what we will do.

The Hodge decomposition for the compact Riemann surface $X_1(N)^{\mathrm{an}}$ supplies us with an isomorphism of $\mathbf{C}$-vector spaces

$$\begin{aligned}
&S_2(\Gamma_1(N),\mathbf{C})\oplus\overline{S_2(\Gamma_1(N),\mathbf{C})}\\
&\qquad\qquad\cong H^0(X_1(N)^{\mathrm{an}},\Omega^1_{X_1(N)^{\mathrm{an}}})\oplus H^0(X_1(N)^{\mathrm{an}},\overline{\Omega}^1_{X_1(N)^{\mathrm{an}}})\\
&\qquad\qquad\xrightarrow{\sim} H^1(X_1(N)^{\mathrm{an}},\underline{\mathbf{C}})\\
&\qquad\qquad\cong H^1(X_1(N)^{\mathrm{an}},\underline{\mathbf{Z}})\otimes_{\mathbf{Z}}\mathbf{C}
\end{aligned}$$

(where $\underline{A}$ denotes the constant sheaf attached to an abelian group A). This will be called the (weight-2) *Shimura isomorphism.* We want to define "geometric" operations on $H^1(X_1(N)^{\mathrm{an}},\underline{\mathbf{Z}})$ which recover the classical Hecke operators on $S_2(\Gamma_1(N),\mathbf{C})$ via the above isomorphism.

The "geometric" (or rather, cohomological) operations we wish to define can be described in two ways. First, we can use explicit matrices and explicit "upper-half plane" models of modular curves. This has the advantage of being concrete, but it provides little conceptual insight and encourages messy matrix calculations. The other point of view is to identify the classical modular curves as the base of certain universal analytic families of (generalized) elliptic curves with level structure. A proper discussion of this latter point of view would take us too far afield, so we will have to settle for only some brief indications along these two lines (though this is how to best verify compatibility with the algebraic theory via schemes).

Choose a matrix $\gamma_n\in\mathrm{SL}_2(\mathbf{Z})$ with $\gamma_n\equiv\left(\begin{smallmatrix}n^{-1}&*\\0&n\end{smallmatrix}\right)\pmod N$, for $n\in(\mathbf{Z}/N\mathbf{Z})^*$. The action of γ_n on $\mathfrak{h}$ induces an action on $Y_1(N)^{\mathrm{an}}$ and even on $X_1(N)^{\mathrm{an}}$. Associating to each $z\in\mathfrak{h}$ the data of the elliptic curve $\mathbf{C}/[1,z]=\mathbf{C}/(\mathbf{Z}+\mathbf{Z}z)$ and the point $1/N$ of exact order N, we may identify $Y_1(N)^{\mathrm{an}}$ as a *set* with the set of isomorphism classes of pairs (E,P) consisting of an elliptic curve E over $\mathbf{C}$ and a point $P\in E$ of exact order N. The map $Y_1(N)^{\mathrm{an}}\to Y_1(N)^{\mathrm{an}}$ induced by γ_n can then described on the underlying set by $(E,P)\mapsto(E,nP)$, so it is "intrinsic", depending only on $n\in(\mathbf{Z}/N\mathbf{Z})^*$. We denote by $I_n : X_1(N)^{\mathrm{an}}\to X_1(N)^{\mathrm{an}}$ the induced map on $X_1(N)^{\mathrm{an}}$. Once this data (E,P) is formulated in a relative context over an analytic base, we could define the analytic map I_n conceptually, without using the matrix γ_n. We ignore this point here.

The map $z\mapsto\frac{-1}{Nz}$ on $\mathfrak{h}$ induces a map $Y_1(N)^{\mathrm{an}}\to Y_1(N)^{\mathrm{an}}$ which extends to $w_N : X_1(N)^{\mathrm{an}}\to X_1(N)^{\mathrm{an}}$. More conceptually and more generally, if $\zeta\in\boldsymbol{\mu}_N(\mathbf{C})$ is a primitive Nth root of unity, consider the rule w_ζ that sends $(E,P)\in Y_1(N)^{\mathrm{an}}$ to $(E/P,P'\mod P)$, where $P'\in E$ has exact order N and $\langle P,P'\rangle_N=\zeta$, with $\langle\,,\,\rangle_N$ the Weil pairing on N-torsion points (following the sign conventions of [**62, 77**]; opposite the convention of [**109**]). More specifically, on $\mathbf{C}/[1,z]$ we have $\langle\frac{1}{N},\frac{z}{N}\rangle_N=e^{2\pi i/N}$. The map w_ζ extends to an analytic map $X_1(N)^{\mathrm{an}}\to X_1(N)^{\mathrm{an}}$. When $\zeta=e^{2\pi i/N}$, we have $w_\zeta=w_N$ due to the above sign convention.

We have induced pullback maps

$$w_\zeta^*,I_n^*:H^1(X_1(N)^{\mathrm{an}},\underline{\mathbf{Z}})\to H^1(X_1(N)^{\mathrm{an}},\underline{\mathbf{Z}}).$$

We write $\langle n\rangle^*$ rather than I_n^*.

Finally, choose a prime p. Define $\Gamma_1(N,p)\subset\mathrm{SL}_2(\mathbf{Z})$ to be $\Gamma_1(N,p)=\Gamma_1(N)\cap\Gamma_0(p)$ when $p\nmid N$ and $\Gamma_1(N,p)=\Gamma_1(N)\cap\Gamma_0(p)^t$ when $p\mid N$, where the group $\Gamma_0(p)^t$ is the transpose of $\Gamma_0(p)$. Define $Y_1(N,p)^{\mathrm{an}}=\Gamma_1(N,p)\backslash\mathfrak{h}$ and let $X_1(N,p)^{\mathrm{an}}$

be its “canonical” compactification. Using the assignment

$$z \mapsto (\mathbf{C}/[1,z], \frac{1}{N}, \langle\frac{1}{p}\rangle)$$

when $p \nmid N$ and

$$z \mapsto (\mathbf{C}/[1,z], \frac{1}{N}, \langle\frac{z}{p}\rangle)$$

when $p \mid N$, we may identify the *set* $Y_1(N,p)^{\mathrm{an}}$ with the set of isomorphism classes of triples (E,P,C) where $P \in E$ has exact order N and $C \subset E$ is a cyclic subgroup of order p, meeting $\langle P\rangle$ trivially (a constraint if $p \mid N$). Here and below, we denote by $\langle P\rangle$ the (cyclic) subgroup generated by P.

There are unique analytic maps

$$\pi_1^{(p)}, \pi_2^{(p)} : X_1(N,p)^{\mathrm{an}} \to X_1(N)^{\mathrm{an}}$$

determined on $Y_1(N,p)^{\mathrm{an}}$ by

$$\pi_1^{(p)}(E,P,C) = (E,P)$$

and

$$\pi_2^{(p)}(E,P,C) = (E/C, P \mod C).$$

For example, $\pi_1^{(p)}$ is induced by $z \mapsto z$ on $\mathfrak{h}$, in terms of the above upper half plane uniformization of $Y_1(N)^{\mathrm{an}}$ and $Y_1(N,p)^{\mathrm{an}}$.

We define

$$T_p^* = (\pi_1^{(p)})_* \circ (\pi_2^{(p)})^* : H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \to H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$$

where $(\pi_1^{(p)})_* : H^1(X_1(N,p)^{\mathrm{an}}, \underline{\mathbf{Z}}) \to H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$ is the canonical trace map associated to the finite map $\pi_1^{(p)}$ of compact Riemann surfaces. More specifically, we have a canonical isomorphism

$$H^1(X_1(N,p)^{\mathrm{an}}, \underline{\mathbf{Z}}) \cong H^1(X_1(N)^{\mathrm{an}}, (\pi_1^{(p)})_*\underline{\mathbf{Z}})$$

since $(\pi_1^{(p)})_*$ is exact on abelian sheaves, and there is a unique trace map of sheaves $(\pi_1^{(p)})_*\underline{\mathbf{Z}} \to \underline{\mathbf{Z}}$ determined on stalks at $x \in X_1(N)^{\mathrm{an}}$ by

$$\begin{aligned} \prod_{\pi_1^{(p)}(y)=x} \mathbf{Z} &\to \mathbf{Z} \\ (a_y) &\mapsto \Sigma_y e_y a_y \end{aligned} \tag{5.1}$$

where e_y is the ramification degree of y over x via $\pi_1^{(p)}$.

A fundamental compatibility, whose proof we omit for reasons of space, is:

Theorem 5.1. *The weight-*2 *Shimura isomorphism*

$$\mathrm{Sh}_{\Gamma_1(N)} : S_2(\Gamma_1(N), \mathbf{C}) \oplus \overline{S_2(\Gamma_1(N), \mathbf{C})} \cong H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \otimes_{\mathbf{Z}} \mathbf{C}$$

from (5.1) *identifies* $\langle n\rangle \oplus \overline{\langle n\rangle}$ *with* $\langle n\rangle^* \otimes 1$, $T_p \oplus \overline{T}_p$ *with* $T_p^* \otimes 1$, *and* $w_N \oplus \overline{w}_N$ *with* $w^*_{e^{2\pi i/N}} \otimes 1$.

Let $\mathbf{T}_1(N) \subset \mathrm{End}_{\mathbf{Z}}(H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}))$ be the subring generated by the T_p^*'s and $\langle n\rangle^*$'s. By Theorem 5.1, this is identified via the Shimura isomorphism with the classical (weight-2) Hecke ring at level N. In particular, this ring is commutative (which can be seen directly via cohomological considerations as well). It is clearly a finite flat $\mathbf{Z}$-algebra.

The natural map

$$\mathbf{T}_1(N) \otimes_{\mathbf{Z}} \mathbf{C} \hookrightarrow \mathrm{End}_{\mathbf{C}}(H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \otimes_{\mathbf{Z}} \mathbf{C}) \tag{5.2}$$

induces an *injection* $\mathbf{T}_1(N) \otimes \mathbf{C} \hookrightarrow \mathrm{End}_{\mathbf{C}}(S_2(\Gamma_1(N), \mathbf{C}))$, by Theorem 5.1. This is the classical realization of Hecke operators in weight 2.

Another compatibility we need is between the cup product on $H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$ and the (non-normalized) Petersson product on $S_2(\Gamma_1(N), \mathbf{C})$. To be precise, we define an isomorphism $H^2(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \cong \mathbf{Z}$ using the i-orientation of the complex manifold $X_1(N)^{\mathrm{an}}$ (i.e., the "$i\mathrm{d}z \wedge \mathrm{d}\overline{z}$" orientation), so we get via cup product a (perfect) pairing

$$(\ ,\ )_{\Gamma_1(N)} : H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \otimes_{\mathbf{Z}} H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \to H^2(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \cong \mathbf{Z}.$$

This induces an analogous pairing after applying $\otimes_{\mathbf{Z}}\mathbf{C}$. For $f, g \in S_2(\Gamma_1(N), \mathbf{C})$ we define

$$\langle f, g\rangle_{\Gamma_1(N)} = \int_{\Gamma_1(N)\backslash\mathfrak{h}} f(z)\overline{g}(z)\mathrm{d}x\mathrm{d}y$$

where this integral is absolutely convergent since f and g have exponential decay near the cusps. This is a perfect Hermitian pairing.

Theorem 5.2. *Under the weight-*2 *Shimura isomorphism* $\mathrm{Sh}_{\Gamma_1(N)}$,

$$\big(\mathrm{Sh}_{\Gamma_1(N)}(f_1 + \overline{g}_1), \mathrm{Sh}_{\Gamma_1(N)}(f_2 + \overline{g}_2)\big)_{\Gamma_1(N)} = 4\pi \cdot (\langle f_1, g_2\rangle_{\Gamma_1(N)} - \langle f_2, g_1\rangle_{\Gamma_1(N)}).$$

Note that *both* sides are antilinear in g_1, g_2 and alternating with respect to interchanging the pair (f_1, g_1) and (f_2, g_2). The extra factor of 4π is harmless for our purposes since it does not affect formation of adjoints. What is important is that in the classical theory, conjugation by the involution w_N takes each $T \in \mathbf{T}_1(N)$ to its adjoint with respect to the Petersson product. The most subtle case of this is $T = T_p^*$ for $p \mid N$. For $p \nmid N$ the adjoint of T_p^* is $\langle p^{-1}\rangle^* T_p^*$ and the adjoint of $\langle n\rangle^*$ is $\langle n^{-1}\rangle^*$. These classical facts (especially for T_p^* with $p \mid N$) yield the following important corollary of Theorem 5.2.

Corollary 5.3. *With respect to the pairing* $[x, y]_{\Gamma_1(N)} = (x, w_\zeta^* y)_{\Gamma_1(N)}$ *with* $\zeta = e^{2\pi i/N}$*, the action of* $\mathbf{T}_1(N)$ *on* $H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$ *is equivariant. That is,*

$$[x, Ty]_{\Gamma_1(N)} = [Tx, y]_{\Gamma_1(N)}$$

for all $T \in \mathbf{T}_1(N)$*. With respect to* $(\ ,\ )_{\Gamma_1(N)}$*, the adjoint of* T_p^* *for* $p \nmid N$ *is* $\langle p^{-1}\rangle^* T_p^*$ *and the adjoint of* $\langle n\rangle^*$ *is* $\langle n^{-1}\rangle^*$ *for* $n \in (\mathbf{Z}/N\mathbf{Z})^*$.

Looking back at the "conceptual" definition of w_ζ^* for an arbitrary primitive Nth root of unity $\zeta \in \boldsymbol{\mu}_N(\mathbf{C})$, which gives an analytic involution of $X_1(N)^{\mathrm{an}}$, one can check that $w_{\zeta^j}^* \circ w_\zeta^* = \langle j\rangle^*$ for $j \in (\mathbf{Z}/N\mathbf{Z})^*$. Since $\langle j\rangle^*$ is a unit in $\mathbf{T}_1(N)$ and $\mathbf{T}_1(N)$ is *commutative*, we conclude that Corollary 5.3 is true with $\zeta \in \boldsymbol{\mu}_N(\mathbf{C})$ *any* primitive Nth root of unity (by reduction to the case $\zeta = e^{2\pi i/N}$).

Our final step on the analytic side is to reformulate everything above in terms of Jacobians. For any compact Riemann surface X, there is an isomorphism of complex Lie groups

$$\mathrm{Pic}^0_X \cong H^1(X, \mathscr{O}_X)/H^1(X, \underline{\mathbf{Z}}) \tag{5.3}$$

via the exponential sequence

$$0 \to \underline{\mathbf{Z}} \to \mathscr{O}_X \xrightarrow{e^{2\pi i(\cdot)}} \mathscr{O}_X^* \to 1$$

and the identification of the underlying group of Pic^0_X with

$$H^1(X, \mathscr{O}_X^*) \cong \check{H}^1(X, \mathscr{O}_X^*)\,,$$

where the line bundle $\mathscr{L}$ with trivializations $\varphi_i : \mathscr{O}_{U_i} \cong \mathscr{L}|U_i$ corresponds to the class of the Čech 1-cocycle

$$\{\varphi_j^{-1} \circ \varphi_i : \mathscr{O}_{U_i \cap U_j} \cong \mathscr{O}_{U_i \cap U_j}\} \in \prod_{i<j} H^0(U_i \cap U_j, \mathscr{O}_X^*)$$

for an ordered open cover $\{U_i\}$. Beware that the tangent space isomorphism

$$T_0(\mathrm{Pic}^0_X) \cong H^1(X, \mathscr{O}_X)$$

coming from (5.3) is $-2\pi i$ times the "algebraic" isomorphism arising from

$$0 \to \mathscr{O}_X \to \mathscr{O}_{X[\varepsilon]}^* \to \mathscr{O}_X^* \to 1,$$

where $X[\varepsilon] = (X, \mathscr{O}_X[\varepsilon]/\varepsilon^2)$ is the non-reduced space of "dual numbers over X". This extra factor of $-2\pi i$ will not cause problems. We will use (5.3) to "compute" with Jacobians.

Let $f : X \to Y$ be a finite map between compact Riemann surfaces. Since f is finite flat, there is a natural trace map $f_*\mathscr{O}_X \to \mathscr{O}_Y$, and it is not difficult to check that this is compatible with the trace map $f_*\underline{\mathbf{Z}} \to \underline{\mathbf{Z}}$ as defined in (5.1). In particular, we have a trace map

$$f_* : H^1(X, \mathscr{O}_X) \cong H^1(Y, f_*\mathscr{O}_X) \to H^1(Y, \mathscr{O}_Y).$$

Likewise, we have compatible pullback maps $f^*\mathscr{O}_Y \cong \mathscr{O}_X$ and $f^*\underline{\mathbf{Z}} \cong \underline{\mathbf{Z}}$.

Thus, any such f gives rise to *commutative* diagrams

$$\begin{tikzcd}
H^1(Y, \mathscr{O}_Y) \arrow[r, "f^*"] & H^1(X, \mathscr{O}_X) & H^1(X, \mathscr{O}_X) \arrow[r, "f_*"] & H^1(Y, \mathscr{O}_Y) \\
H^1(Y, \underline{\mathbf{Z}}) \arrow[r, "f^*"] \arrow[u] & H^1(X, \underline{\mathbf{Z}}) \arrow[u] & H^1(X, \underline{\mathbf{Z}}) \arrow[r, "f_*"] \arrow[u] & H^1(Y, \underline{\mathbf{Z}})\,, \arrow[u]
\end{tikzcd}$$

where the columns are induced by the canonical maps $\underline{\mathbf{Z}} \to \mathscr{O}_Y$ and $\underline{\mathbf{Z}} \to \mathscr{O}_X$. Passing to quotients on the columns therefore gives rise to maps

$$f^* : \mathrm{Pic}^0_Y \to \mathrm{Pic}^0_X, \qquad f_* : \mathrm{Pic}^0_X \to \mathrm{Pic}^0_Y$$

of analytic Lie groups. These maps are "computed" by

Lemma 5.4. *In the above situation, $f^* = \mathrm{Pic}^0(f)$ is the map induced by Pic^0 functoriality and $f_* = \mathrm{Alb}(f)$ is the map induced by Albanese functoriality. These are dual with respect to the canonical autodualities of Pic^0_X, Pic^0_Y.*

The significance of the theory of Jacobians is that by (5.3) we have a canonical isomorphism

$$\begin{aligned} T_\ell(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}) &\cong H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}_\ell) \\ &\cong H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}}) \otimes_{\mathbf{Z}} \mathbf{Z}_\ell, \end{aligned} \tag{5.4}$$

connecting the ℓ-adic Tate module of $\mathrm{Pic}^0_{X_1(N)}$ with the $\mathbf{Z}$-module $H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$ that "encodes" $S_2(\Gamma_1(N), \mathbf{C})$ via the Shimura isomorphism. Note that this isomorphism is defined in terms of the analytic construction (5.3) which depends upon the choice of i. The intrinsic isomorphism (compatible with étale cohomology) has $\mathbf{Z}$ above replaced by $2\pi i\mathbf{Z} = -2\pi i\mathbf{Z}$.

Definition 5.5. We define endomorphisms of $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$ via

$$T_p^* = \mathrm{Alb}(\pi_1^{(p)}) \circ \mathrm{Pic}^0(\pi_2^{(p)}), \quad \langle n\rangle^* = \mathrm{Pic}^0(I_n), \quad w_\zeta^* = \mathrm{Pic}^0(w_\zeta).$$

By Lemma 5.4, it follows that the above isomorphism (5.4) carries the operators on $T_\ell(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}})$ over to the ones *previously defined* on $H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Z}})$ (which are, in turn, compatible with the classical operations via the Shimura isomorphism). By the faithfulness of the "Tate module" functor on complex tori, we conclude that $\mathbf{T}_1(N)$ *acts* on $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$ in a unique manner compatible with the above definition, and (5.4) is an isomorphism of $\mathbf{T}_1(N) \otimes_{\mathbf{Z}} \mathbf{Z}_\ell$-modules. We call this the $(\,)^*$-*action* of $\mathbf{T}_1(N)$ on $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$.

We must warn the reader that under the canonical isomorphism of $\mathbf{C}$-vector spaces

$$\begin{aligned} S_2(\Gamma_1(N), \mathbf{C}) &\cong H^0(X_1(N)^{\mathrm{an}}, \Omega^1_{X_1(N)^{\mathrm{an}}}) \\ &\cong H^0(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}, \Omega^1_{\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}}) \\ &\cong \mathrm{Cot}_0(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}), \end{aligned}$$

the $(\,)^*$-action of $T \in \mathbf{T}_1(N)$ on $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$ does *not* go over to the classical action of T on $S_2(\Gamma_1(N), \mathbf{C})$, but rather the adjoint of T with respect to the Petersson pairing. To clear up this matter, we make the following definition:

Definition 5.6.

$$(T_p)_* = \mathrm{Alb}(\pi_2^{(p)}) \circ \mathrm{Pic}^0(\pi_1^{(p)}), \quad \langle n\rangle_* = \mathrm{Alb}(I_n), \quad (w_\zeta)_* = \mathrm{Alb}(w_\zeta).$$

Since $I_n^{-1} = I_{n^{-1}}$ and $w_\zeta^{-1} = w_\zeta$ on $X_1(N)^{\mathrm{an}}$, we have $(w_\zeta)_* = w_\zeta^*$ and $\langle n\rangle_* = \langle n^{-1}\rangle^*$. We claim that the above $(\,)_*$ operators are the *dual* morphisms (with respect to the canonical principal polarization of $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$) of the $(\,)^*$ operators and induce exactly the *classical* action of T_p and $\langle n\rangle$ on $S_2(\Gamma_1(N), \mathbf{C})$, so we also have a well-defined $(\,)_*$-action of $\mathbf{T}_1(N)$ on $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$, dual to the $(\,)^*$-action. By Theorem 5.2, Corollary 5.3, and Lemma 5.4, this follows from the following general fact about compact Riemann surfaces. The proof is non-trivial.

Lemma 5.7. *Let X be a compact Riemann surface, and use the i-orientation to define $H^2(X, \underline{\mathbf{Z}}) \cong \mathbf{Z}$. Use $1 \mapsto e^{2\pi i/\ell^n}$ to define $\mathbf{Z}/\ell^n \cong \mu_{\ell^n}(\mathbf{C})$ for all n. The* *diagram*

$$\begin{tikzcd}
H^1(X, \underline{\mathbf{Z}}_\ell) \otimes_{\mathbf{Z}_\ell} H^1(X, \underline{\mathbf{Z}}_\ell) \arrow[r, "\cup"] \arrow[d, "\cong"] & \mathbf{Z}_\ell \arrow[d, "\cong"] \\
T_\ell(\mathrm{Pic}^0_X) \otimes_{\mathbf{Z}_\ell} T_\ell(\mathrm{Pic}^0_X) \arrow[r] & \varprojlim \mu_{\ell^n}(\mathbf{C})
\end{tikzcd}$$

anticommutes (*i.e., going around from upper left to lower right in the two possible ways gives results that are negatives of each other*), *where the bottom row is the ℓ-adic Weil pairing* (*with respect to the canonical principal polarization* $\mathrm{Pic}^0_X \cong \widehat{\mathrm{Pic}^0_X}$ *for the "second"* Pic^0_X *in the lower left.*)

Note that the sign doesn't affect formation of adjoints. It ultimately comes from the sign on the bottom of [**77**, pg. 237] since our Weil pairing sign convention agrees with [**77**].

We now summarize our findings in terms of $V_\ell(N) = \mathbf{Q}_\ell \otimes_{\mathbf{Z}_\ell} T_\ell(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}})$, which has a perfect alternating Weil pairing

$$(\ ,\ )_\ell : V_\ell(N) \otimes V_\ell(N) \to \mathbf{Q}_\ell(1)$$

and has two $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$-actions, via the $(\,)^*$-actions and the $(\,)_*$-actions. Since $(w_\zeta)_* = w_\zeta^*$, we simply write w_ζ for this operator on $V_\ell(N)$.

Theorem 5.8. *Let $\mathbf{T}_1(N)$ act on $V_\ell(N)$ with respect to the $(\,)^*$-action or with respect to the $(\,)_*$-action. With respect to $(\ ,\ )_\ell$, the adjoint of T_p for $p \nmid N$ is $\langle p\rangle^{-1}T_p$ and the adjoint of $\langle n\rangle$ is $\langle n\rangle^{-1}$ for $n \in (\mathbf{Z}/N\mathbf{Z})^*$. With respect to*

$$[x, y]_\ell = (x, w_\zeta(y))_\ell$$

for $\zeta \in \boldsymbol{\mu}_N(\mathbf{C})$ a primitive Nth root of unity, the action of $\mathbf{T}_1(N)$ on $V_\ell(N)$ is self-adjoint. In general, adjointness with respect to $(\ ,\ )_\ell$ interchanges the $(\,)_*$-action and $(\,)^*$-action.

It should be noted that when making the translation to étale cohomology, the $(\,)^*$-action plays a more prominent role (since this is what makes (5.4) a $\mathbf{T}_1(N)$-equivariant map). However, when working directly with Tate modules and arithmetic Frobenius elements, it is the $(\,)_*$-action which gives the cleaner formulation of Shimura's results.

An important consequence of Theorem 5.8 is

Corollary 5.9. *The $\mathbf{Q}_\ell \otimes_{\mathbf{Z}} \mathbf{T}_1(N)$-module $V_\ell(N)$ is free of rank 2 for either action, and* $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N), \mathbf{Q})$ *is free of rank 1 over* $\mathbf{Q} \otimes \mathbf{T}_1(N)$ (*hence likewise with* $\mathbf{Q}$ *replaced by any field of characteristic* 0).

Remark 5.10. The assertion about $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N), \mathbf{Q})$ is equivalent to the intrinsic condition that $\mathbf{Q} \otimes \mathbf{T}_1(N)$ is *Gorenstein*. Also, this freeness clearly makes the two assertions about $V_\ell(N)$ for the $(\,)_*$- and $(\,)^*$-actions equivalent. *For the proof*, the $(\,)^*$-action is what we use. But in what follows, it is the case of the $(\,)_*$-action that we need!

Proof. Using (5.4) and the choice of $(\,)^*$-action on $V_\ell(N)$, it suffices to prove

- $H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Q}})$ is free of rank 2 over $\mathbf{Q} \otimes \mathbf{T}_1(N)$,
- $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N), \mathbf{Q})$ is free of rank 1 over $\mathbf{Q} \otimes \mathbf{T}_1(N)$.

Using $[\,,\,]_{\Gamma_1(N)}$, we have

$$H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Q}}) \cong \mathrm{Hom}_{\mathbf{Q}}(H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Q}}), \mathbf{Q}) \tag{5.5}$$

as $\mathbf{Q} \otimes \mathbf{T}_1(N)$-modules, so we may study this $\mathbf{Q}$-dual instead. Since $\mathbf{Q} \otimes \mathbf{T}_1(N)$ is semilocal, a finite module over this ring is locally free of constant rank if and only if it is *free* of that rank. But local freeness of constant rank can be checked after faithfully flat base change. Applying this with the base change $\mathbf{Q} \to \mathbf{C}$, and noting that $\mathbf{C} \otimes \mathbf{T}_1(N)$ is semilocal, it suffices to replace $\mathbf{Q}$ by $\mathbf{C}$ above.

Note that *if* the right hand side of (5.5) is free of rank 2, so is the left side, so choosing a basis of the left side and feeding it into the right hand side shows that $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N)^{\oplus 2}, \mathbf{Q})$ is free of rank 2. In particular, the direct summand $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N), \mathbf{Q})$ is flat over $\mathbf{Q} \otimes \mathbf{T}_1(N)$ with full support over $\mathrm{Spec}(\mathbf{Q} \otimes \mathbf{T}_1(N))$, so it must be locally free with local rank at least 1 at all points of $\mathrm{Spec}(\mathbf{Q} \otimes \mathbf{T}_1(N))$. Consideration of $\mathbf{Q}$-dimensions then forces $\mathrm{Hom}_{\mathbf{Q}}(\mathbf{Q} \otimes \mathbf{T}_1(N), \mathbf{Q})$ to be locally free of rank 1, hence free of rank 1. In other words, it suffices to show that $\mathrm{Hom}_{\mathbf{Q}}(H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{Q}}), \mathbf{Q})$ is free of rank 2 over $\mathbf{T}_1(N) \otimes \mathbf{Q}$, or equivalently that $\mathrm{Hom}_{\mathbf{C}}(H^1(X_1(N)^{\mathrm{an}}, \underline{\mathbf{C}}), \mathbf{C})$ is free of rank 2 over $\mathbf{T}_1(N) \otimes \mathbf{C}$.

Via the Shimura isomorphism (in weight 2), which is compatible with the Hecke actions, we are reduced to showing that $\mathrm{Hom}(S_2(\Gamma_1(N), \mathbf{C}), \mathbf{C})$ is free of rank 1 over $\mathbf{C} \otimes \mathbf{T}_1(N)$. For this purpose, we will study the $\mathbf{C} \otimes \mathbf{T}_1(N)$-equivariant $\mathbf{C}$-bilinear pairing

$$S_2(\Gamma_1(N), \mathbf{C}) \otimes_{\mathbf{C}} (\mathbf{C} \otimes \mathbf{T}_1(N)) \to \mathbf{C}$$
$$(f, T) \mapsto a_1(Tf)$$

were $a_1(\cdot)$ is the "Fourier coefficient of q". This is $\mathbf{C} \otimes \mathbf{T}_1(N)$-equivariant, since $\mathbf{T}_1(N)$ is commutative. It suffices to check that there's no nonzero kernel on either side of this pairing. Since

$$\mathbf{C} \otimes \mathbf{T}_1(N) \to \mathrm{End}_{\mathbf{C}}(S_2(\Gamma_1(N), \mathbf{C}))$$

is *injective* (as noted in (5.2)) and $a_1(TT_n f) = a_n(Tf)$ for $T \in \mathbf{T}_1(N)$, the kernel on the right is trivial. Since $a_1(T_n f) = a_n(f)$, the kernel on the left is also trivial. □

5.2. Algebraic preliminaries

Let S be a scheme. An *elliptic curve* $E \to S$ is a proper smooth group scheme with geometrically connected fibers of dimension 1 (necessarily of genus 1). It follows from [**62**, Ch.2] that the group structure is commutative and uniquely determined by the identity section. Fix $N \geq 1$ and assume $N \in H^0(S, \mathcal{O}_S^*)$ (i.e., S is a $\mathbf{Z}[\frac{1}{N}]$-scheme). Thus, the map $N : E \to E$ is finite *étale* of degree N^2 as can be checked on geometric fibers. A *point of exact order* N on E is a section $P : S \to E$ which is killed by N (i.e., factors through the finite étale group scheme $E[N]$) and induces a point of exact order N on geometric fibers.

It follows from the stack-theoretic methods in [**25**] or the more explicit descent arguments in [**62**] that for $N \geq 5$ there is a proper smooth $\mathbf{Z}[\frac{1}{N}]$-scheme $X_1(N)$ equipped with a finite flat map to $\mathbf{P}^1_{\mathbf{Z}[\frac{1}{N}]}$, such that the open subscheme $Y_1(N)$ lying over $\mathbf{P}^1_{\mathbf{Z}[\frac{1}{N}]} - \{\infty\} = \mathbf{A}^1_{\mathbf{Z}[\frac{1}{N}]}$ is the base of a universal object $(E_1(N), P) \to Y_1(N)$ for elliptic curves with a point of exact order N over variable $\mathbf{Z}[\frac{1}{N}]$-schemes.

Moreover, the fibers of $X_1(N) \to \mathrm{Spec}\,\mathbf{Z}[\frac{1}{N}]$ are *geometrically connected*, as this can be checked on a single geometric fiber and by choosing the complex fiber we may appeal to the fact (whose proof requires some care) that there is an isomorphism $(X_1(N) \times_{\mathbf{Z}[\frac{1}{N}]} \mathbf{C})^{\mathrm{an}} \cong X_1(N)^{\mathrm{an}}$ identifying the "algebraic" data $(\mathbf{C}/[1,z], \frac{1}{N})$ in $Y_1(N)(\mathbf{C}) \subset X_1(N)(\mathbf{C})$ with the class of $z \in \mathfrak{h}$ in $\Gamma_1(N)\backslash\mathfrak{h} = Y_1(N)^{\mathrm{an}} \subset X_1(N)^{\mathrm{an}}$ (and $X_1(N)^{\mathrm{an}}$ *is* connected, as $\mathfrak{h}$ is). These kinds of compatibilities are somewhat painful to check unless one develops a full-blown relative theory of elliptic curves in the analytic world (in which case the verifications become quite mechanical and natural).

Again fixing $N \geq 5$, but now also a prime p, we want an algebraic analogue of $X_1(N,p)^{\mathrm{an}}$ over $\mathbf{Z}[\frac{1}{Np}]$. Let $(E,P) \to S$ be an elliptic curve with a point of exact order N over a $\mathbf{Z}[\frac{1}{Np}]$-scheme S. We're interested in studying triples $(E,P,C) \to S$ where $C \subset E$ is an order-p finite locally free S-subgroup-scheme which is not contained in the subgroup generated by P on geometric fibers (if $p \mid N$). Methods in [**25**] and [**62**] ensure the existence of a universal such object $(E_1(N,p),P,C) \to Y_1(N,p)$ for a smooth affine $\mathbf{Z}[\frac{1}{Np}]$-scheme which naturally sits as the complement of a relative Cartier divisor in a proper smooth $\mathbf{Z}[\frac{1}{Np}]$-scheme $X_1(N,p)$ which is finite flat over $\mathbf{P}^1_{\mathbf{Z}[\frac{1}{Np}]}$ (with $Y_1(N,p)$ the preimage of $\mathbf{A}^1_{\mathbf{Z}[\frac{1}{Np}]}$). Base change to $\mathbf{C}$ and analytification recovers $X_1(N,p)^{\mathrm{an}}$ as before, so $X_1(N,p) \to \operatorname{Spec} \mathbf{Z}[\frac{1}{Np}]$ has geometrically connected fibers.

There are maps of $\mathbf{Z}[\frac{1}{Np}]$-schemes (respectively, $\mathbf{Z}[\frac{1}{N}]$-schemes)

$$\begin{tikzcd} & Y_1(N,p) \arrow[dl, "\pi_1^{(p)}"'] \arrow[dr, "\pi_2^{(p)}"] & & & Y_1(N) \arrow[r, "I_n"] & Y_1(N) \\ Y_1(N)[\frac{1}{p}] & & Y_1(N)[\frac{1}{p}] & & & \end{tikzcd}$$

determined by $(E,P,C) \xrightarrow{\pi_1^{(p)}} (E,P)$ and $(E,P,C) \xrightarrow{\pi_2^{(p)}} (E/C,P)$ (which makes sense in $Y_1(N)$ if $p \mid N$ by the "disjointness" condition on C and P) and $I_n(E,P) = (E,nP)$. Although $\pi_2^{(p)}$ is *not* a map over $\mathbf{A}^1_{\mathbf{Z}[\frac{1}{Np}]}$, it can be shown that these all uniquely extend to (necessarily finite *flat*) maps, again denoted $\pi_1^{(p)}$, $\pi_2^{(p)}$, I_n between $X_1(N,p)$, $X_1(N)[\frac{1}{p}]$, $X_1(N)$. A proof of this fact requires the theory of minimal regular proper models of curves over a Dedekind base; the analogous fact over $\mathbf{Q}$ is an immediate consequence of basic facts about proper smooth curves over a field, but in order to most easily do some later calculations in characteristic $p \nmid N$ it is convenient to know that we have the map I_p defined on $X_1(N)$ over $\mathbf{Z}[1/N]$ (though this could be bypassed by using liftings to characteristic 0 in a manner similar to our later calculations of T_p in characteristic p).

Likewise, over $\mathbf{Z}[\frac{1}{N}, \zeta_N]$ we can define, for any primitive Nth root of unity $\zeta = \zeta_N^i$ ($i \in (\mathbf{Z}/N\mathbf{Z})^*$), an operator $w_\zeta : Y_1(N)_{/\mathbf{Z}[\frac{1}{N},\zeta_N]} \to Y_1(N)_{/\mathbf{Z}[\frac{1}{N},\zeta_N]}$ via $w_\zeta(E,P) = (E/\langle P\rangle, P')$ where $\langle P\rangle$ is the order-N étale subgroup-scheme generated by P and $P' \in (E[N]/\langle P\rangle)(S)$ is uniquely determined by the relative Weil pairing condition $\langle P, P'\rangle_N = \zeta$ (with $P' \in E[N](S)$ here). This really does extend to $X_1(N)_{/\mathbf{Z}[\frac{1}{N},\zeta_N]}$, and one checks that $w_{\zeta^j} w_\zeta = I_j$ for $j \in (\mathbf{Z}/N\mathbf{Z})^*$. In particular, $w_\zeta^2 = 1$.

Since $X_1(N) \to \operatorname{Spec} \mathbf{Z}[\frac{1}{N}]$ is a proper smooth scheme with geometrically connected fibers of dimension 1, $\operatorname{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$ is an abelian scheme over $\mathbf{Z}[\frac{1}{N}]$ and hence is the Néron model of its generic fiber. We have scheme-theoretic Albanese and Pic^0 functoriality for finite (flat) maps between proper smooth curves (with geometrically connected fibers) over any base at all, and analytification of such a situation over $\mathbf{C}$ recovers the classical theory of Pic^0 as used in Section 5.1.

For example, we have endomorphisms

$$\langle n\rangle^* = \mathrm{Pic}^0(I_n), \quad \langle n\rangle_* = \mathrm{Alb}(I_n)$$

on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$,

$$w_\zeta^* = \mathrm{Pic}^0(w_\zeta) = \mathrm{Alb}(w_\zeta) = (w_\zeta)_*$$

on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N},\zeta_N]}}$, and

$$\begin{aligned} T_p^* &= \mathrm{Alb}(\pi_1^{(p)}) \circ \mathrm{Pic}^0(\pi_2^{(p)}) \\ (T_p)_* &= \mathrm{Alb}(\pi_2^{(p)}) \circ \mathrm{Pic}^0(\pi_1^{(p)}) \end{aligned}$$

on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{Np}]}}$. A key point is that by the *Néronian property*, T_p^* and $(T_p)_*$ uniquely extend to endomorphisms of $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$, even though the $\pi_i^{(p)}$ do *not* make sense over $\mathbf{Z}[\frac{1}{N}]$ from what has gone before. In particular, it makes sense to study T_p^* and $(T_p)_*$ on the abelian variety $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{F}_p}}$ over $\mathbf{F}_p$ for $p \nmid N$. This will be rather crucial later, but note it requires the Néronian property in the definition.

Passing to the analytifications, the above constructions recover the operators defined on $\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}$ in Section 5.1. The resulting subring of

$$\mathrm{End}(\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}) \subset \mathrm{End}(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}})$$

generated by T_p^*, $\langle n\rangle^*$ (respectively, by $(T_p)_*$, $\langle n\rangle_*$) is identified with $\mathbf{T}_1(N)$ via its $(\,)^*$-action (respectively, via its $(\,)_*$-action) and using

$$\varprojlim \mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}[\ell^n](\overline{\mathbf{Q}}) \cong T_\ell(\mathrm{Pic}^0_{X_1(N)^{\mathrm{an}}}) \tag{5.6}$$

(using $\overline{\mathbf{Q}} \subset \mathbf{C}$) endows our "analytic" $V_\ell(N)$ with a canonical *continuous* action of $G_{\mathbf{Q}} = \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ unramified at all $p \nmid N\ell$ (via Néron-Ogg-Shafarevich) and *commuting* with the action of $\mathbf{T}_1(N)$ (via either the $(\,)^*$-action or the $(\,)_*$-action). We also have an endomorphism $w_\zeta = w_\zeta^* = (w_\zeta)_*$ on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N},\zeta_N]}}$ and it is easy to see that

$$(g^{-1})^* w_{g(\zeta)} g^* = w_\zeta$$

on $\overline{\mathbf{Q}}$-points, where $g \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ and g^* denotes the natural action of g on $\overline{\mathbf{Q}}$-points (corresponding to base change of degree 0 line bundles on $X_1(N)_{/\overline{\mathbf{Q}}}$). Since $w_\zeta = w_{\zeta^{-1}}$ (as $(E,P) \cong (E,-P)$ via -1), we see that w_ζ is defined over the real subfield $\mathbf{Q}(\zeta_N)^+$. By étale descent, the operator w_ζ is defined over $\mathbf{Z}[\frac{1}{N},\zeta_N]^+$.

In any case, w_ζ acts on $V_\ell(N)$, recovering the operator in Section 5.1, and so this conjugates the $(\,)^*$-action to the $(\,)_*$-action, taking each $T \in \mathbf{T}_1(N)$ (for either action on $V_\ell(N)$) to its Weil pairing adjoint, via the canonical principal polarization of the abelian scheme $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$. Using Corollary 5.3 and (5.6) we obtain

Lemma 5.11. *Let $\mathbf{T}_1(N)$ act on $V_\ell(N)$ through either the $(\,)^*$-action or the $(\,)_*$-action. Then $\rho_{N,\ell} : G_{\mathbf{Q}} \to \mathrm{Aut}(V_\ell(N)) \cong \mathrm{GL}(2, \mathbf{Q}_\ell \otimes \mathbf{T}_1(N))$ is a continuous representation, unramified at $p \nmid N\ell$.*

The main result we are after is

Theorem 5.12. *Let $\mathbf{T}_1(N)$ act on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$ via the $(\,)_*$-action. For any $p \nmid N\ell$, the characteristic polynomial of $\rho_{N,\ell}(\mathrm{Frob}_p)$ is*

$$X^2 - (T_p)_* X + p\langle p\rangle_*$$

relative to the $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$-module structure on $V_\ell(N)$, where Frob_p denotes an arithmetic Frobenius element at p.

The proof of Theorem 5.12 will make essential use of the w_ζ operator. For the remainder of this section, we admit Theorem 5.12 and deduce its consequences. Let $f \in S_2(\Gamma_1(N), \mathbf{C})$ be a *newform* of level N. Let $K_f \subset \mathbf{C}$ be the number field generated by $a_p(f)$ for all $p \nmid N$, where $f = \sum a_n(f)q^n$, so by weak multiplicity one $a_n(f) \in K_f$ for all $n \geq 1$ and the Nebentypus character χ_f has values in K_f. Let $\mathfrak{p}_f \subset \mathbf{T}_1(N)$ be the minimal prime corresponding to f (i.e., the kernel of the map $\mathbf{T}_1(N) \to K_f$ sending each $T \in \mathbf{T}_1(N)$ to its eigenvalue on f).

We now require $\mathbf{T}_1(N)$ to act on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}$ via its $(\,)_*$-action.

Definition 5.13. A_f is the quotient of $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Q}}}$ by $\mathfrak{p}_f \subset \mathbf{T}_1(N)$.

By construction, A_f has good reduction over $\mathbf{Z}[\frac{1}{N}]$ and the action of $\mathbf{T}_1(N)$ on $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Q}}}$ induces an action of $\mathbf{T}_1(N)/\mathfrak{p}$ on A_f, hence an action of $K_f \cong (\mathbf{T}_1(N)/\mathfrak{p}) \otimes_{\mathbf{Z}} \mathbf{Q}$ on A_f in the "up-to-isogeny" category.

Theorem 5.14 (Shimura)**.** *We have $\dim A_f = [K_f : \mathbf{Q}]$ and $V_\ell(A_f)$ is free of rank 2 over $\mathbf{Q}_\ell \otimes_{\mathbf{Q}} K_f$, with Frob_p having characteristic polynomial*

$$X^2 - (1 \otimes a_p(f))X + 1 \otimes p\chi_f(p)$$

for all $p \nmid N\ell$.

Proof. By Lemma 5.11 and Theorem 5.12, we just have to check that the $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$-linear map

$$V_\ell(\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Q}}}) \to V_\ell(A_f)$$

identifies the right hand side with the quotient of the left hand side by $\mathfrak{p}_f$. More generally, for any exact sequence

$$B' \to B \to A \to 0$$

of abelian varieties over a field of characteristic prime to ℓ, we claim

$$V_\ell(B') \to V_\ell(B) \to V_\ell(A) \to 0$$

is exact. We may assume the base field is algebraically closed, and then may appeal to Poincaré reducibility (see [**77**, pg. 173]). □

Choosing a place λ of K_f over ℓ and using the natural realization of $K_{f,\lambda}$ as a factor of $\mathbf{Q}_\ell \otimes K_f$, we deduce from Theorem 5.14:

Corollary 5.15. *Let $f \in S_2(\Gamma_1(N), \mathbf{C})$ be a newform and λ a place of K_f over ℓ. There exists a continuous representation*

$$\rho_{f,\lambda} : G_{\mathbf{Q}} \to GL(2, K_{f,\lambda})$$

unramified at all $p \nmid N\ell$, with Frob_p *having characteristic polynomial*

$$X^2 - a_p(f)X + p\chi_f(p) \in K_{f,\lambda}[X].$$

5.3. Proof of Theorem 5.12

Fix $p \nmid N$ and let

$$J_p = \mathrm{Pic}^0_{X_1(N)_{/\mathbf{F}_p}} \cong \mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}} \times_{\mathbf{Z}[\frac{1}{N}]} \mathbf{F}_p$$

with $\mathbf{T}_1(N)$ acting through the $(\,)_*$-action. Fix a choice of Frob_p, or more specifically fix a choice of place in $\overline{\mathbf{Q}}$ over p. Note that this determines a preferred algebraic closure $\overline{\mathbf{F}}_p$ as a quotient of the ring of algebraic integers, and in particular a map $\mathbf{Z}[1/N, \zeta_N] \to \overline{\mathbf{F}}_p$. Thus, we may view w_ζ as inducing an endomorphism of the abelian variety $J_p \times_{\mathbf{F}_p} \overline{\mathbf{F}}_p$ over $\overline{\mathbf{F}}_p$ (whereas the elements in $\mathbf{T}_1(N)$ induce endomorphisms of J_p over $\mathbf{F}_p$). The canonical isomorphism

$$V_\ell(\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Q}}}) \cong V_\ell(\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}) \cong V_\ell(J_p)$$

identifies the Frob_p-action on $\overline{\mathbf{Q}}$-points on the left hand side with the (arithmetic) Frobenius action on $\overline{\mathbf{F}}_p$-points on the right hand side. Obviously $V_\ell(J_p)$ is a module over the ring $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$ and is free of rank 2 as such. For *any* $\mathbf{F}_p$-schemes Z, Z' and any $\mathbf{F}_p$-map $f : Z \to Z'$ the diagram

(5.7)
$$\begin{tikzcd} Z \arrow[r, "f"] \arrow[d, "F_Z"'] & Z' \arrow[d, "F_{Z'}"] \\ Z \arrow[r, "f"] & Z' \end{tikzcd}$$

commutes, where columns are absolute Frobenius. Taking $Z = \mathrm{Spec}\,\overline{\mathbf{F}}_p$, $Z' = J_p$, we see that the Frob_p action of $V_\ell(J_p)$ through $\overline{\mathbf{F}}_p$-points is *identical* to the action induced by the intrinsic absolute Frobenius morphism $F : J_p \to J_p$ over $\mathbf{F}_p$. Here is the essential input, to be proven later.

Theorem 5.16 (Eichler-Shimura)**.** *In* $\mathrm{End}_{\overline{\mathbf{F}}_p}(J_p)$,

$$(T_p)_* = F + \langle p\rangle_* F^\vee, \qquad w_\zeta^{-1} F w_\zeta = \langle p\rangle_*^{-1} F$$

where $F^\vee$ denotes the dual morphism.

The extra relation involving w_ζ is crucial. The interested reader should compare this with [**108**, Cor. 7.10].

Let us admit Theorem 5.16 and use it to prove Theorem 5.12. We will then prove Theorem 5.16. Using an $\mathbf{F}_p$-rational base point P (e.g., the cusp 0), we get a commutative diagram

$$\begin{tikzcd} X_1(N)_{/\mathbf{F}_p} \arrow[r, hook] \arrow[d, "F_{X_1(N)}"'] & J_p \arrow[d, "F"] \\ X_1(N)_{/\mathbf{F}_p} \arrow[r, hook] & J_p \end{tikzcd}$$

where $F_{X_1(N)}$ denotes the absolute Frobenius morphism of $X_1(N)_{/\mathbf{F}_p}$, so by Albanese functoriality $F = \mathrm{Alb}(F_{X_1(N)})$. Thus

$$\begin{aligned} FF^\vee &= \mathrm{Alb}(F_{X_1(N)}) \circ \mathrm{Pic}^0(F_{X_1(N)}) \\ &= \deg(F_{X_1(N)}) = p \end{aligned}$$

as $X_1(N)_{/\mathbf{F}_p}$ is a smooth *curve*. We conclude from $(T_p)_* = F + \langle p\rangle_* F^\vee$ that

$$F^2 - (T_p)_* F + p\langle p\rangle_* = 0$$

on J_p, hence in $V_\ell(J_p)$. Thus, $\rho_{N,\ell}(\mathrm{Frob}_p)$ satisfies the expected quadratic polynomial

$$X^2 - (T_p)_* X + p\langle p\rangle_* = 0.$$

Let $X^2 - aX + b$ be the *true* characteristic polynomial, which $\rho_{N,\ell}(\mathrm{Frob}_p)$ must also satisfy, by Cayley-Hamilton. We must *prove* that $a = (T_p)_*$, and then $b = p\langle p\rangle_*$ is forced. It is this matter which requires the second relation.

We want $\mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(\rho_{N,\ell}(\mathrm{Frob}_p)) = (T_p)_*$ or equivalently

$$\mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(V_\ell(F)) = (T_p)_*.$$

Using the modified Weil pairing

$$[x, y]_\ell = (x, w_\zeta y)_\ell$$

and using the fact that $V_\ell(J_p) \cong V_\ell(\mathrm{Pic}^0_{X_1(N)/\mathbf{Q}})$ respects Weil pairings (by invoking the relativization of this concept, here over $\mathbf{Z}[\frac{1}{N}]$) we may identify (via Theorem 5.8 and a choice $\mathbf{Q}_\ell(1) \cong \mathbf{Q}_\ell$ as $\mathbf{Q}_\ell$-vector spaces)

$$V_\ell(J_p) \cong \mathrm{Hom}_{\mathbf{Q}_\ell}(V_\ell(J_p), \mathbf{Q}_\ell) := V_\ell(J_p)^*$$

as $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$-modules, but taking the F-action over to the $\langle p\rangle_* F^\vee$-action, since adjoints with respect to Weil pairings are dual morphisms and $w_\zeta^{-1} F^\vee w_\zeta$ is dual to $w_\zeta^{-1} F w_\zeta = \langle p\rangle_*^{-1} F = F\langle p\rangle_*^{-1}$ (absolute Frobenius commutes with all morphisms of $\mathbf{F}_p$-schemes!)

Since $V_\ell(J_p)$ is free of rank 2 over $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$ and $\mathrm{Hom}_{\mathbf{Q}_\ell}(\mathbf{Q}_\ell \otimes \mathbf{T}_1(N), \mathbf{Q}_\ell)$ is free of rank 1 over $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$, by Corollary 5.9, we conclude

$$\mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(F | V_\ell(J_p)) = \mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(\langle p\rangle_* F^\vee | V_\ell(J_p)^*).$$

We wish to invoke the following applied to the $\mathbf{Q}_\ell$-algebra $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$ and the $\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)$-module $V_\ell(J_p)$:

Lemma 5.17. *Let $\mathcal{O}$ be a commutative ring, A a finite locally free $\mathcal{O}$-algebra with* $\mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O})$ *a locally free A-module (necessarily of rank 1). Let M be a finite locally free A-module, $M^* = \mathrm{Hom}_{\mathcal{O}}(M, \mathcal{O})$, so M^* is finite and locally free over A with the same rank as M. For any A-linear map $f : M \to M$ with $\mathcal{O}$-dual $f^* : M^* \to M^*$, automatically A-linear,*

$$\mathrm{char}(f) = \mathrm{char}(f^*)$$

in $A[T]$ (these are the characteristic polynomials).

Proof. Without loss of generality $\mathcal{O}$ is local, so A is semilocal. Making faithfully flat base change to the henselization of $\mathcal{O}$ (or the completion if $\mathcal{O}$ is noetherian or if we first reduce to the noetherian case), we may assume that A is a product of local rings. Without loss of generality, A is then local, so

$$M = \oplus A e_i$$

if free, and $\mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O})$ is free of rank 1 over A. Choose an isomorphism

$$h : A \cong \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O})$$

as A-modules, so the projections

$$\pi_i : M \to Ae_i \cong A$$

satisfy $e_i^* = h(i) \circ \pi_i$ in M^*. These e_i^* are an A-basis of M^* and we compute matrices over A:

$$\mathrm{Mat}_{\{e_i\}}(f) = \mathrm{Mat}_{\{e_i^*\}}(f^*)^t.$$

□

We conclude that

$$\mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(F|V_\ell(J_p)) = \mathrm{tr}_{\mathbf{Q}_\ell \otimes \mathbf{T}_1(N)}(\langle p\rangle_* f^\vee|V_\ell(J_p)).$$

By Theorem 5.16, we have

$$\begin{aligned} 2(T_p)_* &= \mathrm{tr}((T_p)_*|V_\ell(J_p)) \\ &= \mathrm{tr}(F + \langle p\rangle_* F^\vee|V_\ell(J_p)) \\ &= 2\,\mathrm{tr}(F|V_\ell(J_p)). \end{aligned}$$

This proves that $\mathrm{tr}(F|V_\ell(J_p)) = (T_p)_*$, so indeed $X^2 - (T_p)_*X + p\langle p\rangle_*$ *is* the characteristic polynomial. Finally, there remains

Proof of Theorem 5.16. It suffices to check the maps coincide on a Zariski dense subset of $J_p(\overline{\mathbf{F}}_p) = \mathrm{Pic}^0(X_1(N)_{/\overline{\mathbf{F}}_p})$. If g is the genus of $X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}$ and we fix an $\overline{\mathbf{F}}_p$-rational base point, we get an induced surjective map

$$X_1(N)^g_{/\overline{\mathbf{F}}_p} \to J_{p/\overline{\mathbf{F}}_p},$$

so for any dense open $U \subset X_1(N)_{\overline{\mathbf{F}}_p}$, $U^g \to (J_p)_{/\overline{\mathbf{F}}_p}$ hits a Zariski dense subset of $\overline{\mathbf{F}}_p$-points. Taking U to be the ordinary locus of $Y_1(N)_{/\overline{\mathbf{F}}_p}$, it suffices to study what happens to a difference $(x) - (x')$ for $x, x' \in Y_1(N)(\overline{\mathbf{F}}_p)$ corresponding to (E, P), (E', P') over $\overline{\mathbf{F}}_p$ with E and E' *ordinary* elliptic curves.

By the commutative diagram (5.7), the map

$$J_p(\overline{\mathbf{F}}_p) \to J_p(\overline{\mathbf{F}}_p)$$

induced by F is the same as the map induced by the pth power map in $\overline{\mathbf{F}}_p$. By *definition* of Pic^0 functoriality, this corresponds to base change of an invertible sheaf on $X_1(N)_{/\overline{\mathbf{F}}_p}$ by the absolute Frobenius on $\overline{\mathbf{F}}_p$. By *definition* of $Y_1(N)_{/\overline{\mathbf{F}}_p}$ as a universal object, such base change induces on $Y_1(N)(\overline{\mathbf{F}}_p)$ *exactly* "base change by absolute Frobenius" on elliptic curves with a point of exact order N over $\overline{\mathbf{F}}_p$. We conclude

$$F((x) - (x')) = (E^{(p)}, P^{(p)}) - ((E')^{(p)}, P^{(p)})$$

where $(\,)^{(p)}$ denotes base change by absolute Frobenius on $\overline{\mathbf{F}}_p$.

Since $p = FF^\vee = F^\vee F$ and F is bijective on $\overline{\mathbf{F}}_p$-points, we have

$$\begin{aligned} F^\vee((x) - (x')) &= pF^{-1}((x) - (x')) \\ &= p((E^{(p^{-1})}, P^{(p^{-1})}) - ((E')^{(p^{-1})}, (P')^{(p^{-1})})). \end{aligned}$$

Thus,

$$\langle p\rangle_* F^\vee((x) - (x')) = p(E^{(p^{-1})}, pP^{(p^{-1})}) - p((E')^{(p^{-1})}, p(P')^{(p^{-1})})$$

so

$$\begin{aligned}(F + \langle p\rangle_* F^\vee)((x) - (x')) &= (E^{(p)}, P^{(p)}) + p(E^{(p^{-1})}, pP^{(p^{-1})}) \\ &\quad - ((E')^{(p)}, (P')^{(p)}) + p((E')^{(p^{-1})}, p(P')^{(p^{-1})}).\end{aligned}$$

Computing $(T_p)_*$ on $J_p = \mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}} \times_{\mathbf{Z}[\frac{1}{N}]} \mathbf{F}_p$ is more subtle because $(T_p)_*$ was defined over $\mathbf{Z}[\frac{1}{Np}]$ (or over $\mathbf{Q}$) as $(\pi_2)_*\pi_1^*$ and was *extended* over $\mathbf{Z}[\frac{1}{N}]$ by the Néronian property. That is, we do *not* have a direct definition of $(T_p)_*$ in characteristic p, so we will need to lift to characteristic 0 to compute. It is *here* that the ordinariness assumption is crucial, for we shall see that, in some sense,

$$(T_p)_*((x) - (x')) = (F + \langle p\rangle_* F^\vee)((x) - (x'))$$

as *divisors* for ordinary points x, x'. This is, of course, much stronger than the mere linear equivalence that we need to prove.

Before we dive into the somewhat subtle calculation of $(T_p)_*((x) - (x'))$, let's quickly take care of the relation $w_\zeta^{-1} F w_\zeta = \langle p\rangle_*^{-1} F$, or equivalently,

$$F w_\zeta = w_\zeta \langle p^{-1}\rangle_* F.$$

All maps here are induced by maps on $X_1(N)_{/\overline{\mathbf{F}}_p}$, with $F = \mathrm{Alb}(F_{X_1(N)})$, $w_\zeta = \mathrm{Alb}(w_{\zeta|_{X_1(N)}})$, $\langle p^{-1}\rangle_* = \mathrm{Alb}(I_{p^{-1}})$. Thus, it suffices to show

$$F_{X_1(N)} \circ w_\zeta = w_\zeta I_{p^{-1}} F_{X_1(N)}$$

on $X_1(N)_{/\overline{\mathbf{F}}_p}$, and we can check by studying $x = (E, P) \in Y_1(N)(\overline{\mathbf{F}}_p)$:

$$F_{X_1(N)} w_\zeta(x) = F_{X_1(N)}(E/P, P') = (E^{(p)}/P^{(p)}, (P')^{(p)})$$

where $\langle P, P'\rangle_N = \zeta$, so $\langle P^{(p)}, (P')^{(p)}\rangle_N = \zeta^p$ by compatibility of the (relative) Weil pairing with respect to base change. Meanwhile,

$$w_\zeta I_{p^{-1}} F_{X_1(N)}(x) = w_\zeta(E^{(p)}, p^{-1}P^{(p)}) = (E^{(p)}/(p^{-1}P^{(p)}), Q)$$

where $\langle p^{-1}P^{(p)}, Q\rangle_N = \zeta$, or equivalently $\langle P^{(p)}, Q\rangle = \zeta^p$. Since $Q = (P')^{(p)}$ is such a point, this second relation is established.

Now we turn to the problem of computing

$$(T_p)_*((x) - (x'))$$

for "ordinary points" $x = (E, P)$, $x' = (E', P')$ as above. Let $R = \mathbf{Z}_p^{\mathrm{un}}$, $W(\overline{\mathbf{F}}_p)$, or more generally any henselian (e.g., complete) discrete valuation ring with residue field $\overline{\mathbf{F}}_p$ and fraction field K of characteristic 0. Since $p \nmid N$, R is a $\mathbf{Z}[\frac{1}{N}]$-algebra. Since $Y_1(N)$ is *smooth* over $\mathbf{Z}[\frac{1}{N}]$, we conclude from the (strict) henselian property that $Y_1(N)(R) \to Y_1(N)(\overline{\mathbf{F}}_p)$ is surjective. Of course, this can be seen "by hand": if (E, P) is given over $\overline{\mathbf{F}}_p$, choose a Weierstrass model $\mathcal{E} \hookrightarrow \mathbf{P}^2_R$ lifting E (this is canonically an elliptic curve, by [**62**, Ch 2]). The finite *étale* group scheme $\mathcal{E}[N]$ is *constant* since R is strictly henselian. Thus there exists a unique closed immersion of group schemes $\mathbf{Z}/N\mathbf{Z} \hookrightarrow \mathcal{E}[N]$ lifting $P : \mathbf{Z}/N\mathbf{Z} \hookrightarrow E[N]$.

Let $(\mathcal{E}, \mathcal{P})$, $(\mathcal{E}', \mathcal{P}')$ over R lift x, x' respectively. We view these sections to $X_1(N)_{/R} \to \operatorname{Spec} R$ as relative effective Cartier divisors of degree 1. Using the reduction map

$$\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}(R) \to J_p(\overline{\mathbf{F}}_p)$$

and the *definition* of $(T_p)_*$, we see that $(T_p)_*((x)-(x'))$ is the image of $(T_p)_*((\mathcal{E},\mathcal{P})-(\mathcal{E}',\mathcal{P}'))$. Now R is *NOT* a $\mathbf{Z}[\frac{1}{Np}]$-algebra but K *is*, and we have an injection (even bijection)

$$\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}(R) \hookrightarrow \mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}(K),$$

as $\mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}} \to \operatorname{Spec}\mathbf{Z}[\frac{1}{N}]$ is separated (even proper).

Thus, we will first compute $(T_p)_*((x)-(x'))$ by working with $\overline{K}$-points, where $\overline{K}$ is an algebraic closure of K. Since $p \nmid N$, we have

$$(\pi_2)_*\pi_1^*((\mathcal{E},\mathcal{P})_{/\overline{K}}) = \sum_C (\mathcal{E}_{\overline{K}}/C, \mathcal{P}_{\overline{K}} \mod C)$$

where C runs through all $p+1$ order-p subgroups of $\mathcal{E}_{/\overline{K}}$. Since $\mathcal{E} \to \operatorname{Spec} R$ has *ordinary* reduction, and R is strictly henselian, the connected-étale sequence of $\mathcal{E}[p]$ is the short exact sequence of finite flat R-group schemes

$$0 \to \mu_p \to \mathcal{E}[p] \to \underline{\mathbf{Z}/p\mathbf{Z}} \to 0.$$

Enlarging R to a finite extension does not change the residue field $\overline{\mathbf{F}}_p$, so we may assume that

$$\mathcal{E}[p]_{/K} \cong \underline{\mathbf{Z}/p\mathbf{Z}} \times \underline{\mathbf{Z}/p\mathbf{Z}}.$$

Taking the scheme-theoretic closure in $\mathcal{E}[p]$ of the $p+1$ distinct subgroups of $\mathcal{E}[p]_{/K}$ gives $p+1$ *distinct* finite flat subgroup schemes $\mathcal{C} \subset \mathcal{E}$ realizing the $p+1$ distinct C's over $\overline{K}$.

Exactly one of these $\mathcal{C}$'s is killed by $\mathcal{E}[p] \to \underline{\mathbf{Z}/p\mathbf{Z}}$ over R, as this can be checked on the generic fiber, so it must be $\mu_p \hookrightarrow \mathcal{E}[p]$. For the remaining $\mathcal{C}$'s, the map $\mathcal{C} \to \underline{\mathbf{Z}/p\mathbf{Z}}$ is an isomorphism on the generic fiber. We claim these maps

$$\mathcal{C} \to \underline{\mathbf{Z}/p\mathbf{Z}}$$

over R are isomorphisms. Indeed, if $\mathcal{C}$ is *étale* this is clear, yet $\mathcal{C} \hookrightarrow \mathcal{E}[p]$ is a finite flat closed subgroup-scheme of order p, so a consideration of the closed fiber shows that if $\mathcal{C}$ is *not* étale then it is multiplicative. But $\mathcal{E}[p]$ has a *unique* multiplicative subgroup-scheme since

$$\mathcal{E}[p]^\vee \cong \mathcal{E}[p]$$

by Cartier-Nishi duality and $\mathcal{E}[p]$ has a *unique* order-p *étale* quotient (as any such quotient must kill the μ_p we have inside $\mathcal{E}[p]$.)

Thus,

$$\begin{aligned}(\pi_2)_*\pi_1^*((\mathcal{E},\mathcal{P})_{/\overline{K}}) &= \sum_{\mathcal{C}} (\mathcal{E}/\mathcal{C}, \mathcal{P} \mod \mathcal{C}) - \sum_{\mathcal{C}'} (\mathcal{E}'/\mathcal{C}', \mathcal{P}' \mod \mathcal{C}') \\ &\in \mathrm{Pic}^0_{X_1(N)_{/\mathbf{Z}[\frac{1}{N}]}}(R)\end{aligned}$$

coincides with $(T_p)_*((\mathcal{E},\mathcal{P})-(\mathcal{E}',\mathcal{P}'))$ as both induce the same $\overline{K}$-point. Passing to closed fibers,

$$\begin{aligned}(T_p)_*((x)-(x')) = {} & (E/\mu_p, P \mod \mu_p) + p(E/\underline{\mathbf{Z}/p\mathbf{Z}'}, P \mod \mathbf{Z}/p\mathbf{Z}) \\ & - (E'/\mu_p, P' \mod \mu_p) + p(E'/\underline{\mathbf{Z}/p\mathbf{Z}}, P' \mod \mathbf{Z}/p\mathbf{Z})\end{aligned}$$

where $E[p] \cong \mu_p \times \underline{\mathbf{Z}/p\mathbf{Z}}$ and $E'[p] \cong \mu_p \times \underline{\mathbf{Z}/p\mathbf{Z}}$ are the *canonical* splittings of the connected-étale sequence over the perfect field $\overline{\mathbf{F}}_p$.

Now consider the relative Frobenius morphism

$$F_{E/\overline{\mathbf{F}}_p} : E \to E^{(p)},$$

which sends O to O (and P to $P^{(p)}$) and so is a map of *elliptic curves* over $\overline{\mathbf{F}}_p$. Recall that in characteristic p, for any map of schemes $X \to S$ we define the relative Frobenius map $F_{X/S} : X \to X^{(p)}$ to be the unique S-map fitting into the diagram

$$\begin{tikzcd} X \arrow[r, "F_{X/S}"'] \arrow[rr, bend left, "F_X"] \arrow[dr] & X^{(p)} \arrow[r] \arrow[d] & X \arrow[d] \\ & S \arrow[r, "F_S"'] & S \end{tikzcd}$$

where F_S, F_X are the absolute Frobenius maps. Since $E \to \operatorname{Spec} \overline{\mathbf{F}}_p$ is smooth of pure relative dimension 1, $F_{E/\overline{\mathbf{F}}_p}$ is finite flat of degree $p^1 = p$. It is bijective on points, so $\ker(F_{E/\overline{\mathbf{F}}_p})$ must be connected of order p.

The *only* such subgroup-scheme of E is $\mu_p \hookrightarrow E[p]$ by the *ordinariness*. Thus

$$E/\mu_p \cong E^{(p)}$$

is easily seen to take P mod μ_p to $P^{(p)}$.

Similarly, we have

$$\begin{tikzcd} E \arrow[r, "F_{E/\overline{\mathbf{F}}_p}"'] \arrow[rr, bend left, "p"] & E^{(p)} \arrow[r, "F^\vee_{E/\mathbf{F}_p}"'] & E \end{tikzcd}$$

so $F^\vee_{E/\mathbf{F}_p}$ is étale of degree p and base extension by $\mathrm{Frob}^{-1} : \overline{\mathbf{F}}_p \to \overline{\mathbf{F}}_p$ gives

$$\begin{tikzcd} E^{(p^{-1})} \arrow[r] \arrow[rr, bend left, "p"] & E \arrow[r] & E^{(p^{-1})} \\ P^{(p^{-1})} \arrow[r, mapsto] & P \arrow[r, mapsto] & p \cdot P^{(p^{-1})}. \end{tikzcd}$$

As the second map in this composite is étale of degree p, we conclude

$$(E_{/\underline{\mathbf{Z}/p\mathbf{Z}}}, P \bmod \mathbf{Z}/p\mathbf{Z}) \cong (E^{(p^{-1})}, pP^{(p^{-1})}).$$

Thus, in $\mathrm{Pic}^0_{X_1(N)}(\overline{\mathbf{F}}_p)$,

$$\begin{aligned} (T_p)_*((x) - (x')) = {} & (E^{(p)}, P^{(p)}) + p \cdot (E^{(p^{-1})}, p \cdot P^{(p^{-1})}) \\ & - ((E')^{(p)}, (P')^{(p)}) - p \cdot ((E')^{(p^{-1})}, p \cdot (P')^{(p^{-1})}) \end{aligned}$$

which we have seen is equal to $(F + \langle p \rangle_* F^\vee)((x) - (x'))$.

□

CHAPTER 6

Appendix by Kevin Buzzard: A mod ℓ multiplicity one result

In this appendix, we explain how the ideas of [**46**] can be used to prove the following mild strengthening of the multiplicity one results in §9 of [**32**].

The setup is as follows. Let f be a normalised cuspidal eigenform of level N, and weight k, defined over $\overline{\mathbf{F}}_\ell$, with $\ell \nmid N$ and $2 \leq k \leq \ell + 1$. Let N^* denote N if $k = 2$, and $N\ell$ if $k > 2$. Let $J_{\mathbf{Q}}$ be the Jacobian of the curve $X_1(N^*)_{\mathbf{Q}}$, and let H denote the Hecke algebra in $\mathrm{End}(J_{\mathbf{Q}})$ generated over $\mathbf{Z}$ by T_p for all primes p, and all the Diamond operators of level N^*. It is well-known (for example by Proposition 9.3 of [**46**]) that there is a characteristic 0 normalised eigenform F in $S_2(\Gamma_1(N^*))$ lifting f. Let $\mathfrak{m}$ denote the maximal ideal of H associated to F (note that $\mathfrak{m}$ depends only on f and not on the choice of F), and let $\mathbf{F} = H/\mathfrak{m}$, which embeds naturally into $\overline{\mathbf{F}}_\ell$. Suppose the representation $\rho_f : G_{\mathbf{Q}} \to \mathrm{GL}_2(\overline{\mathbf{F}}_\ell)$ associated to f is absolutely irreducible, and furthermore assume that if $k = \ell + 1$ then ρ_f is not isomorphic to a representation coming from a form of weight 2 and level N.

Theorem 6.1. *If ρ_f is ramified at ℓ, or if ρ_f is unramified at ℓ but $\rho_f(\mathrm{Frob}_\ell)$ is not a scalar matrix, then $J_{\mathbf{Q}}(\overline{\mathbf{Q}})[\mathfrak{m}]$ has $H/\mathfrak{m}$-dimension two, and hence is a model for (precisely one copy of) ρ_f.*

The motivation for putting ourselves in the setup above is that every absolutely irreducible modular mod ℓ representation has a twist coming from a modular form of level prime to ℓ and weight at most $\ell + 1$. In particular, every modular mod ℓ representation has a twist coming from a form satisfying the conditions of our setup. Furthermore, if f is as in our setup, then Theorems 2.5 and 2.6 of [**32**] tell us the precise structure of the restriction of ρ_f to D_ℓ, a decomposition group at ℓ. These results are explained in Section 2.2. Using them, it is easy to deduce

Corollary 6.2. *Let ρ be an absolutely irreducible modular mod ℓ representation, such that $\rho_f(D_\ell)$ is not contained within the scalars. Then some twist of ρ comes from a modular form satisfying the conditions of the theorem, and hence ρ is a multiplicity one representation in the sense of Remark 3.4.2.*

The theorem, commonly referred to as a "multiplicity one theorem", is a mild extension of results of Mazur, Ribet, Gross and Edixhoven. It was announced for $\ell = 2$ as Proposition 2.4 of [**9**] but the proof given there is not quite complete—in fact, the last line of the proof there is a little optimistic. I would hence like to thank Ribet and Stein for the opportunity to correct this oversight in [**9**].

Proof of Theorem. Firstly we observe that the only case not dealt with by Theorem 9.2 of [**32**] is the case when $k = \ell$ and ρ_f is unramified at ℓ, with $\rho_f(\mathrm{Frob}_\ell)$ a non-scalar matrix whose eigenvalues are equal. Moreover, using Theorems 2.5 and 2.6 of [**32**] we see that in this case f must be ordinary at ℓ. We are hence in a position to use the detailed construction of ρ_f given in §§11–12 of [**46**]. We will follow the conventions set up in the present paper for normalisations of Hecke operators, and so in particular the formulae below differ from the ones in [**46**] by a twist.

The maximal ideal $\mathfrak{m}$ of H associated to f gives rise as in (12.5) of [**46**] to an idempotent $e \in H_\ell := H \otimes_{\mathbf{Z}} \mathbf{Z}_l$, such that the completion $H_\mathfrak{m}$ of H at $\mathfrak{m}$ is just eH_ℓ. Let G denote $e(J_{\mathbf{Q}_\ell}[\ell^\infty])$, the part of the ℓ-divisible group of J which is associated to $\mathfrak{m}$. Then $H_\mathfrak{m}$ acts on G, and it is proved in Propositions 12.8 and 12.9 of [**46**] that there is an exact sequence of ℓ-divisible groups

$$0 \to G^0 \to G \to G^e \to 0$$

over $\mathbf{Q}_\ell$, which is $H_\mathfrak{m}$-stable. Let

$$0 \to T^0 \to T \to T^e \to 0$$

be the exact sequence of Tate modules of these groups. We now explain explicitly, following [**46**], how the group D_ℓ acts on these Tate modules.

If $k > 2$ then there is a Hecke operator U_ℓ in $H_\mathfrak{m}$, and we define $u = U_\ell$. If $k = 2$ then there is a Hecke operator T_ℓ in $H_\mathfrak{m}$ and because we are in the ordinary case we know that T_ℓ is a unit in $H_\mathfrak{m}$. We define u to be the unique root of the polynomial $X^2 - T_\ell X + \ell\langle\ell\rangle$ in $H_\mathfrak{m}$ which is a unit (u exists by an appropriate analogue of Hensel's lemma).

The calculations of Propositions 12.8 and 12.9 of [**46**] show that, under our conventions, the absolute Galois group D_ℓ of $\mathbf{Q}_\ell$ acts on T^e as $\lambda(u)$, where $\lambda(x)$ denotes the unramified character taking Frob_ℓ to x. Moreover, these propositions also tell us that D_ℓ acts on T^0 via the character $\chi_\ell\lambda(u^{-1}\langle\ell\rangle_N)\chi^{\ell-2}$, where χ_ℓ is the cyclotomic character and χ is the Teichmüller character. The key point is that this character takes values in $H^\times$.

The next key observation is that a standard argument on differentials, again contained in the proof of Propositions 12.8 and 12.9 of [**46**], shows that $G^e[\mathfrak{m}] = \mathfrak{m}^{-1}\ell T^e/\ell T^e$ has $H_\mathfrak{m}/\mathfrak{m}$-dimension 1 and that $G^0[\mathfrak{m}]$ has dimension $d^0 \geq 1$. (Note that the fact that $G^e[\mathfrak{m}]$ has dimension 1 implies, via some simple linear algebra, that the sequence $0 \to G^0[\mathfrak{m}] \to G[\mathfrak{m}] \to G^e[\mathfrak{m}] \to 0$ is exact, as asserted by Gross.) Furthermore, because we can identify $G^0[\mathfrak{m}]$ with $\mathfrak{m}^{-1}\ell T^0/\ell T^0$, we see that the action of D_ℓ on $G^0[\mathfrak{m}]$ is via a character which takes values in $(H/\mathfrak{m})^\times$. In particular, D_ℓ acts as scalars on $G^0[\mathfrak{m}]$.

Let us now assume that ρ_f is unramified at ℓ, and that $\rho_f(\mathrm{Frob}_\ell)$ is a non-diagonalisable matrix with eigenvalue $\alpha \in H/\mathfrak{m}$. Choose a model ρ for ρ_f defined over $\mathrm{GL}_2(H/\mathfrak{m})$. By the theorem of Boston, Lenstra and Ribet, we know that $G[\mathfrak{m}]$ is isomorphic to a direct sum of d copies of ρ, or more precisely, d copies of the restriction of ρ to D_ℓ. Here d is an integer satisfying $2d = d^0 + d^e$. Hence, if $G[\mathfrak{m}]^\alpha$ denotes the subspace of $G[\mathfrak{m}]$ where Frob_ℓ acts as α, then the $H/\mathfrak{m}$-dimension of $G[\mathfrak{m}]^\alpha$ is at most d. On the other hand, Frob_ℓ acts on $G[\mathfrak{m}]^0$ as a scalar, and hence this scalar must be α, and so we see $G[\mathfrak{m}]^0 \subseteq G[\mathfrak{m}]^\alpha$. Hence $d^0 \leq d = (d^0+1)/2$. We deduce that $d^0 \leq 1$ and hence $d^0 = d = 1$ and the theorem is proved. □

We remark that L. Kilford has found examples of mod 2 forms f of weight 2, such that ρ_f is unramified at 2 and $\rho_f(\mathrm{Frob}_2)$ is the identity, and where $J_{\mathbf{Q}}(\overline{\mathbf{Q}})[\mathfrak{m}]$ has $H/\mathfrak{m}$-dimension 4, and so one cannot hope to extend the theorem to this case. See Remark 3.6 for more details, or [**64**]. A detailed analysis of what is happening in this case, at least in the analogous setting of forms of weight 2 on $J_0(p)$, with p prime, has been undertaken by Emerton in [**39**]. In particular, Emerton proves that multiplicity one fails if and only if the analogue of the exact sequence $0 \to T^0 \to T \to T^e \to 0$ fails to split as a sequence of $H_{\mathfrak{m}}$-modules.

8 An introduction to computing modular forms using modular symbols

An introduction to computing modular forms using modular symbols

William A. Stein

Abstract

We explain how weight-two modular forms on $\Gamma_0(N)$ are related to modular symbols, and how to use this to explicitly compute spaces of modular forms.

Introduction

The definition of the spaces of modular forms as functions on the upper half plane satisfying a certain equation is very abstract. The definition of the Hecke operators even more so. Nevertheless, one wishes to carry out explicit investigations involving these objects.

We are fortunate that we now have methods available that allow us to transform the vector space of cusp forms of given weight and level into a concrete object, which can be explicitly computed. We have the work of Atkin-Lehner, Birch, Swinnerton-Dyer, Manin, Mazur, Merel, and many others to thank for this (see, e.g., [3, 6, 15, 16]). For example, we can use the Eichler-Selberg trace formula, as extended in [11], to compute characteristic polynomials of Hecke operators. Then the method described in [25] gives a basis for certain spaces of modular forms. Alternatively, we can compute Θ-series using Brandt matrices and quaternion algebras as in [12, 18], or we can use a closely related geometric method that involves the module of enhanced supersingular elliptic curves [17]. Another related method of Birch [2] is very fast, but gives only a piece of the full space of modular forms. The power of the modular symbols approach was demonstrated by Cremona in his book [6] in which he systematically computes a large table of invariants of all elliptic curves of conductor up to 1000 (his online tables [7] go well beyond $100,000$).

Though the above methods are each beautiful and well suited to certain applications, we will only discuss the modular symbols method further, as it has many advantages. We will primarily discuss the theory in this summary paper, leaving an explicit description of the objects involved for other papers. Nonetheless, there is a definite gap between the theory on the one hand, and an efficient running machine implementation on the other. To implement the algorithms hinted at below requires making absolutely everything completely explicit, then finding intelligent and efficient ways of performing the necessary manipulations. This is a nontrivial and tedious task, with room for error at every step. Fortunately, Sage [24] has extensive capabilities for computing with modular forms and includes Cremona's programs; we will give a few examples below. See also the author's Magma [4] package for computing with modular forms and modular symbols.

In this paper we will focus exclusively on the case of weight-2 modular forms for $\Gamma_0(N)$. The methods explained here extend to modular forms of integer weight greater than 2; for more details see the author's book [23] and Merel's paper [16].

Section 1 contains a brief summary of basic facts about modular forms, Hecke operators, and integral homology. Section 2 introduces modular symbols, and describes how to compute with them. Section 3 outlines an algorithm for constructing cusp forms using modular symbols in conjunction with Atkin-Lehner theory.

This paper assumes some familiarity with algebraic curves, Riemann surfaces, and homology groups of compact surfaces. A few basic facts about modular forms are recalled, but only briefly. In particular, only a roundabout attempt is made to motivate why one might be interested in modular forms; for this, see many of the references in the bibliography. No prior exposure to modular symbols is assumed.

1 Modular forms and Hecke operators

All of the objects we will consider arise from the modular group $\mathrm{SL}_2(\mathbf{Z})$ of two-by-two integer matrices with determinant equal to one. This group acts via linear fractional transformations on the complex upper half plane $\mathfrak{h}$, and also on the extended upper half plane

$$\mathfrak{h}^* = \mathfrak{h} \cup \mathbf{P}^1(\mathbf{Q}) = \mathfrak{h} \cup \mathbf{Q} \cup \{\infty\}.$$

See [21, §1.3–1.5] for a careful description of the topology on $\mathfrak{h}^*$. A basis of neighborhoods for $\alpha \in \mathbf{Q}$ is given by the sets $\{\alpha\} \cup D$, where D is a disc in $\mathfrak{h}$ that is tangent to the real line at α. Let N be a positive integer and consider the group $\Gamma_0(N)$ of matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbf{Z})$ such that $N \mid c$. This group acts on $\mathfrak{h}^*$ by linear fractional transformations, and the quotient $\Gamma_0(N)\backslash\mathfrak{h}^*$ is a Riemann surface, which we denote by $X_0(N)$. Shimura showed in [21, §6.7] that $X_0(N)$ has a canonical structure of algebraic curve over $\mathbf{Q}$.

A *cusp form* is a function f on $\mathfrak{h}$ such that $f(z)dz$ is a holomorphic differential on $X_0(N)$. Equivalently, a cusp form is a holomorphic function f on $\mathfrak{h}$ such that

(a) the expression $f(z)dz$ is invariant under replacing z by $\gamma(z)$ for each $\gamma \in \Gamma_0(N)$, and

(b) $f(z)$ is holomorphic at each element of $\mathbf{P}^1(\mathbf{Q})$, and moreover $f(z)$ tends to 0 as z tends to any element of $\mathbf{P}^1(\mathbf{Q})$.

The space of cusp forms on $\Gamma_0(N)$ is a finite dimensional complex vector space, of dimension equal to the genus g of $X_0(N)$. Viewed topologically, as a 2-dimensional real manifold, $X_0(N)(\mathbf{C})$ is a g-holed torus.

Condition (b) in the definition of $f(z)$ means that $f(z)$ has a Fourier expansion about each element of $\mathbf{P}^1(\mathbf{Q})$. Thus, at ∞ we have

$$\begin{aligned} f(z) &= a_1 e^{2\pi i z} + a_2 e^{2\pi i 2z} + a_3 e^{2\pi i 3z} + \cdots \\ &= a_1 q + a_2 q^2 + a_3 q^3 + \cdots , \end{aligned}$$

where, for brevity, we write $q = q(z) = e^{2\pi i z}$.

Example 1.1. Let E be the elliptic curve defined by the equation $y^2 + xy = x^3 + x^2 - 4x - 5$. For $p \neq 3, 13$, let $a_p = p + 1 - \#\tilde{E}(\mathbf{F}_p)$, where $\tilde{E}$ is the reduction of E mod p, and let $a_3 = -11$, $a_{13} = 1$. For n composite, define a_n using the relations at the end of Section 3. Then

$$f = q + a_2q^2 + a_3q^3 + a_4q^4 + a_5q^5 + \cdots = q + q^2 - 11q^3 + 2q^5 + \cdots$$

is the q-expansion of a modular form on $\Gamma_0(39)$. The Shimura-Taniyama conjecture, which is now a theorem (see [5]) asserts that any q-expansion constructed as above from an elliptic curve over $\mathbf{Q}$ is a modular form. We define the above elliptic curve and compute the associated modular form f using Sage as follows:

```
sage: E = EllipticCurve([1,1,0,-4,-5]); E
Elliptic Curve defined by y^2 + x*y  = x^3 + x^2 - 4*x - 5
over Rational Field
sage: E.q_eigenform(10)
q + q^2 - q^3 - q^4 + 2*q^5 - q^6 - 4*q^7 - 3*q^8 + q^9 + O(q^10)
```

The Hecke operators are a family of *commuting* endomorphisms of $S_2(N)$, which are defined as follows. The complex points of the open subcurve $Y_0(N) = \Gamma_0(N)\backslash\mathfrak{h}$ are in bijection with pairs (E, C), where E is an elliptic curve over $\mathbf{C}$ and C is a cyclic subgroup of $E(\mathbf{C})$ of order N. If $p \nmid N$ then there are two natural maps π_1 and π_2 from $Y_0(pN)$ to $Y_0(N)$; the first, π_1, sends (E, C) to (E, C'), where C' is the unique cyclic subgroup of C of order N, and the second, π_2, sends a point $(E, C) \in Y_0(N)(\mathbf{C})$ to $(E/D, C/D)$, where D is the unique cyclic subgroup of C of order p. These maps extend in a unique way to maps from $X_0(pN)$ to $X_0(N)$:

$$\begin{tikzcd} & X_0(pN) \arrow[dl, "\pi_2"'] \arrow[dr, "\pi_1"] & \\ X_0(N) & & X_0(N). \end{tikzcd}$$

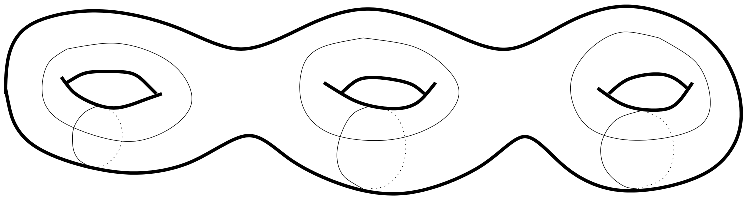
The pth *Hecke operator* T_p is $(\pi_1)_* \circ (\pi_2)^*$; it acts on most objects attached to $X_0(N)$, such as divisors and cusp forms. There is a Hecke operator T_n for every positive integer n, but we will not need to consider those with n composite.

Example 1.2. There is a basis of $S_2(39)$ so that

$$T_2 = \begin{pmatrix} 0 & 2 & -1 \\ 1 & -2 & 1 \\ 0 & -1 & 1 \end{pmatrix} \text{ and } T_5 = \begin{pmatrix} 1 & -1 & -1 \\ -2 & 2 & -2 \\ -3 & -1 & -1 \end{pmatrix}.$$

Notice that these matrices commute, and that 1 is an eigenvalue of T_2, and 2 is an eigenvalue of T_5. We compute each of the above matrices and verify that they commute using Sage as follows:

```
sage: S = CuspForms(39)
sage: T2 = S.hecke_matrix(2); T2
```



$$H_1(X_0(39), \mathbf{Z}) \cong \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z}$$

Figure 1: The homology of $X_0(39)$.

```
[ 0  2 -1]
[ 1 -2  1]
[ 0 -1  1]
sage: T5 = S.hecke_matrix(5); T5
[ 1 -1 -1]
[-2  2 -2]
[-3 -1 -1]
sage: T2*T5 == T5*T2
True
```

The first homology group $H_1(X_0(N), \mathbf{Z})$ is the group of singular 1-cycles modulo homology relations. Recall that topologically $X_0(N)$ is a g-holed torus, where g is the genus of $X_0(N)$. The group $H_1(X_0(N), \mathbf{Z})$ is thus a free abelian group of rank $2g$ (see, e.g., [10, Ex. 19.30]), with two generators corresponding to each hole, as illustrated in the case $N = 39$ in Diagram 1.

The Hecke operators T_p act on $H_1(X_0(N), \mathbf{Z})$, and integration defines a nondegenerate Hecke-equivariant pairing

$$\langle\, , \rangle : S_2(N) \times H_1(X_0(N), \mathbf{Z}) \to \mathbf{C}.$$

Explicitly, for a path x,

$$\langle f, x\rangle = 2\pi i \int_x f(z)dz,$$

where the integral may be viewed as a complex line integral along an appropriate piece of the preimage of x in the upper half plane. The pairing is Hecke equivariant in the sense that for every prime p, we have $\langle fT_p, x\rangle = \langle f, T_p x\rangle$. As we will see, modular symbols allow us to make explicit the action of the Hecke operators on $H_1(X_0(N), \mathbf{Z})$; the above pairing then translates this into a wealth of information about cusp forms.

For a more detailed survey of the basic facts about modular curves and modular forms, we urge the reader to consult the book [9] by Diamond and Shurman along with Diamond and Im's survey paper [8]. For a discussion of how to draw a picture of the ring generated by the Hecke operators, see [19, §3.8].

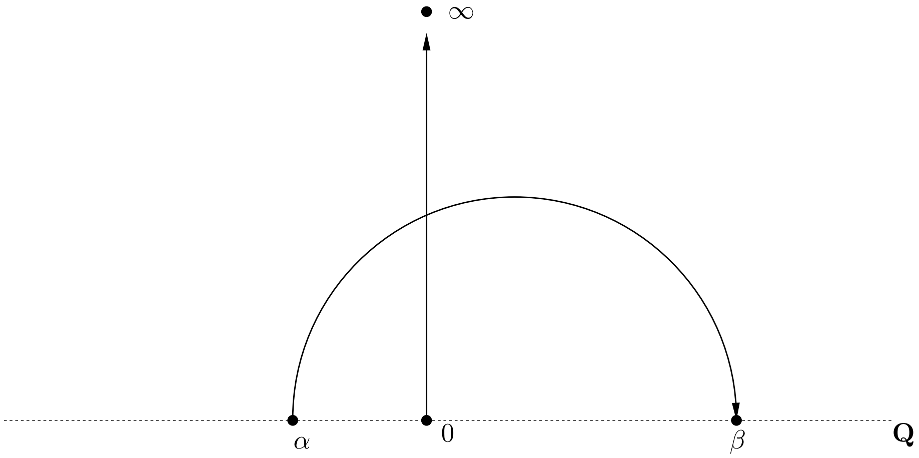


Figure 2: The modular symbols $\{\alpha, \beta\}$ and $\{0, \infty\}$.

2 Modular symbols

The modular symbols formalism provides a presentation of $H_1(X_0(N), \mathbf{Z})$ in terms of paths between elements of $\mathbf{P}^1(\mathbf{Q})$. Furthermore, a trick due to Manin gives an explicit finite list of generators and relations for the space of modular symbols.

The *modular symbol* defined by a pair $\alpha, \beta \in \mathbf{P}^1(\mathbf{Q})$ is denoted $\{\alpha, \beta\}$. As illustrated in Figure 2, this modular symbol should be viewed as the homology class, relative to the cusps, of a geodesic path from α to β in $\mathfrak{h}^*$. The homology group relative to the cusps is a slight enlargement of the usual homology group, in that we allow paths with endpoints in $\mathbf{P}^1(\mathbf{Q})$ instead of restricting to closed loops.

Motivated by this picture, we declare that modular symbols satisfy the following homology relations: if $\alpha, \beta, \gamma \in \mathbf{Q} \cup \{\infty\}$, then

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0.$$

Furthermore, we quotient out by any torsion, so, e.g., $\{\alpha, \alpha\} = 0$ and $\{\alpha, \beta\} = -\{\beta, \alpha\}$.

Denote by $\boldsymbol{\mathcal{M}}_2$ the free abelian group with basis the set of symbols $\{\alpha, \beta\}$ modulo the three-term homology relations above and modulo any torsion. There is a left action of $\mathrm{GL}_2(\mathbf{Q})$ on $\boldsymbol{\mathcal{M}}_2$, whereby a matrix g acts by

$$g\{\alpha, \beta\} = \{g(\alpha), g(\beta)\},$$

and g acts on α and β by a linear fractional transformation. The space $\boldsymbol{\mathcal{M}}_2(N)$ of *modular symbols for* $\Gamma_0(N)$ is the quotient of $\boldsymbol{\mathcal{M}}_2$ by the submodule generated by the infinitely many elements of the form $x - g(x)$, for x in $\boldsymbol{\mathcal{M}}_2$ and g in $\Gamma_0(N)$, and modulo any torsion. A *modular symbol for* $\Gamma_0(N)$ is an element of this space. We frequently denote the equivalence class that defines a modular symbol by giving a representative element.

In [14], Manin proved that there is a natural injection $H_1(X_0(N),\mathbf{Z}) \to \boldsymbol{\mathcal{M}}_2(N)$. The image of $H_1(X_0(N),\mathbf{Z})$ in $\boldsymbol{\mathcal{M}}_2(N)$ can be identified as follows. Let $\boldsymbol{\mathcal{B}}_2(N)$ denote the free abelian group whose basis is the finite set $\Gamma_0(N)\backslash\mathbf{P}^1(\mathbf{Q})$. The *boundary map* $\delta : \boldsymbol{\mathcal{M}}_2(N) \to \boldsymbol{\mathcal{B}}_2(N)$ sends $\{\alpha,\beta\}$ to $[\beta]-[\alpha]$, where $[\beta]$ denotes the basis element of $\boldsymbol{\mathcal{B}}_2(N)$ corresponding to $\beta \in \mathbf{P}^1(\mathbf{Q})$. The kernel $\boldsymbol{\mathcal{S}}_2(N)$ of δ is the subspace of *cuspidal* modular symbols. An element of $\boldsymbol{\mathcal{S}}_2(N)$ can be thought of as a linear combination of paths in $\mathfrak{h}^*$ whose endpoints are cusps, and whose images in $X_0(N)$ are a linear combination of loops. We thus obtain a map $\varphi : \boldsymbol{\mathcal{S}}_2(N) \to H_1(X_0(N),\mathbf{Z})$.

Theorem 2.1. *The map φ given above defines a canonical isomorphism*

$$\boldsymbol{\mathcal{S}}_2(N) \cong H_1(X_0(N),\mathbf{Z}).$$

2.1 Manin's trick

In this section, we describe a trick of Manin that shows that the space of modular symbols can be computed.

By reducing modulo N, one sees that the group $\Gamma_0(N)$ has finite index in $\mathrm{SL}_2(\mathbf{Z})$. Let $r_0, r_1, \ldots, r_m$ be distinct right coset representatives for $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbf{Z})$, so that

$$\mathrm{SL}_2(\mathbf{Z}) = \Gamma_0(N)r_o \cup \Gamma_0(N)r_1 \cup \cdots \cup \Gamma_0(N)r_m,$$

where the union is disjoint. For example, when N is prime, a list of coset representatives is

$$\begin{pmatrix}1&0\\0&1\end{pmatrix}, \begin{pmatrix}1&0\\1&1\end{pmatrix}, \begin{pmatrix}1&0\\2&1\end{pmatrix}, \begin{pmatrix}1&0\\3&1\end{pmatrix}, \ldots, \begin{pmatrix}1&0\\N-1&1\end{pmatrix}, \begin{pmatrix}0&-1\\1&0\end{pmatrix}.$$

In general, the right cosets of $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbf{Z})$ are in bijection with the elements of $\mathbf{P}^1(\mathbf{Z}/N\mathbf{Z})$ (see [6, §2.2] for complete details).

The following trick of Manin (see [14, §1.5] and [6, §2.1.6]) allows us to write every modular symbol as a $\mathbf{Z}$-linear combination of symbols of the form $r_i\{0,\infty\}$. In particular, the finitely many symbols $r_i\{0,\infty\}$ generate $\boldsymbol{\mathcal{M}}_2(N)$.

Because of the relation $\{\alpha,\beta\} = \{0,\beta\} - \{0,\alpha\}$, it suffices to consider modular symbols of the form $\{0, b/a\}$, where the rational number b/a is in lowest terms. Expand b/a as a continued fraction and consider the successive convergents in lowest terms:

$$\frac{b_{-2}}{a_{-2}} = \frac{0}{1}, \quad \frac{b_{-1}}{a_{-1}} = \frac{1}{0}, \quad \frac{b_0}{a_0} = \frac{b_0}{1}, \ldots, \quad \frac{b_{n-1}}{a_{n-1}}, \quad \frac{b_n}{a_n} = \frac{b}{a}$$

where the first two are added formally. Then

$$b_k a_{k-1} - b_{k-1}a_k = (-1)^{k-1},$$

so that

$$g_k = \begin{pmatrix} b_k & (-1)^{k-1}b_{k-1} \\ a_k & (-1)^{k-1}a_{k-1}\end{pmatrix} \in \mathrm{SL}_2(\mathbf{Z}).$$

Hence

$$\left\{\frac{b_{k-1}}{a_{k-1}}, \frac{b_k}{a_k}\right\} = g_k\{0,\infty\} = r_i\{0,\infty\},$$

for some i, is of the required special form.

Example 2.2. Let $N = 11$, and consider the modular symbol $\{0, 4/7\}$. We have

$$\frac{4}{7} = 0 + \frac{1}{1+\frac{1}{1+\frac{1}{3}}},$$

so the partial convergents are

$$\frac{b_{-2}}{a_{-2}} = \frac{0}{1}, \quad \frac{b_{-1}}{a_{-1}} = \frac{1}{0}, \quad \frac{b_0}{a_0} = \frac{0}{1}, \quad \frac{b_1}{a_1} = \frac{1}{1}, \quad \frac{b_2}{a_2} = \frac{1}{2}, \quad \frac{b_3}{a_3} = \frac{4}{7}.$$

Thus

$$\begin{aligned}\{0,4/7\} &= \{0,\infty\} + \{\infty,0\} + \{0,1\} + \{1,1/2\} + \{1/2,4/7\} \\ &= \begin{pmatrix}1 & -1\\ 2 & -1\end{pmatrix}\{0,\infty\} + \begin{pmatrix}4 & 1\\ 7 & 2\end{pmatrix}\{0,\infty\} \\ &= 2\cdot\left[\begin{pmatrix}1 & 4\\ 1 & 5\end{pmatrix}\{0,\infty\}\right]\end{aligned}$$

2.2 Manin symbols

As above, fix coset representatives $r_0, \ldots, r_m$ for $\Gamma_0(N)$ in $\mathrm{SL}_2(\mathbf{Z})$. Denote the modular symbol $r_i\{0,\infty\}$ by $[r_i]$. The symbols $[r_0], \ldots, [r_m]$ are called *Manin symbols*, and they are equipped with a right action of $\mathrm{SL}_2(\mathbf{Z})$, which is given by $[r_i]g = [r_j]$, where $\Gamma_0(N)r_j = \Gamma_0(N)r_ig$. Recall that $\mathrm{SL}_2(\mathbf{Z})$ is generated by the two matrices $\sigma = \left(\begin{smallmatrix}0 & -1\\ 1 & 0\end{smallmatrix}\right)$ and $\tau = \left(\begin{smallmatrix}1 & -1\\ 1 & 0\end{smallmatrix}\right)$ (see Theorem 2 of [20, VII.1.2]).

Theorem 2.3 (Manin)**.** *The Manin symbols* $[r_0], \ldots, [r_m]$ *satisfy the following relations:*

$$[r_i] + [r_i]\sigma = 0$$
$$[r_i] + [r_i]\tau + [r_i]\tau^2 = 0.$$

Furthermore, these relations generate all relations (modulo torsion relations).

This theorem, which is proved in [14, §1.7], provides a finite presentation for the space of modular symbols.

2.3 Hecke operators on modular symbols

When p is a prime not dividing N, define

$$T_p\{\alpha,\beta\} = \begin{pmatrix}p & 0\\ 0 & 1\end{pmatrix}\{\alpha,\beta\} + \sum_{r \bmod p}\begin{pmatrix}1 & r\\ 0 & p\end{pmatrix}\{\alpha,\beta\}.$$

As mentioned before, this definition is compatible with the integration pairing $\langle\, ,\, \rangle$ of Section 1, in the sense that $\langle fT_p, x\rangle = \langle f, T_p x\rangle$. When $p \mid N$, the definition is the same, except that the matrix $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ is dropped.

For example, when $N = 11$ we have

$$\begin{aligned} T_2\{0, 1/5\} &= \{0, 2/5\} + \{0, 1/10\} + \{1/2, 3/5\} \\ &= -2\{0, 1/5\}. \end{aligned}$$

In [16], L. Merel gives a description of the action of T_p directly on Manin symbols $[r_i]$ (see also, [6, §2.4]). For example, when $p = 2$ and N is odd, we have

$$T_2([r_i]) = [r_i]\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} + [r_i]\begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} + [r_i]\begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix} + [r_i]\begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix}.$$

3 Computing the space of modular forms

In this section we describe how to use modular symbols to construct a basis of $S_2(N)$ consisting of modular forms that are eigenvectors for every element of the ring $\mathbf{T}'$ generated by the Hecke operator T_p, with $p \nmid N$. Such eigenvectors are called *eigenforms*.

Suppose M is a positive integer that divides N. As explained in [13, VIII.1–2], for each divisor d of N/M there is a natural *degeneracy map* $\beta_{M,d} : S_2(M) \to S_2(N)$ given by $\beta_{M,d}(f(q)) = f(q^d)$. The *new subspace* of $S_2(N)$, denoted $S_2(N)^{\text{new}}$, is the orthogonal complement with respect to the Petersson inner product of the images of all maps $\beta_{M,d}$, with M and d as above.

The theory of Atkin and Lehner [1] asserts that, as a $\mathbf{T}'$-module, $S_2(N)$ is built up as follows:

$$S_2(N) \quad = \bigoplus_{M|N,\ d|N/M} \beta_{M,d}(S_2(M)^{\text{new}}).$$

To compute $S_2(N)$ it thus suffices to compute $S_2(M)^{\text{new}}$ for each positive divisor M of N.

We now turn to the problem of computing $S_2(N)^{\text{new}}$. Atkin and Lehner [1] also proved that $S_2(N)^{\text{new}}$ is spanned by eigenforms, each of which occurs with multiplicity one in $S_2(N)^{\text{new}}$. Moreover, if $f \in S_2(N)^{\text{new}}$ is an eigenform then the coefficient of q in the q-expansion of f is nonzero, so it is possible to normalize f so that coefficient of q is 1. With f so normalized, if $T_p(f) = a_p f$, then the pth Fourier coefficient of f is a_p. If $f = \sum_{n=1}^{\infty} a_n q^n$ is a normalized eigenvector for all T_p, then the a_n, with n composite, are determined by the a_p, with p prime, by the following formulas: $a_{nm} = a_n a_m$ when n and m are relatively prime, and $a_{p^r} = a_{p^{r-1}} a_p - p a_{p^{r-2}}$ for $p \nmid N$ prime. When $p \mid N$, $a_{p^r} = a_p^r$. We conclude that in order to compute $S_2(N)^{\text{new}}$, it suffices to compute all systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$ of the Hecke operators $T_2, T_3, T_5, \ldots$ acting on $S_2(N)^{\text{new}}$. Given a system of eigenvalues, the corresponding eigenform is $f = \sum_{n=1}^{\infty} a_n q^n$, where the a_n, for n composite, are determined by the recurrence given above.

In light of the pairing $\langle\, ,\, \rangle$ introduced in Section 1, computing the above systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$ amounts to computing the systems of eigenvalues of the Hecke operators T_p on the subspace V of $\boldsymbol{\mathcal{S}}_2(N)$ that corresponds to the new subspace of $S_2(N)$. For each proper divisor M of N and each divisors d of N/M, let $\phi_{M,d} : \boldsymbol{\mathcal{S}}_2(N) \to \boldsymbol{\mathcal{S}}_2(M)$ be the map sending x to $\left(\begin{smallmatrix} t & 0 \\ 0 & 1 \end{smallmatrix}\right) x$. Then V is the intersection of the kernels of all maps $\phi_{M,d}$.

The computation of the systems of eigenvalues of a collection of commuting diagonalizable endomorphisms involves standard linear algebra techniques, such as computation of characteristic polynomials and kernels of matrices. There are, however, several tricks that greatly speed up this process, some of which are described in [22, §3.5.4].

Example 3.1. All forms in $S_2(39)$ are new. Up to Galois conjugacy, the eigenvalues of the Hecke operators T_2, T_3, T_5, and T_7 on $\boldsymbol{\mathcal{S}}_2(39)$ are $\{1, -1, 2, -4\}$ and $\{a, 1, -2a - 2, 2a+2\}$, where $a^2+2a-1 = 0$. (Note that these eigenvalues occur with multiplicity two.) Thus $S_2(39)$ has dimension 3, and is spanned by

$$f_1 = q + q^2 - q^3 - q^4 + 2q^5 - q^6 - 4q^7 + \cdots ,$$

$$f_2 = q + aq^2 + q^3 + (-2a - 1)q^4 + (-2a - 2)q^5 + aq^6 + (2a + 2)q^7 + \cdots ,$$

and the Galois conjugate of f_2. We compute f_1 and f_2 using Sage as follows:

```
sage: CuspForms(39).newforms('a')
[q + q^2 - q^3 - q^4 + 2*q^5 + O(q^6),
 q + a1*q^2 + q^3 + (-2*a1 - 1)*q^4 + (-2*a1 - 2)*q^5 + O(q^6)]
```

3.1 Summary

To compute the q-expansion, to some precision, of each eigenforms in $S_2(N)$, we use the degeneracy maps so that we only have to solve the problem for $S_2(N)^{\mathrm{new}}$. Here, using modular symbols we compute the systems of eigenvalues $\{a_2, a_3, a_5, \ldots\}$, then write down each of the corresponding eigenforms $q + a_2q^2 + a_3q^3 + \cdots$.

9 The field generated by the points of small prime order on an elliptic curve, with L. Merel

The field generated by the points of small prime order on an elliptic curve

Loïc Merel and William A. Stein

Introduction

Let $\bar{\mathbf{Q}}$ be an algebraic closure of $\mathbf{Q}$, and for any prime number p, denote by $\mathbf{Q}(\mu_p)$ the cyclotomic subfield of $\bar{\mathbf{Q}}$ generated by the pth roots of unity.

Theorem . — *Let p be a prime. If there exists an elliptic curve E over $\mathbf{Q}(\mu_p)$ such that the points of order p of $E(\bar{\mathbf{Q}})$ are all $\mathbf{Q}(\mu_p)$-rational, then $p = 2, 3, 5, 13$ or $p > 1000$.*

The case $p = 7$ was treated by Emmanuel Halberstadt. The part of the theorem that concerns the case $p \equiv 3 \pmod 4$ is given in [3]. In this paper, we give the details that permit our treating the more difficult case in which $p \equiv 1 \pmod 4$. We treat this last case with the aid of Proposition 2 below, which is not present in *loc. cit.*. The case $p = 13$ is currently under investigation by Marusia Rebolledo, as part of her Ph.D. thesis.

1. Counterexamples define points on $X_0(p)(\mathbf{Q}(\sqrt{p}))$

First we recall some of the results and notation of [3]. Let $S_2(\Gamma_0(p))$ denote the space of cusp forms of weight 2 for the congruence subgroup $\Gamma_0(p)$. Denote by $\mathbf{T}$ the subring of $\operatorname{End} S_2(\Gamma_0(p))$ generated by the Hecke operators T_n for all integers n. Let $f \in S_2(\Gamma_0(p))$ have q-expansion $\sum_{n=1}^{\infty} a_n q^n$. When χ is a Dirichlet character, denote by $L(f, \chi, s)$ the entire function which extends the Dirichlet series $\sum_{n=1}^{\infty} a_n \chi(n)/n^s$.

Let S be the set of isomorphism classes of supersingular elliptic curves in characteristic p. Denote by Δ_S the group formed by the divisors of degree 0 with support on S. It is equipped with a structure of $\mathbf{T}$-module (induced, for example, from the action of the Hecke correspondences on the fiber at p of the regular minimal model of $X_0(p)$ over $\mathbf{Z}$).

Let $j \in \bar{\mathbf{F}}_p - J_S$, where J_S denotes the set of supersingular modular invariants. We denote by ι_j the homomorphism of groups $\Delta_S \longrightarrow \bar{\mathbf{F}}_p$ that associates to $\sum_E n_E[E]$ the quantity $\sum_E n_E/(j - j(E))$, where $j(E)$ denotes the modular invariant of E.

One says that an element $j \in \mathbf{F}_p$ is *anomalous* if there exists an elliptic curve over $\mathbf{F}_p$ with modular invariant j that possesses an $\mathbf{F}_p$-rational point of order p (then necessarily $j \notin J_S$).

Let p be a prime that is congruent to 1 modulo 4. In the following proposition we prove, under a hypothesis on p, that if E is an elliptic curve over $\mathbf{Q}(\mu_p)$ all of whose torsion is $\mathbf{Q}(\mu_p)$-rational, then for each subgroup $C \subset E(\bar{\mathbf{Q}})$ of order p, the point (E, C) on $X_0(p)$ is defined over $\mathbf{Q}(\sqrt{p})$. As we will see in Proposition 2, this $\mathbf{Q}(\sqrt{p})$-rationality conclusion is contrary to fact, from which we conclude that such elliptic curves E do not exist when the hypothesis on p is satisfied. In Section 3 we verify this hypothesis for $p = 11$ and $13 < p < 1000$.

Proposition 1. — *Suppose that p is congruent to* 1 *modulo* 4*. Suppose that for all anomalous $j \in \mathbf{F}_p$ and all non-quadratic Dirichlet characters $\chi\colon (\mathbf{Z}/p\mathbf{Z})^* \longrightarrow \mathbf{C}^*$, there exists $t_\chi \in \mathbf{T}$ and $\delta \in \Delta_S$ such that $L(f, \chi, 1) \neq 0$ for every newform $f \in t_\chi S_2(\Gamma_0(p))$ and $\iota_j(t_\chi \delta) \neq 0$.*

Let E be an elliptic curve over $\mathbf{Q}(\mu_p)$, such that the points of order p of $E(\bar{\mathbf{Q}})$ are all $\mathbf{Q}(\mu_p)$-rational. Then for all subgroups C of order p of $E(\bar{\mathbf{Q}})$, there exists an elliptic curve E_C over $\mathbf{Q}(\sqrt{p})$ equipped with a $\mathbf{Q}(\sqrt{p})$-rational subgroup D_C of order p, and the pairs (E, C) and (E_C, D_C) are $\bar{\mathbf{Q}}$-isomorphic.

Proof. — We prove the proposition using the results of [3]. The hypothesis $\iota_j(t_\chi \delta) \neq 0$ forces $t_\chi \notin p\mathbf{T}$ and, *a fortiori*, $t_\chi \neq 0$; in addition, the non-vanishing hypothesis on the L-series forces the hypothesis $H_p(\chi)$ of *loc. cit.*, introduction.

By assumption, hypothesis $H_p(\chi)$ is satisfied for all non-quadratic Dirichlet characters χ of conductor p. Thus Corollary 3 of Proposition 6 of *loc. cit.* implies that E has potentially good reduction at the prime ideal $\mathcal{P}$ of $\mathbf{Z}[\mu_p]$ that lies above p.

Denote by j the modular invariant of the fiber at $\mathcal{P}$ of the Néron model of E. According to the corollary of Proposition 15 of *loc. cit.*, j is anomalous.

Let C be a subgroup of $E(\bar{\mathbf{Q}})$ of order p. By assumption E is an elliptic curve over $\mathbf{Q}(\mu_p)$ whose points of order p are all $\mathbf{Q}(\mu_p)$-rational, so the pair (E, C) defines a $\mathbf{Q}(\mu_p)$-rational point P of the modular curve $X_0(p)$.

Consider the morphism $\phi_\chi = \phi_{t_\chi} : X_0(p) \to J_0(p)$ obtained by composing the standard embedding of $X_0(p)$ into $J_0(p)$ with t_χ. As in section 1.3 of *loc. cit.*, ϕ_χ extends to a map from the minimal regular model of $X_0(p)$ to the Néron model of $J_0(p)$. When $\iota_j(t_\chi \delta) \neq 0$, this map is a formal immersion at the point $P_{/\mathbf{F}_p}$, according to *loc. cit.*, Proposition 4. The hypothesis that $L(f, \chi, 1) \neq 0$ for every newform $f \in t_\chi S_2(\Gamma_0(p))$, translates into $L(t_\chi J_0(p), \chi, 1) \neq 0$, which in turn implies that the χ-isotypical component of $t_\chi J_0(p)(\mathbf{Q}(\mu_p))$ is finite (this is Kato's theorem, see the discussion in section 1.5 of *loc. cit.*). We can then apply Corollary 1 of Proposition 6 of *loc. cit.*. This proves that P is $\mathbf{Q}(\sqrt{p})$-rational, which translates into the conclusion of Proposition 1.

Remark 1: Proposition 1 is true even under the weaker hypothesis that t_χ lies in $\mathbf{T} \otimes \mathbf{Z}[\chi]$, which acts $\mathbf{Z}[\chi]$-linearly on modular forms.

2. Elliptic curves and quadratic fields

PROPOSITION 2. — *Let p be a prime number > 5 and congruent to 1 modulo 4. Let E be an elliptic curve over $\bar{\mathbf{Q}}$. There exists a subgroup $C \subset E(\bar{\mathbf{Q}})$ of order p such that (E, C) can not be defined over $\mathbf{Q}(\sqrt{p})$.*

Proof. — We procede by contradiction, i.e., we assume that for all cyclic subgroups C of order p of $E(\bar{\mathbf{Q}})$, the pair (E, C) can be defined over $\mathbf{Q}(\sqrt{p})$. We choose such a pair (E_0, C_0) over $\mathbf{Q}(\sqrt{p})$.

Assume first that all twists of E are quadratic, i.e. that $j(E)$ is neither 0 nor 1728. We show that the group $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$ acts by scalars on the $\mathbf{F}_p$-vector space $E_0(\bar{\mathbf{Q}})[p]$. For this it suffices to show that all subgroups of order p of $E_0(\bar{\mathbf{Q}})[p]$ are stable by $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$.

Suppose C_1 is a cyclic subgroup of order p of $E_0(\bar{\mathbf{Q}})[p]$. By assumption, there exists a quadratic twist E_1 of E_0 and a cyclic subgroup C_1' of $E_1(\bar{\mathbf{Q}})[p]$ that is defined over $\mathbf{Q}(\sqrt{p})$, such that the image of C_1 by the isomorphism $E_0 \simeq E_1$ is C_1'. Since $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$ leaves C_1' stable and the action of $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$ on $E_0(\bar{\mathbf{Q}})[p]$ is a quadratic twist of the action on $E_1(\bar{\mathbf{Q}})[p]$, we see that $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$ leaves C_1 stable. Thus $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$ fixes all lines in $E_0(\bar{\mathbf{Q}})[p]$, and hence acts by scalars. Denote by α the corresponding character of $\mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p}))$.

Because of the Weil pairing, α^2 coincides with the cyclotomic character modulo p, and it factors through $\mathrm{Gal}(\mathbf{Q}(\mu_p)/\mathbf{Q}(\sqrt{p}))$. But, when $p \equiv 1 \pmod 4$, the group $\mathrm{Gal}(\mathbf{Q}(\mu_p)/\mathbf{Q}(\sqrt{p}))$ is of even order, and the characters modulo p form a group generated by the reduction modulo p of the cyclotomic character, which, therefore, can not be a square.

Next suppose that $j(E) = 0$ or $j(E) = 1728$. Indeed, in these two cases E has complex multiplication by an order of $K = \mathbf{Q}[\sqrt{-3}]$ or $\mathbf{Q}[\sqrt{-1}]$. Let $d_K = 3$ or $d_K = 2$ in these two cases respectively. Let C be a subgroup of order p of $E(\bar{\mathbf{Q}})$. Consider the map $\rho_0 : \mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}(\sqrt{p})) \longrightarrow \mathrm{Aut}\, E_0(\bar{\mathbf{Q}})[p]$. Since E has complex multiplication, the image of ρ_0 has no element of order p. Therefore, there are at least two subgroups, including C_0, of order p of $E(\bar{\mathbf{Q}})$ stable under the image of ρ_0. Call the other subgroup C_1. Let C_2 be a subgroup of order p of $E(\bar{\mathbf{Q}})$ which is distinct from C_0 and C_1. The pair (E, C_2) can be defined over $\mathbf{Q}(\sqrt{p})$. Therefore, there exists an extension field K_2 of $\mathbf{Q}(\sqrt{p})$, whose degree d_2 divides $2d_K$, such that the image of the restriction of ρ_0 to $\mathrm{Gal}(\bar{\mathbf{Q}}/K_2)$ leaves stable three distinct subgroups of order p of $E_0(\bar{\mathbf{Q}})$, and therefore consists only of scalars. If $d_2 \leq 2$, one concludes as in the cases where $j(E) \neq 0$ and $j(E) \neq 1728$. We suppose now that $d_2 > 2$. The projective image of ρ_0 has order d_K.

Since E is an elliptic curve over $\bar{\mathbf{Q}}$ with complex multiplication by a field of class number one, there is a model for E that is defined over $\mathbf{Q}$. Consider the map $\rho : \mathrm{Gal}(\bar{\mathbf{Q}}/\mathbf{Q}) \longrightarrow \mathrm{Aut}\, E(\bar{\mathbf{Q}})[p]$. By the theory of complex multiplication, the projective image of ρ has order $2(p+1)$ or $2(p-1)$. There exists a field extension L of degree dividing d_K of $\mathbf{Q}(\sqrt{p})$ such that the restrictions to $\mathrm{Gal}(\bar{\mathbf{Q}}/L)$ of the projective images of ρ and ρ_0 coincide. Therefore one has $(p-1)|d_K^2$ or $(p+1)|d_K^2$. This imposes $p = 5$ and $d_K = 2$.

3. Verification of the hypothesis of Proposition 1 Let p be a prime number. In this section we explain how we used a computer to verify that the second hypothesis of Proposition 1 are satisfied for $p = 11$ and $13 < p < 1000$. (In the present paper, this verification is only required for p that are congruent to 1 modulo 4.)

We first list the anomalous j-invariants $j \in \mathbf{F}_p$. Since p is fairly small in the range of our computations, we created this list by simply enumerating all of the elliptic curves over $\mathbf{F}_p$ and counting the number of points on each curve. For example, when $p = 31$ the anomalous j-invariants are $j = 10, 14$.

Let $\chi : \mathbf{Z}/p\mathbf{Z} \longrightarrow \mathbf{C}$ be a non-quadratic Dirichlet character, and denote by $\mathbf{Z}[\chi]$ the subring of $\mathbf{Q}(\zeta_{p-1})$ generated by the image of χ. Denote by $S_2(\Gamma_0(p); \mathbf{Z})$ the set of modular forms $f \in S_2(\Gamma_0(p))$ whose Fourier expansion at the cusp ∞ lies in $\mathbf{Z}[[q]]$.

We study the $\mathbf{T}$-modules $\mathbf{T}$, Δ_S, and $S_2(\Gamma_0(p); \mathbf{Z})$. After extension of scalars to $\mathbf{Q}$, these are $\mathbf{T} \otimes \mathbf{Q}$-modules that are free of rank 1, of which the irreducible sub-$\mathbf{T} \otimes \mathbf{Q}$ modules are the annihilators of the minimal prime ideals of $\mathbf{T}$. We compute a list of the minimal prime ideals of $\mathbf{T}$ by computing appropriate kernels and characteristic polynomials of Hecke operators of small index on Δ_S, which we find using the graph method of Mestre and Oesterlé [4].

Having computed the minimal prime ideals of $\mathbf{T}$, we verify that some nontrivial ideal $\mathcal{I}$ of $\mathbf{T}$ (always a minimal prime ideal in the range of our computations) simultaneously satisfies the following three conditions:

1) For each anomalous j-invariant, there exists $x \in \Delta_S$ such that $\mathcal{I}x = 0$ and $\iota_j(x) \neq 0$.

2) Each of the newforms $f \in S_2(\Gamma_0(p))$ with $\mathcal{I}f = 0$ satisfies $L(f, \chi, 1) \neq 0$.

3) The image of $\mathcal{I}$ in the $\mathbf{T}$-module $\mathbf{T}/p\mathbf{T}$ is a direct factor.

Let $\mathcal{I}$ be an ideal of $\mathbf{T}$. Here is how we verify these conditions for $\mathcal{I}$.

Verification of condition 1.

We verified that $\mathcal{I}$ satisfies the first condition by finding a $\mathbf{T}$-eigenvector v of $\Delta_S \otimes \bar{\mathbf{Z}}$ that is annihilated by $\mathcal{I}$ and satisfies $\iota_j(v) \neq 0$ for all anomalous j-invariants. Because ι_j is a homomorphism, this implies the existence of x as in condition 1.

Verification of condition 2.

We verified the second condition using modular symbols. Our method is purely algebraic, so we do not perform any approximate computation of integrals. Using the algorithm described in [2], we compute the action of the Hecke algebra $\mathbf{T}$ on the space $\mathrm{Hom}_{\mathbf{Q}[\chi]}(H_1(X_0(p); \mathbf{Q}[\chi]), \mathbf{Q}[\chi])$. By intersecting the kernels of appropriate elements of $\mathbf{T}$, we find a basis $\varphi_1, \ldots, \varphi_n$ for the subspace of $\mathrm{Hom}_{\mathbf{Q}[\chi]}(H_1(X_0(p); \mathbf{Q}[\chi]), \mathbf{Q}[\chi])$ that is annihilated by $\mathcal{I}$. Let $\Phi_{\mathcal{I}} = \varphi_1 \times \cdots \times \varphi_n$ denote the linear map $H_1(X_0(p); \mathbf{Q}[\chi]) \longrightarrow \mathbf{Q}[\chi]^n$ defined by the φ_i.

Let $\mathbf{T}_{\mathbf{Q}[\chi]} = \mathbf{T} \otimes \mathbf{Q}[\chi]$, where $\mathbf{Q}[\chi]$ is the number field generated the image of χ. The *χ-twisted winding element* (denoted θ_χ in [3])

$$\mathbf{e}_\chi = \sum_{a \in (\mathbf{Z}/p\mathbf{Z})^*} \bar{\chi}(a) \left\{ \infty, \frac{a}{p} \right\}$$

generates the χ-*twisted winding submodule* $\mathbf{T}_{\mathbf{Q}[\chi]} \cdot \mathbf{e}_\chi$. To compute this submodule, we use that $\mathbf{T}$ is generated, even as a $\mathbf{Z}$-module, by $T_1, T_2, \ldots, T_b$, for any $b \geq (p+1)/6$ (see [1]).

Lemma 3. — *Let $\mathcal{I}$ be a minimal prime ideal of $\mathbf{T}$, and let $\chi : (\mathbf{Z}/N\mathbf{Z})^* \longrightarrow \mathbf{C}^*$ be a nontrivial Dirichlet character. Then the dimension of the $\mathbf{Q}[\chi]$-vector space $\Phi_{\mathcal{I}}(\mathbf{T}_{\mathbf{Q}[\chi]} \cdot \mathbf{e}_\chi)$ is equal to the cardinality of the set of newforms f such that $\mathcal{I}f = 0$ and $L(f, \chi, 1) \neq 0$.*
Proof. — We have

$$\dim_{\mathbf{Q}[\chi]} \Phi_{\mathcal{I}}(\mathbf{T}_{\mathbf{Q}[\chi]} \cdot \mathbf{e}_\chi) = \dim_{\mathbf{C}} \Phi_{\mathcal{I}}(\mathbf{T}_{\mathbf{C}} \cdot \mathbf{e}_\chi).$$

This dimension is invariant upon changing the basis $\varphi_1, \ldots, \varphi_n$ used to define $\Phi_{\mathcal{I}}$. In particular, over $\mathbf{C}$ there is a basis $\varphi'_1, \ldots, \varphi'_n$ so that the resulting map $\Phi'_{\mathcal{I}}$ satisfies

$$\Phi'_{\mathcal{I}}(x) = \Big(\mathrm{Re}(\int_x f^{(1)}), \mathrm{Im}(\int_x f^{(1)}), \ldots, \mathrm{Re}(\int_x f^{(d)}), \mathrm{Im}(\int_x f^{(d)})\Big),$$

where $f^{(1)}, \ldots, f^{(d)}$ are the Galois conjugates of a newform $f^{(1)} = \sum a_n^{(1)} q^n$ such that $\mathcal{I}f^{(1)} = 0$. Furthermore, $\Phi'_{\mathcal{I}}$ is a $\mathbf{T}_{\mathbf{C}}$-module homomorphism if we declare that $\mathbf{T}_{\mathbf{C}}$ acts on $\mathbf{R}^{2d} = \mathbf{C}^d$ via

$$T_n(x_1, y_1, \ldots, x_d, y_d) = T_n(z_1, \ldots, z_d) = (a_n^{(1)} z_1, \ldots, a_n^{(d)} z_d),$$

where $z_j = x_j + iy_j$ and the $a_n^{(j)}$ are Fourier coefficients of the $f^{(j)}$.

As explained in Section 2.2 of [3], $\int_{\mathbf{e}_\chi} f = * \cdot L(f, \chi, 1)$, where $*$ is some nonzero real or pure-imaginary complex number, according to whether $\chi(-1)$ equals 1 or -1, respectively. Combining this observation with the equality

$$\dim_{\mathbf{C}} \Phi_{\mathcal{I}}(\mathbf{T}_{\mathbf{C}} \cdot \mathbf{e}_\chi) = \dim_{\mathbf{C}}(\mathbf{T}_{\mathbf{C}} \cdot \Phi_{\mathcal{I}}(\mathbf{e}_\chi)),$$

and that the image of $\mathbf{T}_{\mathbf{C}}$ in $\mathrm{End}(\mathbf{C}^d)$ is equal to the diagonal matrices, proves the asserted equality.

Remark 2: The dimension of $\Phi_{\mathcal{I}}(\mathbf{T}_{\mathbf{Q}[\chi]} \cdot \mathbf{e}_\chi)$ is unchanged if χ is replaced by a Galois-conjugate character.

In practice, computations over the cyclotomic field $\mathbf{Q}[\chi]$ are extremely expensive. Fortunately, for our application it suffices to give a lower bound on the dimension appearing in the lemma. Such a bound can be efficiently obtained by instead computing the reductions of Φ, χ, and the χ-twisted winding submodule modulo a suitable maximal ideal of the ring of integers of $\mathbf{Q}[\chi]$ that splits completely; this amounts to performing the above linear algebra over a relatively small finite field $\mathbf{F}_\ell$ where ℓ is congruent to 1 modulo $p-1$.

Remark 3: For every newform f in $S_2(\Gamma_0(p))$, with $p \leq 1000$, and every mod p Dirichlet character χ, we found that $L(f, \chi, 1) \neq 0$ if and only if $L(f^\sigma, \chi, 1) \neq 0$ for all conjugates f^σ of f. More generally, for any f and χ, this equivalence holds if $\mathbf{Q}[\chi]$ is linearly disjoint from the field $K_f = (\mathbf{T}/\mathcal{I}) \otimes \mathbf{Q}$. The first few primes for which there is a form f and a mod p character χ such that the linear disjointness hypothesis fails are $p = 31, 113, 127$, and 191. The analogue of this nonvanishing observation is false if we instead consider newforms on $\Gamma_1(p)$ and allow χ to be arbitrary. For example, let f be one of the two Galois-conjugate newforms in $S_2(\Gamma_1(13))$. Then there is a character $\chi : (\mathbf{Z}/7\mathbf{Z})^* \longrightarrow \mathbf{C}^*$ of order 3 such that $L(f, \chi, 1) = 0$ and $L(f^\sigma, \chi, 1) \neq 0$.

Verification of condition 3.

The third condition is satisfied for all $p < 10000$, except possibly $p = 389$, because we have verified that the discriminant of $\mathbf{T}$ is prime to p for all such $p \neq 389$, so the ring $\mathbf{T}/p\mathbf{T}$ is semisimple. The discriminant computation was carried out by the second author as follows. Using the method of [4], we computed discrimininants of characteristic polynomials mod p of the Hecke operators T_2, T_3, T_5, and T_7. In the few cases when all four of these characteristic polynomials had discriminant equal to 0 mod p, we resorted to modular symbols to compute several more characteristic polynomials until we found one having nonzero discriminant modulo p.

We consider the remaining case $p = 389$ in detail. There are exactly five minimal prime ideals of $\mathbf{T}$, which we denote $\mathcal{P}_1$, $\mathcal{P}_2$, $\mathcal{P}_3$, $\mathcal{P}_6$, and $\mathcal{P}_{20}$, where the quotient field of $\mathbf{T}/\mathcal{P}_i$ has dimension i. The discriminant of the characteristic polynomial of T_2 is exactly divisible by 389. Since the field of fractions of $\mathbf{T}/\mathcal{P}_{20}$ has discriminant divisible by 389, we see that 389 is not the residue characteristic of any congruence prime. Let $\mathcal{O}_i = \mathbf{T}/\mathcal{P}_i$. The natural map $\mathbf{T} \to \prod \mathcal{O}_i$ has finite kernel and cokernel each of order coprime to 389, so $\mathbf{T}/389\mathbf{T} \cong \prod \mathcal{O}_i/389\mathcal{O}_i$. The nonquadratic characters $\chi : (\mathbf{Z}/p\mathbf{Z})^* \to \mathbf{C}^*$ have orders $1, 4, 97, 193, 388$. We must verify that for each of these degrees, one of the ideals $\mathcal{P}_i$ satisfies conditions 1–3. We check as above that conditions 1–3 for χ of order 4 are satisfied by $\mathcal{P}_2$ and conditions 1–3 for χ of order greater than 4 are satisfied by $\mathcal{P}_1$. When χ is the trivial character, conditions 1–3 are satisfied only by $\mathcal{P}_{20}$.

Summary.

For each prime $p < 1000$ different than $2, 3, 5, 7, 13$, we verified the existence of an ideal that satisfies the three conditions given above, as follows. We consider each Galois conjugacy class of non-quadratic characters χ. We find a single newform f such that $L(f, \chi, 1) \neq 0$ for all conjugates of f and of χ. Then we let $\mathcal{I}$ be the annihilator of f, and try to verify condition 1 for *all* of the anamolous j-invariants in $\mathbf{F}_p$. When the three conditions are satisfied for an ideal $\mathcal{I}$ of $\mathbf{T}$, there exists $t_\chi \in \mathbf{T}$ that is annihilated by $\mathcal{I}$ and is the inverse image of a projector of $\mathbf{T}/p\mathbf{T}$ on the complement of $\mathcal{I} + p\mathbf{T}$. Putting $\delta = x$, one has $\iota_j(t_\chi \delta) = \iota_j(\delta) \neq 0$ (because ι_j takes its values in characteristic p, it follows that δ is annihilated by $\mathcal{I}$ and $t_\chi \in 1 + p\mathbf{T} + \mathcal{P}$). Every newform $f \in t_\chi S_2(\Gamma_0(p))$ satisfies $\mathcal{I}f = 0$, and therefore, by our second condition, $L(f, \chi, 1) \neq 0$. The pair (t_χ, δ) then satisfies the conditions required by Proposition 1.

Acknowledgment: We would like to thank Barry Mazur for providing us several useful comments.

10 Appendex on Generating the Hecke algebra, with A. Agashe

Appendix by A. Agashe and W. Stein.

In this appendix, we apply a result of J. Sturm* to obtain a bound on the number of Hecke operators needed to generate the Hecke algebra as an abelian group. This bound was suggested to the authors of this appendix by Loïc Merel and Ken Ribet.

Theorem. *The ring* $\mathbf{T}$ *of Hecke operators acting on the space of cusp forms of weight* k *and level* N *is generated as an abelian group by the Hecke operators* T_n *with*

$$n \leq \frac{kN}{12} \cdot \prod_{p|N} \left(1 + \frac{1}{p}\right).$$

Proof. For any ring R, let $S_k(N; R) = S_k(N; \mathbf{Z}) \otimes R$, where $S_k(N; \mathbf{Z})$ is the subgroup of cusp forms with integer Fourier expansion at the cusp ∞, and let $\mathbf{T}_R = \mathbf{T} \otimes_{\mathbf{Z}} R$. There is a perfect pairing $S_k(N; R) \otimes_R \mathbf{T}_R \to R$ given by $\langle f, T\rangle \mapsto a_1(T(f))$.

Let M be the submodule of $\mathbf{T}$ generated by $T_1, T_2, \ldots, T_r$, where r is the largest integer $\leq \frac{kN}{12} \cdot \prod_{p|N} \left(1 + \frac{1}{p}\right)$. Consider the exact sequence of additive abelian groups

$$0 \to M \xrightarrow{i} \mathbf{T} \to \mathbf{T}/M \to 0.$$

Let p be a prime and use that tensor product is right exact to obtain an exact sequence

$$M \otimes \mathbf{F}_p \xrightarrow{\bar{i}} \mathbf{T} \otimes \mathbf{F}_p \to (\mathbf{T}/M) \otimes \mathbf{F}_p \to 0.$$

Suppose that $f \in S_k(N; \mathbf{F}_p)$ pairs to 0 with each of $T_1, \ldots, T_r$. Then $a_m(f) = a_1(T_m f) = \langle f, T_m\rangle = 0$ in $\mathbf{F}_p$ for each $m \leq r$. By Theorem 1 of Sturm's paper, it follows that $f = 0$. Thus the pairing restricted to the image of $M \otimes \mathbf{F}_p$ in $\mathbf{T} \otimes \mathbf{F}_p$ is nondegenerate, so

$$\dim_{\mathbf{F}_p} \bar{i}(M \otimes \mathbf{F}_p) = \dim_{\mathbf{F}_p} S_k(N, \mathbf{F}_p) = \dim_{\mathbf{F}_p} \mathbf{T} \otimes \mathbf{F}_p.$$

It follows that $(\mathbf{T}/M) \otimes \mathbf{F}_p = 0$; repeating the argument for all primes p shows that $\mathbf{T}/M = 0$, as claimed.

Remark. In general, the theorem is not true if one considers only T_n where n runs over the *primes* less than the bound. Consider, for example, $S_2(11)$, where the bound is 2 and T_2 is the 1×1 matrix $[2]$, which does not generate the full Hecke algebra as a $\mathbf{Z}$-submodule of $\mathrm{End}(S_2(\Gamma_0(N), \mathbf{Z}))$. One needs, in addition, the matrix $[1]$.

11 Component Groups of Purely Toric Quotients, with B. Conrad

Component Groups of Purely Toric Quotients

William A. Stein Brian Conrad

April 21, 2003

Abstract

Suppose $\pi : J \to A$ is an optimal quotient of abelian varieties over a p-adic field, optimal in the sense that $\ker(\pi)$ is connected. Assume that J is equipped with a symmetric principal polarization θ (e.g., any Jacobian of a curve has such a polarization), that J has semistable reduction, and that A has purely toric reduction. In this paper, we express the group of connected components of the Néron model of A in terms of the monodromy pairing on the character group of the torus associated to J. We apply our results in the case when A is an optimal quotient of the modular Jacobian $J_0(N)$. For each prime p that exactly divides N, we obtain an algorithm to compute the component group of A at p.

1 Introduction

Let A be an abelian variety over the rational numbers $\mathbf{Q}$. Birch and Swinnerton-Dyer found a conjectural formula for the order of the Shafarevich-Tate group of A. The Tamagawa numbers c_p of A are among the quantities that appear in this formula. We now recall the definition of the Tamagawa numbers of an abelian variety (the definition of Néron model and component groups is given in Section 2).

Definition 1.1 (Tamagawa number). Let p be a prime, let $\mathcal{A}$ be the Néron model of A over the p-adic integers $\mathbf{Z}_p$, and let $\Phi_{A,p}$ be the component group of $\mathcal{A}$ at p. Then the *Tamagawa number* c_p of A at p is the order of the subgroup $\Phi_{A,p}(\mathbf{F}_p)$ of $\mathbf{F}_p$-rational points in $\Phi_{A,p}(\overline{\mathbf{F}}_p)$.

Remark 1.2. The Tamagawa number is defined in a different way in some other papers, but the definitions are equivalent.

When A has dimension one, A is called an elliptic curve, and A can be defined by a Weierstrass equation $y^2 = x^3 + ax + b$. Using that elliptic curves (and their related integral models) can be described by simple equations, Tate found an efficient algorithm to compute all of the Tamagawa numbers of A (see [18]). In the case when A is the Jacobian of a genus 2 curve, [7] discusses a method for computing the Tamagawa numbers of A. In this paper, we consider the situation in which A has purely toric reduction at p, with no constraint on the dimension of A. For such A we give an explicit description of the order of the group of connected components of the closed fiber of the Néron model of A. In the case when $A = A_f$ is a quotient of $J_0(N)$ attached to a newform $f \in S_2(\Gamma_0(N))$ and $p \mid\mid N$, our method is completely explicit, and yields an algorithm to compute the Tamagawa number c_p of A (up to a bounded power of 2).

This paper is structured as follows. In Sections 2–6 we state and prove an explicit formula involving component groups of fairly general abelian varieties. Then in Section 7 we turn to quotients of modular Jacobians $J_0(N)$. We give some tables and discussed the arithmetic of quotients of $J_0(N)$ when N is prime. In Section 8 we prove a couple of facts about toric reduction that are used in the proof of Theorem 6.1.

Acknowledgement: This paper was inspired by lectures of R. Coleman and K. Ribet, and a letter from Ribet to Mestre (see [17]), which contains some of the results of the present paper in the case when A has dimension 1. The second author would like to thank A. Abbes, A. Agashe, D. Kohel, and D. Lorenzini, for helpful conversations. Both authors were partially supported by the NSF and the Clay Mathematics Institute during work on this paper.

2 The Main Results

In this section, we summarize the main contributions of this paper. First we recall the precise definition of the component group of an abelian variety, then we state our main theorem.

Let R be a discrete valuation ring with field of fractions K and maximal ideal $\mathfrak{m}$, and let $k = R/\mathfrak{m}$ be the residue class field. Let A be an abelian variety over K.

Definition 2.1 (Néron model). A *Néron model* of A is a smooth commutative group scheme $\mathcal{A}$ over R such that A is its generic fiber and $\mathcal{A}$ satisfies the Néron mapping property: the restriction map

$$\mathrm{Hom}_R(S, \mathcal{A}) \longrightarrow \mathrm{Hom}_K(S_K, A)$$

is bijective for all smooth schemes S over R.

The Néron mapping property implies that $\mathcal{A}$ is unique up to a unique isomorphism, so we will refer without hesitation to "the" Néron model of A. Néron models are separated and of finite type as opposed to just locally of finite type, even though their universal property is on the category of arbitrary smooth R-schemes. For more about Néron models see [2].

The closed fiber $\mathcal{A}_k$ of $\mathcal{A}$ is a group scheme over k, which need not be connected. Denote by $\mathcal{A}_k^0$ the connected component of $\mathcal{A}_k$ that contains the identity. We have an exact sequence

$$0 \longrightarrow \mathcal{A}_k^0 \longrightarrow \mathcal{A}_k \longrightarrow \Phi_A \longrightarrow 0,$$

where Φ_A is a finite étale group scheme over k. Equivalently, Φ_A is a commutative finite group equipped with a continuous action of $\mathrm{Gal}(\overline{k}/k)$.

Definition 2.2 (Component group). The *component group* of an abelian variety A over K is the group scheme $\Phi_A = \mathcal{A}_k/\mathcal{A}_k^0$.

2.1 Statement of the Theorem

We now state our main result, supressing some of the definitions of the terms used until later (see Section 6 below for a more complete statement and the proof). Let K be as above, and suppose $\pi : J \to A$ is an optimal quotient. Assume that J is equipped with a symmetric principal polarization λ, in the sense of Definition 5.1. For example, the θ polarization of the Jacobian of a curve is a symmetric principal polarization. Also assume that J has semistable reduction, and that A has purely toric reduction.

We express the component group of A in terms of the monodromy pairing associated to J. Let $m_A = \sqrt{\deg(\theta_A)}$, where $\theta_A : A^\vee \to A$ is induced by the canonical principal polarization of J arising from the θ-divisor. Let X_J be the character group of the toric part of the closed fiber of the Néron model of J. Let $\mathcal{L}$ be the saturation of the image of X_A in

X_J. The monodromy pairing induces a map $\alpha : X_J \to \mathrm{Hom}(\mathcal{L}, \mathbf{Z})$. Let Φ_X be the cokernel of α and $m_X = [\alpha(X_J) : \alpha(\mathcal{L})]$ be the order of the finite group $\alpha(X_J)/\alpha(\mathcal{L})$. The main result of this paper is that

$$\frac{\#\Phi_A}{m_A} = \frac{\#\Phi_X}{m_X},$$

and this is recorded as Theorem 6.1 below.

Using the snake lemma, one sees that Φ_X is isomorphic to the image of the natural map $\Phi_J \to \Phi_A$, and the above formula implies that the cokernel of the map $\Phi_J \to \Phi_A$ has order m_A/m_X. A non-obvious consequence of this is that $m_X \mid m_A$.

In the context of modular forms, if the optimal quotient $J \to A$ arises from a newform on $\Gamma_0(N)$, then the quantities m_A, m_X and Φ_X can be explicitly computed, hence we can compute $\#\Phi_A$. Note that the authors have not computed the structure of Φ_A as a group.

3 Optimal Quotients

Let K be as in Section 2, let J be an abelian variety equipped with a symmetric principal polarization θ_J (see Definition 5.1). For example, J could be the Jacobian of a curve equipped with the canonical principal polarization arising from the θ-divisor.

Definition 3.1 (Optimal quotient). An *optimal quotient* of J is an abelian variety A and a smooth surjective morphism $\pi : J \to A$ whose kernel is connected (i.e., an abelian variety).

Remark 3.2. Any connected scheme of finite type over a field is geometrically connected if it contains a rational point (e.g., if it is a group scheme). See [8, IV$_2$, §4.5.13].

Let $\pi : J \to A$ be an optimal quotient. Denote by $J^\vee$ and $A^\vee$ the abelian varieties dual to J and A, respectively. Upon composing the dual of π with $\theta_J^\vee = \theta_J$, we obtain a map

$$A^\vee \xrightarrow{\pi^\vee} J^\vee \xrightarrow{\theta_J} J.$$

Proposition 3.3. *The map $\theta_J \circ \pi^\vee : A^\vee \to J$ is a closed immersion.*

Proof. Since θ_J is an isomorphism, we want to prove that $\pi^\vee$ is a closed immersion. It is a general fact that duals to surjections of abelian varieties with abelian variety kernel are closed immersions, but for lack of an adequate reference we recall the proof. Since a monomorphism between smooth finite type group schemes over a field is necessarily a closed immersion, it suffices to show that the commutative proper group scheme $\ker(\pi^\vee)$ vanishes. Since a non-zero commutative proper group scheme G over a field F necessarily has a non-zero finite subgroup scheme $G[n]$ for some n (since either $(G_{/\overline{F}})^0_{\mathrm{red}}$ is an abelian variety or else G is finite and non-zero), it suffices to show that $\ker(\pi^\vee)[n]$ vanishes for all positive integers n. In other words, it suffices to show that the induced map $A^\vee[n] \to J^\vee[n]$ is a closed immersion for all n.

Since Cartier duality interchanges faithfully flat maps and closed immersions, and the scheme-theoretic Weil pairing identifies the Cartier dual of the map induced by $\pi^\vee$ on n-torsion with $\pi : J[n] \to A[n]$, we just have to show that these latter maps are faithfully flat for all integers n. Using the short exact sequence

$$0 \to \ker(\pi) \to J \to A \to 0$$

in the abelian category of fppf abelian sheaves over $\mathrm{Spec}(K)$, the snake lemma gives an exact sequence

$$0 \to \ker(\pi)[n] \to J[n] \to A[n] \to 0$$

because $n : \ker(\pi) \to \ker(\pi)$ is a faithfully flat map (hence fppf surjective), as $\ker(\pi)$ is an abelian variety. This gives an isomorphism of group schemes

$$J[n]/\ker(\pi)[n] \simeq A[n]$$

compatible with the maps from $J[n]$, whence $J[n] \to A[n]$ is faithfully flat.

□

Henceforth we will abuse notation and denote the injection $A^\vee \to J$ by $\pi^\vee$. We define θ_A to be the composite $\pi \circ \pi^\vee$, so the kernel of θ_A equals the scheme-theoretic intersection of $A^\vee$ and $B = \ker(\pi)$, as depicted in the following diagram:

$$\begin{tikzcd}
A^\vee \cap B \arrow[r] \arrow[d] & B \arrow[d] \\
A^\vee \arrow[r, hook, "\pi^\vee"] \arrow[rd, "\theta_A"'] & J \arrow[d, "\pi"] \\
& A.
\end{tikzcd}$$

Since θ_A is a polarization (due to how its definition uses the polarization θ_J) the degree of θ_A is a perfect square (see [16, §16, p. 150]).

Definition 3.4 (Degree). Define the *degree* of A as a quotient of J to be the integer

$$m_A = \sqrt{\# \ker(\theta_A)}.$$

4 The Closed Fiber of the Néron Model

In this section we recall some terminology associated with closed fibers of Néron models. Let K, R, and k be as in Section 2, and let $\Phi_A = \mathcal{A}_k/\mathcal{A}_k^0$ be the group scheme of connected components of the closed fiber $\mathcal{A}_k$. By Chevalley's structure theorem (see [3], or [4] for a modern account), if K is a perfect extension field of k (e.g., $K = \overline{k}$) then there is a unique short exact sequence

$$0 \to \mathcal{C} \to \mathcal{A}_K^0 \to \mathcal{B} \to 0$$

with $\mathcal{C}$ a smooth affine algebraic K-group and $\mathcal{B}$ an abelian variety. Moreover, there is a unique exact sequence

$$0 \to \mathcal{T} \to \mathcal{C} \to \mathcal{U} \to 0$$

with $\mathcal{T}$ a torus and $\mathcal{U}$ unipotent.

Using the rigidity of tori, one can show that $\mathcal{T}$ is induced by a unique torus in $\mathcal{A}_k^0$. In particular, the condition that $\mathcal{B} = \mathcal{U} = 0$ is equivalent to the condition that $\mathcal{A}_k^0$ be a torus, and the condition that $\mathcal{U} = 0$ is equivalent to the condition that $\mathcal{A}_k^0$ be the extension of an abelian variety by a torus (i.e., be a semi-abelian variety). These conditions can be checked on a geometric closed fiber.

Definition 4.1. The abelian variety A is said to have *purely toric reduction* if $\mathcal{A}_k^0$ is torus, and to have *semistable reduction* if $\mathcal{A}_k^0$ is a semi-abelian variety (i.e., $\mathcal{A}_{\overline{k}}^0$ has vanishing unipotent part).

4.1 The Monodromy Pairing on the Character Group

Definition 4.2 (Character group of torus). The *character group*

$$X_A = \mathrm{Hom}_{\overline{k}}(\mathcal{T}_{\overline{k}}, \mathbf{G}_{m\overline{k}})$$

is a free abelian group of rank t contravariantly associated to A.

As discussed in [9], if A is semistable there is a *monodromy pairing* $X_A \times X_{A^\vee} \to \mathbf{Z}$ and an exact sequence

$$0 \to X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

Also, the canonical isomorphism $(A^\vee)^\vee \cong A$ induces an isomorphism

$$X_{A^\vee} \times X_{(A^\vee)^\vee} \cong X_A \times X_{A^\vee},$$

which identifies the monodromy pairing associated to $A^\vee$ with that associated to A.

Example 4.3 *(Tate curve).* Suppose $E = \mathbf{G}_m/q^{\mathbf{Z}}$ is a Tate curve over $\mathbf{Q}_p^{\mathrm{ur}}$. The monodromy pairing on $X_E = q^{\mathbf{Z}}$ is

$$\langle q, q \rangle = \mathrm{ord}_p(q) = -\,\mathrm{ord}_p(j).$$

Thus Φ_E is cyclic of order $-\,\mathrm{ord}_p(j)$.

Suppose J is an abelian variety equipped with a symmetric principal polarization. Since J is self dual via the given symmetric principal polarization, we can view the monodromy pairing on J as a pairing $X_J \times X_J \to \mathbf{Z}$. Because the principal polarization on J is symmetric the resulting pairing $X_J \times X_J \to \mathbf{Z}$ is symmetric, so there is no ambiguity about left versus right definitions of $X_J \to \mathrm{Hom}(X_J, \mathbf{Z})$. The above exact sequence then becomes

$$0 \to X_J \to \mathrm{Hom}(X_J, \mathbf{Z}) \to \Phi_J \to 0.$$

5 The Degree of a Symmetric Isogeny

We next relate the degree of the isogeny $A^\vee \to A$ defined at the end of Section 3 to the order of the cokernel of the induced map on the character groups of tori defined in Section 4.1. Let K be as in Section 2, and let A be an abelian variety over K.

Definition 5.1 (Symmetric isogeny). A *symmetric isogeny* $\varphi : A^\vee \to A$ is an isogeny such that the map

$$\varphi^\vee : A^\vee \to (A^\vee)^\vee = A$$

is equal to φ.

If J and A are as in Section 3 then the principal polarization θ_J of J is symmetric, so the natural map $A^\vee \to A$ is a symmetric isogeny.

Lemma 5.2. *Suppose that A is a purely toric abelian variety over K and that $\varphi : A^\vee \to A$ is a symmetric isogeny. Let $\varphi_a : X_A \to X_{A^\vee}$ denote the induced map on character groups. Then*

$$\deg(\varphi) = \#\,\mathrm{coker}(\varphi_a)^2.$$

Proof. By Corollary 8.7 applied to our isogeny φ (so what we are presently calling $A^\vee$ and A are respectively called A and B in the discussion surrounding Theorem 8.6), we deduce that

$$\deg(\varphi) = \#\ker(\varphi) = \#\ker(\varphi_t) \cdot \#\ker(\varphi_t^\vee)$$

where φ_t and $\varphi_t^\vee$ are the maps induced by φ and $\varphi^\vee$ on closed fiber tori.

Since the character group X_A is, by definition, $\mathrm{Hom}_{\overline{k}}(\mathcal{T}_{\overline{k}}, \mathbf{G}_{m\overline{k}})$, where $\mathcal{T}$ is the toric part of the closed fiber of A, it follows that $\#\ker(\varphi_t) = \#\,\mathrm{coker}(\varphi_a)$. Since $\varphi = \varphi^\vee$, this proves the lemma. □

6 Statement and Proof of the Main Theorem

Let K be as in Section 2, and let $\pi : J \to A$ be an optimal quotient. Assume that J is equipped with a symmetric principal polarization λ, that J has semistable reduction, and that A has purely toric reduction. Let X_A, $X_{A^\vee}$, and X_J denote the character groups of the toric parts of the closed fibers of the abelian varieties A, $A^\vee$, and J, respectively.

Let $\pi : J \to A$ be an optimal quotient, and let $\theta : A^\vee \to A$ denote the induced polarization. Let π_*, π^*, θ_*, and θ^* be the maps induced on character groups by the various functorialities, as indicated in the following two key diagrams:

$$\begin{tikzcd}
A^\vee \arrow[r, hook, "\pi^\vee"] \arrow[dr, "\theta"'] & J \arrow[d, "\pi"] \\
& A
\end{tikzcd}
\qquad\qquad
\begin{tikzcd}
X_A \arrow[r, hook, "\pi^*"] \arrow[dr, "\theta^*"] & X_J \arrow[d, "\pi_*"] \\
& X_{A^\vee}. \arrow[ul, bend left, "\theta_*"]
\end{tikzcd}$$

The surjectivity of π_* is proved in Theorem 8.2. The injectivity of π^* follows because

$$\theta_*\pi_*\pi^* = \theta_*\theta^* = \deg(\theta) \neq 0,$$

and multiplication by a nonzero integer on a free abelian group is injective.

Let $\mathcal{L}$ be the *saturation* of π^*X_A in X_J; thus π^*X_A is a finite-index subgroup of $\mathcal{L}$ and the quotient $X_J/\mathcal{L}$ is torsion free. Let

$$\alpha : X_J \to \mathrm{Hom}(\pi^*X_A, \mathbf{Z})$$

be the map defined by the monodromy pairing restricted to $X_J \times \pi^*X_A$. For L of finite index in $\mathcal{L}$, define the *degree* of L to be

$$m_L = [\alpha(X_J) : \alpha(L)],$$

and the *component group* of L to be

$$\Phi_L = \mathrm{coker}(X_J \to \mathrm{Hom}(L, \mathbf{Z})).$$

When $L = \mathcal{L}$ and A is fixed, for simplicity we write $m_X = m_{\mathcal{L}}$ and $\Phi_X = \Phi_{\mathcal{L}}$.

Recall that Φ_A is the component group of A and m_A is the square root of the degree of the induced map $A^\vee \to A$.

Theorem 6.1. *For any subgroup L of finite index in $\mathcal{L}$, the following relation holds:*

$$\frac{\#\Phi_A}{m_A} = \frac{\#\Phi_L}{m_L}.$$

6.1 Proof of the Main Theorem

The notation in this section is as in previous section.

Lemma 6.2. *Let $\pi_* : X_J \to X_{A^\vee}$ and $\alpha : X_J \to \mathrm{Hom}(\pi^*X_A, \mathbf{Z})$ be as in previous section. Then*

$$\ker(\pi_*) = \ker(\alpha).$$

Proof. Suppose $x \in \ker(\pi_*)$, and let $y = \pi^* z$ with $z \in X_A$. Then

$$\langle x, y\rangle = \langle x, \pi^* z\rangle = \langle \pi_* x, z\rangle = 0,$$

so $x \in \ker(\alpha)$. Next let $x \in \ker(\alpha)$. Then for all $z \in X_A$,

$$0 = \langle x, \pi^* z\rangle = \langle \pi_* x, z\rangle,$$

so $\pi_* x$ is in the kernel of the monodromy map

$$X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}).$$

Since $X_{A^\vee}$ and $\mathrm{Hom}(X_A, \mathbf{Z})$ are free of the same finite rank and the cokernel is torsion, the monodromy map is injective. Thus $\pi_* x = 0$ and $x \in \ker(\pi_*)$. □

Let $\pi^* : X_A \to X_J$ be as in previous section.

Lemma 6.3. *The monodromy-pairing map* $X_J \to \mathrm{Hom}(X_J, \mathbf{Z})$ *composed with restriction* $\mathrm{Hom}(X_J, \mathbf{Z}) \to \mathrm{Hom}(\pi^* X_A, \mathbf{Z})$ *gives rise to an exact sequence*

$$X_J \to \mathrm{Hom}(\pi^* X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

Proof. Lemma 6.2 gives the following commutative diagram with exact rows

$$\begin{tikzcd}
0 \arrow[r] & X_J/\ker(\alpha) \arrow[r] \arrow[d, "\cong"] & \mathrm{Hom}(\pi^* X_A, \mathbf{Z}) \arrow[r] \arrow[d, "\cong"] & \mathrm{coker}(\alpha) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & X_{A^\vee} \arrow[r] & \mathrm{Hom}(X_A, \mathbf{Z}) \arrow[r] & \Phi_A \arrow[r] & 0.
\end{tikzcd}$$

By Lemma 6.2, the first vertical map is an isomorphism. The second is an isomorphism because it is induced by the isomorphism $\pi^* : X_A \to \pi^* X_A$. It follows that $\mathrm{coker}(\alpha) \cong \Phi_A$, as claimed. □

Recall that $\mathcal{L}$ denotes the saturation of $\pi^* X_A$ in X_J, and that $L \subset \mathcal{L}$ denotes a subgroup of finite index.

Lemma 6.4. *The rational number* $\dfrac{\#\Phi_L}{m_L}$ *is independent of the choice of* L.

Proof. Suppose L' is another finite index subgroup of $\mathcal{L}$, and let $n = [L : L']$. Here n is a rational number, the lattice index of L' in L. Since α is injective when restricted to $\mathcal{L}$, it follows that

$$m_{L'} = [\alpha(X_J) : \alpha(L')] = [\alpha(X_J) : \alpha(L)] \cdot [\alpha(L) : \alpha(L')] = m_L \cdot n.$$

Similarly, $\#\Phi_{L'} = \#\Phi_L \cdot n$. □

Recall that $m_A = \sqrt{\deg(\theta)}$ and

$$\Phi_A \cong \mathrm{coker}(X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z})),$$

where m_A is the degree of A and Φ_A is the component group of A.

Proof of Theorem 6.1. By Lemma 6.4 we may assume that $L = \pi^* X_A$. With this choice of L, Lemma 6.3 asserts that $\Phi_L \cong \Phi_A$. By Lemma 6.2, properties of the index, and Lemma 5.2 we have

$$\begin{aligned} m_L &= [\alpha(X_J) : \alpha(L)] \\ &= [\pi_*(X_J) : \pi_*(L)] \\ &= [X_{A^\vee} : \pi_*(\pi^* X_A)] \\ &= [X_{A^\vee} : \theta^* X_A] \\ &= \#\operatorname{coker}(\theta^*) \\ &= \sqrt{\deg(\theta)} = m_A. \end{aligned}$$

□

Recall that $\Phi_{\mathcal{L}}$ denotes the cokernel of the natural map $X_J \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})$ induced by composing the monodromy map $X_J \to \operatorname{Hom}(X_J, \mathbf{Z})$ with the natural restriction map $\operatorname{Hom}(X_J, \mathbf{Z}) \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})$.

Proposition 6.5. *The group $\Phi_{\mathcal{L}}$ is canonically isomorphic to the image of the map from Φ_J to Φ_A induced by $\pi : J \to A$. Thus*

$$\operatorname{image}(\Phi_J \to \Phi_A) \cong \Phi_{\mathcal{L}}.$$

Proof. Since $\pi^* X_A \subset \mathcal{L} \subset X_J$, an application of Lemma 6.3 gives the following commutative diagram with exact rows:

$$\begin{tikzcd}
X_J \arrow[r] \arrow[d, equal] & \operatorname{Hom}(X_J, \mathbf{Z}) \arrow[r] \arrow[d] & \Phi_J \arrow[r] \arrow[d] & 0 \\
X_J \arrow[r] \arrow[d, equal] & \operatorname{Hom}(\mathcal{L}, \mathbf{Z}) \arrow[r] \arrow[d] & \Phi_{\mathcal{L}} \arrow[r] \arrow[d] & 0 \\
X_J \arrow[r] & \operatorname{Hom}(\pi^* X_A, \mathbf{Z}) \arrow[r] & \Phi_A \arrow[r] & 0.
\end{tikzcd}$$

The map $\operatorname{Hom}(\mathcal{L}, \mathbf{Z}) \to \operatorname{Hom}(\pi^* X_A, \mathbf{Z})$ is an isomorphism, so the map $\Phi_{\mathcal{L}} \to \Phi_A$ is injective. Thus

$$\operatorname{image}(\Phi_J \to \Phi_A) \cong \operatorname{image}(\Phi_J \to \Phi_{\mathcal{L}}).$$

The cokernel of $\operatorname{Hom}(X_J, \mathbf{Z}) \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})$ surjects onto the cokernel of $\Phi_J \to \Phi_{\mathcal{L}}$. Using the exact sequence

$$0 \to \mathcal{L} \to X_J \to X_J/\mathcal{L} \to 0,$$

we find that

$$\operatorname{coker}(\operatorname{Hom}(X_J, \mathbf{Z}) \to \operatorname{Hom}(\mathcal{L}, \mathbf{Z})) \subset \operatorname{Ext}^1(X_J/\mathcal{L}, \mathbf{Z}).$$

Because $\mathcal{L}$ is saturated, the quotient $X_J/\mathcal{L}$ is torsion free, so the indicated Ext^1 group vanishes. Thus the map $\Phi_J \to \Phi_{\mathcal{L}}$ is surjective, from which the proposition follows. □

Corollary 6.6. *The cokernel of the map from Φ_J to Φ_A induced by $\pi : J \to A$ has order $m_A/m_{\mathcal{L}}$. Thus*

$$\#\operatorname{coker}(\Phi_J \to \Phi_A) = \frac{m_A}{m_{\mathcal{L}}}.$$

Proof. Combine Theorem 6.1 and Proposition 6.5. □

7 Optimal Quotients of $J_0(N)$

In this section we specialize the general results of the rest of this paper to the concrete case in which $J = J_0(N)$ is the Jacobian of a modular curve, and $A = A_f$ is an optimal quotient of J attached to a modular forms. The paper [12] contains more computations like these.

7.1 Modular Curves and Semistable Reduction

Let $X_0(N)$ be the modular curve associated to the subgroup $\Gamma_0(N)$ of $\mathrm{SL}_2(\mathbf{Z})$ that consists of those matrices which are upper triangular modulo N. The algebraic curve $X_0(N)_{\mathbf{C}}$ can be constructed as a Riemann surface as the quotient

$$\Gamma_0(N)\backslash\left(\{z : z \in \mathbf{C}, \operatorname{Im}(z) > 0\} \cup \mathbf{P}^1(\mathbf{Q})\right),$$

and $X_0(N)$ has a canonical structure of algebraic curve over $\mathbf{Q}$.

It is well known that the p-new part of the Jacobian $J_0(N)$ of $X_0(N)$ has purely toric reduction at p when $p \mid\mid N$. Let us briefly recall the reason, writing $N = Mp$. Using the description of closed fibers of modular curves [10, Ch. 13] and Raynaud's result relating Néron models and Picard functors (as summarized in [2, Ch. 9]), the standard finite *flat* degeneracy maps $X_0(Mp) \to X_0(M)$ over $\mathbf{Z}_{(p)}$ induce a *"pushfoward"* map on Néron model connected components

$$\mathrm{Pic}^0_{X_0(Mp)/\mathbf{Z}_{(p)}} \longrightarrow \mathrm{Pic}^0_{X_0(M)/\mathbf{Z}_{(p)}} \times \mathrm{Pic}^0_{X_0(M)/\mathbf{Z}_{(p)}}$$

which on the closed fiber is the map induced by *pullback* to the two components $X_0(M)_{/\mathbf{F}_p}$ in $X_0(Mp)_{/\mathbf{F}_p}$. The kernel of this latter map is a torus [2, Ex. 9.2.8], yet this kernel is visibly isogenous to the semistable mod p fiber of the dual of $J_0(Mp)^{\mathrm{new}}$, whence the purely toric conclusion.

7.2 Newforms and Optimal Quotients

The Hecke algebra

$$\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots] \subset \mathrm{End}(J_0(N))$$

is a commutative ring of endomorphisms of $J_0(N)$ of $\mathbf{Z}$-rank equal to the dimension of $J_0(N)$. The character group $X_{J,p}$ of $J_0(N)$ at p is equipped with a functorial action of $\mathbf{T}$. The Hecke algebra $\mathbf{T}$ also acts on the complex vector space $S = S_2(\Gamma_0(N), \mathbf{C})$ of cusp forms.

Let f be a newform, and associate to f the ideal I_f of the Hecke algebra $\mathbf{T}$ of elements which annihilate f. Then $\mathcal{O}_f = \mathbf{T}/I_f$ is an order in the ring of integers of the totally real number field K_f obtained by adjoining the Fourier coefficients of f to $\mathbf{Q}$. The quotient

$$A_f = J_0(N)/I_f J_0(N)$$

is an optimal quotient of $J_0(N)$ of dimension equal to $[K_f : \mathbf{Q}]$. As discussed in the previous section, A_f is purely toric at p.

7.3 Tamagawa Numbers

Let $\mathrm{Frob}_p : X_J \to X_J$ denote the map induced by the Frobenius automorphism. We have $\mathrm{Frob}_p = -W_p$, where W_p is the map induced by the Atkin-Lehner involution on $J_0(p)$. Let f be a newform, $A = A_f$ the corresponding optimal quotient, and w_p the sign of the eigenvalue of W_p on f.

Proposition 7.1.

$$\Phi_A(\mathbf{F}_p) = \begin{cases} \Phi_A(\overline{\mathbf{F}}_p) & \textit{if } w_p = -1, \\ \Phi_A(\overline{\mathbf{F}}_p)[2] & \textit{if } w_p = 1. \end{cases}$$

Proof. If $w_p = -1$, then $\mathrm{Frob}_p = 1$ and the $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$-action of $\Phi_A(\overline{\mathbf{F}}_p)$ is trivial. In this case $\Phi(\mathbf{F}_p) = \Phi(\overline{\mathbf{F}}_p)$. Next suppose $w_p = 1$. Recall that we have an exact sequence

$$0 \to X_{A^\vee} \to \mathrm{Hom}(X_A, \mathbf{Z}) \to \Phi_A \to 0.$$

Since W_p acts as $+1$ on f, it also acts as $+1$ on each of the modules A, X_A, $\mathrm{Hom}(X_A, \mathbf{Z})$, and Φ_A. Thus $\mathrm{Frob}_p = -W_p$ acts as -1 on Φ_A. Since the subgroup of 2-torsion elements of a finite abelian group equals the subgroup of elements fixed under -1, it follows that $\Phi_A(\mathbf{F}_p) = \Phi_A(\overline{\mathbf{F}}_p)[2]$. □

Warning: When extending this result to the whole of $J_0(N)$, be careful. The action of $\mathrm{Frob}_p = T_p$ need not be by ± 1, even though it must be by an involution of order 2. For example, the component group of $J_0(65)$ at 5 is cyclic of order 42. The action of Frob_5 is by multiplication by -13. Note that $(-13)^2 = 1 \pmod{42}$. The fixed points of multiplication by -13 is the order 14 subgroup of $\mathbf{Z}/42\mathbf{Z}$.

7.4 Computing Component Groups

Using modular symbols, we can enumerate the optimal quotients A_f of $J_0(N)$ (see, e.g., [1]) and compute the degree m_A (see [12, §3.1]). Suppose p is a prime that exactly divides N. As explained in [12], the method of graphs (see [14]) or the ideal theory of quaternion algebras (see [11]) can be used to compute $X = X_{J_0(N),p}$ with its $\mathbf{T}$-action and the monodromy pairing. We can then compute the following three modules:

1. the saturated submodule $\mathcal{L} = \bigcap_{t \in I_f} \ker(t)$ of X,
2. the character group degree $m_X = m_{\mathcal{L}}$, and
3. $\Phi_X = \Phi_{\mathcal{L}}$.

By Theorem 6.1 we obtain

$$\#\Phi_{A,p} = \#\Phi_X \cdot \frac{m_A}{m_X}.$$

7.5 The Eisenstein Nature of Component Groups

The theorem below, which generalizes some of the results of [13] and [15], was conjectured by the second author after computing many component groups of quotients of $J_0(p)$ using the results of this paper. M. Emerton read an early version of this paper and subsequently announced a proof of the theorem below (see [6]).

Theorem 7.2 (Emerton). *Let p be a prime and let $f_1, \ldots, f_n$ be a set of representatives for the Galois-conjugacy classes of newforms in $S_2(\Gamma_0(p))$. Let $A_1, \ldots, A_n$ be the optimal quotients associated to $f_1, \ldots, f_n$, respectively. Then for each i, $i = 1, \ldots, n$, we have*

$$\#A_i(\mathbf{Q})_{\mathrm{tor}} = \#\Phi_{A_i}(\overline{\mathbf{F}}_p) = \#\Phi_{A_i}(\mathbf{F}_p).$$

Furthermore,

$$\#\Phi_{J_0(p)}(\overline{\mathbf{F}}_p) = \prod_{i=1}^{n} \#\Phi_{A_i}(\overline{\mathbf{F}}_p).$$

Before Emerton proved the above assertion, the second author verified it using the algorithm of this paper for all $p \leq 757$, and, up to a power of 2, for all $p < 2000$.

Remark 7.3. It is tempting to guess that, e.g., the natural map

$$\Phi_{J_0(113)}(\overline{\mathbf{F}}_{113}) \to \prod_{i=1}^{4} \Phi_{A_i}(\overline{\mathbf{F}}_{113})$$

is an isomorphism, but this is incorrect. Two of the $\Phi_{A_i}(\overline{\mathbf{F}}_{113})$ have order 2, so the product $\prod_{i=1}^{4} \Phi_{A_i}(\overline{\mathbf{F}}_{113})$ is not a cyclic group. However, Mazur proved that the groups $\Phi_{J_0(p)}(\overline{\mathbf{F}}_p)$ are cyclic for all primes p.

7.6 Examples

In this section we give some examples of the numbers involved in computing component groups of quotients of $J_0(N)$. For more examples, see [12]. We use the notation for abelian varieties that is described in [1]. For example **65A** is the "first" abelian variety quotient of $J_0(65)$ attached to a newform.

7.6.1 Quotients of $J_0(N)$

Table 1 contains many of the quantities involved in the computation of component groups for each of the newform optimal quotients for $N \in \{65, 66, 68, 69\}$.

7.6.2 Quotients of $J_0(p)^-$

We computed the quantities m_A, m_X, and Φ_X for each abelian variety A_f associated to a newform of prime level p with $p \leq 631$. Table 2 lists those A_f for which $w_p = -1$, along with the order of the corresponding component group. The first column, which is labeled "A" contains a description of A_f, the second column, labeled "d", contains the dimension of A_f, and the third column, labeled "$\#\Phi_A$", contains the order $\#\Phi_{A_f,p}(\overline{\mathbf{F}}_p)$ of the component group.

Remark 7.4. Theorem 7.2 together with [13, Prop. II.17.10] imply that the component groups of the A_f for which $w_p = +1$ are trivial, so we do not list them. An optimal quotient A_f of $J_0(p)$ with nonzero component group has nonzero rational torsion (by Theorem 7.2), so it factors through the Eisenstein quotient of $J_0(p)$. Also w_p acts as -1 on the Eisenstein quotient of $J_0(p)$, which is [13, Prop. II.17.10], and which is a deep result because of subtleties at the prime 2 (see the discussion in [13, III.1]).

Table 1: Component groups of quotients of $J_0(N)$

A	dim	p	w_p	$\#\Phi_X$	m_X	m_A	$\#\Phi_A$

8 Appendix: Some Facts Concerning Toric Reduction

Let R be a discrete valuation ring with fraction field K and residue field k. For any abelian variety A over K, with Néron model $\mathcal{A}$ over R, we denote by X_A the character group of the toric part of $\mathcal{A}_k^0$ (the connected component of the closed fiber of $\mathcal{A}$). All group schemes below are understood to be commutative.

Our aim in this appendix is to prove a couple of facts (Theorem 8.2 and Theorem 8.6) which are no doubt well-known to experts but for which published proofs do not appear to be readily available. We begin with a simple and basic lemma.

Lemma 8.1. *Let $f : G \to G'$ be a map between multiplicative (resp. étale) finite flat group schemes over R. The map f is a closed immersion (resp. faithfully flat) if and only if the generic fiber map f_K is a closed immersion (resp. faithfully flat).*

Proof. Cartier duality interchanges étaleness and multiplicativeness, as well as closed immersions and faithfully flat maps (as the latter two properties may be checked on the closed fiber, for which one is reduced to the standard case of finite commutative group schemes over a field). Thus, it suffices to consider the étale case. By faithfully flat base change to a strict henselization of R, we are reduced to the case where our finite étale group schemes are constant. Since faithful flatness is equivalent to surjectivity (for maps between étale schemes over a base), the lemma is now physically clear.

□

Now we turn to the first of the two main results we want to prove. Let $\pi : J \to A$ be an optimal quotient of abelian varieties over K (i.e., we assume that $\ker \pi$ is an abelian variety over K), and assume that J has semistable reduction over R (so A does too). We do not yet make any hypotheses of purely toric reduction. The dual abelian varieties $A^\vee$ and $J^\vee$ again have semistable reduction, as they are isogenous to A and J respectively.

Theorem 8.2. *With notation as above, the map $X_{J^\vee} \to X_{A^\vee}$ induced by π is surjective.*

Proof. The underlying idea comes down to two facts: Lemma 8.1 and the fact that we can lift tori on the level of ℓ-divisible groups for any prime ℓ. More precisely, we argue as follows. By Proposition 3.3, the map $\pi^\vee : A^\vee \to J^\vee$ is a closed immersion of abelian varieties. We will use this to prove that the induced map $\pi_t^\vee$ on closed fiber tori of Néron models is a closed immersion. Since the "character group" functor sets up an anti-equivalence of categories between tori over a field F and finite free $\mathbf{Z}$-modules with continuous action of $\mathrm{Gal}(F_s/F)$, identifying closed immersions of tori with surjections of character groups and surjections of tori with "saturated injections" of character groups (i.e., injections with torsion-free cokernel), the closed immersion property for $\pi_t^\vee$ on the closed fiber tori will yield the desired surjection of character groups.

In general the "Néron model" functor doesn't behave well for closed immersions. That is, just because $\pi^\vee$ is a closed immersion, it does not follow purely formally that $\pi^\vee$ induces a closed immersion on Néron models. Nevertheless, we claim quite generally that if $B \to B'$ is a closed immersion of abelian varieties over K with semistable Néron models, then the induced map $T \to T'$ on closed fiber tori is a closed immersion. For this it is sufficient to prove that the induced map on ℓ-divisible groups $T[\ell^\infty] \to T'[\ell^\infty]$ is a closed immersion for *all* primes ℓ (i.e., all maps $T[\ell^n] \to T'[\ell^n]$ are closed immersions). Indeed, suppose we verify this closed immersion property on torsion, and let H be the kernel of $T \to T'$, so $H[\ell^n] = 0$ for all primes ℓ and positive integers n. The torus $(H^0_{/\overline{k}})_{\mathrm{red}}$ must vanish (as it has no non-trivial torsion) and hence H is finite. If N is the order of H, then $H = H[N] = 0$. The map $T \to T'$ is then a monomorphism between algebraic groups over a field and hence is a closed immersion, as desired.

In order to verify that the ℓ-divisible group maps $T[\ell^\infty] \to T'[\ell^\infty]$ are closed immersions for all ℓ, we can make the faithfully flat base change to the henselization of R (which commutes with formation of Néron models) to reduce to the case where R is henselian. Now we recall the following basic result of Grothendieck:

Lemma 8.3. *Let R be a henselian local ring, G a quasi-finite separated R-scheme of finite presentation. There is a unique decomposition*

$$G = G_f \coprod G'$$

into disjoint clopen pieces with G_f finite over R (called the "finite part"of G) and G' having empty closed fiber. The formation of G_f is functorial in G and is compatible with henselian local base change and formation of fiber products over R.

If moreover G is a group scheme over R, then G_f is a clopen subgroup scheme and there exists a unique multiplicative closed R-subgroup scheme G_μ inside of G whose closed fiber is the multiplicative part of the closed fiber of G (G_μ is called the "multiplicative part" of G). The formation of G_μ is functorial in G.

Proof. For the first part, see [8, IV_4, 18.5.11(c)] (aside from the functorial properties, which are obvious). The second part, concerning group schemes, is a mechanical consequence of the first part (including the functoriality of the finite part). For example, the existence of G_μ follows from considering the connected-étale sequence of the Cartier dual of G_f over the henselian local base R, and the uniqueness and functoriality follows from the functoriality of $G \rightsquigarrow G_f$ and the functoriality of the connected-étale sequence.

□

Remark 8.4. Assuming R in Lemma 8.3 is a discrete valuation ring (with fraction field K and residue field k), let us make some observations concerning the behavior of Lemma 8.3 with respect to primary components, as this will be useful later. Let's suppose that N and M are relatively prime integers with NM divisible by the order of G_K, and hence killing G. Thus, by functoriality we have $G = G[N] \times_R G[M]$ where $G[N]$ and $G[M]$ are quasi-finite separated R-group schemes. We claim that $G[N]$ and $G[M]$ are also *flat* over R, whence it follows that the formation of G_f and G_μ is compatible with passage to "primary components".

In other words, if ℓ is a prime and ℓ^n is divisible by the ℓ-part of the order of G_K, then we claim that $G[\ell^n]$ is R-flat. From the clopen decomposition $G = G_f \coprod G'$, it is easy to see that $G[\ell^n] = G_f[\ell^n] \coprod X_n$ for some finite K-scheme X_n, so for the issue of R-flatness we can replace G with G_f. We are thereby reduced to the finite flat case, so we can use the proof of [10, 1.7.2].

The significance of Lemma 8.3 for our purposes is the following standard consequence.

Corollary 8.5. *Let A be an abelian variety over the fraction field K of a henselian discrete valuation ring R with residue field k. Let $\mathcal{A}$ be the Néron model of A, and assume that $\mathcal{A}$ has semistable reduction. For every prime ℓ, there exists a unique multiplicative ℓ-divisible group Γ_ℓ inside of $\mathcal{A}$ whose closed fiber is the ℓ-divisible group of the torus T of $\mathcal{A}_k^0$. The formation of Γ_ℓ is functorial in A.*

Proof. Fix ℓ. By the semistability hypothesis, the multiplication maps $\ell^n : \mathcal{A} \to \mathcal{A}$ are quasi-finite flat, so $\mathcal{A}[\ell^n]$ is a quasi-finite flat separated R-group scheme. Let $\mathcal{A}[\ell^n]_\mu$ denote its multiplicative part (as in Lemma 8.3), so the multiplicative $T[\ell^n] \hookrightarrow \mathcal{A}[\ell^n]_k$ lies inside of $(\mathcal{A}[\ell^n]_\mu)_k$. The "closed fiber" functor is an equivalence of categories between finite flat multiplicative group schemes over R and k (since Cartier duality reduces this to the étale case, and the "closed fiber" functor is an equivalence of categories between finite étale R-schemes and finite étale k-schemes [8, IV$_4$, 18.5.12]). Thus, there exists a unique multiplicative closed R-subgroup scheme $\Gamma^{(n)} \hookrightarrow \mathcal{A}[\ell^n]_\mu$ whose closed fiber is $T[\ell^n]$.

Moreover, using the equivalence of categories just mentioned, $\mathcal{A}[\ell^n]_\mu$ lies inside of $\mathcal{A}[\ell^{n+1}]_\mu$ and $\Gamma^{(n)}$ lies inside of $\Gamma^{(n+1)}$. The resulting system $\Gamma_\ell = \{\Gamma^{(n)}\}$ over R forms an ℓ-divisible group on the closed fiber and hence is an ℓ-divisible group over R. This settles the desired existence, as well as the desired uniqueness. The functoriality of Γ_ℓ in A follows from the functoriality of toric parts on the closed fiber of Néron models.

□

Returning to the proof of Theorem 8.2, recall that we were studying the map of toric parts $j_t : T \to T'$ induced by a closed immersion $j : B \hookrightarrow B'$ of semistable abelian varieties over K, with R henselian. We wanted the map

$$j_t[\ell^\infty] : T[\ell^\infty] \to T'[\ell^\infty]$$

to be a closed immersion for all primes ℓ (as we have seen that this forces $T \to T'$ to be a closed immersion, which is what we really want to show). Fix ℓ. By Corollary 8.5 there exist unique multiplicative ℓ-divisible groups Γ and Γ' over R in the respective Néron models $\mathcal{B}$ and $\mathcal{B}'$ such that Γ and Γ' respectively lift the ℓ-divisible groups of the tori of the closed fibers. Hence, it suffices to show that the R-map $\gamma : \Gamma \to \Gamma'$ induced by the Néron functoriality map $\mathrm{N}(j)$ is a closed immersion. The generic fiber map γ_K is a closed immersion since it "sits inside" the generic fiber ℓ-divisible groups of B and B', the map between which is a closed immersion since $j : B \to B'$ is a closed immersion. Now we use Lemma 8.1 (applied at all finite torsion levels) to conclude that γ is a closed immersion. This completes the proof of Theorem 8.2.

□

We now turn to a result which requires a stronger hypothesis on the closed fiber. Note that we retain the hypothesis that R is henselian (this hypothesis arose in the proof of Theorem 8.2, even though it wasn't needed for the statement). Let A and B be abelian varieties over K with purely toric reduction (i.e., their Néron models have closed fiber connected components which are tori). Let $\varphi : A \to B$ be an isogeny, and let $\varphi_t : T_A \to T_B$ be the induced map on the closed fiber toric parts (i.e., connected components) of the Néron models. We denote by $\varphi_t^\vee : T_{B^\vee} \to T_{A^\vee}$ the analogous map induced by the dual isogeny $\varphi^\vee$. Since the map φ_t is an isogeny (by functoriality), the kernel $\ker(\varphi_t)$ is a finite multiplicative k-group scheme.

For any finite multiplicative k-group scheme G, we let $\widetilde{G}$ denote the (unique) multiplicative finite flat R-group scheme with closed fiber G. For example, $\widetilde{\ker(\varphi_t)}$ is a multiplicative R-group scheme which lies inside of

$$\ker(\mathrm{N}(\varphi))_\mu$$

(where $\mathrm{N}(\varphi)$ is the map induced by Néron functoriality). Thus, we have a natural closed immersion

$$(\widetilde{\ker\varphi_t})_K \hookrightarrow \ker\varphi$$

and likewise we have a natural quotient map

$$\ker(\varphi^\vee)^\vee \to \widetilde{\ker(\varphi_t^\vee)}^\vee_K$$

dual to the natural closed immersion using the isogeny $\varphi^\vee$.

By the duality theory for abelian varieties (particularly the adjointness of φ and $\varphi^\vee$ with respect to the scheme-theoretic Weil pairing over K), there is a canonical perfect duality K-group scheme duality between $\ker(\varphi)$ and $\ker(\varphi^\vee)$ over K, whence there is a natural quotient map of K-group schemes

$$\ker(\varphi) \simeq \ker(\varphi^\vee)^\vee \to \widetilde{\ker(\varphi_t^\vee)}_K^\vee.$$

Theorem 8.6. *The diagram of K-group schemes*

$$0 \to \widetilde{\ker(\varphi_t)}_K \to \ker(\varphi) \to \widetilde{\ker(\varphi_t^\vee)}_K^\vee \to 0$$

is exact.

The content of the proof is the Grothendieck Orthogonality Theorem. Moreover, Theorem 8.6 is implicit in Grothendieck's construction of the monodromy pairing for semiabelian varieties.

Proof. The exact sequence of the theorem says that the finite flat K-group schemes p

$$\ker(\varphi)/\widetilde{\ker(\varphi_t)}_K \quad \text{and} \quad \widetilde{\ker(\varphi_t^\vee)}_K$$

are canonically Cartier dual to each other compatibly with the perfect duality between $\ker(\varphi)$ and $\ker(\varphi^\vee)$. More precisely, let $\mathcal{A}$ and $\mathcal{B}$ denote the Néron models of A and B, respectively, let

$$G = \ker(\mathcal{A} \to \mathcal{B}), \quad G^\vee = \ker(\mathcal{B}^\vee \to \mathcal{A}^\vee),$$

so G and $G^\vee$ are both quasi-finite flat separated R-group schemes whose generic fibers are the $\ker(\varphi)$ and $\ker(\varphi^\vee)$ in the theorem (the R-flatness of G and $G^\vee$ arises from the semiabelian condition, since any quasi-finite morphism between semi-abelian schemes is necessarily flat, as can be checked on geometric fibers). Being quasi-finite flat and separated, the R-group schemes G and $G^\vee$ have canonical respective "finite parts" G_f and $G_f^\vee$ and "multiplicative parts" G_μ and $G_\mu^\vee$ (as in Lemma 8.3). Beware that we do *not* claim $G_f^\vee$ (resp. $G_\mu^\vee$) is the Cartier dual to G_f (resp. G_μ); usually such duality does not hold.

Since G_μ and $G_\mu^\vee$ are finite flat R-group schemes, the quotients G/G_μ and $G^\vee/G_\mu^\vee$ make sense as quasi-finite flat separated R-group schemes. The theorem almost says that there is a canonical duality between $(G/G_\mu)_K = G_K/(G_\mu)_K$ and $(G_\mu^\vee)_K$, induced by the duality between $G_K = \ker(\varphi)$ and $G_K^\vee = \ker(\varphi^\vee)$, except for the mild problem that G_μ might be larger than $\widetilde{\ker(\varphi_t)}$ (i.e., possibly $(G_\mu)_k$ is not entirely inside of $\mathcal{A}_k^0$) and likewise $G_\mu^\vee$ might be larger than $\widetilde{\ker(\varphi_t^\vee)}$.

We will work on ℓ-primary components for each prime ℓ individually. In order to permit this, we use Remark 8.4. We will first treat the more subtle case when ℓ is the residue characteristic, and then we'll handle the case when it isn't. The advantage of working with the case in which ℓ is the residue characteristic is that multiplicative finite k-group schemes are automatically *connected*. Thus, in this case $(G_\mu)_\ell = \widetilde{\ker(\varphi_t)}_\ell$ and $(G_\mu^\vee)_\ell = \widetilde{\ker(\varphi_t^\vee)}_\ell$.

Since

$$0 \to G_K \to A \to B \to 0$$

is an exact sequence of abelian sheaves on the fppf site over $\mathrm{Spec}(K)$, by the usual snake lemma argument (and the fact that the ℓ-part $(G_K)_\ell$ of G_K is killed by a big power of ℓ) we obtain an exact sequence

$$0 \to (G_K)_\ell \to A[\ell^\infty] \to B[\ell^\infty] \to 0.$$

Arguing as in Corollary 8.5, there is an exact sequence over $\mathrm{Spec}(R)$

$$0 \to (G_\mu)_\ell \to \mathcal{A}[\ell^\infty]_t \to \mathcal{B}[\ell^\infty]_t \to 0$$

which lifts the exact sequence involving ℓ-divisible groups of tori on the closed fiber (as $(G_\mu)_\ell$ *must* be in the relative connected component of $\mathcal{A}$). Passing to the generic fiber over K gives us a commutative diagram with exact rows and closed immersions along columns

$$\begin{tikzcd}
0 \arrow[r] & ((G_\mu)_K)_\ell \arrow[r] \arrow[d] & A[\ell^\infty]_t \arrow[r] \arrow[d] & B[\ell^\infty]_t \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & (G_K)_\ell \arrow[r] & A[\ell^\infty] \arrow[r] & B[\ell^\infty] \arrow[r] & 0
\end{tikzcd}$$

where $A[\ell^\infty]_t$ denotes the K-fiber of the ℓ-divisible group $\{\mathcal{A}[\ell^n]_t\}$, and likewise for $B[\ell^\infty]_t$.

Using the snake lemma in the category of fppf abelian sheaves over $\mathrm{Spec}(K)$, we get a short exact sequence of cokernels

$$0 \to ((G/G_\mu)_K)_\ell \to A[\ell^\infty]/(\text{toric}) \to B[\ell^\infty]/(\text{toric}) \to 0$$

where all maps are the natural ones, and right two terms are ℓ-divisible groups over K.

The Grothendieck Orthogonality Theorem (see [9, Exp. IX, Prop 5.6]) asserts that the perfect scheme-theoretic Weil pairing between $A[\ell^n]$ and $A^\vee[\ell^n]$ makes $A[\ell^n]_t$ and $A^\vee[\ell^n]_f$ exact annhilators, where $A[\ell^n]_f$ denotes the K-fiber of the finite part of the $\mathcal{A}^0[\ell^n]$ and $A[\ell^n]_t$ denotes the K-fiber of the unique R-subgroup scheme in $\mathcal{A}^0[\ell^n]$ lifting the ℓ^n-torsion on the closed fiber torus. By the purely toric condition applied to $A^\vee$, we see $A^\vee[\ell^n]_f = A^\vee[\ell^n]_t$. Thus, the orthogonality theorem says that $A[\ell^n]/A[\ell^n]_t$ and $A^\vee[\ell^n]_t$ are in perfect duality via the scheme-theoretic Weil pairing over K.

Passing to the limit, we get a canonical isomorphism of ℓ-divisible groups

$$A[\ell^\infty]/(\text{toric}) = (A^\vee[\ell^\infty]_t)^\vee.$$

But φ and $\varphi^\vee$ are adjoint with respect to Weil pairing, so we conclude that the diagram

$$\begin{tikzcd}
A[\ell^\infty]/(\text{toric}) \arrow[r, equal] \arrow[d, "\varphi"] & (A^\vee[\ell^\infty]_t)^\vee \arrow[d, "(\varphi_t^\vee)^\vee"] \\
B[\ell^\infty]/(\text{toric}) \arrow[r, equal] & (B^\vee[\ell^\infty]_t)^\vee
\end{tikzcd}$$

commutes. Thus, we get an isomorphism between the kernels of these vertical isogenies. The kernel of the left column is $((G/G_\mu)_K)_\ell$, as we saw above. Meanwhile, the kernel of the right is (by duality theory of ℓ-divisible groups) exactly the dual of $\ker(\varphi_t^\vee) = (G_\mu^\vee)_K$. This gives the desired perfect duality between $(G/G_\mu)_K$ and $(G_\mu^\vee)_K$ on ℓ-primary parts for ℓ equal to the residue characteristic.

Now we consider the case when ℓ is not equal to the residue characteristic. There is no loss of generality in passing to the case of a strictly henselian base R. Thus, the closed fiber tori have *constant* ℓ-divisible groups. Also, we can work with $\mathbf{Z}_\ell$-modules of geometric points (over K) via Tate's construction. The "toric" part of the ℓ-adic Tate module $T_\ell(A)$ is exactly the (saturated) maximal submodule with trivial Galois action, since a compatible system of ℓ-power torsion points in $A(K) = \mathcal{A}(R)$ must lie entirely inside of $\mathcal{A}^0(R)$ (thanks to the finiteness of the component group) and we can identify $\mathcal{A}^0(R)[\ell^n]$ with the (constant) ℓ^n-torsion on the split torus $\mathcal{A}_k^0$ over the separably closed k.

Using inverse limits, we see that $T_\ell(A) \to T_\ell(B)$ is injective with cokernel $(G_K)_\ell$ (= geometric points of ℓ-part), and this cokernel is exactly $\ker(\varphi)_\ell$. Likewise, the cokernel of the map

$$T_\ell(A)_t \to T_\ell(B)_t$$

on "toric" parts (i.e., ℓ-adic Tate module generic fibers of the lifts of the ℓ-divisible groups of closed fiber tori) is $(\widetilde{\ker(\varphi_t)}_K)_\ell$.

Thus, we get a commutative diagram with horizontal exact sequences

$$\begin{tikzcd}
0 \arrow[r] & T_\ell(A)_t \arrow[r] \arrow[d] & T_\ell(B)_t \arrow[r] \arrow[d] & (\widetilde{\ker(\varphi_t)}_K)_\ell \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & T_\ell(A) \arrow[r] & T_\ell(B) \arrow[r] & \ker(\varphi)_\ell \arrow[r] & 0
\end{tikzcd}$$

with columns given by the natural maps. These vertical maps are all injective, so by the snake lemma we get a short exact sequence of cokernels. We can now use the exact same Weil pairing arguments with the Grothendieck orthogonality theorem (now in the easier "$\ell \neq p$" form of the orthogonality theorem [9, Exp IX, 2.4]), essentially just as we argued in the previous case. One distinction is that the use of inverse limit Tate modules rather than direct limits causes some maps to switch direction.

More specifically we have a commutative square with horizontal isomporphisms (thanks to the orthogonality theorem)

$$\begin{tikzcd}
T_\ell(A)/T_\ell(A)_t \arrow[r, equal] \arrow[d, "\varphi"'] & T_\ell(A^\vee)_t^\vee \arrow[d, "T_\ell(\varphi_t^\vee)^\vee"] \\
T_\ell(B)/T_\ell(B)_t \arrow[r, equal] & T_\ell(B^\vee)_t^\vee
\end{tikzcd}$$

This induces an isomorphism

$$((\ker\varphi)/\widetilde{\ker(\varphi_t)}_K)_\ell \simeq ((\widetilde{\ker\varphi_t^\vee})_K)_\ell^\vee$$

between the vertical cokernels, and by construction this isomorphism is compatible with Weil pairings, whence the desired perfect pairing has been shown.

□

Let R be an arbitrary dvr (not necessarily henselian), let $\varphi : A \to B$ be an isogeny, and let $\varphi_t : T_A \to T_B$ be the induced map on the closed fiber toric parts, as above.

Corollary 8.7. *The order of* $\ker(\varphi)$ *is the product of the orders of* $\ker\varphi_t$ *and* $\ker\varphi_t^\vee$*.*

Proof. Pass to the henselization of R and use Theorem 8.6. □

Received November 24, 2001; revised February 27, 2002

We investigate Mazur's notion of visibility of elements of Shafarevich–Tate groups of abelian varieties. We give a proof that every cohomology class is visible in a suitable abelian variety, discuss the visibility dimension, and describe a construction of visible elements of certain Shafarevich–Tate groups. This construction can be used to give some of the first evidence for the Birch and Swinnerton–Dyer conjecture for abelian varieties of large dimension. We then give examples of visible and invisible Shafarevich–Tate groups. © 2002 Elsevier Science (USA)

Key Words: visibility; Shafarevich–Tate group; Birch and Swinnerton–Dyer conjecture; modular abelian variety.

INTRODUCTION

If a genus 0 curve X over $\mathbf{Q}$ has a point in every local field $\mathbf{Q}_p$ and in $\mathbf{R}$, then it has a global point over $\mathbf{Q}$. For genus 1 curves, this "local-to-global principle" frequently fails. For example, the nonsingular projective curve defined by the equation $3x^3 + 4y^3 + 5z^3 = 0$ has a point over each local field and $\mathbf{R}$, but has no $\mathbf{Q}$-point. The Shafarevich–Tate group of an elliptic curve E, denoted $Ш(E)$, is a group that measures the extent to which a local-to-global principle fails for the genus one curves with Jacobian E. More generally, if A is an abelian variety over a number field K, then the elements of the Shafarevich–Tate group $Ш(A)$ of A correspond to the torsors for A that have a point everywhere locally, but not globally. In this paper, we study a geometric way of realizing (or "visualizing") torsors corresponding to elements of $Ш(A)$.

Let A be an abelian variety over a field K. If $\iota : A \hookrightarrow J$ is a closed immersion of abelian varieties, then the subgroup of $H^1(K, A)$ *visible in* J (with respect to ι) is $\ker(H^1(K, A) \to H^1(K, J))$. We prove that every element of $H^1(K, A)$ is visible in some abelian variety, and give bounds on the smallest size of an abelian variety in which an element of $H^1(K, A)$ is visible. Next assume that K is a number field. We give a construction of visible elements of $Ш(A)$, which we demonstrate by giving evidence for the Birch and Swinnerton–Dyer conjecture for a certain 20-dimensional abelian variety. We also give an example of an elliptic curve E over $\mathbf{Q}$ of conductor N whose Shafarevich–Tate group is not visible in $J_0(N)$ but is visible in $J_0(Np)$ for some prime p.

This paper is organized as follows. Section 1 contains the definition of visibility for cohomology classes and elements of Shafarevich–Tate groups. Then in Section 1.3, we use a restriction of scalars construction to prove that every cohomology class is visible in some abelian variety. Next, in Section 2, we investigate the visibility dimension of cohomology classes. Section 3 contains a theorem that can be used to construct visible elements of Shafarevich–Tate groups. Finally, Section 4, contains examples and applications of our visibility results in the context of modular abelian varieties.

1. VISIBILITY

In Section 1.1 we introduce visible cohomology classes, then in Section 1.2 we discuss visible elements of Shafarevich–Tate groups. In Section 1.3, we use restriction of scalars to deduce that every cohomology class is visible somewhere.

For a field K and a smooth commutative K-group scheme G, we write $H^i(K, G)$ to denote the group cohomology $H^i(\mathrm{Gal}(K_s/K), G(K_s))$ where K_s is a fixed separable closure of K; equivalently, $H^i(K, G)$ denotes the ith étale cohomology of G viewed as an étale sheaf on $\mathrm{Spec}(K)_{\text{ét}}$.

1.1. *Visible elements of* $H^1(K, A)$.

In [Maz99], Mazur introduced the following definition. Let A be an abelian variety over an arbitrary field K.

Definition 1.1. Let $\iota : A \hookrightarrow J$ be an embedding, of A into an abelian variety J over K. Then the *visible subgroup of* $H^1(K, A)$ *with respect to the embedding* ι is

$$\mathrm{Vis}_J(H^1(K, A)) = \mathrm{Ker}(H^1(K, A) \to H^1(K, J)).$$

The visible subgroup $\mathrm{Vis}_J(H^1(K, A))$ depends on the choice of embedding ι, but we do not include ι in the notation, as it is usually clear from context.

The Galois cohomology group $H^1(K, A)$ has a geometric interpretation as the group of classes of torsors X for A (see [LT58]). To a cohomology class $c \in H^1(K, A)$, there is a corresponding variety X over K and a map $A \times X \to X$ that satisfies axioms similar to those for a simply transitive group action. The set of equivalence classes of such X forms a group, the Weil–Chatelet group of A, which is canonically isomorphic to $H^1(K, A)$.

There is a close relationship between visibility and the geometric interpretation of Galois cohomology. Suppose $\iota : A \to J$ is an embedding and $c \in \mathrm{Vis}_J(H^1(K, A))$. We have an exact sequence of abelian varieties $0 \to A \to J \to C \to 0$, where $C = J/A$. A piece of the associated long exact sequence of Galois cohomology is

$$0 \to A(K) \to J(K) \to C(K) \to H^1(K, A) \to H^1(K, J) \to \cdots,$$

so there is an exact sequence

$$0 \to J(K)/A(K) \to C(K) \to \mathrm{Vis}_J(H^1(K, A)) \to 0. \tag{1.1}$$

Thus there is a point $x \in C(K)$ that maps to c. The fiber X over x is a subvariety of J, which, when equipped with its natural action of A, lies in the class of torsors corresponding to c. This is the origin of the terminology "visible". Also, we remark that when K is a number field, $\mathrm{Vis}_J(H^1(K, A))$ is finite because it is torsion and is the surjective image of the finitely generated group $C(K)$.

1.2. *Visible Elements of* Ш(A). Let A be an abelian variety over a number field K. The Shafarevich–Tate group of A, which is defined below, measures the failure of the local-to-global principle for certain torsors. The *Shafarevich–Tate group* of A is

$$Ш(A) := \mathrm{Ker}\left(H^1(K, A) \to \prod_v H^1(K_v, A)\right),$$

where the product is over all places of K.

Definition 1.2. If $\iota : A \hookrightarrow J$ is an embedding then the *visible subgroup of* Ш(A) *with respect to* ι is

$$\mathrm{Vis}_J(Ш(A)) := Ш(A) \cap \mathrm{Vis}_J(H^1(K, A)) = \mathrm{Ker}(Ш(A) \to Ш(J)).$$

1.3. *Every Element is Visible Somewhere.*

Proposition 1.3. *Every element of $H^1(K, A)$ is visible in some abelian variety J.*

Proof. Fix $c \in H^1(K, A)$. There is a finite separable extension L of K such that $\mathrm{res}_L(c) = 0 \in H^1(K, A)$. Let $J = \mathrm{Res}_{L/K}(A_L)$ be the Weil restriction of scalars from L to K of the abelian variety A_L (see [BLR90, Sect. 7.6]). Thus J is an abelian variety over K of dimension $[L : K] \cdot \dim(A)$, and for any scheme S over K, we have a natural (functorial) group isomorphism $A_L(S_L) \cong J(S)$. The functorial injection $A(S) \hookrightarrow A_L(S_L) \cong J(S)$ corresponds via Yoneda's Lemma to a natural K-group scheme map $\imath : A \to J$, and by construction $\imath$, is a monomorphism. But $\imath$ is proper and thus is a closed immersion (see [Gro66, Sect. 8.11.5]). Using the Shapiro lemma one finds, after a tedious computation, that there is a canonical isomorphism $H^1(K, J) \cong H^1(L, A)$ which identifies $\imath_*(c)$ with $\mathrm{res}_L(c) = 0$. ∎

Remark 1.4. 1. In [CM00], de Jong gave a totally different proof of the above proposition in the case when A is an elliptic curve over a number field. His argument actually displays A as visible inside the Jacobian of a curve.

2. L. Clozel has remarked that the method of proof above is a standard technique in the theory of algebraic groups.

2. THE VISIBILITY DIMENSION

Let A be an abelian variety over a field K and fix $c \in H^1(K, A)$.

Definition 2.1. The *visibility dimension* of c is the minimum of the dimensions of the abelian varieties J such that c is visible in J.

In Section 2.1 we prove an elementary lemma which, when combined with the proof of Proposition 1.3, gives an upper bound on the visibility dimension of c in terms of the order of c and the dimension of A. Then, in Section 2.2, we consider the visibility dimension in the case when $A = E$ is an elliptic curve. After summarizing the results of Mazur and Klenke on the visibility dimension, we apply a theorem of Cassels to deduce that the visibility dimension of $c \in \text{Ш}(E)$ is at most the order of c.

2.1. *A Simple Bound.*

The following elementary lemma, which the second author learned from Hendrik Lenstra, will be used to give a bound on the visibility dimension in terms of the order of c and the dimension of A.

Lemma 2.2. *Let G be a group, M be a finite (discrete) G-module, and $c \in H^1(G, M)$. Then there is a subgroup H of G such that* $\mathrm{res}_H(c) = 0$ *and* $\#(G/H) \leqslant \#M$.

Proof. Let $f : G \to M$ be a cocycle corresponding to c, so $f(\tau\sigma) = f(\tau) + \tau f(\sigma)$ for all $\tau, \sigma \in G$. Let $H = \ker(f) = \{\sigma \in G : f(\sigma) = 0\}$. The map $\tau H \mapsto f(\tau)$ is a well-defined injection from the coset space G/H to M. ∎

The following is a general bound on the visibility dimension.

PROPOSITION 2.3. *The visibility dimension of any $c \in H^1(K, A)$ is at most $d \cdot n^{2d}$ where n is the order of c and d is the dimension of A.*

Proof. The map $H^1(K, A[n]) \to H^1(K, A)[n]$ is surjective and $A[n]$ has order n^{2d}, so Lemma 2.2 implies that there is an extension L of K of degree at most n^{2d} such that $\mathrm{res}_L(c) = 0$. The proof of Proposition 1.3 implies that c is visible in an abelian variety of dimension $[L : K] \cdot \dim A \leqslant dn^{2d}$. ∎

2.2. *The Visibility Dimension for Elliptic Curves.* We now consider the case when $A = E$ is an elliptic curve over a number field K. Mazur proved in [Maz99] that every nonzero $c \in \text{Ш}(E)[3]$ has visibility dimension 2 (note that Proposition 2.3 only implies that the visibility dimension is $\leqslant 3$). Mazur's result is particularly nice because it shows that c is visible in an abelian variety that is isogenous to the product of two elliptic curves. Using similar techniques, Klenke proved in [Kle01] that every nonzero $c \in H^1(K, E)[2]$ has visibility dimension 2 (note that Proposition 2.3 only implies that the visibility dimension of any $c \in H^1(K, E)[2]$ is $\leqslant 4$). It is unknown whether the visibility dimension of every nonzero element of $H^1(K, E)[3]$ is 2, and it is not known whether elements of $\text{Ш}(E)[5]$ must have visibility dimension 2.

When c lies in $\text{Ш}(E)$ we use a classical result of Cassels to strengthen the conclusion of Proposition 2.3.

PROPOSITION 2.4. *Let E be an elliptic curve over a number field K and let $c \in \text{Ш}(E)$. Then the visibility dimension of c is at most the order of c.*

Proof. Let n be the order of c. In view of the restriction of scalars construction in the proof of Proposition 1.3, it suffices to show that there is an extension L of K of degree n such that $\mathrm{res}_L(c) = 0$. Without the hypothesis that c lies in $\text{Ш}(E)$, such an extension L might not exist, as Cassels observed in [Cas63]. However, in that same paper, Cassels proved that such an L exists when $c \in \text{Ш}(E)$ (see also [O'N01] for another proof). ∎

Remark 2.5. In contrast to the case of dimension 1, it seems to be an open problem to determine whether or not elements of $\text{Ш}(A)[n]$ split over an extension of degree n.

3. CONSTRUCTION OF VISIBLE ELEMENTS

The goal of this section is to state and prove the main result of this paper, which we use to construct visible elements of Shafarevich–Tate groups and sometimes give a nontrivial lower bound for the order of the Shafarevich–Tate group of an abelian variety thus providing new evidence for the conjecture of Birch and Swinnerton–Dyer (see Section 4.1 and [AS02]). The Tamagawa numbers $c_{A,v}$ and $c_{B,v}$ will be defined in Section 3.1.

Theorem 3.1. *Let A and B be abelian subvarieties of an abelian variety J over a number field K such that $A \cap B$ is finite. Let N be an integer divisible by the residue characteristics of primes of bad reduction for B. Suppose n is an integer such that for each prime $p|n$, we have $e_p < p-1$ where e_p is the largest ramification of any prime of K lying over p, and that*

$$\gcd\left(n, N \cdot \#(J/B)(K)_{\text{tor}} \cdot \#B(K)_{\text{tor}} \cdot \prod_{\text{all places } v} (c_{A,v} \cdot c_{B,v})\right) = 1,$$

where $c_{A,v} = \#\Phi_{A,v}(\mathbf{F}_\ell)$ (resp., $c_{B,\ell}$) is the Tamagawa number of A (resp., B) at v (see Section 3.1 for the definition of $\Phi_{A,v}$). Suppose furthermore that $B[n] \subset A$ as subgroup schemes of J. Then there is a natural map

$$\varphi : B(K)/nB(K) \to \mathrm{Vis}_J(\text{Ш}(A)),$$

such that $\ker(\varphi) \subset J(K)/(B(K) + A(K))$. *If $A(K)$ has rank* 0, *then* $\ker(\varphi) = 0$ (*more generally*, $\ker(\varphi)$ *has order at most n^r where r is the rank of $A(K)$*).

Remark 3.2. Mazur has proved similar results for elliptic curves using flat cohomology (unpublished), and discussions with him motivated this theorem.

In Section 3.1 we recall a definition of the Tamagawa numbers of an abelian variety. In Section 3.2 we prove a lemma, which gives a condition under which there is an unramified nth root of an unramified point. In Section 3.3, we use the snake lemma to produce a map

$$B(K)/nB(K) \hookrightarrow \mathrm{Vis}_J(H^1(K, A))$$

with bounded kernel. Finally, in Section 3.4, we use a local analysis at each place of K to show that the image of the above map lies in Ш(A).

3.1. *Tamagawa Numbers.* Let A be an abelian variety over a local field K with residue class field k, and let $\mathscr{A}$ be the Néron model of A over the ring of integers of K. The closed fiber $\mathscr{A}_k$ of $\mathscr{A}$ need not be connected. Let $\mathscr{A}_k^0$ denote the geometric component of $\mathscr{A}$ that contains the identity. The group

$\Phi_{\mathscr{A}} = \mathscr{A}_k/\mathscr{A}_k^0$ of connected components is a finite group scheme over k. This group scheme is called the *component group* of $\mathscr{A}$, and the *Tamagawa number* of A is $c_A = \#\Phi_{\mathscr{A}}(k)$.

Now suppose that A is an abelian variety over a global field K. For every place v of K, the *Tamagawa number* of A at v, denoted $c_{A,v}$ or just c_v, is the Tamagawa number of A_{K_v}, where K_v is the completion of K at v.

3.2. *Smoothness and Surjectivity.* In this section, we recall some well-known lemmas that we will use in Section 3.4 to produce unramified cohomology classes. The authors are grateful to B. Conrad for explaining the proofs of these lemmas.

LEMMA 3.3. *If G is a finite-type smooth commutative group scheme over a strictly henselian local ring R and the fibers of G over R are (geometrically) connected, then the multiplication map*

$$n_G : G(R) \to G(R)$$

is surjective when $n \in R^\times$.

Proof. Pick an element $g \in G(R)$ and form the cartesian diagram

$$\begin{tikzcd} Y_g \arrow[r, "\psi"] \arrow[d] & \mathrm{Spec}(R) \arrow[d, "g"] \\ G \arrow[r, "n_G"] & G \end{tikzcd}$$

We want to prove that ψ has a section. Since R is strictly henselian, by [Gro67, 18.8.1] it suffices to show that Y_g is étale over R with nonempty closed fiber, or more generally that n_G is étale and surjective.

By Lemma 2(b) of [BLR90, Sect. 7.3], n_G is étale. The image of the étale n_G must be an open subgroup scheme, and on fibers over $\mathrm{Spec}(R)$ we get surjectivity since an open subgroup scheme of a smooth connected (hence irreducible) group scheme over a field must fill up the whole space [Gro70, $\mathrm{VI_A}$, 0.5]. ∎

LEMMA 3.4. *Let A be an abelian variety over the fraction field K of a strictly henselian dvr (e.g., K could be the maximal unramified extension a local field). Let n be an integer not divisible by the residue characteristic of K. Suppose that x is a point of $A(K)$ whose reduction lands in the identity* *component of the closed fiber of the Néron model of A. Then there exists $z \in A(K)$ such that $nz = x$.*

Proof. Let $\mathscr{A}$ denote the Néron model of A over the valuation ring R of K, and let $\mathscr{A}^0$ denote the "identity component" (i.e., the open subgroup scheme obtained by removing the nonidentity components of the closed fiber of $\mathscr{A}$). The hypothesis on the reduction of $x \in A(K) = \mathscr{A}^0(R)$ says exactly that $x \in \mathscr{A}^0(R)$. Since connected schemes over a field are geometrically connected when there is a rational point [Gro65, Proposition 4.5.13], the fibers of $\mathscr{A}^0$ over $\operatorname{Spec}(R)$ are geometrically connected. The lemma now follows from Lemma 3.3 with $G = \mathscr{A}^0$. ∎

Remark 3.5. M. Baker noted that this argument can also be formulated in terms of formal groups when R is the strict henselization of a *complete* dvr.

Lemma 3.6. *Let $\mathscr{J} \xrightarrow{\phi} \mathscr{C}$ be a smooth surjective morphism of schemes over a strictly Henselian local ring R. Then the induced map $\mathscr{J}(R) \to \mathscr{C}(R)$ is surjective.*

Proof. The argument is similar to that of the proof of Lemma 3.3. Pick an element $g \in \mathscr{C}(R)$ and form the cartesian diagram

$$\begin{tikzcd}
Y_g \arrow[r, "\psi"] \arrow[d] & \operatorname{Spec}(R) \arrow[d, "g"] \\
\mathscr{J} \arrow[r, "\phi"] & \mathscr{C}
\end{tikzcd}$$

We want to prove that ψ has a section. Since ϕ is smooth, ψ is also smooth. By Grothendieck [Gro67, 18.5.17], to show that ψ has a section, we just need to show that the closed fiber of ψ has a section (i.e., a rational point). But this closed fiber is smooth and nonempty (since ϕ is surjective); also its base field is separably closed since R is strictly Henselian. Hence by Bosma *et al.* [BLR90, Corollary 2.2.13], the closed fiber has an R-rational point. ∎

3.3. *Visible Elements of $H^1(K, A)$.* In this section, we produce a map $B(K)/nB(K) \to \operatorname{Vis}_J(H^1(K, A))$ with bounded kernel.

Lemma 3.7. *Let A and B be abelian subvarieties of an abelian variety J over a number field K such that $A \cap B$ is finite. Suppose n is a natural number such that*

$$\gcd(n, \#(J/B)(K)_{\mathrm{tor}} \cdot \#B(K)_{\mathrm{tor}}) = 1$$

and $B[n] \subset A$ as subgroup schemes of J. Then there is a natural map

$$\varphi : B(K)/nB(K) \to \mathrm{Vis}_J(H^1(K, A))$$

such that $\ker(\varphi) \subset J(K)/(B(K) + A(K))$. *If $A(K)$ has rank* 0, *then* $\ker(\varphi) = 0$ (*more generally*, $\ker(\varphi)$ *has order at most n^r where r is the rank of $A(K)$*).

Proof. First we produce a map $\varphi : B(K)/nB(K) \to \mathrm{Vis}(H^1(K, A))$ by using that $B[n] \subset A$ hence a certain map factors through multiplication by n. Then we use the snake lemma and our hypothesis that n does not divide the orders of certain torsion groups to bound the dimension of the kernel of φ.

The quotient J/A is an abelian variety C over K. The long exact sequence of Galois cohomology associated to the short exact sequence

$$0 \to A \to J \to C \to 0$$

begins

$$0 \to A(K) \to J(K) \to C(K) \xrightarrow{\delta} H^1(K, A) \to \cdots. \tag{3.1}$$

Let ψ be map $B \to C$ obtained by composing the inclusion $B \hookrightarrow J$ with the quotient map $J \to C$. Since $B[n] \subset A$, we see that ψ factors through multiplication by n, so the following diagram commutes:

$$\begin{tikzcd}
 & B \arrow[r, "n"] \arrow[d] \arrow[dr, "\psi"] & B \arrow[d] \\
A \arrow[r] & J \arrow[r] & C.
\end{tikzcd}$$

Using that $B[n](K) = \{0\}$, we obtain the following commutative diagram, all of whose rows and columns are exact:

$$\begin{tikzcd}
 & K_0 \arrow[d] & K_1 \arrow[d] & K_2 \arrow[d] & \\
0 \arrow[r] & B(K) \arrow[r, "n"] \arrow[d] & B(K) \arrow[r] \arrow[d] \arrow[dr, "\pi"] & B(K)/nB(K) \arrow[r] \arrow[d, "\varphi"] & 0 \\
0 \arrow[r] & J(K)/A(K) \arrow[r] \arrow[d] & C(K) \arrow[r] & \delta(C(K)) \arrow[r] & 0 \\
 & K_3, & & &
\end{tikzcd} \tag{3.2}$$

where K_0, K_1 and K_2 are the indicated kernels and K_3 is the indicated cokernel. Exactness of the top row expresses the fact that $B[n](K) = \{0\}$, and the bottom exact row arises from the exact sequence (3.1) above. The first vertical map $B(K) \to J(K)/A(K)$ is induced by the inclusion $B(K) \hookrightarrow J(K)$ composed with the quotient map $J(K) \to J(K)/A(K)$. The second vertical map $B(K) \to C(K)$ exists because the composition $B \hookrightarrow J \to C$ has kernel $B \cap A$, which contains $B[n]$, by assumption. The third vertical map exists because π contains $nB(K)$ in its kernel, so that π factors through $B(K)/nB(K)$.

Sequence (1.1) implies that the image of φ is contained in $\mathrm{Vis}_J(H^1(K, A))$. The snake lemma gives an exact sequence

$$K_0 \to K_1 \to K_2 \to K_3.$$

Because $B \to C$ has finite kernel, $K_1 \subset B(K)_{\mathrm{tor}}$. Since $B[n](K) = \{0\}$ and K_2 is an n-torsion group, the map $K_1 \to K_2$ is the 0 map. Thus, $K_2 = \ker(\varphi)$ is isomorphic to a subgroup of $K_3 = J(K)/(A(K) + B(K))$, as claimed.

Any torsion in the quotient $J(K)/B(K)$ is of order coprime to n because $J(K)/B(K)$ is a subgroup of $(J/B)(K)$, and $\gcd(n, \#(J/B)(K)_{\mathrm{tor}}) = 1$, by assumption. Thus if $A(K)$ is a torsion group, $K_3 = (J(K)/B(K))/A(K)$ has no nontrivial torsion of order dividing n, so when $A(K)$ has rank zero, $\ker(\varphi) = 0$.

Consider the map $\psi : A(K) \to J(K)/B(K)$. To show that $\ker(\phi)$ has order at most n^r, where r is the rank of $A(K)$, it suffices to show that $\mathrm{coker}(\psi)[n]$ has order at most n^r. To prove the latter statement, by the structure theorem for finite abelian groups, it suffices to prove it for the case when n is a power of a prime. Moreover, we may assume that $A(K)$ and $J(K)/B(K)$ have no prime-to-n torsion. Then $J(K)/B(K)$ is in fact torsion-free, and so we may also assume $A(K)$ is torsion-free. With these assumptions, the statement we want to prove follows easily by elementary group-theoretic arguments (in particular, by considering of the Smith normal form of the matrix representing ψ). ∎

3.4. *Proof of Theorem 3.1.*

Proof of Theorem 3.1. The proof proceeds in two steps. The first step is to use the hypothesis that $B[n] \subset A$ to produce a map $B(K)/nB(K) \to \mathrm{Vis}_J(H^1(K, A))[n]$. This was done in Section 3.3. The second step is to perform a local analysis at each place v of K in order to prove that the image of this map consists of locally trivial cohomology classes. We divide this local analysis into three cases:

1. When v is real archimedian, we use that $\gcd(2, n) = 1$. (We know that for any $p|n$ we have $p > 2$ because $1 \leqslant e_p < p - 1$, by assumption.)

2. When $\gcd(\mathrm{char}(v), n) = 1$, we use the result of Section 3.2 and a relationship between unramified cohomology and the cohomology of a component group.

3. When $\gcd(\mathrm{char}(v), n) \neq 1$, for each prime $p|n$, the reduction of J is abelian and by hypothesis $e_p < p - 1$, so we can apply an exactness theorem from [BLR90].

We now deduce that the image of $B(K)/nB(K)$ in $H^1(K, A)$ lies in $Ш(A)$. Fix an element $x \in B(K)$. To show that $\pi(x) \in Ш(A)$, it suffices to show that $\mathrm{res}_v(\pi(x)) = 0$ for all places v of K.

Case 1: *v real archimedian*. At a real archimedian place v, the restriction $\mathrm{res}_v(\pi(x))$ is killed by 2 and the odd n, hence $\mathrm{res}_v(\pi(x)) = 0$.

Case 2: $\gcd(\mathrm{char}(v), n) = 1$. Suppose that $\gcd(\mathrm{char}(v), n) = 1$. Let $m = c_{B,v} = \Phi_{B,v}(\mathbf{F}_v)$ be the Tamagawa number of B at v. The reduction of mx lies in the identity component of the closed fiber $\mathscr{B}_{\mathbf{F}_v}$ of the Néron model of B at v, so by Lemma 3.4, there exists $z \in B(K_v^{\mathrm{ur}})$ such that $nz = mx$. Thus the cohomology class $\mathrm{res}_v(\pi(mx))$ is defined by a cocycle that sends $\sigma \in \mathrm{Gal}(\overline{K_v}/K_v)$ to $\sigma(z) - z \in A(K_v^{\mathrm{ur}})$ (see diagram (3.2) for the definition of π). In particular, $\mathrm{res}_v(\pi(mx))$ is unramified at v. By Milne [Mil86, Proposition 3.8].

$$H^1(K_v^{\mathrm{ur}}/K_v, A(K_v^{\mathrm{ur}})) = H^1(K_v^{\mathrm{ur}}/K_v, \Phi_{A,v}(\bar{\mathbf{F}}_v)),$$

where $\Phi_{A,v}$ is the component group of A at v. The Herbrand quotient of a finite module is 1 (see, e.g., [Ser79, VIII.4.8]), so

$$\#\Phi_{A,v}(\mathbf{F}_v) = \#H^1(K_v^{\mathrm{ur}}/K_v, \Phi_{A,v}(\bar{\mathbf{F}}_v)).$$

Thus, the order of $\mathrm{res}_v(\pi(mx))$ divides both $\#\Phi_{A,v}(\mathbf{F}_v)$ and n. Since by assumption $\gcd(\#\Phi_{A,v}(\mathbf{F}_v), n) = 1$, it follows that $\mathrm{res}_v(\pi(mx)) = 0$, hence $m\,\mathrm{res}_v(\pi(x)) = 0$. Again, since the order of $\pi(x)$ divides n, and $\gcd(n, m) = 1$, we have $\mathrm{res}_v(\pi(x)) = 0$.

Case 3: $\gcd(\mathrm{char}(v), n) = p \neq 1$. Suppose that $\mathrm{char}(v) = p|n$. Let R be the ring of integers of K_v^{ur}, and let $\mathscr{A}$, $\mathscr{J}$, and $\mathscr{C}$ be the Néron models of A, J, and C, respectively. Since $e_p < p - 1$ and J has abelian reduction at v (since $p \nmid N$), by Bosch *et al.* [BLR90, Theorem 7.5.4(iii)], the induced sequence $0 \to \mathscr{A} \to \mathscr{J} \xrightarrow{\phi} \mathscr{C} \to 0$ is exact, which means that ϕ is faithfully flat and surjective with scheme-theoretic kernel $\mathscr{A}$. Since ϕ is faithfully flat with smooth kernel, ϕ is smooth (see, e.g., [BLR90, 2.4.8]). By Lemma 3.6, $\mathscr{J}(R) \to \mathscr{C}(R)$ is a surjection; i.e., $J(K_v^{\mathrm{ur}}) \to C(K_v^{\mathrm{ur}})$ is a surjection.

So $\mathrm{res}_v(\pi(x))$ is unramified, and again by Milne [Mil86, Proposition 3.8],

$$H^1(K_v^{\mathrm{ur}}/K_v, A) \cong H^1(K_v^{\mathrm{ur}}/K_v, \Phi_{A,v}(\bar{\mathbf{F}}_v)).$$

But $H^1(K_v^{\mathrm{ur}}/K_v, \Phi_{A,v}(\bar{\mathbf{F}}_v)) = \{0\}$, since $\Phi_{A,v}(\bar{\mathbf{F}}_v)$ is trivial, as A has good reduction at v (because $p \nmid N$). Thus $\mathrm{res}_v(\pi(x)) = 0$. ∎

4. SOME EXAMPLES

This section contains some examples of visible and invisible elements of Shafarevich–Tate groups. Section 4.1 uses Theorem 3.1 to produce nontrivial visible elements of $\text{Ш}(A)$, where A is a 20-dimensional modular abelian variety, thus giving evidence for the BSD conjecture. In Section 4.2 we show that an invisible Shafarevich–Tate group from [CM00] becomes visible at a higher level.

In [AS02], we describe the notation used (which is standard) and the algorithms that we used to carry out the computations described below. We also report on a large number of similar computations, which were performed using the second author's modular symbols package, which is part of Magma (see [BCP97]).

4.1. *Visibility in an Abelian Variety of Dimension 20.* Using the methods described in [AS02], we find that $S_2(\Gamma_0(389))$ contains exactly five Galois-conjugacy classes of newforms, and these are defined over extensions of $\mathbf{Q}$ of degrees 1, 2, 3, 6, and 20. Thus, $J = J_0(389)$ decomposes, up to isogeny, as a product $A_1 \times A_2 \times A_3 \times A_6 \times A_{20}$ of abelian varieties, where $d = \dim A_d$ and A_d is the quotient corresponding to the appropriate Galois-conjugacy class of newforms.

Next we consider the arithmetic of each A_d. Using [AS02], we find that

$$L(A_1, 1) = L(A_2, 1) = L(A_3, 1) = L(A_6, 1) = 0,$$

and

$$\frac{L(A_{20}, 1)}{\Omega_{A_{20}}} = \frac{5^2 \cdot 2^?}{97},$$

where $2^?$ is a power of 2. Using [AS02], we find that $\#A_{20}(Q) = 97$ and the Tamagawa number of A_{20} at 389 is also 97. The BSD Conjecture then predicts that $\#\text{Ш}(A_{20}) = 5^2 \cdot 2^?$. The following proposition provides support for this conjecture.

Proposition 4.1. *There is an inclusion*

$$(\mathbf{Z}/5\mathbf{Z})^2 \cong A_1(\mathbf{Q})/5A_1(\mathbf{Q}) \hookrightarrow \mathrm{Vis}_J(\text{Ш}(A_{20}^\vee)).$$

Proof. Let $A = A_{20}^\vee, B = A_1^\vee = A_1$ and $J = A + B \subset J_0(389)$. Using algorithms in [AS02], we find that $A \cap B \cong (Z/4)^2 \times (Z/5Z)^2$, so $B[5] \subset$

A. Since 5 does not divide the numerator of $(389-1)/12$, it does not divide the Tamagawa numbers or the orders of the torsion subgroups of A, B, J, and J/B (we also verified this using a modular symbols computations), so Theorem 3.1 implies that there is an injective map

$$A_1(\mathbf{Q})/5A_1(\mathbf{Q}) \hookrightarrow \mathrm{Vis}_J(\text{Ш}(A_{20}^{\vee})).$$

To finish, note that Cremona [Cre97] has verified that $A_1(\mathbf{Q}) \approx \mathbf{Z}\times\mathbf{Z}$. ∎

4.2. *Invisible Elements that Becomes Visible at Higher Level.* Consider the elliptic curve E of conductor $5389 = 17\cdot 317$ defined by the equation

$$y^2 + xy + y = x^3 - 35\,590x - 2\,587\,197.$$

In [CM00], Cremona and Mazur observe that the BSD conjecture implies that $\#\text{Ш}(E) = 9$, but they find that $\mathrm{Vis}_{J_0(5389)}(\text{Ш}(E)[3]) = \{0\}$. We will now verify, without assuming any conjectures, that $9|\#\text{Ш}(E)$ and that these 9 elements of $\text{Ш}(E)$ are visible in $J_0(5389\cdot 7)$.

First note that the mod 3 representation $\rho_{E,3}$ attached to E is irreducible because E is semistable and admits no 3-isogeny (according to [Cre]). The newform attached to E is

$$f_E = q + q^2 - 2q^3 - q^4 + 2q^5 - 2q^6 - 2q^7 + \cdots,$$

and $a_7^2 = (-2)^2 \equiv (7+1)^2 \pmod 3$, so Ribet's level-raising theorem [Rib90] implies that there is a newform g of level $7\cdot 5389$ that is congruent modulo 3 to f_E. This observation led us to the following proposition.

PROPOSITION 4.2. *Map E to $J_0(7\cdot 5389)$ by the sum of the two maps on Jacobians induced by the two degeneracy maps $X_0(7\cdot 5389) \to X_0(5389)$. The image E' of E in $J_0(7\cdot 5389)$ is 2-isogenous to E and*

$$(\mathbf{Z}/3\mathbf{Z})^2 \subset \mathrm{Vis}_{J_0(7\cdot 5389)}(\text{Ш}(E')).$$

Proof. It is easy to see from the discussion in [Rib90] that the kernel of the sum of the two degeneracy maps $J_0(5389) \to J_0(7\cdot 5389)$ is a group of 2-power order, so E' is isogenous to E via an isogeny of degree a power of 2.

Consider the elliptic curve F defined by $y^2 - y = x^3 + x^2 + 34x - 248$. Using Cremona's programs `tate` and `mwrank` we find that F has conductor $7\cdot 5389$, and that $F(\mathbf{Q}) \cong \mathbf{Z}\times\mathbf{Z}$. The Tamagawa numbers of F at 7, 17, and 317 are 1, 2, and 1, respectively. The newform attached to F is

$$f_F = q - 2q^2 + q^3 + 2q^4 - q^5 - 2q^6 - q^7 + \cdots$$

and, by Sturm [Stu87], we prove that $f_E(q) + f_E(q^7) \equiv f_F \pmod{3}$ by checking this congruence for the first $7632 = [\mathrm{SL}_2(\mathbf{Z}) : \Gamma_0(7 \cdot 5389)]/6$ terms. Since $2 \leqslant k < 3$ and $3 \nmid 7 \cdot 5389$, the first part of the multiplicity one theorem of [Edi92, Sect. 9] implies that $F[3] = E'[3]$.

Finally, we apply Theorem 3.1 with $A = E', B = F, J = A + B \subset J_0(7 \cdot 5389), N = 7 \cdot 5389$, and $n = 3$. It is routine to check the hypothesis. For example, the hypothesis that J/B has no $\mathbf{Q}$-rational 3-torsion can be checked as follows. Cremona's online tables imply that E admits no 3-isogeny, so $E[3]$ is irreducible. Since J/B is isogenous to E, the representation $(J/B)[3]$ is also irreducible, so $(J/B)(\mathbf{Q})[3] = \{0\}$. Thus, by Theorem 3.1, we have $(\mathbf{Z}/3\mathbf{Z})^2 \subset \mathrm{Vis}_J(\text{Ш}(E'))$. To finish the proof, note that $\mathrm{Vis}_J(\text{Ш}(E')) \subset \mathrm{Vis}_{J_0(7 \cdot 5389)}(\text{Ш}(E'))$. ∎

Since E' is 2-isogenous to E and $9 | \#\text{Ш}(E')$, it follows that $9 | \#\text{Ш}(E)$, as predicted by the BSD conjecture.

ACKNOWLEDGMENTS

We thank Barry Mazur for his generous guidance, Brian Conrad for his extensive assistance, Ralph Greenberg for suggesting the use of restriction of scalars in Section 1.3, Fabrizio Andreatta for suggesting that a semistability hypothesis was unnecessary in Theorem 3.1, and Loic Merel, Bjorn Poonen, and Ken Ribet for helpful conversations. The first author would like to thank the Mathematical Sciences Research Institute in Berkeley and the Institut des Hautes Études Scientifiques in France, and the second author the Max Planck Institute in Bonn, for their generous hospitality.

VISIBLE EVIDENCE FOR THE BIRCH AND SWINNERTON-DYER CONJECTURE FOR MODULAR ABELIAN VARIETIES OF ANALYTIC RANK ZERO (WITH AN APPENDIX BY J. CREMONA AND B. MAZUR)

AMOD AGASHE AND WILLIAM STEIN

Abstract. This paper provides evidence for the Birch and Swinnerton-Dyer conjecture for analytic rank 0 abelian varieties A_f that are optimal quotients of $J_0(N)$ attached to newforms. We prove theorems about the ratio $L(A_f, 1)/\Omega_{A_f}$, develop tools for computing with A_f, and gather data about certain arithmetic invariants of the nearly 20000 abelian varieties A_f of level ≤ 2333. Over half of these A_f have analytic rank 0, and for these we compute upper and lower bounds on the conjectural order of $Ш(A_f)$. We find that there are at least 168 such that the Birch and Swinnerton-Dyer Conjecture implies that $Ш(A_f)$ is divisible by an odd prime, and we prove for 39 of these that the odd part of the conjectural order of $Ш(A_f)$ really divides $\#Ш(A_f)$ by constructing nontrivial elements of $Ш(A_f)$ using visibility theory. We also give other evidence for the conjecture. The appendix, by Cremona and Mazur, fills in some gaps in the theoretical discussion in their paper on visibility of Shafarevich-Tate groups of elliptic curves.

1. Introduction

Let N be a positive integer, and f be a newform of weight 2 on $\Gamma_0(N)$. A construction due to Shimura associates to f an abelian variety quotient A_f of $J_0(N)$. We say that A_f has *analytic rank zero* if its L-function $L(A_f, s)$ is nonzero at $s = 1$. In this paper we give evidence for the Birch and Swinnerton-Dyer conjecture for analytic rank 0 abelian varieties A_f of arbitrary dimension. For such abelian varieties, the conjecture asserts that $A_f(\mathbf{Q})$ is finite, and gives a formula for the order of the Shafarevich-Tate group Ш(A_f).

Kolyvagin and Logachev proved in [KL89, KL92] that if $L(A_f, 1) \neq 0$, then $A_f(\mathbf{Q})$ and Ш(A_f) are both finite. To the best of our knowledge, Birch and Swinnerton-Dyer's formula for #Ш(A_f) has not been completely verified for a single abelian variety A_f of dimension greater than one. In [KL92, §1.6] Kolyvagin and Logachev remark that if one were able to compute the height of a certain Heegner point, their methods could be used to find an upper bound on #Ш(A_f), but we have not done this. Instead, in this paper we focus on computing *nonzero subgroups* of Ш(A_f) when the conjecture predicts that Ш(A_f) is nonzero.

Inspired by work of Cremona and Mazur (see [CM]), we had the idea to reverse their methods and prove, in some cases, that #Ш(A_f) is at least as big as predicted by the Birch and Swinnerton-Dyer conjecture. Instead of assuming that Ш(A_f) is as predicted by the conjecture and trying to understand whether or not it is visible in $J_0(N)$, we prove a theorem (see [AS02]) that allows us to sometimes construct the odd part of Ш(A_f) without assuming any conjectures. After developing algorithms that allow us to compute the conjectural order of Ш(A_f) in most cases, we analyzed the 19608 abelian varieties A_f of level ≤ 2333, and constructed the tables of Section 5. This resulted in the first systematic experimental evidence for the Birch and Swinnerton-Dyer conjecture for modular abelian varieties of dimension greater than 2 (see [FpS$^+$01] for dimension 2).

This paper is organized as follows. In Section 2 we review background about modular abelian varieties and state the Birch and Swinnerton-Dyer conjecture. Section 3 explains the basic facts about quotients A_f of $J_0(N)$ that one needs to know in order to compute with them. In Section 4 we discuss a generalization of the Manin constant, derive a formula for the ratio $L(A_f, 1)/\Omega_{A_f}$, and bound the denominator of this ratio, thus giving some theoretical evidence towards the Birch and Swinnerton-Dyer conjecture. Section 5 reports on our construction of a table of 168 rank 0 abelian varieties A_f of level ≤ 2333 such that the Birch and

Swinnerton-Dyer conjecture predicts that $\#\text{Ш}(A_f)$ is divisible by an odd prime, and discusses what we computed to show that for 39 of the A_f there are *at least* as many elements of the odd part of $\#\text{Ш}(A_f)$ as predicted. The part of $\#\text{Ш}(A_f)$ that is coprime to the modular degree of A_f (which we define below) is a perfect square, and in the several cases where we could compute the odd part of the conjectured value of $\#\text{Ш}(A_f)$, we found the odd part to be a perfect square, which gives computational evidence for the conjecture. The appendix, written by Cremona and Mazur, fills in some gaps in the theoretical discussion in [CM].

Acknowledgment. It is a pleasure to thank Bryan Birch, Robert Coleman, Benedict Gross, Hednrik Lenstra, Dino Lorenzini, Loïc Merel, Bjorn Poonen, Ken Ribet, and John Tate for many helpful comments and discussions. Special thanks go to Barry Mazur for guiding our ideas on visibility and purchasing the second author a powerful computer, and to Allan Steel and David Kohel at Magma for their crucial computational support.

2. Background and Definitions

2.1. **Modular Forms.** Fix a positive integer N. The group

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbf{Z}) : N \mid c \right\}$$

acts by linear fractional transformations on the extended complex upper halfplane $\mathfrak{h}^*$. As a Riemann surface, $X_0(N)(\mathbf{C})$ is the quotient $\Gamma_0(N)\backslash\mathfrak{h}^*$. There is a standard model for $X_0(N)$ over $\mathbf{Q}$ (see [Shi94, Ch. 6]), and the Jacobian $J_0(N)$ of $X_0(N)$ is an abelian variety over $\mathbf{Q}$ of dimension equal to the genus g of $X_0(N)$, which is equipped with an action of the Hecke algebra $\mathbf{T} = \mathbf{Z}[\ldots T_n \ldots]$. The space $S_2(\Gamma_0(N))$ of cuspforms of weight 2 on $\Gamma_0(N)$ is a module over $\mathbf{T}$ and $S_2(\Gamma_0(N)) \cong H^0(X_0(N), \Omega_{X_0(N)})$ as $\mathbf{T}$-modules.

2.2. **Abelian Varieties Attached to Newforms.** A *newform*

$$f = \sum_{n \geq 1} a_n q^n \in S_2(\Gamma_0(N))$$

is an eigenvector for $\mathbf{T}$ that is normalized so that $a_1 = 1$ and which lies in the orthogonal complement of the old subspace of $S_2(\Gamma_0(N))$. Let I_f denote the annihilator $\mathrm{Ann}_{\mathbf{T}}(f)$ of f in $\mathbf{T}$. Following Shimura [Shi73], attach to I_f the quotient

$$A_f = J_0(N)/I_f J_0(N),$$

which is an abelian variety over $\mathbf{Q}$ of dimension $[\mathbf{Q}(\ldots, a_n, \ldots) : \mathbf{Q}]$, which is equipped with a faithful action of $\mathbf{T}/I_f$. Moreover, A_f is an *optimal quotient* of $J_0(N)$, in the sense that $A_f^\vee \to J_0(N)$ is a closed immersion, or equivalently that the kernel of $J_0(N) \to A_f$ is connected (see [CS01, Prop. 3.3]).

Also, the complex torus $A_f(\mathbf{C})$ fits into the exact sequence

$$H_1(X_0(N), \mathbf{Z}) \to \mathrm{Hom}(S_2(\Gamma_0(N))[I_f], \mathbf{C}) \to A_f(\mathbf{C}) \to 0.$$

2.3. **The Birch and Swinnerton-Dyer Conjecture.** The conjecture of Birch and Swinnerton-Dyer makes sense for abelian varieties over fairly general global fields, but we only state a special case. This conjecture involves the L-function attached to $A = A_f$:

$$L(A, s) = \prod_{i=1}^{d} L(f^{(i)}, s) = \prod_{i=1}^{d} \left(\sum_{n \geq 1} \frac{a_n^{(i)}}{n^s} \right),$$

where $f^{(i)}$ is the ith Galois conjugate of f and $a_n^{(i)}$ is the ith Galois conjugate of a_n. It follows from work of Hecke that $L(A, s)$ has an analytic continuation to the whole complex plane and satisfies a functional equation. Birch and Swinnerton-Dyer made the following conjecture, which relates the rank of A to the order of vanishing of $L(A, s)$ at $s = 1$.

Conjecture 2.1 (Birch and Swinnerton-Dyer)**.** *The Mordell-Weil rank of A is equal to the order of vanishing of $L(A, s)$ at $s = 1$, i.e.,*

$$\dim(A(\mathbf{Q}) \otimes \mathbf{Q}) = \operatorname{ord}_{s=1} L(A, s).$$

Birch and Swinnerton-Dyer also furnished a conjectural formula for the order of the Shafarevich-Tate group

$$Ш(A) := \ker \left(H^1(\mathbf{Q}, A) \longrightarrow \prod_{\text{all places } v} H^1(\mathbf{Q}_v, A) \right).$$

(They only made their conjecture for elliptic curves, but Tate [Tat66] reformulated it a functorial way which makes sense for abelian varieties. See also [Lan91, §III.5] for another formulation.) We now state their conjecture in the special case when $L(A, 1) \neq 0$, where [KL89, KL92] implies that $Ш(A)$ is finite. The conjecture involves the Tamagawa numbers c_p of A (see Section 3.7), and the canonical volume Ω_A of $A(\mathbf{R})$ (see Section 4.2).

Conjecture 2.2 (Birch and Swinnerton-Dyer)**.** *Suppose $L(A, 1) \neq 0$. Then*

$$\frac{L(A, 1)}{\Omega_A} = \frac{\#Ш(A) \cdot \prod_{p \mid N} c_p}{\#A(\mathbf{Q})_{\text{tor}} \cdot \#A^\vee(\mathbf{Q})_{\text{tor}}},$$

where $A^\vee$ is the abelian variety dual of A.

Remark 2.3. Since $L(A, 1) \neq 0$, finiteness of $Ш(A)$ and the existence of the Cassels-Tate pairing implies that $\#Ш(A) = \#Ш(A^\vee)$, so Conjecture 2.2 can also be viewed as a formula for $\#Ш(A^\vee)$.

The algorithms outlined in this paper take advantage of the fact that A is attached to a newform in order to compute the conjectural order of $Ш(A)$ away from certain bad primes.

3. Explicit Approaches to Modular Abelian Varieties

We use the algorithms of this section to enumerate the A_f, compute information about the invariants of A_f that appear in Conjecture 2.2, and to verify the hypothesis of Theorem 3.13 in order to construct nontrivial subgroups of $Ш(A_f)$. The second author has implemented the algorithms discussed in this paper, and made many of them part of the Magma computer algebra system [BCP97].

In Section 3.1, we discuss modular symbols, which are the basic tool we use in many of the computations, and in Section 3.2 we discuss how we systematically enumerate modular abelian varieties. There is an analogue for A_f of the usual elliptic-curve modular degree, which we discuss in Section 3.3, and which we use to rule out the existence of visible elements of $\text{Ш}(A_f)$ of a certain order. In Section 3.4 we describe how to compute the intersection of two abelian varieties, which will be needed to verify the hypothesis of Theorem 3.13. In Sections 3.5 and 3.6, we describe standard methods for bounding the torsion subgroup of an abelian variety above and below. Section 3.7 reviews an algorithm for computing the odd part of the Tamagawa number c_p when $p \mid\mid N$, and discusses the Lenstra-Oort bound in the case when $p^2 \mid N$.

Unless otherwise stated, f is a newform, I_f its annihilator, and $A = A_f$ is the corresponding optimal quotient of $J_0(N)$.

3.1. **Modular Symbols.** Modular symbols are crucial to many algorithms for computing with modular abelian varieties, because they can be used to construct a *finite* presentation for $H_1(X_0(N), \mathbf{Z})$ in terms of paths between elements of $\mathbf{P}^1(\mathbf{Q}) = \mathbf{Q} \cup \{\infty\}$. They were introduced by Birch [Bir71] and studied by Manin, Mazur, Merel, Cremona, and others.

Let $\mathfrak{M}_2$ be the free abelian group with basis the set of all symbols $\{\alpha, \beta\}$, with $\alpha, \beta \in \mathbf{P}^1(\mathbf{Q})$, modulo the three-term relations

$$\{\alpha, \beta\} + \{\beta, \gamma\} + \{\gamma, \alpha\} = 0,$$

and modulo any torsion. The group $\mathrm{GL}_2(\mathbf{Q})$ acts on the left on $\mathfrak{M}_2$ by

$$g\{\alpha, \beta\} = \{g(\alpha), g(\beta)\},$$

where g acts on α and β by a linear fractional transformation. The space $\mathfrak{M}_2(\Gamma_0(N))$ of *modular symbols* for $\Gamma_0(N)$ is the quotient of $\mathfrak{M}_2$ by the subgroup generated by all elements of the form $x - g(x)$, for $x \in \mathfrak{M}_2$ and g in $\Gamma_0(N)$, modulo any torsion. A *modular symbol* for $\Gamma_0(N)$ is an element of this space, and we frequently denote the equivalence class that defines a modular symbol by giving a representative element.

Let $\mathfrak{B}_2(\Gamma_0(N))$ be the free abelian group with basis the finite set $\Gamma_0(N)\backslash\mathbf{P}^1(\mathbf{Q})$. The boundary map $\delta : \mathfrak{M}_2(\Gamma_0(N)) \to \mathfrak{B}_2(\Gamma_0(N))$ sends $\{\alpha, \beta\}$ to $[\beta] - [\alpha]$, where $[\beta]$ denotes the basis element of $\mathfrak{B}_2(\Gamma_0(N))$ corresponding to $\beta \in \mathbf{P}^1(\mathbf{Q})$. The *cuspidal modular symbols* are the kernel $\mathfrak{S}_2(\Gamma_0(N))$ of δ, and the integral homology $H_1(X_0(N), \mathbf{Z})$ is canonically isomorphic to $\mathfrak{S}_2(\Gamma_0(N))$.

Cremona's book [Cre97, §2.2] contains a concrete description of how to compute $\mathfrak{M}_2(\Gamma_0(N)) \otimes \mathbf{Q}$ using Manin symbols, which are a finite set of generators for $\mathfrak{M}_2(\Gamma_0(N))$. In general, the easiest way we have found to compute $\mathfrak{M}_2(\Gamma_0(N))$ is to compute $\mathfrak{M}_2(\Gamma_0(N)) \otimes \mathbf{Q}$, then compute the $\mathbf{Z}$-submodule of $\mathfrak{M}_2(\Gamma_0(N)) \otimes \mathbf{Q}$ generated by the Manin symbols.

3.2. **Enumerating Newforms.** Since $X_0(N)$ is defined over $\mathbf{Q}$ it is defined over $\mathbf{R}$, so complex conjugation acts on $X_0(N)(\mathbf{C})$ hence on the homology $H_1(X_0(N), \mathbf{Z})$. In terms of modular symbols, complex conjugation acts by sending $\{\alpha, \beta\}$ to $\{-\alpha, -\beta\}$. Let $H_1(X_0(N), \mathbf{Z})^+$ denote the $+1$-eigenspace for the action of the involution induced by complex conjugation, which we can compute using modular symbols. We list all newforms of a given level N by decomposing the new subspace of $H_1(X_0(N), \mathbf{Q})^+$ under the action of the the Hecke operators and listing the corresponding systems of Hecke eigenvalues (see [Ste02a]). First we compute the characteristic polynomial of T_2, and use it to break up the new space. We apply this process recursively with $T_3, T_5, \ldots$ until either we have exceeded the bound coming from [Stu87] (see [LS02]), or we have found a Hecke operator T_n whose characteristic polynomial is irreducible.

We *order the newforms* in a way that extends the ordering in [Cre97]: First sort by dimension, with smallest dimension first; within each dimension, sort in binary by the signs of the Atkin-Lehner involutions, e.g., $+++$, $++-$, $+-+$, $+--$, $-++$, etc. When two forms have the same Atkin-Lehner sign sequence, order by $|\operatorname{Tr}(a_p)|$ with ties broken by taking the positive trace first. We denote a Galois-conjugacy class of newforms by a bold symbol such as **389E**, which consists of a level and isogeny class, where **A** denotes the first class, **B** the second, **E** the fifth, **BB** the 28th, etc. As discussed in [Cre97, pg. 5], for certain small levels the above ordering, when restricted to elliptic curves, does not agree with the ordering used in the tables of [Cre97]. For example, our **446B** is Cremona's **446D**.

3.3. The Modular Degree.

Since A_f is an optimal quotient, the dual map $A_f^\vee \to J_0(N)$ is injective and the composite $\theta_f : A_f^\vee \to A_f$ has finite degree. The map θ_f is a polarization, so $\deg(\theta_f)$ is a perfect square (see Lemma 3.14). The *modular degree* of A_f is the square root of the degree of θ_f:

$$\operatorname{moddeg}(A_f) = \sqrt{\deg(\theta_f)}.$$

When $\dim A_f = 1$, $\operatorname{moddeg}(A_f)$ is the usual modular degree, i.e., the degree of $X_0(N) \to A_f$.

If M is an abelian group, let $M^* = \operatorname{Hom}_{\mathbf{Z}}(M, \mathbf{Z})$. The Hecke algebra acts in a natural way on $H_1(X_0(N), \mathbf{Z})$ and $H_1(X_0(N), \mathbf{Z})^*$, and we have a natural restriction map

$$r_f : H_1(X_0(N), \mathbf{Z})^*[I_f] \to (H_1(X_0(N), \mathbf{Z})[I_f])^*.$$

The following proposition leads to an algorithm for computing the modular degree.

Proposition 3.1. $\operatorname{coker}(r_f) \cong \ker(\theta_f)$, *so* $\operatorname{moddeg}(A_f) = \sqrt{\#\operatorname{coker}(r_f)}$.

The proposition is proved in [KS00]. The proof makes use of the *Abel-Jacobi theorem*, which realizes the Jacobian $J_0(N)(\mathbf{C})$ as a complex torus:

$$0 \to H_1(X_0(N), \mathbf{Z}) \to \operatorname{Hom}(S_2(\Gamma_0(N)), \mathbf{C}) \to J_0(N)(\mathbf{C}) \to 0,$$

where $H_1(X_0(N), \mathbf{Z})$ is embedded as a lattice of full rank in the complex vector space $\operatorname{Hom}(S_2(\Gamma_0(N)), \mathbf{C})$ using the integration pairing, and this description of $J_0(N)(\mathbf{C})$ is compatible with the action of Hecke operators.

3.4. Intersecting Complex Tori.

Let V be a finite dimensional complex vector space and let Λ be a lattice in V, so that $T = V/\Lambda$ is a complex torus. Suppose that V_A and V_B are subspaces of V such that $\Lambda_A = V_A \cap \Lambda$ and $\Lambda_B = V_B \cap \Lambda$ are lattices in V_A and V_B, respectively.

Proposition 3.2. *If $A \cap B$ is finite, then there is an isomorphism*

$$A \cap B \cong \left(\frac{\Lambda}{\Lambda_A + \Lambda_B}\right)_{\text{tor}}.$$

Proof. Extend the exact sequence

$$0 \to A \cap B \to A \oplus B \xrightarrow{(x,y)\mapsto x-y} T$$

to the following diagram:

$$\begin{tikzcd}
 & \Lambda_A \oplus \Lambda_B \arrow[r] \arrow[d] & \Lambda \arrow[r] \arrow[d] & \Lambda/(\Lambda_A + \Lambda_B) \arrow[d] \\
0 \arrow[r] \arrow[d] & V_A \oplus V_B \arrow[r] \arrow[d] & V \arrow[r] \arrow[d] & V/(V_A + V_B) \arrow[d] \\
A \cap B \arrow[r] & A \oplus B \arrow[r] & T \arrow[r] & T/(A+B).
\end{tikzcd}$$

The middle row is exact because $A \cap B$ is finite so $V_A \cap V_B = 0$.

Using the snake lemma, which connects the kernel $A \cap B$ of $A \oplus B \to T$ to the cokernel of $\Lambda_A \oplus \Lambda_B \to \Lambda$, we obtain an exact sequence

$$0 \to A \cap B \to \Lambda/(\Lambda_A + \Lambda_B) \to V/(V_A + V_B).$$

Since $V/(V_A + V_B)$ is a $\mathbf{C}$-vector space, the torsion part of $\Lambda/(\Lambda_A + \Lambda_B)$ must map to 0. No non-torsion in $\Lambda/(\Lambda_A + \Lambda_B)$ could map to 0, because if it did then $A \cap B$ would not be finite. The proposition follows. □

For abelian subvarieties of $J_0(N)$ attached to newforms, we use the proposition above as follows. The complex vector space $V = \mathrm{Hom}(S_2(\Gamma_0(N)), \mathbf{C})$ is the tangent space of $J_0(N)(\mathbf{C})$ at the identity. Setting $\Lambda = H_1(X_0(N), \mathbf{Z})$ and considering Λ as a lattice in V via the integration pairing, we have $J_0(N)(\mathbf{C}) \cong V/\Lambda$. Suppose f and g are non-conjugate newforms, and let I_f and I_g be their annihilators in the Hecke algebra $\mathbf{T}$, and let $A = A_f^\vee$ and $B = A_g^\vee$. Then $V_A = V[I_f]$ and $V_B = V[I_g]$ are the tangent spaces to A and B at the identity, respectively. The above proposition shows that the group $A \cap B$ is canonically isomorphic to $(\Lambda/(\Lambda_A + \Lambda_B))_{\mathrm{tor}}$. Here $\Lambda_A = \Lambda[I_f]$ and $\Lambda_B = \Lambda[I_g]$, because A_f and A_g are optimal quotients.

The following formula for the intersection of n subtori is obtained in a similar way to that of Proposition 3.2.

Proposition 3.3. *For $i = 1, \ldots, n$, with $n \geq 2$, let $A_i = V_i/\Lambda_i$ be a subtorus of $T = V/\Lambda$, and assume that each pairwise intersection $A_i \cap A_j$ is finite. Define a linear map*

$$f : V_1 \times \cdots \times V_n \longrightarrow V^{\oplus(n-1)}.$$

by $f(x_1, \ldots, x_n) = (x_1 - x_2,\, x_2 - x_3,\, x_3 - x_4,\, \ldots,\, x_{n-1} - x_n)$. Then

$$A_1 \cap \cdots \cap A_n \cong \left(\frac{\Lambda^{\oplus(n-1)}}{f(\Lambda_1 \oplus \cdots \oplus \Lambda_n)} \right)_{\mathrm{tor}}.$$

3.5. **Bounding the Torsion From Above.** In this section we recall the standard upper bound on the order of $\#A(\mathbf{Q})_{\mathrm{tor}}$, and illustrate its usefulness.

Let $f = \sum a_n q^n$ be a weight 2 newform on $\Gamma_1(N)$ with Nebentypus character $\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{C}^*$ (recall that f is a form on $\Gamma_0(N)$ if and only if $\varepsilon = 1$), and let $A = A_f$ be the corresponding optimal quotient of $J_1(N)$, as in [Shi73]. Shimura proved in [Shi94, Ch. 7] that the local Euler factor of A_f at p is

$$L_p(A_f, s) \;=\; \prod_{\sigma : K_f \hookrightarrow \overline{\mathbf{Q}}} \frac{1}{1 - \sigma(a_p) p^{-s} + \sigma(\varepsilon(p)) p^{1-2s}}$$

by showing that the characteristic polynomial F_p of Frobenius on any ℓ-adic Tate module of $A_{\mathbf{F}_p}$ (for $\ell \nmid pN$) is

$$F_p(X) = \prod_{\sigma : K_f \hookrightarrow \overline{\mathbf{Q}}} X^2 - \sigma(a_p)X + \sigma(\varepsilon(p))p,$$

where $K_f = \mathbf{Q}(\ldots, a_n, \ldots)$. Let $\mathbf{Q}(\varepsilon)$ be the field generated by the values of ε (note that $\mathbf{Q}(\varepsilon) \subset K_f$), and for any $p \nmid N$ let $G_p(X) \in \mathbf{Q}(\varepsilon)[X]$ be the characteristic polynomial of left multiplication by a_p on the $\mathbf{Q}(\varepsilon)$-vector space K_f, which is a polynomial of degree $d' = [K_f : \mathbf{Q}(\varepsilon)]$. Then

$$F_p(X) = \mathrm{Norm}_{\mathbf{Q}(\varepsilon)/\mathbf{Q}} \left(X^{d'} \cdot G_p \left(X + \frac{\varepsilon(p)p}{X} \right) \right),$$

so

$$\begin{aligned} \#A_{\mathbf{F}_p}(\mathbf{F}_p) &= \deg(1 - \mathrm{Frob}_p) = |\det(1 - \mathrm{Frob}_p)| \\ &= |F_p(1)| = |\,\mathrm{Norm}_{\mathbf{Q}(\varepsilon)/\mathbf{Q}}(G_p(1 + \varepsilon(p)p))|. \end{aligned}$$

If $p \nmid N$ is odd, standard facts about formal groups imply that the reduction map $A(\mathbf{Q})_{\mathrm{tor}} \to A_{\mathbf{F}_p}(\mathbf{F}_p)$ is injective, so

$$\#A(\mathbf{Q})_{\mathrm{tor}} \mid \gcd \left\{ \#A_{\mathbf{F}_p}(\mathbf{F}_p) \,:\, \text{primes } p \nmid 2N \right\}.$$

Likewise, since $A^\vee$ is isogenous to A, the same bound applies to $A^\vee(\mathbf{Q})_{\mathrm{tor}}$, since $A^\vee$ and A have the same L-series.

The upper bound is the same for every abelian variety isogenous to A, so it is not surprising that it is not sharp in general. For example, let E (resp., F) be the elliptic curve labeled **30A1** (resp. **30A2**) in Cremona's tables [Cre97]. Then E and F are isogenous, $E(\mathbf{Q}) \approx \mathbf{Z}/6\mathbf{Z}$, and $F(\mathbf{Q}) \approx \mathbf{Z}/12\mathbf{Z}$, so

$$12 \mid \gcd \left\{ \#E_{\mathbf{F}_p}(\mathbf{F}_p) \,:\, \text{primes } p \nmid 2N \right\}.$$

(Incidentally, since $\#E(\mathbf{F}_5) = 12$, the gcd is 12.) For answers to some related deep questions about this gcd, see [Kat81].

Example 3.4. Let

$$f = q + (-1 + \sqrt{2})q^2 + q^3 + (-2\sqrt{2} + 1)q^4 - 2\sqrt{2}q^5 + \cdots \in S_2(\Gamma_0(39))$$

be the form **39B**. Then $G_5(X) = X^2 - 8$, so

$$\#A_f(\mathbf{Q})_{\mathrm{tor}} \mid G_5(1 + 5) = 28.$$

We find in [FpS$^+$01] that A_f is isogenous to the Jacobian J of $y^2 + (x^3 + 1)y = -5x^4 - 2x^3 + 16x^2 - 12x + 2$ and that $\#J(\mathbf{Q}) = 28$. However A_f is not isomorphic to J since, as reported in Table 2 of [FpS$^+$01], the Tamagawa numbers of J are $c_3 = 28$, $c_{13} = 1$, whereas the methods of Section 3.7 below show that the Tamagawa numbers of A_f are $c_3 = 14$, $c_{13} = 2$. The authors do not know for sure whether $\#A_f(\mathbf{Q}) = 28$, but in Example 3.6 below we show that $14 \mid \#A_f(\mathbf{Q})$. (Also, using the computational techniques of this paper one sees that the Birch and Swinnerton-Dyer conjecture implies that $\#A_f(\mathbf{Q}) = 28$.)

Example 3.5. Let

$$f = q + (-\zeta_6 - 1)q^2 + (2\zeta_6 - 2)q^3 + \zeta_6 q^4 + (-2\zeta_6 + 1)q^5 + \cdots$$

be one of the two Galois-conjugate newforms in $S_2(\Gamma_1(13))$. This form has character $\varepsilon : (\mathbf{Z}/13\mathbf{Z})^* \to \mathbf{C}^*$ of order 6, and $A_f = J_1(13)$. We have $G_3(X) = X - 2\zeta_6 + 2$ and $\varepsilon(3) = -\zeta_6$, so

$$\begin{aligned}\#J_1(13)(\mathbf{Q})_{\mathrm{tor}} \mid \#J_1(13)(\mathbf{F}_3) &= |\operatorname{Norm}(G_3(1-3\zeta_6))| \\ &= |\operatorname{Norm}(-5\zeta_6+3)| = 19.\end{aligned}$$

In fact Ogg proved that $J_1(13)(\mathbf{Q})_{\mathrm{tor}} \approx \mathbf{Z}/19\mathbf{Z}$ (see [Ogg73] and [MT74]).

3.6. **Bounding the Torsion From Below.** A cusp $\alpha \in \Gamma_0(N)\backslash\mathbf{P}^1(\mathbf{Q}) \subset X_0(N)$ defines a point $(\alpha) - (\infty) \in J_0(N)(\overline{\mathbf{Q}})_{\mathrm{tor}}$. The rational cuspidal subgroup C of $J_0(N)(\mathbf{Q})_{\mathrm{tor}}$ generated by $\mathbf{Q}$-rational cusps is of interest because the order of the image of C in $A_f(\mathbf{Q})_{\mathrm{tor}}$ provides a lower bound on $\#A_f(\mathbf{Q})_{\mathrm{tor}}$. Stevens [Ste82, §1.3] computed the action of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ on the subgroup of $J_0(N)(\overline{\mathbf{Q}})$ generated by all cusps (and for other congruence subgroups besides $\Gamma_0(N)$). He found that $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ acts on the cusps through $\mathrm{Gal}(\mathbf{Q}(\zeta_N)/\mathbf{Q}) \cong (\mathbf{Z}/N\mathbf{Z})^*$, and that $d \in (\mathbf{Z}/N\mathbf{Z})^*$ acts by $x/y \mapsto x/(d'y)$, where $dd' \equiv 1 \pmod{N}$. Thus, e.g., $(0) - (\infty) \in J_0(N)(\mathbf{Q})_{\mathrm{tor}}$, and if N is square-free then all cusps are rational.

To compute the image of C in $A_f(\mathbf{Q})_{\mathrm{tor}}$, first make a list of inequivalent cusps using, e.g., the method described in [Cre97, §2.2, pg. 17]. Keep only the $\mathbf{Q}$-rational cusps, which can be determined using the result of Stevens above and [Cre97, Prop. 2.2.3] (when N is squarefree all cusps are rational). Next compute the subgroup $\mathcal{C}$ of $\mathfrak{M}_2(\Gamma_0(N))$ generated by modular symbols $\{\alpha, \infty\}$, where α is a $\mathbf{Q}$-rational cusp. The image of C in $A_f(\mathbf{Q})_{\mathrm{tor}}$ is isomorphic to the image of $\mathcal{C}$ in

$$P = \Phi_f(\mathfrak{M}_2(\Gamma_0(N)))/\Phi_f(\mathfrak{S}_2(\Gamma_0(N))),$$

where $\Phi_f : \mathfrak{M}_2(\Gamma_0(N)) \to \mathrm{Hom}(S_2(\Gamma_0(N))[I_f], \mathbf{C})$ is defined by the integration pairing. To keep everything rational, note that P can be computed using any map with the same kernel as Φ_f; for example, such a map can be constructed by finding a basis for $\mathrm{Hom}(\mathfrak{M}_2(\Gamma_0(N)), \mathbf{Q})[I_f]$ as described at the end of Section 4.2).

Example 3.6. Let the notation be as in Example 3.4. The cusps on $X_0(39)$ are represented by 0, ∞, $-1/9$, and $-4/13$, and since $N = 39$ is squarefree, these cusps are all rational. Using Magma we find that the image of C in $A_f(\mathbf{Q})_{\mathrm{tor}}$ is isomorphic to $\mathbf{Z}/14\mathbf{Z}$. Thus $A_f(\mathbf{Q})_{\mathrm{tor}}$ is isomorphic to one of $\mathbf{Z}/14\mathbf{Z}$, $\mathbf{Z}/28\mathbf{Z}$, or $\mathbf{Z}/14\mathbf{Z} \times \mathbf{Z}/2\mathbf{Z}$, but we do not know which.

Example 3.7. Let

$$f = q + \frac{1+\sqrt{5}}{2}q^2 + \frac{1-\sqrt{5}}{2}q^3 + \frac{5+\sqrt{5}}{2}q^4 + \cdots \in S_2(\Gamma_0(175))$$

be the form **175D**. The cusps of $X_0(175)$ are represented by

$$0,\ \infty,\ \frac{1}{25},\ \frac{1}{28},\ \frac{1}{30},\ \frac{1}{35},\ \frac{1}{45},\ \frac{1}{60},\ \frac{1}{65},\ \frac{1}{70},\ \frac{1}{105},\ \frac{1}{140}.$$

The $\mathbf{Q}$-rational cusps in this list are $0, \infty, \frac{1}{25}, \frac{1}{28}$, and these generate a subgroup of $A_f(\mathbf{Q})_{\mathrm{tor}}$ of order 2. (Incidentally, the group generated by all cusps, both rational and not, is isomorphic to $\mathbf{Z}/32\mathbf{Z}$.) Using a_p for $p \leq 17$ and the method of the previous section, we see that $\#A_f(\mathbf{Q})_{\mathrm{tor}} \mid 4$. The authors do not know if the cardinality is 2 or 4.

Example 3.8. The form **209C** is

$$f = q + \alpha q^2 + (1/2\alpha^4 - \alpha^3 - 5/2\alpha^2 + 4\alpha + 1)q^3 + (\alpha^2 - 2)q^4 + \cdots,$$

where $\alpha^5 - 2\alpha^4 - 6\alpha^3 + 10\alpha^2 + 5\alpha - 4 = 0$. As above, we find that $\#A_f(\mathbf{Q})_{\mathrm{tor}}$ divides 5. The image of the (rational) cuspidal subgroup in $A_f(\overline{\mathbf{Q}})_{\mathrm{tor}}$ is isomorphic to $\mathbf{Z}/5\mathbf{Z}$, so $A_f(\mathbf{Q})_{\mathrm{tor}} \approx \mathbf{Z}/5\mathbf{Z}$.

3.7. **Tamagawa Numbers.** Suppose $p \mid N$ and let $\Phi_{A,p}$ denote the component group of A at p, which is defined by the following exact sequence:

$$0 \to \mathcal{A}^0_{\mathbf{F}_p} \to \mathcal{A}_{\mathbf{F}_p} \to \Phi_{A,p} \to 0,$$

where $\mathcal{A}_{\mathbf{F}_p}$ is the closed fiber of the Néron model of A over $\mathbf{Z}_p$ and $\mathcal{A}^0_{\mathbf{F}_p}$ is the component of $\mathcal{A}_{\mathbf{F}_p}$ that contains the identity.

Definition 3.9. The *Tamagawa number* of A at p is

$$c_p = c_{A,p} = \#\Phi_{A,p}(\mathbf{F}_p).$$

When $p \mid\mid N$, the second author found a computable formula for $\#\Phi_{A,p}(\overline{\mathbf{F}}_p)$ and (sometimes only up to a power of 2) for $\#\Phi_{A,p}(\mathbf{F}_p)$. There is a discussion about how to compute this number in [KS00] and [CS01] contains a proof of the formula. Note also that in this case the Tamagawa number of A at p is the same as the Tamagawa number of $A^\vee$ at p.

When $p^2 \mid N$ the authors do not know an algorithm to compute c_p. However, in this case Lenstra and Oort (see [LO85]) proved that

$$\sum_{\ell \neq p} (\ell - 1) \operatorname{ord}_\ell(\#\Phi_{A,p}(\overline{\mathbf{F}}_p)) \leq 2 \dim(A_f),$$

so if $\ell \mid \#\Phi_{A,p}(\overline{\mathbf{F}}_p)$ then $\ell \leq 2 \cdot \dim(A_f) + 1$ or $\ell = p$. (Here $\operatorname{ord}_\ell(x)$ denotes the exponent of the largest power of ℓ that divides x.)

Example 3.10. Let f be **39B** as in Example 3.4. Running the algorithm of [KS00], we find that $c_3 = 14$ and $c_{13} = 2$.

Example 3.11. Let f be **175D** as in Example 3.7. Running the algorithm of [KS00], we find that $c_7 = 1$, and the Lenstra-Oort bound implies that the only possible prime divisors of c_5 are 2, 3, and 5.

3.8. **Visibility Theory.** We briefly recall visibility theory, which we will use to construct elements of Shafarevich-Tate groups. Section 6 contains another approach to the results reported in this section, but in the special case of elliptic curves.

Definition 3.12. Let $\iota : A \hookrightarrow J$ be an embedding of abelian varities over $\mathbf{Q}$. The *visible subgroup of* Ш(A) *with respect to the embedding* ι is

$$\mathrm{Vis}_J(Ш(A)) = \mathrm{Ker}(Ш(A) \to Ш(J)).$$

The following is a special case of Theorem 3.1 of [AS02].

Theorem 3.13. *Let A and B be abelian subvarieties of an abelian variety J over $\mathbf{Q}$ such that $A(\overline{\mathbf{Q}}) \cap B(\overline{\mathbf{Q}})$ is finite. Let N be an integer divisible by the residue characteristics of primes of bad reduction for J (e.g., the conductor of J). Suppose p is a prime such that*

$$p \nmid 2 \cdot N \cdot \#(J/B)(\mathbf{Q})_{\mathrm{tor}} \cdot \#B(\mathbf{Q})_{\mathrm{tor}} \cdot \prod_\ell c_{A,\ell} \cdot c_{B,\ell},$$

where $c_{A,\ell} = \#\Phi_{A,\ell}(\mathbf{F}_\ell)$ (resp., $c_{B,\ell}$) is the Tamagawa number of A (resp., B) at ℓ. Suppose furthermore that $B[p](\overline{\mathbf{Q}}) \subset A(\overline{\mathbf{Q}})$ as subgroups of $J(\overline{\mathbf{Q}})$. Then there is a natural map

$$\varphi : B(\mathbf{Q})/pB(\mathbf{Q}) \to \mathrm{Vis}_J(\text{Ш}(A))$$

such that $\dim_{\mathbf{F}_p} \ker(\varphi) \leq \dim_{\mathbf{Q}} A(\mathbf{Q}) \otimes \mathbf{Q}$.

We return to the situation where $A = A_f$ is an optimal quotient of $J_0(N)$ attached to a newform. In Proposition 3.15 below we show that $\mathrm{Vis}_{J_0(N)}(\text{Ш}(A^\vee))$ is annihilated by multiplication by $\mathrm{moddeg}(A)$ (see also [CM, p.19]). We first state a lemma; the outline of the proof was indicated to us by B. Poonen.

Lemma 3.14. *Let A be an abelian variety over k, where k is a field, and let $\lambda : A \to A^\vee$ be a polarization. Suppose either that k has characteristic 0 or that its characteristic does not divide the degree of λ. Then there is a finite abelian group H such that $\ker(\lambda) \approx H \times H$ as groups.*

Proof. We work in the setting of Section 16 of [Mil86], using the notation used there. Consider the pairing

$$e^\lambda : \mathrm{Ker}(\lambda) \times \mathrm{Ker}(\lambda) \to \mu_m \subseteq \overline{k}^*,$$

as in [Mil86, p. 135], where m is an integer that kills $\mathrm{Ker}(\lambda)$. We will show that this pairing is nondegenerate.

Suppose $a \in \mathrm{Ker}(\lambda)$ is such that $e^\lambda(a, a') = 1$ for all $a' \in \mathrm{Ker}(\lambda)$. Let $a'' \in A^\vee[m]$. There exists an isogeny $\lambda' : A^\vee \to A$ such that $\lambda' \circ \lambda$ is multiplication by m on A and $\lambda \circ \lambda'$ is multiplication by m on $A^\vee$ (to construct λ', note that λ' is the quotient map $A^\vee \to A^\vee/\lambda(A[m])$). Pick an element $b \in A(\overline{k})$ such that $\lambda b = a''$. Then $mb = \lambda'(\lambda b) = \lambda'(a'')$. So $\overline{e}_m(a, a'') = \overline{e}_m(a, \lambda b) = e^\lambda(a, \lambda' a'') = 0$ (note that $\lambda(\lambda' a'') = ma'' = 0$, so that $\lambda' a'' \in \mathrm{Ker}(\lambda)$). This is true for all $a'' \in A^\vee[m]$, so the non-degeneracy of $\overline{e}_m$ ([Mil86, p. 131]) implies that $a = 0$.

Similarly, suppose $a' \in \mathrm{Ker}(\lambda)$ is such that $e^\lambda(a, a') = 1$ for all $a \in \mathrm{Ker}(\lambda)$. Since e^λ is skew-symmetric ([Mil86, p. 135]), this implies that $e^\lambda(a', a) = 1$ for all $a \in \mathrm{Ker}(\lambda)$. Then by the previous paragraph, $a' = 0$. This finishes the proof of non-degeneracy.

As mentioned before, the pairing e^λ is skew-symmetric. It is alternating because it extends to pairings on Tate modules (denoted by e^λ_ℓ in [Mil86, p. 132]), and the latter take values in a torsion-free group, so there is no distinction between skew-symmetric and alternating.

Now the lemma follows from the fact that if G is a finite abelian group with an alternating nondegenerate pairing, then there is a finite abelian group H such that $G \approx H \times H$ as groups (e.g., see [Del01, Prop. 2]). □

Proposition 3.15. *Let $m_A = \mathrm{moddeg}(A)$. We have*

$$\mathrm{Vis}_{J_0(N)}(\text{Ш}(A^\vee)) \subset \text{Ш}(A^\vee)[m_A].$$

Proof. The polarization θ_f (from Section 3.3) is the composite map $A^\vee \to J_0(N) \to A$. Let e_A be the exponent of the finite group $\ker(\theta_f)$. By Lemma 3.14, multiplication by m_A kills $\ker(\theta_f)$, so $e_A \mid m_A$. Also θ_f factors through multiplication by e_A, so there is a map $\theta'_f : A \to A^\vee$ such that $\theta'_f \circ \theta_f$ is multiplication by e_A. If ϕ is a map of abelian varieties (over $\mathbf{Q}$), let ϕ_* denote the corresponding map on

Shafarevich-Tate groups. Since $\mathrm{Vis}_{J_0(N)}(Ш(A^\vee))$ is contained in $\ker((\theta_f)_*)$, it is also contained in

$$\ker((\delta' \circ \delta)_*) = Ш(A^\vee)[e_A] \subset Ш(A^\vee)[m_A].$$

□

Since $Ш(A^\vee)[n]$ is finite for any n, we obtain the following corollary.

Corollary 3.16. $\mathrm{Vis}_{J_0(N)}(Ш(A^\vee))$ *is finite.*

4. The Quotient $L(A,1)/\Omega_A$

Fix a newform $f \in S_2(\Gamma_0(N))$, let I_f be the annihilator of f in $\mathbf{T}$, and $A = A_f = J_0(N)/I_f J_0(N)$ the corresponding optimal quotient. Suppose for the rest of this section that $L(A,1) \neq 0$.

4.1. The Manin Constant.

When trying to compute the conjectural order of $Ш(A)$, we try to compute the quotient $L(A,1)/\Omega_A$, but find that it is easier to compute $c_A \cdot L(A,1)/\Omega_A$ where c_A is the Manin constant of A, which is defined as follows:

Definition 4.1 (Manin constant)**.** The *Manin constant* of A is

$$c_A = \#\left(\frac{S_2(\Gamma_0(N),\mathbf{Z})[I_f]}{H^0(\mathcal{A},\Omega_{\mathcal{A}/\mathbf{Z}})}\right) \in \mathbf{Z},$$

where we consider $H^0(\mathcal{A},\Omega_{\mathcal{A}/\mathbf{Z}})$ as a submodule of $S_2(\Gamma_0(N),\mathbf{Q})$ using

$$H^0(\mathcal{A},\Omega_{\mathcal{A}/\mathbf{Z}}) \to H^0(\mathcal{J},\Omega_{\mathcal{J}/\mathbf{Z}})[I_f] \to H^0(J,\Omega_{J/\mathbf{Q}})[I_f] \to S_2(\Gamma_0(N),\mathbf{Q})[I_f],$$

where $\mathcal{A}$ and $\mathcal{J}$ are the Néron models of A and J, respectively. (See [AS04] for a discussion of why the image of $H^0(\mathcal{A},\Omega_{\mathcal{A}/\mathbf{Z}})$ is contained in $S_2(\Gamma_0(N),\mathbf{Z})$.)

Theorem 4.2. *If $\ell \mid c_A$ is a prime then $\ell^2 \mid 4N$.*

Proof. Mazur proved this when $\dim A = 1$ in [Maz78, §4], and we generalized his proof in [AS04]. □

When $\dim A = 1$, Edixhoven [Edi91] obtained strong results towards the folklore conjecture that $c_A = 1$, and when A has arbitrary dimension the authors have made the following conjecture (see [AS04] for evidence):

Conjecture 4.3. $c_A = 1$.

4.2. A Formula for $L(A,1)/\Omega_A$.

If L and M are lattices in a real vector space V, then the *lattice index* $[L : M]$ is the absolute value of the determinant of a linear transformation of V taking L onto M. The lattice index satisfies the usual properties suggested by the notation, e.g., $[L : M] \cdot [M : N] = [L : N]$.

The *real volume* Ω_A is defined as follows. If L^* is a lattice in the cotangent space

$$T^* = H^0(A_{\mathbf{R}},\Omega_{A_{\mathbf{R}}}) = S_2(\Gamma_0(N),\mathbf{R})[I_f]$$

of $A_{\mathbf{R}}$, then L^* determines a lattice $L = \mathrm{Hom}(L^*,\mathbf{Z})$ in the tangent space $T = \mathrm{Hom}(T^*,\mathbf{R})$, and hence a measure on T by declaring that the quotient T/L has measure 1. Let $A(\mathbf{R})^0$ denote the identity component of $A(\mathbf{R})$. Then $A(\mathbf{R})^0$ inherits a measure by virtue of being viewed as $T/H_1(A(\mathbf{R})^0,\mathbf{Z})$, and we have

$$\mu_L(A(\mathbf{R})^0) = [L : H_1(A(\mathbf{R})^0,\mathbf{Z})].$$

We also set

$$\mu_L(A(\mathbf{R})) = \mu_L(A(\mathbf{R})^0) \cdot c_\infty,$$

where $c_\infty = \#(A(\mathbf{R})/A(\mathbf{R})^0)$. Let $\mathcal{A}$ be the Néron model of A (see [BLR90]). The Néron differentials $H^0(\mathcal{A}, \Omega_{\mathcal{A}/\mathbf{Z}})$ define a lattice Λ^* in T^*, and we define $\Omega_A = \mu_\Lambda(A(\mathbf{R}))$.

Lemma 4.4. $H_1(A(\mathbf{R})^0, \mathbf{Z}) \cong H_1(A(\mathbf{C}), \mathbf{Z})^+$.

Proof. This lemma is well known, but we give a proof for the reader's convenience (which was suggested by H. Lenstra and B. Poonen). We have the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & H_1(A(\mathbf{R})^0, \mathbf{Z}) \arrow[r] \arrow[d, "\psi"] & H_1(A(\mathbf{R})^0, \mathbf{R}) \arrow[r] \arrow[d, "\cong"] & A(\mathbf{R})^0 \arrow[r] \arrow[d, hook, "i"] & 0 \\
0 \arrow[r] & H_1(A(\mathbf{C}), \mathbf{Z})^+ \arrow[r] & H_1(A(\mathbf{C}), \mathbf{R})^+ \arrow[r, "\pi"] & A(\mathbf{C})^+ &
\end{tikzcd}$$

where the upper horizontal sequences is exact (we view the real torus $A(\mathbf{R})^0$ as the quotient of the tangent space at the identity by the first integral homology), and the lower horizontal sequence is exact because it is the beginning of the long exact sequence of $\mathrm{Gal}(\mathbf{R}/\mathbf{C})$-cohomology that arises from

$$0 \to H_1(A(\mathbf{C}), \mathbf{Z}) \to H_1(A(\mathbf{C}), \mathbf{R}) \to A(\mathbf{C}) \to 0.$$

The middle vertical map is an isomorphism because if it were not then its kernel would be an uncountable set that maps to 0 in $A(\mathbf{R})^0$. The snake lemma then yields an exact sequence

$$0 \to \ker(\psi) \to 0 \to 0 \to \mathrm{coker}(\psi) \to 0,$$

which implies that ψ is an isomorphism. □

Let

$$\Phi : H_1(X_0(N), \mathbf{Q}) \to \mathrm{Hom}(S_2(\Gamma_0(N))[I_f], \mathbf{C})$$

be the map induced by integration, scaled so that

$$\Phi(\{0, \infty\})(f) = L(f, 1)$$

(that $\{0, \infty\} \in H_1(X_0(N), \mathbf{Q})$ is the Manin-Drinfeld theorem, and that $\int_0^\infty f$ is a multiple of $L(f, 1)$ follows from the definition of $L(f, s)$ as a Mellin transform).

Theorem 4.5. *Recall that A is an abelian variety attached to a newform $f \in S_2(\Gamma_0(N))$, that c_∞ is the number of connected components of $A(\mathbf{R})$, that c_A is the Manin constant of A, that Ω_A is the Néron canonical volume of $A(\mathbf{R})$, and that Φ is the period mapping on homology induced by integrating homology classes on $X_0(N)$ against the $\mathbf{C}$-vector space spanned by the $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$-conjugates of f. Then we have the following equation:*

$$c_\infty \cdot c_A \cdot \frac{L(A, 1)}{\Omega_A} = [\Phi(H_1(X_0(N), \mathbf{Z}))^+ : \Phi(\mathbf{T}\{0, \infty\})] \in \mathbf{Q},$$

where the lattice index on the right hand side should be interpreted as 0 if $\Phi(\mathbf{T}\{0, \infty\})$ has rank less than the dimension of A.

Proof. It is easier to compute with $\tilde{\Lambda}^* = S_2(\Gamma_0(N), \mathbf{Z})[I_f]$ than with Λ^*, so let $\tilde{\Omega}_A = \mu_{\tilde{\Lambda}}(A(\mathbf{R}))$. Note that $\tilde{\Omega}_A \cdot c_A = \Omega_A$, where c_A is the Manin constant. By Lemma 4.4 and Section 2.2,

$$\begin{aligned}\tilde{\Omega}_A &= c_\infty \cdot [\tilde{\Lambda} : H_1(A(\mathbf{R})^0, \mathbf{Z})] \\ &= c_\infty \cdot [\mathrm{Hom}(S_2(\Gamma_0(N), \mathbf{Z})[I_f], \mathbf{Z}) : \Phi(H_1(X_0(N), \mathbf{Z}))^+].\end{aligned}$$

For any ring R the pairing

$$\mathbf{T}_R \times S_2(\Gamma_0(N), R) \to R$$

given by $\langle T_n, f\rangle = a_1(T_n f)$ is perfect, so $(\mathbf{T}/I_f) \otimes R \cong \mathrm{Hom}(S_2(\Gamma_0(N), R)[I_f], R)$. Using this pairing, we may view Φ as a map

$$\Phi : H_1(X_0(N), \mathbf{Q}) \to (\mathbf{T}/I_f) \otimes \mathbf{C},$$

so that

$$\tilde{\Omega}_A = c_\infty \cdot [\mathbf{T}/I_f : \Phi(H_1(X_0(N), \mathbf{Z}))^+].$$

Note that $(\mathbf{T}/I_f) \otimes \mathbf{C}$ is isomorphic as a ring to a product of copies of $\mathbf{C}$, with one copy corresponding to each Galois conjugate $f^{(i)}$ of f. Let $\pi_i \in (\mathbf{T}/I_f) \otimes \mathbf{C}$ be the projector onto the subspace of $(\mathbf{T}/I_f) \otimes \mathbf{C}$ corresponding to $f^{(i)}$. Then $\Phi(\{0, \infty\}) \cdot \pi_i = L(f^{(i)}, 1) \cdot \pi_i$. Since the π_i form a basis for the complex vector space $(\mathbf{T}/I_f) \otimes \mathbf{C}$, we see that

$$\det(\Phi(\{0, \infty\})) = \prod_i L(f^{(i)}, 1) = L(A, 1).$$

Letting $H = H_1(X_0(N), \mathbf{Z})$, we have

$$\begin{aligned}[\Phi(H)^+ : \Phi(\mathbf{T}\{0, \infty\})] &= [\Phi(H)^+ : (\mathbf{T}/I_f) \cdot \Phi(\{0, \infty\})] \\ &= [\Phi(H)^+ : \mathbf{T}/I_f] \cdot [\mathbf{T}/I_f : \mathbf{T}/I_f \cdot \Phi(\{0, \infty\})] \\ &= \frac{c_\infty}{\tilde{\Omega}_A} \cdot \det(\Phi(\{0, \infty\})) \\ &= \frac{c_\infty c_A}{\Omega_A} \cdot L(A, 1),\end{aligned}$$

which proves the theorem. □

Theorem 4.5 was inspired by the case when A is an elliptic curve (see [Cre97, §II.2.8]) or the winding quotient of $J_0(p)$ (see [Aga99]), and it generalizes to forms of weight > 2 (see [Ste00]).

Theorem 4.5 is true with Φ replaced by any linear map with the same kernel as Φ. One way to find such a linear map with image in a $\mathbf{Q}$-vector space is to compute a basis $\varphi_1, \ldots \varphi_d$ for $\mathrm{Hom}(H_1(X_0(N), \mathbf{Q}), \mathbf{Q})[I_f]$ and let $\Phi = \varphi_1 \times \cdots \times \varphi_d$. Also, since $H_1(X_0(N), \mathbf{Z})^+$ and $\mathbf{T}\{0, \infty\}$ are contained in $H_1(X_0(N), \mathbf{Q})^+$, Theorem 4.5 implies that $L(A, 1)/\Omega_A \in \mathbf{Q}$, a fact well known to the experts (see [Gro94, Prop. 2.7] for the statement, but without proof).

4.3. The Denominator of $L(A, 1)/\Omega_A$.

In this section, we prove a result about the denominator of the rational number $L(A, 1)/\Omega_A$ and compare it to what is predicted by the Birch and Swinnerton-Dyer conjecture.

Proposition 4.6. *Let z be the point in $J_0(N)(\mathbf{Q})$ defined by the degree 0 divisor $(0) - (\infty)$ on $X_0(N)$, and let $n = n_f$ be the order of the image of z in $A(\mathbf{Q})$. Then the denominator of $c_\infty \cdot c_A \cdot L(A, 1)/\Omega_A$ divides n.*

Proof. Let x be the image of z in $A(\mathbf{Q})$, and let $I = \mathrm{Ann}_{\mathbf{T}}(x)$ be the ideal of elements of $\mathbf{T}$ that annihilate x. Since f is a newform, the Hecke operators T_p, for $p \mid N$, act as 0 or ± 1 on $A(\mathbf{Q})$ (see, e.g., [DI95, §6]). If $p \nmid N$, then a standard calculation (see, e.g., [Cre97, §2.8]) shows that $T_p(x) = (p+1)x$.

Let C be the cyclic subgroup of $A(\mathbf{Q})$ of order n generated by x. Consider the map $\mathbf{T} \to C$ given by $T_p \mapsto T_p(x)$. The kernel of this map is I, and the map is surjective because its image is an additive group that contains x, and C is the smallest such group. Thus the map induces an isomorphism $\mathbf{T}/I \xrightarrow{\cong} C$. □

Conjecture 2.2 predicts that

$$\#A(\mathbf{Q}) \cdot \#A^\vee(\mathbf{Q}) \cdot \frac{L(A,1)}{\Omega_A} = \#\text{Ш}(A) \cdot \prod c_p \in \mathbf{Z},$$

and since $n \mid \#A(\mathbf{Q})$, Proposition 4.6 implies that

$$c_\infty \cdot c_A \cdot \#A(\mathbf{Q}) \cdot \frac{L(A,1)}{\Omega_A} \in \mathbf{Z}.$$

Since c_∞ is a power of 2, and c_A is conjecturally 1 (if N is prime, then by Theorem 4.2 it is a power of 2), Proposition 4.6 provides theoretical evidence for Conjecture 2.2, and also reflects a surprising amount of cancellation between $\prod c_p$ and $\#A^\vee(\mathbf{Q})$.

5. Results and Conclusions

We computed all 19608 abelian varieties $A = A_f$ attached to newforms of level $N \leq 2333$. Interesting data about some of these abelian varieties is summarized in Tables 1–4, which use the notation described in this section.

Suppose that A is one of the 10360 of these for which $L(A,1) \neq 0$, so Conjecture 2.2 asserts that Ш(A) has order

$$\#\text{Ш}_? = \frac{L(A,1)}{\tilde{\Omega}_A \cdot c_A} \cdot \frac{\#A(\mathbf{Q})_{\mathrm{tor}} \cdot \#A^\vee(\mathbf{Q})_{\mathrm{tor}}}{\prod_{p \mid N} c_p}.$$

(See Section 4.2 for the definition of $\tilde{\Omega}_A$ and c_A.)

For any rational number x, let x^{odd} be the *odd part* of x. If a and b are rational numbers with $a \neq 0$, we say that $a \mid b$ if b/a is an integer.

Define integers S_l and S_u such that

$$S_l \mid \mathrm{numer}(\#\text{Ш}_?^{\mathrm{odd}}) \mid S_u$$

as follows:

$\mathbf{S}_u$ The *upper bound* S_u is the odd part of the numerator of

$$\frac{L(A,1)}{\tilde{\Omega}_A} \cdot \frac{T^2}{\prod_{p \| N} c_p},$$

where T is the upper bound on $\#A(\mathbf{Q})$ and $\#A^\vee(\mathbf{Q})$ computed using Section 3.5 using a_p for $p \leq 17$. Since the Manin constant and the Tamagawa numbers are integers, S_u is an upper bound on the odd part of $\#\text{Ш}_?$.

$\mathbf{S}_l$ The *lower bound* S_l is defined as follows: Let $S_{l,1}$ be the odd part of the rational number

$$\frac{L(A,1)}{\tilde{\Omega}_A} \cdot \frac{\#C \cdot \#D}{\prod_{p \| N} c_p},$$

where $C \subset A(\mathbf{Q})_{\mathrm{tor}}$ and D is the part of C coprime to the modular degree of A. Usually C is the group generated by the image of $(0)-(\infty)$, and in all cases it contains this subgroup. More precisely, when A is an elliptic curve, we instead let C and D be the full torsion subgroup $A(\mathbf{Q})_{\mathrm{tor}}$, because it is easy to calculate. When A is not an elliptic curve it would be better to let C be the subgroup generated by all rational cusps, but the authors only realized this after completing the calculations, so we did not do this.

If N is square free, we let $S_l = S_{l,1}$. Otherwise, let $S_{l,2}$ be the largest part of $S_{l,1}$ coprime to all primes whose square divides N. This takes care of the Manin constant, which only involves primes whose square divides N. To take care of Tamagawa numbers, remove all primes $p \leq 2\dim(A)+1$ from $S_{l,2}$ to obtain S_l.

Remark 5.1. When N is square free we have

$$S_l \mid \#\text{Ш}_?^{\mathrm{odd}} \mid S_u$$

since c_A is a power of 2 and no Tamagawa numbers have been omitted from the formulas for S_l and S_u. For every $N \leq 2333$ we found that S_l is an integer, so when $N \leq 2333$ is squarefree, $\#\text{Ш}_?^{\mathrm{odd}}$ is an integer. Since Conjecture 2.2 asserts that $\#\text{Ш}_?$ is the order of a group, hence an integer, our data gives evidence for Conjecture 2.2.

Tables 1–4 list every A of level $N \leq 2333$ such that $S_l > 1$. The A column contains the label of A (see Section 3.2), and the next column (labeled dim) contains $\dim A$. A star next to the label for A indicates that we have proved that the odd part of $\#\text{Ш}(A)$ is at least as large as conjectured by the Birch and Swinnerton-Dyer conjecture. *This is the case for* 39 *of the* 168 *examples.* The columns labeled S_l contains the number S_l defined above. If $S_l = S_u$ then the column labeled S_u contains an = sign, and otherwise, it contains S_u (there are only 13 cases in which $S_u \neq S_l$). The column labeled $\mathrm{moddeg}(A)^{\mathrm{odd}}$ contains the odd part m of the modular degree of A, written as a product $\gcd(m, S_u)\cdot {\scriptstyle m/\gcd(S_u,m)}$, where ${\scriptstyle m/\gcd(S_u,m)}$ is shrunk to save space. The only non-square-free levels of A_f for which $S_l > 1$ are 1058, 1664, 2224, and 2264.

The column labeled B contains all B such that $L(B,1)=0$ and

$$\gcd(S_l, \#(A^\vee \cap \tilde{B}^\vee)) > 1.$$

(In retrospect, it would probably have been more interesting to list those B such that $\gcd(S_u, \#(A^\vee \cap \tilde{B}^\vee)) > 1$.) Here if $B = A_g$ for some newform g of level dividing N, and $\tilde{B}^\vee$ is the abelian subvariety of $J_0(N)$ generated by all images of $B^\vee$ under the degeneracy maps. Thus, e.g., when $B^\vee$ is of level N, $\tilde{B}^\vee = B^\vee$. The next column, labeled dim, contains the dimension of B.

The final two columns contain information about the relationship between A and B. The one labeled $A^\vee \cap \tilde{B}^\vee$ contains the abelian group structure of the indicated abelian group, where e.g., $[a^b c^d]$ means the abelian group $(\mathbf{Z}/a\mathbf{Z})^b \times (\mathbf{Z}/c\mathbf{Z})^d$. The column labeled Vis contains a divisor of the order of $\mathrm{Vis}_C(\text{Ш}(A^\vee))$, where $C = A^\vee + \tilde{B}^\vee$ (note that $\mathrm{Vis}_C(\text{Ш}(A^\vee)) \subset \mathrm{Vis}_{J_0(N)}(\text{Ш}(A^\vee))$).

The table is divided into three vertical regions, where the columns in the first region are about A only, the columns of the second region are about B only, and the third column is about the relationship between A and B.

5.1. **Example: Level 389.** We illustrate what is involved in computing the first line of Table 1. Using the method sketched in Section 3.2, we find that $S_2(\Gamma_0(389))$ contains exactly five Galois-conjugacy classes of newforms, and these are defined over extensions of $\mathbf{Q}$ of degrees 1, 2, 3, 6, and 20. Thus $J = J_0(389)$ decomposes, up to isogeny, as a product $A_1 \times A_2 \times A_3 \times A_6 \times A_{20}$ of abelian varieties, where $\dim A_d = d$ and A_d is the optimal quotient corresponding to the appropriate Galois-conjugacy class of newforms.

Next we consider the arithmetic of the A_d. Using Theorem 4.5 we find that

$$L(A_1, 1) = L(A_2, 1) = L(A_3, 1) = L(A_6, 1) = 0,$$

and

$$\frac{L(A_{20}, 1)}{\Omega_{A_{20}}} = \frac{5^2 \cdot 2^{11}}{97 \cdot c_A},$$

where c_A is the Manin constant attached to A_{20}, which, by Theorem 4.2, is of the form 2^n with $n \geq 0$. Using the algorithms of Sections 3.5, 3.6, 3.7, we find that $\#A_{20}(\mathbf{Q}) = c_{389} = 97$. Thus Conjecture 2.2 predicts that $\#Ш(A_{20}) = 5^2 \cdot 2^{11}/c_A$. The following proposition provides support for this conjecture.

Proposition 5.2. *There is a natural inclusion*

$$(\mathbf{Z}/5\mathbf{Z})^2 \cong A_1(\mathbf{Q})/5A_1(\mathbf{Q}) \hookrightarrow \mathrm{Vis}_{J_0(389)}(Ш(A_{20}^\vee)).$$

Proof. Let $A = A_{20}^\vee$, $B = A_1^\vee$ and $J = A + B \subset J_0(389)$. Using Proposition 3.3, we find that $A \cap B \cong (\mathbf{Z}/4)^2 \times (\mathbf{Z}/5\mathbf{Z})^2$, so $B[5] \subset A$. Since 5 does not divide the numerator of $(389-1)/12$, it does not divide the Tamagawa numbers or the orders of the torsion groups, so Theorem 3.13 yields the asserted injection. To see that $(\mathbf{Z}/5\mathbf{Z})^2 \cong A_1(\mathbf{Q})/5A_1(\mathbf{Q})$ use the standard elliptic curves algorithms [Cre97]. □

5.2. **Invisible Elements of $Ш(A)$.** Tables 1–4 suggest that much of $Ш(A^\vee)$ is invisible in $J_0(N)$. This is because Proposition 3.15 implies that if a prime divides $\#Ш(A^\vee)$ but not $\mathrm{moddeg}(A^\vee)$ then $Ш(A^\vee)$ contains an element of order p that is invisible. We find many examples in the table where p divides the conjectural order of $Ш(A^\vee)$, but $p \nmid \mathrm{moddeg}(A^\vee)$.

Invisible elements might become visible at higher level (see [AS02, §4.3] for a discussion and example).

5.3. **The Part of $Ш(A)$ That Must be a Perfect Square.** When $\dim A = 1$, properties of the Cassels-Tate pairing imply that if $Ш(A)$ is finite then $\#Ш(A)$ is a perfect square, and the fact that one finds in examples (see [Cre97]) that $\#Ш_?$ is a perfect square is computational evidence for Conjecture 2.2.

In contrast, when the dimension is greater than one, Poonen and Stoll [PS99] discovered Jacobians J such that $Ш(J)$ has order twice a square, and the second author found for each prime $p < 25000$ an abelian variety A of dimension $p-1$ such that $\#Ш(A) = pn^2$ for some integer n (see [Ste02b]).

Proposition 5.3. *Let $A = A_f$ be a quotient of $J_0(N)$ and ℓ be a prime that does not divide the modular degree of A. Suppose that $Ш(A)[\ell^\infty]$ is finite. Then $\#Ш(A)[\ell^\infty]$ is a perfect square.*

Proof. The Cassels-Tate pairing (see [Tat63, §3]) induces a pairing

$$\phi : Ш(A)[\ell^\infty] \times Ш(A^\vee)[\ell^\infty] \to \mathbf{Q}/\mathbf{Z}.$$

Since $Ш(A)[\ell^\infty]$ is finite, it follows from [Tat63, Thm. 3.2] that $Ш(A^\vee)[\ell^\infty]$ is also finite and ϕ is non-degenerate. In particular, $\#Ш(A^\vee)[\ell^\infty] = \#Ш(A)[\ell^\infty]$.

Since $J_0(N)$ is a Jacobian, it possesses a canonical polarization arising from the theta divisor; this divisor is rational over $\mathbf{Q}$, since $X_0(N)$ always has a point over $\mathbf{Q}$ (the cusp ∞ is rational). This polarization induces a polarization $\theta : A^\vee \to A$, which also comes from a divisor that is rational over $\mathbf{Q}$. Hence, by [Tat63, Thm. 3.3] (see also [PS99, Thm. 5]), the pairing

$$\phi' : Ш(A^\vee)[\ell^\infty] \times Ш(A^\vee)[\ell^\infty] \to \mathbf{Q}/\mathbf{Z}$$

obtained by composing θ with the pairing ϕ above is alternating.

Since ℓ does not divide the modular degree of A, it does not divide the degree of the isogeny θ. Hence θ induces an isomorphism $Ш(A^\vee)[\ell^\infty] \xrightarrow{\cong} Ш(A)[\ell^\infty]$. Thus by the non-degeneracy of the pairing ϕ, the pairing ϕ' is also non-degenerate. Since ϕ' is also alternating, it follows from arguments similar to those in [Cas62, p. 260] that $\#Ш(A^\vee)[\ell^\infty]$ is a perfect square. Since $\#Ш(A)[\ell^\infty] = \#Ш(A^\vee)[\ell^\infty]$, we see that $\#Ш(A)[\ell^\infty]$ is also a perfect square.

□

For the entries in Tables 1–4, $Ш(A)$ is finite, so if $\ell \nmid \mathrm{moddeg}(A)$ then the ℓ-power part of $\#Ш(A)$ must be a perfect square. When $S_l = S_u$ and the level is square free, then S_l is the odd part of the conjectural order of $Ш(A)$. We found that S_l is a perfect square whenever $S_l = S_u$, which provides evidence for Conjecture 2.2.

Table 1. Visibility of Nontrivial Odd Parts of Shafarevich-Tate Groups

6. Appendix by J. Cremona and B. Mazur: "Explaining" Shafarevich-Tate via Mordell-Weil

Introduction. In our article [CM] we discussed the notion of visibility and offered some tables of examples of that phenomenon. We gave, however, very little theoretical discussion in that article. Here we wish to take the opportunity to correct some gaps in our commentary on our tables and to offer the details of the proof of a general criterion that is sometimes useful to test visibility. Regarding Table 1 of [CM] we said that for each pair (E, p) that occurs there and for which there is a corresponding "F" on the table of the same conductor of E, the Shafarevich-Tate group of E is *explained* by the Mordell-Weil group of F, in the technical sense that we gave to the word *explained* in that article. Now this is indeed the case for all entries of our table such that E has semistable reduction at p and it is also the case for those entries where the conductor of F properly divides the conductor of E. We will review why this is so, below. It is also true that for each of the remaining 7 entries ($E =$ **2601H**, **2718D**, **2900D**, **3555E**, **3879E**, **3933A**, **5499E**) a nontrivial subgroup of the Shafarevich-Tate group of E is *explained* by the Mordell-Weil group of the corresponding F, but we wish to notify our readers that we have not yet checked whether or not *all* of the "Ш" of these 7 elliptic curves is so explained. These 7 cases deserve to be looked at (the issue being local at the prime 3 for all but **2900D**, where it is local at the prime 5). Regarding Table 2 of [CM], although our commentary in [CM] does not say this clearly, for all the entries E of that table for which there is a corresponding F of the same conductor we only have checked that $E[2] = F[2]$ in $J_0(N)$ and nothing more, except, of course, for those entries we particularly signal to have shown something less; namely, in the language of our article, that they "seem to satisfy a 2-congruence." In these latter cases where we signal that we have shown something less, W. Stein has checked that in fact $E[2] \neq F[2]$ in $J_0(N)$.

Let p be an odd prime number. If E is an (optimal) elliptic curve over $\mathbf{Q}$ of conductor N then E may be unambiguously identified (up to sign) with a subabelian variety of the modular jacobian $J_0(N)$ (over $\mathbf{Q}$). If (E, F, p) is an entry of Table 1 of [CM] such that E and F are of the same conductor N we checked that we have equality of the finite group schemes $E[p]_{/\mathbf{Q}} = F[p]_{/\mathbf{Q}}$ in $J_0(N)_{/\mathbf{Q}}$. For the remaining three entries we checked that there is an isomorphism of finite group schemes $\iota : E[p]_{/\mathbf{Q}} \cong F[p]_{/\mathbf{Q}}$. In both cases, identifying the two finite group schemes let H denote the common cohomology group,

$$H := H^1(G_{\mathbf{Q}}, E[p]_{/\mathbf{Q}}) = H^1(G_{\mathbf{Q}}, F[p]_{/\mathbf{Q}}),$$

and $S_E \subset H$, and $S_F \subset H$ the p-Selmer groups of, respectively, E and F. What we will show is that

Proposition 6.1. *For each of the entries (E, p) in Table 1 of* [CM] *such that p is a prime of semistable reduction for E and for which there is a "corresponding" F, we have*

$$S_E = S_F \subset H.$$

To discuss this, we need some notation.

Let $X := \mathrm{Spec}(\mathbf{Z})$, $Y := \mathrm{Spec}(\mathbf{Z}[1/p]) = X - \mathrm{Spec}(\mathbf{F}_p)$, and $\eta := \mathrm{Spec}(\mathbf{Q})$. Let $E_\eta := E$ be our elliptic curve over $\mathbf{Q}$ of conductor N, $E_{/X}$ the Néron model over X of E_η and $E^o_{/X} \subset E_{/X}$ the "connected component" of Néron (meaning the open subgroup scheme every fiber of which is connected). We have, of course, similar notation for the corresponding elliptic curve F. Let $E[p]_{/X}$ denote the closed subgroup scheme given as the kernel of multiplication by p in the Néron model: $E[p]_{/X} \subset E_{/X}$. We have, in general, that the restriction $E[p]_{/Y}$ of $E[p]_{/X}$ to the base Y is an étale quasi-finite flat group scheme; and if p^2 doesn't divide N we have that the group scheme $E[p]_{/X}$ is a quasi-finite flat group scheme [Gro72, Prop. 3.1(d), pg. 343]. The étale quasi-finite flat group scheme $E[p]_{/Y}$ can be characterized by the following features:

(i) Its generic fiber is the group scheme $E[p]_{/\eta} \subset J_0(N)_{/\eta}$,

and (one has a choice here) either:

(ii) $E[p]_{/Y} \subset J_0(N)_{/Y}$ is a closed étale quasi-finite flat) subgroup scheme,

or:

(ii') $E[p]_{/Y}$ enjoys the Néronian property over the base Y.

Similar statements hold for $F[p]_{/X}$.

Let Φ be the (punctual) sheaf of abelian groups for the flat topology over X which fits into the exact sequence (of abelian sheaves over X)

$$0 \to E^o \to E \to \Phi \to 0. \tag{1}$$

We will use the same notation to indicate the corresponding exact sequence of sheaves for the étale topology over X. Since E^0 and E are smooth group schemes, the long exact sequences of cohomology derived from the short exact sequence (1), viewed either as sheaves of abelian groups for the flat or étale topology, coincide; cf Section 11 *Appendice: Un théorème de comparaison de la cohomologie étale et de la cohomologie fppf* in [Gro68]. Thinking now of Φ as a sheaf for the étale topology, denote by Φ_ℓ its stalk at the prime ℓ. So Φ_ℓ is representable as a finite étale group scheme over the field $\mathbf{F}_\ell$. We have that

$$\Phi = \bigoplus_{\ell \mid N} (i_\ell)_* \Phi_\ell,$$

where $i_\ell : \mathrm{Spec}\mathbf{F}_\ell \hookrightarrow X$ is the natural closed immersion. We have an exact sequence

$$0 \to E^o(X) \to E(\mathbf{Q}) \to H^0(X,\Phi) \to H^1(X,E^o) \to H^1(X,E) \to H^1(X,\Phi), \tag{2}$$

where cohomology is computed for the étale topology. We have, for either topology,

$$H^i(X,\Phi) = \bigoplus_{\ell \mid N} H^i(\mathrm{Spec}(\mathbf{F}_\ell), \Phi_\ell).$$

Viewing (1) as an exact sequence of sheaves for the flat topology, and passing to the associated cohomology sequence we see that (2) may be thought of, ambiguously as computed for either the étale or the flat topology.

If p is an odd prime number, the p-primary component of the Shafarevich-Tate group of E is the p-primary component of the image of $H^1(X,E^o) \to H^1(X,E)$ (see the appendix to [Maz72]), or equivalently the intersection of the kernels of

$$H^1(X,E) \to H^1(\mathrm{Spec}(\mathbf{F}_\ell), \Phi_\ell).$$

Let p be an odd prime number. Let $E' \subset E$ be the open subgroup scheme of E which is the inverse image of $p\Phi \subset \Phi$, so that we have an exact sequence of sheaves for the flat (or étale) topology:

$$0 \to E' \to E \to \Phi/p\Phi \to 0, \tag{3}$$

and if p is a prime of semistable reduction for E (equivalently: p^2 doesn't divide N) we have an exact sequence of flat group schemes

$$0 \to E[p] \to E \to E' \to 0. \tag{4}$$

Put

$$E[p]^o_{/X} := E[p]_{/X} \bigcap E^o_{/X}.$$

Then $E[p]^o_{/X}$ is an open (quasi-finite) subgroup scheme of $E[p]_{/X}$. Let $\tilde{E}[p]_{/X}$ be any "intermediate" open (quasi-finite) subgroup scheme

$$E[p]^o_{/X} \subset \tilde{E}[p]_{/X} \subset E[p]_{/X}$$

so that we have the exact sequence of sheaves for the finite flat topology

$$0 \to \tilde{E}[p]_{/X} \to E[p]_{/X} \to \Psi \to 0, \tag{5}$$

with Ψ a subquotient of Φ.

Consider the following hypothesis:

$\mathbf{A}(E,p,\ell)$: The Galois module $\Phi_\ell/p\Phi_\ell$ is either trivial, or else is a non-constant cyclic Galois module over $\mathbf{F}_\ell$.

Let $\mathbf{A}(E,p)$ denote the conjunction of Hypotheses $\mathbf{A}(E,p,\ell)$ for all prime numbers ℓ, or equivalently, for all ℓ dividing N.

Lemma 6.2. *These are equivalent formulations of Hypothesis* $\mathbf{A}(E,p)$.

(a) $\Phi/p\Phi$ *is cohomologically trivial; that is,* $H^0(X,\Phi/p\Phi) = H^1(X,\Phi/p\Phi) = 0$.

(b) *If* Ψ *is any subquotient of* Φ, Ψ *is "p-cohomologically trivial" in the sense that the p-primary components of* $H^i(X,\Psi)$ *vanish for all* i.

Moreover, if $p \geq 5$, *or if* $p = 3$ *and* E *has no Néron fibers of type IV or IV*, the above conditions are equivalent to:*

(c) *For every* ℓ *at which* E *has split multiplicative reduction,* p *does not divide the order of the group of connected components of the Néron fiber of* E *at* ℓ.

Proof. The equivalence of Hypothesis $\mathbf{A}(E,p)$ with (a) and with (b) is straightforward using standard exact sequences plus the fact that the p-primary components of the (underlying abelian group of) Φ_ℓ is cyclic since $p > 2$; and noting that a (finite) G-module of prime order with nontrivial G-action has trivial cohomology. For (c) we are using that if $p > 2$ the p-primary component of Φ_ℓ vanishes for all primes ℓ of additive reduction for E except when $p = 3$ and the Néron fiber type of E at ℓ is IV or IV*. □

A morphism $G_1 \to G_2$ of flat (commutative, finite type) groups schemes over X will be said to *induce an isomorphism on p-cohomology* if the induced mappings

$$H^i(X,G_1) \otimes \mathbf{Z}_p \to H^i(X,G_2) \otimes \mathbf{Z}_p$$

are isomorphisms for all $i \geq 0$, where cohomology is computed for the flat topology.

Lemma 6.3. *Let* p *be an odd prime number for which* $\mathbf{A}(E,p)$ *holds. We have that the natural morphisms*

$$E^o_{/X} \to E'_{/X} \qquad \textit{and} \qquad E'_{/X} \to E_{/X}$$

induce isomorphisms on p-cohomology. If p *is of semistable reduction for* E, *we also have that*

$$\tilde{E}[p]_{/X} \to E[p]_{/X}$$

induces isomorphisms on p-cohomology, for any of the open subgroup schemes $\tilde{E}[p]_{/X}$ in $E[p]_{/X}$ described above.

Proof. These all sit in short exact sequences of sheaves of abelian groups for the flat topology over X where the third sheaf is p-cohomologically trivial. □

Corollary 6.4. *If $p > 2$ and $\mathbf{A}(E, p)$ holds we have natural isomorphisms*

$$H^0(X, E^o) \otimes \mathbf{Z}_p \cong H^0(X, E') \otimes \mathbf{Z}_p \cong E(\mathbf{Q}) \otimes \mathbf{Z}_p$$

and

$$Ш(E) \otimes \mathbf{Z}_p \cong H^1(X, E^o) \otimes \mathbf{Z}_p \cong H^1(X, E') \otimes \mathbf{Z}_p \cong H^1(X, E) \otimes \mathbf{Z}_p.$$

Corollary 6.5. *Let p be an odd prime number, semistable for E, and suppose that $\mathbf{A}(E, p)$ holds.*

(i) *The image of the natural (injective) coboundary mapping*

$$0 \to E(\mathbf{Q})/pE(\mathbf{Q}) \hookrightarrow H^1(G_{\mathbf{Q}}, E[p])$$

attached to the Kummer sequence is contained in the image of the natural injection

$$H^1(X, E[p]^o) \hookrightarrow H^1(G_{\mathbf{Q}}, E[p]).$$

(ii) *We have an exact sequence*

$$0 \to E(\mathbf{Q})/pE(\mathbf{Q}) \to H^1(X, \tilde{E}[p]) \to Ш(E)[p] \to 0$$

for any of the open subgroup schemes $\tilde{E}[p]_{/X} \subset E[p]_{/X}$ defined above.

(iii) *The image of $H^1(X, \tilde{E}[p]) \hookrightarrow H^1(G_{\mathbf{Q}}, E[p])$ is equal to the p-Selmer subgroup,*

$$S_p(E) \subset H^1(G_{\mathbf{Q}}, E[p]).$$

Proof. All this follows from straightforward calculations using the cohomological exact sequences associated to the exact sequences (1)–(5) in the light of the previous discussion. □

To set things up for our application, let us record the following:

Corollary 6.6. *Let $E_{/\mathbf{Q}}$ and $F_{/\mathbf{Q}}$ be elliptic curves over $\mathbf{Q}$. Let p be an odd prime number of semistable reduction for E and F, and for which $\mathbf{A}(E, p)$ and $\mathbf{A}(F, p)$ both hold. Define $\tilde{E}[p]_{/X} \subset E[p]_{/X}$ to be the open quasi-finite subgroup scheme whose restriction to Y is equal to $E[p]_{/Y}$ and whose fiber at $\mathbf{F}_p$ is equal to $E[p]^o_{/\mathbf{F}_p} = (E[p] \bigcap E^o)_{/\mathbf{F}_p}$. Define $\tilde{F}[p]_{/X}$ similarly. Suppose, finally, that we have an isomorphism of $G_{\mathbf{Q}}$-modules $\iota : F[p]_{/\mathbf{Q}} \cong E[p]_{/\mathbf{Q}}$ which extends to an injection of quasi-finite flat group schemes*

$$\tilde{F}[p]_{/X} \hookrightarrow \tilde{E}[p]_{/X}.$$

Letting

$$H := H^1(G_{\mathbf{Q}}, E[p]) = H^1(G_{\mathbf{Q}}, F[p])$$

(making the identification via ι) we have that the p-Selmer groups $S_p(E) \subset H$ and $S_p(F) \subset H$ are the same.

Proposition 6.7. *Let (E, F, p) be a triple which is an entry of Table 1 of* [CM]. *Suppose further that p is of semistable reduction for E and for F. Then, with the notation of the previous corollary, the p-Selmer groups $S_p(E) \subset H$ and $S_p(F) \subset H$ are the same. In the terminology of* [CM] *the Shafarevich-Tate group of E is explained by the Mordell-Weil group of F.*

Proof. As mentioned above, we have checked that $E[p]_{/\mathbf{Q}} = F[p]_{/\mathbf{Q}} \subset J_0(N)$ whenever the pair E and F (appearing as entry of Table 1 of [CM]) have the same conductor. We have checked that $E[p]_{/\mathbf{Q}} \cong F[p]_{/\mathbf{Q}}$ for the three entries where E and F have different conductor ($E =$ **2932A**, **3306B**, and **5136B**). We have checked that Hypothesis $A(E, p, \ell)$ and $A(F, p, \ell)$ hold for all quadruples (E, F, p, ℓ) such that (E, F, p) occurs as an entry in Table 1 of [CM] (even when p is not semistable for E and F) with the exception of the entry $(E, F, p, \ell) = (\mathbf{2366D}, \mathbf{2366E}, 3, 13)$.

Sublemma 6.8. *Under the hypotheses of our proposition, the isomorphism of $G_{\mathbf{Q}}$-modules $\iota : E[p]_{/\mathbf{Q}} \cong F[p]_{/\mathbf{Q}}$ extends to an injection of quasi-finite flat group schemes*

$$\tilde{E}[p]_{/X} \hookrightarrow \tilde{F}[p]_{/X}$$

which is an isomorphism except in two instances ($E =$ **3306B**, *and* **5136B***).*

Proof. First, since $\tilde{E}[p]_{/Y} = E[p]_{/Y}$, $\tilde{F}[p]_{/Y} = F[p]_{/Y}$, and, as we mentioned at the beginning, both of these quasi-finite, flat (étale) group schemes $F[p]_{/Y}$ and $E[p]_{/Y}$ enjoy the Néronian property, the isomorphism ι extends to an isomorphism $\tilde{E}[p]_{/Y} \cong \tilde{F}[p]_{/Y}$. The remaining question is then local about p. If p is of good reduction for E, then $\tilde{E}[p]_{/X_p}$ and $\tilde{F}[p]_{/X_p}$ are both finite flat group schemes of odd order, so by Fontaine's Theorem [Fon75], the isomorphism between their generic fibers extends to an isomorphism over X_p. (Compare: Theorem I.1.4 in [Maz77].) A standard result allows us to *patch* the isomorphism extending ι over Y with the isomorphism ("extending ι") over X_p to get the extension of ι to an isomorphism of group schemes over X, $\tilde{E}[p]_{/X} \cong \tilde{F}[p]_{/X}$. Now consider the case where p is of bad reduction. By the assumptions of our proposition, p is then of multiplicative reduction for E, and hence the fiber of E over $\mathbf{F}_p$ is a finite multiplicative type group scheme of order p. We therefore have that $\tilde{E}[p]_{/X_p}$ sits in an exact sequence

$$0 \to \mathcal{C}_{/X_p} \to \tilde{E}[p]_{/X_p} \to \mathcal{E}_{/X_p} \to 0 \tag{6}$$

where $\mathcal{C}_{/X_p}$ is a finite flat group scheme of order p (and with fiber of multiplicative type in characteristic p) and where $\mathcal{E}_{/X_p}$ is an étale quasi-finite group scheme, with trivial fiber in characteristic p.

Let us take a moment to recall (see [Maz78, Lem. 1.1]) the construction of such an exact sequence (6): working in the category of formal schemes, let $\hat{X}_p := \mathrm{Spf}(\mathbf{Z}_p)$, and let $\hat{\mathcal{C}}_{/\hat{X}_p}$ be the formal completion of the zero-section in $\tilde{E}[p]_{/X_p}$. One checks that $\hat{\mathcal{C}}_{/\hat{X}_p}$ may be identified with a finite flat formal group scheme over $\hat{X}_p$ which admits a closed immersion into the formal group scheme over $\hat{X}_p$ associated to $\tilde{E}[p]_{/X_p}$. A standard algebrization argument establishes that there is a (unique) finite flat subgroup scheme $\mathcal{C}_{/X_p} \subset \tilde{E}[p]_{/X_p}$ whose associated formal group scheme over $\hat{X}_p$ is $\hat{\mathcal{C}}_{/\hat{X}_p}$. The exact sequence (6) is then obtained by letting $\mathcal{E}_{/X_p}$ be the evident quotient (quasi-finite flat) group scheme, and noting that, by construction, its special fiber is trivial.

Now let us return to the proof of the sublemma. Since the restriction of ι to $\mathcal{C}_{/X_p}$ (a finite flat multiplicative type group scheme of order p) is injective over the generic point, it follows (by elementary considerations, or by Fontaine's Theorem cited above) that ι restricted to $\mathcal{C}_{/X_p}$ is an injection over X_p. Since $\mathcal{E}_{/X_p}$ has trivial fiber in characteristic p, ι is an injection as was to be proved. In all cases under consideration, then,

$$\iota : \tilde{E}[p]_{/X} \hookrightarrow \tilde{F}[p]_{/X}$$

is an injection. If E is of good reduction at p, or if F is of bad reduction at p, ι is therefore an isomorphism. The cases remaining are when E is of bad reduction at p and F is of good reduction (i.e., $E =$ **3306B**, and **5136B**) in which case we can only assert that ι is an injection. □

Returning to our proposition, suppose that $\tilde{F}[p]_{/X_p}$ is finite flat (which happens in the two cases signalled above: $E =$ **3306B**, and **5136B**). Then the isomorphism induced by ι on generic fibers

$$\tilde{E}[p]_{/\mathbf{Q}_p} \cong \tilde{F}[p]_{/\mathbf{Q}_p}$$

restricted to the $G_{\mathbf{Q}_p}$-stable subgroup $\mathcal{C}_{/\mathbf{Q}_p} \subset \tilde{E}[p]_{/\mathbf{Q}_p}$ extends to a morphism of the finite flat group scheme $\mathcal{C}_{/X_p}$ into $\tilde{F}[p]_{/X_p}$. This extended morphism $j : \mathcal{C}_{/X_p} \to \tilde{F}[p]_{X_p}$ is necessarily a closed immersion since $\mathcal{C}_{/X_p}$ is a multiplicative type finite flat group scheme. Since $\mathcal{E}_{/X_p}$ has trivial fiber in characteristic p an application of the standard patching argument (as used in the previous case) allows us to put together the isomorphism of group schemes over Y extending ι with the closed immersion j over X_p to get a closed immersion

$$\tilde{E}[p]_{/X} \hookrightarrow \tilde{F}[p]_{/X}.$$

Finally suppose that both E and F have multiplicative reduction at p. We then have exact sequences (6) for each of our quasi-finite flat group schemes $\tilde{E}[p]_{/X_p}$ and $\tilde{F}[p]_{/X_p}$. Let V denote their common generic fiber (identified via ι) considered as two-dimensional $\mathbf{F}_p$-vector space with $G_{\mathbf{Q_p}}$-action. Let $\mathcal{C}(E) \subset V$ and $\mathcal{C}(F) \subset V$ denote the one-dimensional subspaces given by the generic fibers of the finite flat subgroup schemes $\mathcal{C}_{/X_p}$ corresponding to the exact sequence (6) for for E and for F respectively. Suppose, first, that these one-dimensional $\mathbf{F}_p$-subspaces $\mathcal{C}(E)$ and $\mathcal{C}(F)$ are different. It then follows that the $G_{\mathbf{Q}_p}$-representation V splits as the direct sum of $\mathcal{C}(E)$ and $\mathcal{C}(F)$, both $\mathbf{F}_p$-subspaces being isomorphic, as $I_{\mathbf{Q_p}}$-modules to μ_p, where $I_{\mathbf{Q_p}} \subset G_{\mathbf{Q_p}}$ is the inertia subgroup of $G_{\mathbf{Q}_p}$. But this contradicts the fact that V is self-Cartier dual (under the Weil pairing). Consequently, $\mathcal{C}(E) = \mathcal{C}(F) \subset V$. From the above discussion it follows that we can extend ι to an isomorphism $\tilde{E}[p]_{/X_p} \cong \tilde{F}[p]_{/X_p}$.

Our proposition then follows (from Corollary 6.6) for all entries in Table 1 of [CM] where p is of semistable reduction for E once we produce special arguments to cover the three special cases $E =$ **3306B**, **5136B** and **2366D**. The first two of these cases are "special" because we only have an injection $\tilde{E}[p]_{/X_p} \hookrightarrow \tilde{F}[p]_{/X_p}$ and not an isomorphism. However, the cokernel of this morphism restricted to the fiber in characteristic 3 is, in both of these cases, a cyclic group with nontrivial $G_{\mathbf{Q_3}}$-action and hence is 3-cohomologically trivial. In particular, the injection $\tilde{E}[p]_{/X_p} \hookrightarrow \tilde{F}[p]_{/X_p}$ induces an isomorphism on flat cohomology over X, and the argument for these two cases proceeds as before. This leaves $(E, F, p) = (\mathbf{2366D}, \mathbf{2366E}, 3)$

which is the only example of an entry (E, F, p) in our table, where E has a $\mathbf{Q}$-rational point of order p, and (this is no accident) where Hypothesis $\mathbf{A}(E, p)$ and Hypothesis $\mathbf{A}(F, p)$ fail. (Indeed there are no other failures of Hypothesis $\mathbf{A}(F, p)$ for any of the (E, F, p)'s occurring in Table 1 of [CM] and only one other failure of Hypothesis $\mathbf{A}(E, p)$, which is for $(E, p, \ell) = (\mathbf{2932A}, 3, 2)$.)

Let us now deal with the case $(E, F, p) = (\mathbf{2366D}, \mathbf{2366E}, 3)$. The subgroup C of $\mathbf{Q}$-rational points of order 3 on E specialize in characteristic 13 to yield an isomorphism

$$C \cong \Phi_{13}$$

and the same for the subgroup of $\mathbf{Q}$-rational points of order 3 on F. We make use of this information to cut down the group schemes $\tilde{E}[3]_{/X}$ and $\tilde{F}[3]_{/X}$ and define open subgroup schemes: $\tilde{\tilde{E}}[3]_{/X} \subset \tilde{E}[3]_{/X}$ and $\tilde{\tilde{E}}[3]_{/X} \subset \tilde{E}[3]_{/X}$ by requiring that these closed immersions of subgroup schemes be isomorphisms outside characteristic 13, and that the "double-tilded" group schemes each have trivial fiber in characteristic 13. We get via the above argument an isomorphism of group schemes $\tilde{\tilde{E}}[3]_{/X} \cong \tilde{\tilde{F}}[3]_{/X}$ extending ι, and an identification of the 3-Selmer groups of E and F with $H^1(X, \tilde{\tilde{E}}[3])$ and $H^1(X, \tilde{\tilde{F}}[3])$ respectively. Our proposition is proved. □

It remains to say a few words about why, in the 7 cases of entries (E, F, p) in our Table 1 of [CM] for which p is a prime of additive reduction for E *some* nontrivial elements of the Shafarevich-Tate group of E are explained by the Mordell-Weil group of F. Briefly, the reason is as follows. By the *inflated* p-Selmer group of E (and of F) let us mean the subgroup of H obtained by insisting upon all the local Selmer conditions at primes different from p, but putting no condition at p. The p-Selmer group of E (and of F) are, in all 7 instances, $\mathbf{F}_p$-vector spaces of dimension 2 and therefore, the inflated p-Selmer groups are of dimensions either 2 or 3. Working over Y rather than over X, the above argument applied to these 7 remaining cases gives us an identification of the *inflated* p-Selmer groups of E and of F in H. But the true p-Selmer groups (vector spaces of dimension 2) being subspaces in a vector space of dimension ≤ 3 must have a nontrivial intersection.

14 $J_1(p)$ Has Connected Fibers, with B. Conrad and B. Edixhoven

$J_1(p)$ Has Connected Fibers

Brian Conrad, Bas Edixhoven, William Stein

Received: November 23, 2002

Communicated by Stephen Lichtenbaum

Abstract. We study resolution of tame cyclic quotient singularities on arithmetic surfaces, and use it to prove that for any subgroup $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ the map $X_H(p) = X_1(p)/H \to X_0(p)$ induces an injection $\Phi(J_H(p)) \to \Phi(J_0(p))$ on mod p component groups, with image equal to that of H in $\Phi(J_0(p))$ when the latter is viewed as a quotient of the cyclic group $(\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$. In particular, $\Phi(J_H(p))$ is always Eisenstein in the sense of Mazur and Ribet, and $\Phi(J_1(p))$ is trivial: that is, $J_1(p)$ has connected fibers. We also compute tables of arithmetic invariants of optimal quotients of $J_1(p)$.

1 Introduction

Let p be a prime and let $X_1(p)_{/\mathbf{Q}}$ be the projective smooth algebraic curve over $\mathbf{Q}$ that classifies elliptic curves equipped with a point of exact order p. Let $J_1(p)_{/\mathbf{Q}}$ be its Jacobian. One of the goals of this paper is to prove:

Theorem 1.1.1. *For every prime p, the Néron model of $J_1(p)_{/\mathbf{Q}}$ over $\mathbf{Z}_{(p)}$ has closed fiber with trivial geometric component group.*

This theorem is obvious when $X_1(p)$ has genus 0 (*i.e.*, for $p \leq 7$), and for $p = 11$ it is equivalent to the well-known fact that the elliptic curve $X_1(11)$ has j-invariant with a simple pole at 11 (the j-invariant is $-2^{12}/11$). The strategy of the proof in the general case is to show that $X_1(p)_{/\mathbf{Q}}$ has a regular proper model $\mathcal{X}_1(p)_{/\mathbf{Z}_{(p)}}$ whose closed fiber is geometrically integral. Once we have such a model, by using the well-known dictionary relating the Néron model of a generic-fiber Jacobian with the relative Picard scheme of a regular proper model (see [9, Ch. 9], esp. [9, 9.5/4, 9.6/1], and the references therein), it follows that the Néron model of $J_1(p)$ over $\mathbf{Z}_{(p)}$ has (geometrically) connected closed fiber, as desired. The main work is therefore to prove the following theorem:

Theorem 1.1.2. *Let p be a prime. There is a regular proper model $\mathcal{X}_1(p)$ of $X_1(p)_{/\mathbf{Q}}$ over $\mathbf{Z}_{(p)}$ with geometrically integral closed fiber.*

What we really prove is that if $X_1(p)^{\mathrm{reg}}$ denotes the minimal regular resolution of the normal (typically non-regular) coarse moduli scheme $X_1(p)_{/\mathbf{Z}_{(p)}}$, then a minimal regular contraction $\mathcal{X}_1(p)$ of $X_1(p)^{\mathrm{reg}}$ has geometrically integral closed fiber; after all the contractions of -1-curves are done, the component that remains corresponds to the component of $X_1(p)_{/\mathbf{F}_p}$ classifying étale order-p subgroups. When $p > 7$, so the generic fiber has positive genus, such a minimal regular contraction is the unique minimal regular proper model of $X_1(p)_{/\mathbf{Q}}$.

Theorem 1.1.2 provides natural examples of a finite map π between curves of arbitrarily large genus such that π does not extend to a morphism of the minimal regular proper models. Indeed, consider the natural map

$$\pi : X_1(p)_{/\mathbf{Q}} \to X_0(p)_{/\mathbf{Q}}.$$

When $p = 11$ or $p > 13$, the target has minimal regular proper model over $\mathbf{Z}_{(p)}$ with reducible geometric closed fiber [45, Appendix], while the source has minimal regular proper model with (geometrically) integral closed fiber, by Theorem 1.1.2. If the map extended, it would be proper and dominant (as source and target have unique generic points), and hence surjective. On the level of closed fibers, there cannot be a surjection from an irreducible scheme onto a reducible scheme. By the valuative criterion for properness, π is defined in codimension 1 on minimal regular proper models, so there are finitely many points of $\mathcal{X}_1(p)$ in codimension 2 where π cannot be defined.

Note that the fiber of $J_1(p)$ at infinity need not be connected. More specifically, a modular-symbols computation shows that the component group of $J_1(p)(\mathbf{R})$ has order 2 for $p = 17$ and $p = 41$. In contrast, A. Agashe has observed that [47, §1.3] implies that $J_0(p)(\mathbf{R})$ is always connected.

Rather than prove Theorem 1.1.2 directly, we work out the minimal regular model for $X_H(p)$ over $\mathbf{Z}_{(p)}$ for any subgroup $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ and use this to study the mod p component group of the Jacobian $J_H(p)$; note that $J_H(p)$ usually does not have semistable reduction. Our basic method is to use a variant on the classical Jung–Hirzebruch method for complex surfaces, adapted to the case of a proper curve over an arbitrary discrete valuation ring. We refer the reader to Theorem 2.4.1 for the main result in this direction; this is the main new theoretical contribution of the paper. This technique will be applied to prove:

Theorem 1.1.3. *For any prime p and any subgroup H of $(\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$, the natural surjective map $J_H(p) \to J_0(p)$ of Albanese functoriality induces an injection on geometric component groups of mod-p fibers, with the component* *group $\Phi(\mathcal{J}_H(p)_{/\overline{\mathbf{F}}_p})$ being cyclic of order $|H|/\gcd(|H|,6)$. In particular, the finite étale component-group scheme $\Phi(\mathcal{J}_H(p)_{/\mathbf{F}_p})$ is constant over $\mathbf{F}_p$.*

If we view the constant cyclic component group $\Phi(\mathcal{J}_0(p)_{/\mathbf{F}_p})$ as a quotient of the cyclic $(\mathbf{Z}/p)^\times/\{\pm 1\}$, then the image of the subgroup $\Phi(\mathcal{J}_H(p)_{/\mathbf{F}_p})$ in this quotient is the image of $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ in this quotient.

Remark 1.1.4. The non-canonical nature of presenting one finite cyclic group as a quotient of another is harmless when following images of subgroups under maps, so the final part of Theorem 1.1.3 is well-posed.

The constancy in Theorem 1.1.3 follows from the injectivity claim and the fact that $\Phi(\mathcal{J}_0(p)_{/\mathbf{F}_p})$ is constant. Such constancy was proved by Mazur-Rapoport [45, Appendix], where it is also shown that this component group for $J_0(p)$ is cyclic of the order indicated in Theorem 1.1.3 for $H = (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$.

Since the Albanese map is compatible with the natural map $\mathbf{T}_H(p) \to \mathbf{T}_0(p)$ on Hecke rings and Mazur proved [45, §11] that $\Phi(\mathcal{J}_0(p)_{/\overline{\mathbf{F}}_p})$ is Eisenstein as a $\mathbf{T}_0(p)$-module, we obtain:

Corollary 1.1.5. *The Hecke module $\Phi(\mathcal{J}_H(p)_{/\overline{\mathbf{F}}_p})$ is Eisenstein as a $\mathbf{T}_H(p)$-module* (i.e., *T_ℓ acts as $1+\ell$ for all $\ell \neq p$ and $\langle d\rangle$ acts trivially for all $d \in (\mathbf{Z}/p\mathbf{Z})^\times$*).

In view of Eisenstein results for component groups due to Edixhoven [18] and Ribet [54], [55] (where Ribet gives examples of non-Eisenstein component groups), it would be of interest to explore the range of validity of Corollary 1.1.5 when auxiliary prime-to-p level structure of $\Gamma_0(N)$-type is allowed. A modification of the methods we use should be able to settle this more general problem. In fact, a natural approach would be to aim to essentially reduce to the Eisenstein results in [54] by establishing a variant of the above injectivity result on component groups when additional $\Gamma_0(N)$ level structure is allowed away from p. This would require a new idea in order to avoid the crutch of cyclicity (the case of $\Gamma_1(N)$ seems much easier to treat using our methods because the relevant groups tend to be cyclic, though we have not worked out the details for $N > 1$), and preliminary calculations of divisibility among orders of component groups are consistent with such injectivity.

In order to prove Theorem 1.1.3, we actually first prove a surjectivity result:

Theorem 1.1.6. *The map of Picard functoriality $J_0(p) \to J_H(p)$ induces a surjection on mod p component groups, with the mod p component group for $J_H(p)$ having order $|H|/\gcd(|H|,6)$.*

In particular, each connected component of $\mathcal{J}_H(p)_{/\mathbf{F}_p}$ contains a multiple of the image of $(0)-(\infty) \in \mathcal{J}_0(p)(\mathbf{Z}_{(p)})$ in $\mathcal{J}_H(p)(\mathbf{F}_p)$.

Let us explain how to deduce Theorem 1.1.3 from Theorem 1.1.6. Recall [28, Exposé IX] that for a discrete valuation ring R with fraction field K and an abelian variety A over K over R, Grothendieck's biextension pairing sets up a bilinear pairing between the component groups of the closed fibers of the Néron models of A and its dual A'. Moreover, under this pairing the component-group map induced by a morphism $f : A \to B$ (to another abelian variety) has as an adjoint the component-group map induced by the dual morphism $f' : B' \to A'$. Since Albanese and Picard functoriality maps on Jacobians are dual to each other, the surjectivity of the Picard map therefore implies the injectivity of the Albanese map provided that the biextension pairings in question are perfect pairings (and then the description of the image of the resulting Albanese injection in terms of H as in Theorem 1.1.3 follows immediately from the order calculation in Theorem 1.1.6).

In general the biextension pairing for an abelian variety and its dual need not be perfect [8], but once it is known to be perfect for the $J_H(p)$'s then surjectivity of the Picard map in Theorem 1.1.6 implies the injectivity of the Albanese map as required in Theorem 1.1.3. To establish the desired perfectness, one can use either that the biextension pairing is always perfect in case of generic characteristic 0 with a perfect residue field [6, Thm. 8.3.3], or that surjectivity of the Picard map ensures that $J_H(p)$ has mod p component group of order prime to p, and the biextension pairing is always perfect on primary components prime to the residue characteristic [7, §3, Thm. 7].

It is probable that the results concerning the component groups $\Phi(\mathcal{J}_H(p)_{/\overline{\mathbf{F}}_p})$ and the maps between them that are proved in this article via models of $X_H(p)$ over $\mathbf{Z}_{(p)}$ can also be proved using [20, 5.4, Rem. 1], and the well-known stable model of $X_1(p)$ over $\mathbf{Z}_{(p)}[\zeta_p]$ that one can find for example in [30]. (This observation was prompted by questions of Robert Coleman.) However, such an approach does not give information on regular models of $X_H(p)$ over $\mathbf{Z}_{(p)}$. Hence we prefer the method of this paper.

Acknowledgements. This paper was inspired by the following question of Shuzo Takehashi: "What can be said about component groups of optimal quotients of $J_1(p)$?". Edixhoven was partially supported by the European Research Training Network Contract HPRN-CT-2000-00120 "arithmetic algebraic geometry", while Conrad and Stein are grateful to the NSF for support during work on this paper. Conrad is also grateful to the Sloan Foundation for support and to Henri Darmon, Paul Hacking, and Victor Kac. Dino Lorenzini made a large number of helpful remarks. Stein thanks Ken Ribet and Sheldon Kamienny for discussions about the torsion subgroup of $J_1(p)$, Allan Steel of Magma for computational support, and William R. Hearst III and Sun Microsystems for donating computers that were used for computations in this paper. The authors thank the referee for a thoughtful report.

1.2 Outline

Section 1.3 contains a few background notational remarks. In Section 2 we develop the basic Jung–Hirzebruch resolution technique in the context of tame cyclic quotient surface singularities. This includes mod-p singularities on many (coarse) modular curves when $p > 3$ and the p-power level structure is only on p-torsion. In Section 3, we recall some general results on moduli problems for elliptic curves and coarse moduli schemes for such problems. In Section 4, we use the results of Sections 2 and 3 to locate all the non-regular points on the coarse moduli scheme $X_H(p)_{/\mathbf{Z}_{(p)}}$ (*e.g.*, when H is trivial this is the set of $\mathbf{F}_p$-rational points $(E, 0)$ with $j = 0, 1728$). In Section 5, we use the Jung–Hirzebruch formulas to compute the minimal regular resolution $X_H(p)^{\mathrm{reg}}$ of $X_H(p)_{/\mathbf{Z}_{(p)}}$, and we use use a series of intersection number computations to obtain a regular proper model for $X_H(p)_{/\mathbf{Q}}$; from this, the desired results on component groups follow. We conclude in Section 6 with some computer computations concerning the arithmetic of $J_1(p)$ for small p, where (among other things) we propose a formula for the order of the torsion subgroup of $J_1(p)(\mathbf{Q})$.

To avoid using Weierstrass equations in proofs, we have sometimes argued more abstractly than is strictly necessary, but this has the merit of enabling us to treat cusps by essentially the same methods as the other points. We would prefer to avoid mentioning j-invariants, but it is more succinct to say "cases with $j = 0$" than it is to say "cases such that $\mathrm{Aut}(E_{/k})$ has order 6."

Because we generally use methods of abstract deformation theory, the same approach should apply to Drinfeld modular curves, as well as to cases with auxiliary level structure away from p (including mod p component groups of suitable Shimura curves associated to indefinite quaternion algebras over $\mathbf{Q}$, with p not dividing the discriminant). However, since a few additional technicalities arise, we leave these examples to be treated at a future time.

1.3 Notation and terminology

Throughout this paper, p denotes an arbitrary prime unless otherwise indicated. Although the cases $p \leq 3$ are not very interesting from the point of view of our main results, keeping these cases in mind has often led us to more conceptual proofs. We write $\Phi_p(T) = (T^p - 1)/(T - 1) \in \mathbf{Z}[T]$ to denote the pth cyclotomic polynomial (so $\Phi_p(T + 1)$ is p-Eisenstein).

We write $V^\vee$ to denote the dual of a vector space V, and we write $\mathcal{F}^\vee$ to denote the dual of a locally free sheaf $\mathcal{F}$.

If X and S' are schemes over a scheme S then $X_{/S'}$ and $X_{S'}$ denote $X \times_S S'$. If S is an integral scheme with function field K and X is a K-scheme, by a *model* of X (over S) we mean a flat S-scheme with generic fiber X.

By an *S-curve* over a scheme S we mean a flat separated finitely presented map $X \to S$ with fibers of pure dimension 1 (the fibral dimension condition need only be checked on generic fibers, thanks to [27, IV$_3$, 13.2.3] and a reduction to the noetherian case). Of course, when a map of schemes $X \to S$ is proper flat and finitely presented with geometrically connected generic fibers, then the other fibers are automatically geometrically connected (via reduction to the noetherian case and a Stein factorization argument). For purely technical reasons, we do *not* require S-curves to be proper or to have geometrically connected fibers. The main reason for this is that we want to use étale localization arguments on X without having to violate running hypotheses. The use of Corollary 2.2.4 in the proof of Theorem 2.4.1 illustrates this point.

2 RESOLUTION OF SINGULARITIES

Our eventual aim is to determine the component groups of Jacobians of intermediate curves between $X_1(p)$ and $X_0(p)$. Such curves are exactly the quotient curves $X_H(p) = X_1(p)/H$ for subgroups $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$, where we identify the group $\mathrm{Aut}_{\mathbf{Q}}(X_1(p)/X_0(p)) = \mathrm{Aut}_{\overline{\mathbf{Q}}}(X_1(p)/X_0(p))$ with $(\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ via the diamond operators (in terms of moduli, $n \in (\mathbf{Z}/p\mathbf{Z})^\times$ sends a pair (E, P) to the pair $(E, n \cdot P)$). The quotient $X_H(p)_{/\mathbf{Z}_{(p)}}$ is an arithmetic surface with tame cyclic quotient singularities (at least when $p > 3$).

After some background review in Section 2.1 and some discussion of generalities in Section 2.2, in Section 2.3 we will describe a class of curves that give rise to (what we call) *tame cyclic quotient singularities*. Rather than work with global quotient situations X/H, it is more convenient to require such quotient descriptions only on the level of complete local rings. For example, this is what one encounters when computing complete local rings on coarse modular curves: the complete local ring is a subring of invariants of the universal deformation ring under the action of a finite group, but this group-action might not be induced by an action on the global modular curve. In Section 2.4 we establish the Jung–Hirzebruch continued-fraction algorithm that minimally resolves tame cyclic quotient singularities on curves over an arbitrary discrete valuation ring. The proof requires the Artin approximation theorem, and for this reason we need to define the concept of a *curve* as in Section 1.3 without requiring properness or geometric connectivity of fibers.

We should briefly indicate here why we need to use Artin approximation to compute minimal resolutions. Although the end result of our resolution process is intrinsic and of étale local nature on the curve, the mechanism by which the proof gets there depends on coordinatization and is not intrinsic (*e.g.*, we do not blow-up at points, but rather along certain codimension-1 subschemes). The only way we can relate the general case to a coordinate-dependent calculation in a special case is to use Artin approximation to find a common étale neighborhood over the general case and a special case (coupled with the étale local nature of the intrinsic minimal resolution that we are seeking to describe).

These resolution results are applied in subsequent sections to compute a regular proper model of $X_H(p)_{/\mathbf{Q}}$ over $\mathbf{Z}_{(p)}$ in such a way that we can compute both the mod-p geometric component group of the Jacobian $J_H(p)$ and the map induced by $J_0(p) \rightarrow J_H(p)$ on mod-p geometric component-groups. In this way, we will prove Theorem 1.1.6 (as well as Theorem 1.1.2 in the case of trivial H).

2.1 Background review

Some basic references for intersection theory and resolution of singularities for connected proper flat regular curves over Dedekind schemes are [29, Exposé X], [13], and [41, Ch. 9].

If S is a connected Dedekind scheme with function field K and X is a normal S-curve, when S is excellent we can construct a resolution of singularities as follows: blow-up the finitely many non-regular points of X (all in codimension 2), normalize, and then repeat until the process stops. That this process always stops is due to a general theorem of Lipman [40]. For more general (*i.e.*, possibly non-excellent) S, and $X_{/S}$ with *smooth* generic fiber, the same algorithm works (including the fact that the non-regular locus consists of only finitely many closed points in closed fibers). Indeed, when $X_{/K}$ is smooth then the non-smooth locus of $X \to S$ is supported on finitely many closed fibers, so we may assume $S = \mathrm{Spec}(R)$ is local. We can then use Lemma 2.1.1 below to bring results down from $X_{/\widehat{R}}$ since $\widehat{R}$ is excellent.

See Theorem 2.2.2 for the existence and uniqueness of a canonical minimal regular resolution $X^{\mathrm{reg}} \to X$ for any connected Dedekind S when $X_{/K}$ smooth. A general result of Lichtenbaum [39] and Shafarevich [61] ensures that when $X_{/S}$ is also proper (with smooth generic fiber if S isn't excellent), by beginning with X^{reg} (or any regular proper model of $X_{/K}$) we can successively blow down -1-curves (see Definition 2.2.1) in closed fibers over S until there are no more such -1-curves, at which point we have reached a relatively minimal model among the regular proper models of $X_{/K}$. Moreover, when $X_{/K}$ is in addition geometrically integral with positive arithmetic genus (*i.e.*, $\mathrm{H}^1(X_{/K}, \mathscr{O}) \neq 0$), this is the unique relatively minimal regular proper model, up to unique isomorphism.

In various calculations below with proper curves, it will be convenient to work over a base that is complete with algebraically closed residue field. Since passage from $\mathbf{Z}_{(p)}$ to $W(\overline{\mathbf{F}}_p)$ involves base change to a strict henselization followed by base change to a completion, in order to not lose touch with the situation over $\mathbf{Z}_{(p)}$ it is useful to keep in mind that formation of the minimal regular proper model (when the generic fiber is smooth with positive genus) is compatible with base change to a completion, henselization, and strict henselization on the base. We will not really require these results, but we do need to use the key fact in their proof: certain base changes do not destroy regularity or normality (and so in particular commute with formation of normalizations). This is given by:

Lemma 2.1.1. *Let R be a discrete valuation ring with fraction field K and let X be a locally finite type flat R-scheme that has* regular *generic fiber. Let $R \to R'$ be an extension of discrete valuation rings for which $\mathfrak{m}_R R' = \mathfrak{m}_{R'}$ and the residue field extension $k \to k'$ is separable. Assume either that the fraction field extension $K \to K'$ is separable or that $X_{/K}$ is smooth* (*so either way, $X_{/K'}$ is automatically regular*).

For any $x' \in X' = X \times_R R'$ lying over $x \in X$, the local ring $\mathcal{O}_{X',x'}$ is regular (*resp. normal*) *if and only if the local ring $\mathcal{O}_{X,x}$ is regular* (*resp. normal*).

Proof. Since $\mathfrak{m}_R R' = \mathfrak{m}_{R'}$, the map $\pi : X' \to X$ induces $\pi_k : X_{/k} \times_k k' \to X_{/k}$ upon reduction modulo $\mathfrak{m}_R$. The separability of k' over k implies that π_k is a regular morphism. Thus, if x and x' lie in the closed fibers then $\mathcal{O}_{X,x} \to \mathcal{O}_{X',x'}$ is faithfully flat with regular fiber ring $\mathcal{O}_{X',x'}/\mathfrak{m}_x$. Consequently, X is regular at x if and only if X' is regular at x' [44, 23.7]. Meanwhile, if x and x' lie in the generic fibers then they are both regular points since the generic fibers are regular. This settles the regular case.

For the normal case, when X' is normal then the normality of X follows from the faithful flatness of π [44, Cor. to 23.9]. Conversely, when X is normal then to deduce normality of X' we use Serre's "$R_1 + S_2$" criterion. The regularity of X' in codimensions ≤ 1 is clear at points on the regular generic fiber. The only other points of codimension ≤ 1 on X' are the generic points of the closed fiber, and these lie over the (codimension 1) generic points of the closed fiber of X. Such points on X are regular since X is now being assumed to be normal, so the desired regularity on X' follows from the preceding argument. This takes care of the R_1 condition. It remains to check that points $x' \in X'$ in codimensions ≥ 2 contain a regular sequence of length 2 in their local rings. This is clear if x' lies on the regular generic fiber, and otherwise x' is a point of codimension ≥ 1 on the closed fiber. Thus, $x = \pi(x')$ is either a generic point of $X_{/k}$ or is a point of codimension ≥ 1 on $X_{/k}$. In the latter case the normal local ring $\mathcal{O}_{X,x}$ has dimension at least 2 and hence contains a regular sequence of length 2; this gives a regular sequence in the faithfully flat extension ring $\mathcal{O}_{X',x'}$. If instead x is a generic point of $X_{/k}$ then $\mathcal{O}_{X,x}$ is a regular ring. It follows that $\mathcal{O}_{X',x'}$ is regular, so we again get the desired regular sequence (since $\dim \mathcal{O}_{X',x'} \geq 2$). □

We wish to record an elementary result in intersection theory that we will use several times later on. First, some notation needs to be clarified: if X is a connected regular proper curve over a discrete valuation ring R with residue field k, and D and D' are two *distinct* irreducible and reduced divisors in the closed fiber, then

$$D.D' := \dim_k \mathrm{H}^0(D \cap D', \mathcal{O}) = \sum_{d \in D \cap D'} \dim_k \mathcal{O}_{D \cap D',d}.$$

This is generally larger than the length of the artin ring $\mathrm{H}^0(D \cap D', \mathcal{O})$, and is called the *$k$-length* of $D \cap D'$. If $F = \mathrm{H}^0(D, \mathcal{O}_D)$, then $D \cap D'$ is also an F-scheme, and so it makes sense to define

$$D._F D' = \dim_F \mathrm{H}^0(D \cap D', \mathcal{O}) = D.D'/[F : k].$$

We call this the *F-length* of $D \cap D'$. We can likewise define $D._{F'} D'$ for the field $F' = \mathrm{H}^0(D', \mathcal{O})$. If $D' = D$, we define the relative self-intersection $D._F D$ to be $(D.D)/[F : k]$ where $D.D$ is the usual self-intersection number on the k-fiber.

Theorem 2.1.2. *Let X be a connected regular proper curve over a discrete valuation ring, and let $P \in X$ be a closed point in the closed fiber. Let C_1, C_2 be two (possibly equal) effective divisors supported in the closed fiber of X, with each C_j passing through P, and let C_j' be the strict transform of C_j under the blow-up $\pi : X' = \mathrm{Bl}_P(X) \to X$. We write $E \simeq \mathbf{P}^1_{k(P)}$ to denote the exceptional divsor.*

We have $\pi^{-1}(C_j) = C_j' + m_j E$ where $m_j = \mathrm{mult}_P(C_j)$ is the multiplicity of the curve C_j at P. Also, $m_j = (C_j')._{k(P)}E$ and

$$C_1.C_2 = C_1'.C_2' + m_1 m_2 [k(P) : k].$$

Proof. Recall that for a regular local ring R of dimension 2 and any non-zero non-unit $g \in R$, the 1-dimensional local ring R/g has multiplicity (*i.e.*, leading coefficient of its Hilbert-Samuel polynomial) equal to the unique integer $\mu \geq 1$ such that $g \in \mathfrak{m}_R^{\mu}$, $g \notin \mathfrak{m}_R^{\mu+1}$.

We have $\pi^{-1}(C_j) = C_j' + m_j E$ for some positive integer m_j that we must prove is equal to the multiplicity $\mu_j = \mathrm{mult}_P(C_j)$ of C_j at P. We have $E._{k(P)}E = -1$, so $E.E = -[k(P) : k]$, and we also have $\pi^{-1}(C_j).E = 0$, so $m_j = (C_j'.E)/[k(P) : k] = (C_j')._{k(P)}E$. The strict transform C_j' is the blow-up of C_j at P, equipped with its natural (closed immersion) map into X'. The number m_j is the $k(P)$-length of the scheme-theoretic intersection $C_j' \cap E$; this is the fiber of $\mathrm{Bl}_P(C_j) \to C_j$ over P. Intuitively, this latter fiber is the scheme of tangent directions to C_j at P, but more precisely it is $\mathrm{Proj}(S_j)$, where

$$S_j = \bigoplus_{n \geq 0} \mathfrak{m}_j^n / \mathfrak{m}_j^{n+1},$$

and $\mathfrak{m}_j$ is the maximal ideal of $\mathcal{O}_{C_j,P} = \mathcal{O}_{X,P}/(f_j)$, with f_j a local equation for C_j at P. We have $\mathfrak{m}_j = \mathfrak{m}/(f_j)$ with $\mathfrak{m}$ the maximal ideal of $\mathcal{O}_{X,P}$. Since $f_j \in \mathfrak{m}^{\mu_j}$ and $f_j \notin \mathfrak{m}^{\mu_j+1}$,

$$S_j \simeq \mathrm{Sym}_{k(P)}(\mathfrak{m}/\mathfrak{m}^2)/\overline{f}_j = k(P)[u,v]/(\overline{f}_j)$$

with $\overline{f}_j$ denoting the nonzero image of f_j in degree μ_j. We conclude that $\mathrm{Proj}(S_j)$ has $k(P)$-length μ_j, so $m_j = \mu_j$. Thus, we may compute

$$\begin{aligned} C_1.C_2 = \pi^{-1}(C_1).\pi^{-1}(C_2) &= C_1'.C_2' + 2m_1 m_2 [k(P) : k] + m_1 m_2 E.E \\ &= C_1'.C_2' + m_1 m_2 [k(P) : k]. \end{aligned}$$

□

2.2 Minimal resolutions

It is no doubt well-known to experts that the classical technique of resolution for cyclic quotient singularities on complex surfaces [25, §2.6] can be adapted to the case of tame cyclic quotient singularities on curves over a complete equicharacteristic discrete valuation ring. We want the case of an arbitrary discrete valuation ring, and this seems to be less widely known (it is not addressed in the literature, and was not known to an expert in log-geometry with whom we consulted). Since there seems to be no adequate reference for this more general result, we will give the proof after some preliminary work (*e.g.*, we have to define what we mean by a *tame cyclic quotient singularity*, and we must show that this definition is applicable in many situations. Our first step is to establish the existence and uniqueness of a minimal regular resolution in the case of relative curves over a Dedekind base (the case of interest to us); this will eventually serve to make sense of the *canonical resolution* at a point.

Since we avoid properness assumptions, to avoid any confusion we should explicitly recall a definition.

Definition 2.2.1. Let $X \to S$ be a regular S-curve, with S a connected Dedekind scheme. We say that an integral divisor $D \hookrightarrow X$ in a closed fiber X_s is a -1-*curve* if D is proper over $k(s)$, $\mathrm{H}^1(D, \mathcal{O}_D) = 0$, and $\deg_k \mathcal{O}_D(D) = -1$, where $k = \mathrm{H}^0(D, \mathcal{O}_D)$ is a finite extension of $k(s)$.

By Castelnuovo's theorem, a -1-curve $D \hookrightarrow X$ as in Definition 2.2.1 is k-isomorphic to a projective line over k, where $k = \mathrm{H}^0(D, \mathcal{O}_D)$.

The existence and uniqueness of minimal regular resolutions is given by:

Theorem 2.2.2. *Let $X \to S$ be a normal S-curve over a connected Dedekind scheme S. Assume either that S is excellent or that $X_{/S}$ has smooth generic fiber.*

There exists a birational proper morphism $\pi : X^{\mathrm{reg}} \to X$ such that X^{reg} is a regular S-curve and there are no -1-curves in the fibers of π. Such an X-scheme is unique up to unique isomorphism, and every birational proper morphism $X' \to X$ with a regular S-curve X' admits a unique factorization through π. Formation of X^{reg} is compatible with base change to $\operatorname{Spec} \mathcal{O}_{S,s}$ *and* $\operatorname{Spec} \widehat{\mathcal{O}}_{S,s}$ *for closed points $s \in S$. For local S, there is also compatibility with ind-étale base change $S' \to S$ with local S' whose closed point is residually trivial over that of S.*

We remind that reader that, for technical reasons in the proof of Theorem 2.4.1, we avoid requiring curves to be proper and we do not assume the generic fiber to be geometrically connected. The reader is referred to [41, 9/3.32] for an alternative discussion in the proper case.

Proof. We first assume S to be excellent, and then we shall use Lemma 2.1.1 and some descent considerations to reduce the general case to the excellent case by passage to completions.

As a preliminary step, we wish to reduce to the proper case (to make the proof of uniqueness easier). By Nagata's compactification theorem [43] and the finiteness of normalization for excellent schemes, we can find a schematically dense open immersion $X \hookrightarrow \overline{X}$ with $\overline{X}_{/S}$ normal, proper, and flat over S (hence a normal S-curve). By resolving singularities along $\overline{X} - X$, we may assume the non-regular locus on $\overline{X}$ coincides with that on X. Thus, the existence and uniqueness result for X will follow from that for $\overline{X}$. The assertion on regular resolutions (uniquely) factorizing through π goes the same way. Hence, we now assume (for excellent S) that $X_{/S}$ is proper. We can also assume X to be connected.

By Lemma 2.1.1 and resolution for excellent surfaces, there exists a birational *proper* morphism $X' \to X$ with X' a regular proper S-curve. If there is a -1-curve in the fiber of X' over some (necessarily closed) point of X, then by Castelnuovo we can blow down the -1-curve and $X' \to X$ will factor through the blow-down. This blow-down process cannot continue forever, so we get the existence of $\pi : X^{\text{reg}} \to X$ with no -1-curves in its fibers.

Recall the Factorization Theorem for birational *proper* morphisms between regular connected S-curves: such maps factor as a composite of blow-ups at closed points in closed fibers. Using the Factorization Theorem, to prove uniqueness of π and the (unique) factorization through π for any regular resolution of X we just have to show that if $X'' \to X' \to X$ is a tower of birational proper morphisms with regular S-curves X' and X'' such that X' has no -1-curves in its fibers over X, then any -1-curve C in a fiber of $X'' \to X$ is necessarily contracted by $X'' \to X'$. Also, via Stein factorization we can assume that the proper normal connected S-curves X, X', and X'' with common generic fiber over S have geometrically connected fibers over S. We may assume that S is local. Since the map $q : X'' \to X'$ is a composite of blow-ups, we may assume that C meets the exceptional fiber E of the first blow-down $q_1 : X'' \to X''_1$ of a factorization of q. If $C = E$ we are done, so we may assume $C \neq E$. In this case we will show that X is regular, so again uniqueness holds (by the Factorization Theorem mentioned above).

The image $q_1(C)$ is an irreducible divisor on X''_1 with strict transform C, so by Theorem 2.1.2 we conclude that $q_1(C)$ has non-negative self-intersection number, so this self-intersection must be zero. Since $X''_1 \to S$ is its own Stein factorization, and hence has geometrically connected closed fiber, $q_1(C)$ must be the entire closed fiber of X''_1. Thus, X''_1 has irreducible closed fiber, and so the (surjective) proper birational map $X''_1 \to X$ is quasi-finite and hence finite. Since X and X''_1 are normal and connected (hence integral), it follows that $X''_1 \to X$ must be an isomorphism. Thus, X is regular, as desired.

With X^{reg} unique up to (obviously) unique isomorphism, for the base change compatibility we note that the various base changes $S' \to S$ being considered (to completions on S, or to local S' ind-étale surjective over local S and residually trivial at closed points), the base change $X^{\text{reg}}_{/S'}$ is regular and proper birational over the normal curve $X_{/S'}$ (see Lemma 2.1.1). Thus, we just have to check that the fibers of $X^{\text{reg}}_{/S'} \to X_{/S'}$ do not contain -1-curves. The closed-fiber situation is identical to that before base change, due to the residually trivial condition at closed points, so we are done.

Now suppose we do not assume S to be excellent, but instead assume $X_{/S}$ has smooth generic fiber. In this case all but finitely many fibers of $X_{/S}$ are smooth. Thus, we may reduce to the local case $S = \mathrm{Spec}(R)$ with a discrete valuation ring R. Consider $X_{/\widehat{R}}$, a normal $\widehat{R}$-curve by Lemma 2.1.1. Since $\widehat{R}$ is excellent, there is a minimal regular resolution

$$\pi : (X_{/\widehat{R}})^{\mathrm{reg}} \to X_{/\widehat{R}}.$$

By [40, Remark C, p. 155], the map π is a blow-up along a 0-dimensional closed subscheme $\widehat{Z}$ physically supported in the non-regular locus of $X_{/\widehat{R}}$. This $\widehat{Z}$ is therefore physically supported in the closed fiber of $X_{/\widehat{R}}$, yet $\widehat{Z}$ is artinian and hence lies in some infinitesimal closed fiber of $X_{/\widehat{R}}$. Since $X \times_R \widehat{R} \to X$ induces isomorphisms on the level of nth infinitesimal closed-fibers for all n, there is a unique 0-dimensional closed subscheme Z in X with $Z_{/\widehat{R}} = \widehat{Z}$ inside of $X_{/\widehat{R}}$.

Since the blow-up $\mathrm{Bl}_Z(X)$ satisfies

$$\mathrm{Bl}_Z(X)_{/\widehat{R}} \simeq \mathrm{Bl}_{\widehat{Z}}(X_{/\widehat{R}}) = (X_{/\widehat{R}})^{\mathrm{reg}},$$

by Lemma 2.1.1 we see that $\mathrm{Bl}_Z(X)$ is a regular S-curve. There are no -1-curves in its fibers over X since $\mathrm{Spec}\,\widehat{R} \to \mathrm{Spec}\,R$ is an isomorphism over $\mathrm{Spec}\,R/\mathfrak{m}$. This establishes the existence of $\pi : X^{\mathrm{reg}} \to X$, as well as its compatibility with base change to completions on S. To establish uniqueness of π, or more generally its universal factorization property, we must prove that certain birational maps from regular S-curves to X^{reg} are morphisms. This is handled by a standard graph argument that can be checked after faithfully flat base change to $\widehat{R}$ (such base change preserves regularity, by Lemma 2.1.1). Thus, the uniqueness results over the excellent base $\widehat{R}$ carry over to our original R. The same technique of base change to $\widehat{R}$ shows compatibility with ind-étale base change that is residually trivial over closed points.

□

One mild enhancement of the preceding theorem rests on a pointwise definition:

Definition 2.2.3. Let $X_{/S}$ be as in Theorem 2.2.2, and let $\Sigma \subseteq X$ be a finite set of closed points in closed fibers over S. Let U be an open in X containing Σ such that U does not contain the finitely many non-regular points of X outside of Σ. We define the *minimal regular resolution along* Σ to be the morphism $\pi_\Sigma : X_\Sigma \to X$ obtained by gluing $X - \Sigma$ with the part of X^{reg} lying over U (note: the choice of U does not matter, and X_Σ is not regular if there are non-regular points of X outside of Σ).

It is clear that the minimal regular resolution along Σ is compatible with local residually-trivial ind-étale base change on a local S, as well as with base change to a (non-generic) complete local ring on S. It is also uniquely characterized among normal S-curves C equipped with a proper birational morphism $\varphi : C \to X$ via the following conditions:

- π_Σ is an isomorphism over $X - \Sigma$,
- X_Σ is regular at points over Σ,
- X_Σ has no -1-curves in its fibers over Σ.

This yields the crucial consequence that (under some mild restrictions on residue field extensions) formation of X_Σ is étale-local on X. This fact is ultimately the reason we did not require properness or geometrically connected fibers in our definition of S-*curve*:

Corollary 2.2.4. *Let $X_{/S}$ be a normal S-curve over a connected Dedekind scheme S, and let $\Sigma \subseteq X$ be a finite set of closed points in closed fibers over S. Let $X' \to X$ be étale (so X' is an S-curve), and let Σ' denote the preimage of Σ. Assume that S is excellent or $X_{/S}$ has smooth generic fiber.*

If $X_\Sigma \to X$ denotes the minimal regular resolution along Σ, and $X' \to X$ is residually trivial over Σ, then the base change $X_\Sigma \times_X X' \to X'$ is the minimal regular resolution along Σ'.

Remark 2.2.5. The residual triviality condition over Σ is satisfied when S is local with separably closed residue field, as then all points of Σ have separably closed residue field (and so the étale $X' \to X$ must induce trivial residue field extensions over such points).

Proof. Since $X_\Sigma \times_X X'$ is étale over X_Σ, we conclude that $X_\Sigma \times_X X'$ is an S-curve that is regular along the locus over $\Sigma' \subseteq X'$, and its projection to X' is proper, birational, and an isomorphism over $X' - \Sigma'$. It remains to check that

$$X_\Sigma \times_X X' \to X' \tag{2.2.1}$$

has no -1-curves in the proper fibers over Σ'. Since $X' \to X$ is residually trivial over Σ (by hypothesis), so this is clear.

□

2.3 Nil-semistable curves

In order to compute minimal regular resolutions of the sort that arise on $X_H(p)$'s, it is convenient to study the following concept before we discuss resolution of singularities. Let S be a connected Dedekind scheme and let X be an S-curve.

Definition 2.3.1. For a closed point $s \in S$, a closed point $x \in X_s$ is *nil-semistable* if the reduced fiber-curve $X_s^{\rm red}$ is semistable over $k(s)$ at x and all of the analytic branch multiplicities through x are not divisible by $\mathrm{char}(k(s))$. If $X_s^{\rm red}$ is semistable for all closed points $s \in S$ and all irreducible components of X_s have multiplicity not divisible by $\mathrm{char}(k(s))$, X is a *nil-semistable curve* over S.

Considerations with excellence of the fiber X_s show that the number of analytic branches in Definition 2.3.1 may be computed on the formal completion at a point over x in $X_{s/k'}$ for any separably closed extension k' of $k(s)$. We will use the phrase "analytic branch" to refer to such (formal) branches through a point over x in such a geometric fiber over s.

As is well-known from [34], many fine moduli schemes for elliptic curves are nil-semistable.

Fix a closed point $s \in S$. From the theory of semistable curves over fields [24, III, §2], it follows that when $x \in X_s^{\mathrm{red}}$ is a semistable non-smooth point then the finite extension $k(x)/k(s)$ is separable. We have the following analogue of the classification of semistable curve singularities:

Lemma 2.3.2. *Let $x \in X_s$ be a closed point and let $\pi_s \in \mathcal{O}_{S,s}$ be a uniformizer.*

If x is a nil-semistable point at which X is regular, then the underlying reduced scheme of the geometric closed fiber over s has either one or two analytic branches at a geometric point over x, with these branches smooth at x. When moreover $k(x)/k(s)$ is separable and there is exactly one analytic branch at $x \in X_s$, with multiplicity m_1 in $\mathcal{O}^{\mathrm{sh}}_{X_s,x}$, then

$$\widehat{\mathcal{O}^{\mathrm{sh}}_{X,x}} \simeq \widehat{\mathcal{O}^{\mathrm{sh}}_{S,s}}[\![t_1,t_2]\!]/(t_1^{m_1}-\pi_s). \tag{2.3.1}$$

If there are two analytic branches (so $k(x)/k(s)$ is automatically separable), say with multiplicities m_1 and m_2 in $\mathcal{O}^{\mathrm{sh}}_{X_s,x}$, then

$$\widehat{\mathcal{O}^{\mathrm{sh}}_{X,x}} \simeq \widehat{\mathcal{O}^{\mathrm{sh}}_{S,s}}[\![t_1,t_2]\!]/(t_1^{m_1}t_2^{m_2}-\pi_s). \tag{2.3.2}$$

Conversely, if $\widehat{\mathcal{O}^{\mathrm{sh}}_{X,x}}$ admits one of these two explicit descriptions with the exponents not divisible by $\mathrm{char}(k(s))$, then x is a nil-semistable regular point on X with $k(x)/k(s)$ separable.

In view of this lemma, we call the exponents in the formal isomorphisms (2.3.1) and (2.3.2) the *analytic geometric multiplicities* of X_s at x (this requires $k(x)/k(s)$ to be separable). We emphasize that these exponents can be computed after base change to any separably closed extension of $k(s)$ when x is nil-semistable with $k(x)/k(s)$ separable.

Proof. First assume $x \in X_s^{\mathrm{red}}$ is a non-smooth semistable point and X is regular at x. Since $k(x)$ is therefore finite separable over $k(s)$, we can make a base change to the completion of a strict henselization of $\mathcal{O}_{S,s}$ to reduce to the case $S = \mathrm{Spec}(W)$ with a complete discrete valuation ring W having separably closed residue field k such that x a k-rational point. Since $\widehat{\mathcal{O}}_{X,x}$ is a 2-dimensional complete regular local W-algebra with residue field k, it is a quotient of $W[\![t_1,t_2]\!]$ and hence has the form $W[\![t_1,t_2]\!]/(f)$ where f is a regular parameter. The semistability condition and non-smoothness of $X^{\mathrm{red}}_{/k}$ at x imply

$$k[\![t_1,t_2]\!]/\mathrm{rad}(\overline{f}) = (k[\![t_1,t_2]\!]/(\overline{f}))_{\mathrm{red}} \simeq \widehat{\mathcal{O}}_{X^{\mathrm{red}}_{/k},x} \simeq k[\![u_1,u_2]\!]/(u_1u_2)$$

where $\overline{f} = f \bmod \mathfrak{m}_W$, so $\overline{f}$ has exactly two distinct irreducible factors and these have distinct (non-zero) tangent directions in $X^{\rm red}_{/k}$ through x. We can choose t_1 and t_2 to lift these tangent directions, so upon replacing f with a unit multiple we may assume $\overline{f} = t_1^{m_1} t_2^{m_2} \bmod \mathfrak{m}_W$ for some $m_1, m_2 \geq 1$ not divisible by $p = \mathrm{char}(k) \geq 0$. Let π be a uniformizer of W, so $f = t_1^{m_1} t_2^{m_2} - \pi g$ for some g, and g must be a unit since f is a regular parameter. Since some m_j is not divisible by p, and hence the unit g admits an m_jth root, by unit-rescaling of the corresponding t_j we get to the case $g = 1$.

In the case when $X^{\rm red}_s$ is smooth at x and $k(x)/k(s)$ is separable, we may again reduce to the case in which $S = \mathrm{Spec}\, W$ with complete discrete valuation ring W having separably closed residue field k and $k(x) = k$. In this case, there is just one analytic branch and we see by a variant of the preceding argument that the completion of $\mathcal{O}^{\rm sh}_{X,x}$ has the desired form.

The converse part of the lemma is clear.

□

In Definition 2.3.6, we shall give a local definition of the class of curve-singularities that we wish to resolve, but we will first work through some global considerations that motivate the relevance of the local Definition 2.3.6.

Assume X is *regular*, and let H be a finite group and assume we are given an action of H on $X_{/S}$ that is free on the scheme of generic points (*i.e.*, no non-identity element of H acts trivially on a connected component of X). A good example to keep in mind is the (affine) fine moduli scheme over $S = \mathrm{Spec}(\mathbf{Z}_{(p)})$ of $\Gamma_1(p)$-structures on elliptic curves equipped with auxiliary full level ℓ-structure for an odd prime $\ell \neq p$, and $H = \mathrm{GL}_2(\mathbf{F}_\ell)$ acting in the usual manner (see Section 3 for a review of these basic level structures).

We wish to work with a quotient S-curve $X' = X/H$, so we now also assume that X is quasi-projective Zariski-locally on S. Clearly $X \to X'$ is a finite H-equivariant map with the expected universal property; in the above modular-curve example, this quotient X' is the coarse moduli scheme $Y_1(p)$ over $\mathbf{Z}_{(p)}$. We also now assume that S is excellent or $X_{/K}$ is smooth, so that there are only finitely many non-regular points (all in codimension 2) and various results centering on resolution of singularities may be applied.

The S-curve X' has regular generic fiber (and even smooth generic fiber when $X_{/S}$ has smooth generic fiber), and X' is regular away from finitely many closed points in the closed fibers. Our aim is to understand the *minimal regular resolution* ${X'}^{\rm reg}$ of X', or rather to describe the geometry of the fibers of ${X'}^{\rm reg} \to X'$ over non-regular points x' satisfying a mild hypothesis on the structure of $X \to X'$ over x'.

We want to compute the minimal regular resolution for $X' = X/H$ at non-regular points x' that satisfy several conditions. Let $s \in S$ be the image of x', and let $p \geq 0$ denote the common characteristic of $k(x')$ and $k(s)$. Pick $x \in X$ over x'.

- We assume that X is nil-semistable at x (by the above hypotheses, X is also regular at x).

- We assume that the inertia group $H_{x|x'}$ in H at x (*i.e.*, the stablizer in H of a geometric point over x) has order not divisible by p (so this group acts semi-simply on the tangent space at a geometric point over x).

- When there are two analytic branches through x, we assume $H_{x|x'}$ does not interchange them.

These conditions are independent of the choice of x over x' and can be checked at a geometric point over x, and when they hold then the number of analytic branches through x coincides with the number of analytic branches through x' (again, we are really speaking about analytic branches on a geometric fiber over s).

Since p does not divide $|H_{x|x'}|$, it follows that $k(x')$ is the subring of invariants under the action of $H_{x|x'}$ on $k(x)$, so a classical theorem of Artin ensures that $k(x)/k(x')$ is separable (and even Galois). Thus, $k(x)/k(s)$ is separable if and only if $k(x')/k(s)$ is separable, and such separability holds when the point $x \in X_s^{\rm red}$ is semistable but not smooth. Happily for us, this separability condition over $k(s)$ is always satisfied (we are grateful to Lorenzini for pointing this out):

Lemma 2.3.3. *With notation and hypotheses as above, particularly with $x' \in X' = X/H$ a non-regular point, the extension $k(x')/k(s)$ is separable.*

Proof. Recall that, by hypothesis, $x \in X_s^{\rm red}$ is either a smooth point or an ordinary double point. If x is a non-smooth point on the curve $X_s^{\rm red}$, then the desired separability follows from the theory of ordinary double point singularities. Thus, we may (and do) assume that x is a smooth point on $X_s^{\rm red}$.

We may also assume S is local and strictly henselian, so $k(s)$ is separably closed and hence $k(x)$ and $k(x')$ are separably closed. Thus, $k(x) = k(x')$ and $H_{x|x'}$ is the physical stabilizer of the point $x \in X$. We need to show that the common residue field $k(x) = k(x')$ is separable over $k(s)$. If we let $X'' = X/H_{x|x'}$, then the image x'' of x in X'' has complete local ring isomorphic to that of $x' \in X'$, so we may replace X' with X'' to reduce to the case when H has order not divisible by p and x is in the fixed-point locus of H. By [20, Prop. 3.4], the fixed-point locus of H in X admits a closed-subscheme structure in X that is smooth over S. On the closed fiber this smooth scheme is finite and hence étale over $k(s)$, so its residue fields are separable over $k(s)$.

□

The following refinement of Lemma 2.3.2 is adapted to the $H_{x|x'}$-action, and simultaneously handles the cases of one and two (geometric) analytic branches through x'.

Lemma 2.3.4. *With hypotheses as above, there is an $\widehat{\mathcal{O}_{S,s}^{\rm sh}}$-isomorphism*

$$\widehat{\mathcal{O}_{X,x}^{\rm sh}} \simeq \widehat{\mathcal{O}_{S,s}^{\rm sh}}[\![t_1, t_2]\!]/(t_1^{m_1} t_2^{m_2} - \pi_s)$$

(with $m_1 > 0$, $m_2 \geq 0$) such that the $H_{x|x'}$-action looks like $h(t_j) = \chi_j(h)t_j$ for characters $\chi_1, \chi_2 : H_{x|x'} \to \widehat{\mathcal{O}^{\mathrm{sh}}_{S,s}}^{\times}$ that are the Teichmüller lifts of characters giving a decomposition of the semisimple $H_{x|x'}$-action on the 2-dimensional cotangent space at a geometric point over x. Moreover, $\chi_1^{m_1}\chi_2^{m_2} = 1$.

The characters χ_j also describe the action of $H_{x|x'}$ on the tangent space at (a geometric point over) x. There are two closed-fiber analytic branches through x when m_1 and m_2 are positive, and then the branch with formal parameter t_2 has multiplicity m_1 since

$$(k[\![t_1, t_2]\!]/(t_1^{m_1}t_2^{m_2}))[1/t_2] = k(\!(t_2)\!)[t_1]/(t_1^{m_1})$$

has length m_1. Likewise, when $m_2 > 0$ it is the branch with formal parameter t_1 that has multiplicity m_2.

Proof. We may assume $S = \operatorname{Spec} W$ with W a complete discrete valuation ring having separably closed residue field k and uniformizer π, so x is k-rational. Let $R = \widehat{\mathcal{O}^{\mathrm{sh}}_{X,x}} = \widehat{\mathcal{O}}_{X,x}$. We have seen in Lemma 2.3.2 that there is an isomorphism of the desired type as W-algebras, but we need to find better such t_j's to linearize the $H_{x|x'}$-action.

We first handle the easier case $m_2 = 0$. In this case there is only one minimal prime (t_1) over (π), so $h(t_1) = u_h t_1$ for a unique unit $u_h \in R^{\times}$. Since $t_1^{m_1} = \pi$ is $H_{x|x'}$ invariant, we see that $u_h \in \mu_{m_1}(R)$ is a Teichmüller lift from k (since $p \nmid m_1$). Thus, $h(t_1) = \chi_1(h)t_1$ for a character $\chi_1 : H_{x|x'} \to R^{\times}$ that is a lift of a character for $H_{x|x'}$ on $\mathrm{Cot}_x(X)$. Since $H_{x|x'}$ acts semisimply on the 2-dimensional cotangent space $\mathrm{Cot}_x(X)$ and there is a stable line spanned by $t_1 \bmod \mathfrak{m}_x^2$, we can choose t_2 to lift an $H_{x|x'}$-stable line complementary to the one spanned by $t_1 \bmod \mathfrak{m}_x^2$. If χ_2 denotes the Teichmüller lift of the character for $H_{x|x'}$ on this complementary line, then

$$h(t_2) = \chi_2(h)(t_2 + \delta_h)$$

with $\delta_h \in \mathfrak{m}_x^i$ for some $i \geq 2$. It is straightfoward to compute that

$$h \mapsto \delta_h \bmod \mathfrak{m}_x^{i+1}$$

is a 1-cocycle with values in the twisted $H_{x|x'}$-module $\chi_2^{-1} \otimes (\mathfrak{m}_x^i/\mathfrak{m}_x^{i+1})$. Changing this 1-cocycle by a 1-coboundary corresponds to adding an element of $\mathfrak{m}_x^i/\mathfrak{m}_x^{i+1}$ to $t_2 \bmod \mathfrak{m}_x^{i+1}$. Since

$$\mathrm{H}^1(H_{x|x'}, \chi_2^{-1} \otimes (\mathfrak{m}_x^i/\mathfrak{m}_x^{i+1})) = 0,$$

we can successively increase $i \geq 2$ and pass to the limit to find a choice of t_2 such that $H_{x|x'}$ acts on t_2 through the character χ_2. That is, $h(t_1) = \chi_1(h)t_1$ and $h(t_2) = \chi_2(h)t_2$ for all $h \in H_{x|x'}$. This settles the case $m_2 = 0$.

Now we turn to the more interesting case when also $m_2 > 0$, so there are two analytic branches through x. By hypothesis, the $H_{x|x'}$-action preserves the two minimal primes (t_1) and (t_2) over (π) in R. We must have $h(t_1) = u_h t_1$, $h(t_2) = v_h t_2$ for unique units $u_h, v_h \in R^\times$. Since $t_1^{m_1} t_2^{m_2} = \pi$, by applying h we get $u_h^{m_1} v_h^{m_2} = 1$.

Consider what happens if we replace t_2 with a unit multiple $t_2' = vt_2$, and then replace t_1 with the unit multiple $t_1' = v^{-m_2/m_1} t_1$ so as to ensure $t_1'^{m_1} t_2'^{m_2} = \pi$. Note that an m_1th root v^{-m_2/m_1} of the unit v^{-m_2} makes sense since k is separably closed and $p \nmid m_1$. The resulting map $W[\![t_1', t_2']\!]/(t_1'^{m_1} t_2'^{m_2} - \pi) \to R$ is visibly surjective, and hence is an isomorphism for dimension reasons. Switching to these new coordinates on R has the effect of changing the 1-cocycle $\{v_h\}$ by a 1-coboundary, and *every* 1-cocycle cohomologous to $\{v_h\}$ is reached by making such a unit multiple change on t_2.

By separately treating residue characteristic 0 and positive residue characteristic, an inverse limit argument shows that $\mathrm{H}^1(H_{x|x'}, U)$ vanishes, where $U = \ker(R^\times \twoheadrightarrow k^\times)$. Thus, the natural map $\mathrm{H}^1(H_{x|x'}, R^\times) \to \mathrm{H}^1(H_{x|x'}, k^\times)$ is injective. The $H_{x|x'}$-action on $k^\times$ is trivial since $H_{x|x'}$ acts trivially on W, so

$$\mathrm{H}^1(H_{x|x'}, k^\times) = \mathrm{Hom}(H_{x|x'}, k^\times) = \mathrm{Hom}(H_{x|x'}, k^\times_{\mathrm{tors}}),$$

with all elements in the torsion subgroup $k^\times_{\mathrm{tors}}$ of order not divisible by p and hence uniquely multiplicatively lifting into R. Thus,

$$\mathrm{H}^1(H_{x|x'}, R^\times) \to \mathrm{H}^1(H_{x|x'}, k^\times)$$

is bijective, and so replacing t_1 and t_2 with suitable unit multiples allows us to assume $h(t_2) = \chi_2(h) t_2$, with $\chi_2 : H_{x|x'} \to W^\times_{\mathrm{tors}}$ some homomorphism of order not divisible by p (since $H_{x|x'}$ acts trivially on $k^\times$ and $p \nmid |H_{x|x'}|$).

Since

$$1 = u_h^{m_1} v_h^{m_2} = u_h^{m_1} \chi_2(h)^{m_2}$$

and $p \nmid m_1$, we see that u_h is a root of unity of order not divisible by p. Viewing $k^\times_{\mathrm{tors}} \subseteq R^\times$ via the Teichmüller lifting, we conclude that $u_h \in k^\times_{\mathrm{tors}} \subseteq R^\times$. Thus, we can write $h(t_1) = \chi_1(h) t_1$ for a homomorphism $\chi_1 : H_{x|x'} \to W^\times_{\mathrm{tors}}$ also necessarily of order not divisible by p. The preceding calculation also shows that $\chi_1^{m_1} \chi_2^{m_2} = 1$ since $u_h^{m_1} v_h^{m_2} = 1$.

□

Although Lemma 2.3.4 provides good (geometric) coordinate systems for describing the inertia action, one additional way to simplify matters is to reduce to the case in which the tangent-space characters χ_1 and χ_2 are powers of each other. We wish to explain how this special situation is essentially the general case (in the presence of our running assumption that H acts freely on the scheme of generic points of X).

First, observe that $H_{x|x'}$ acts faithfully on the tangent space $T_x(X)$ at x. Indeed, if an element in $H_{x|x'}$ acts trivially on the tangent space $T_x(X)$, then by Lemma 2.3.4 it acts trivially on the completion of $\mathcal{O}^{\mathrm{sh}}_{X,x}$ and hence acts trivially on the corresponding connected component of the normal X. By hypothesis, H acts freely on the scheme of generic points of X, so we conclude that the product homomorphism

$$\chi_1 \times \chi_2 : H_{x|x'} \hookrightarrow k(x)_{\mathrm{sep}}^{\times} \times k(x)_{\mathrm{sep}}^{\times}, \tag{2.3.3}$$

is *injective* (where $k(x)_{\mathrm{sep}}$ is the separable closure of $k(x)$ used when constructing $\mathscr{O}_{X,x}^{\mathrm{sh}}$). In particular, $H_{x|x'}$ is a product of two cyclic groups (one of which might be trivial).

Lemma 2.3.5. *Let $\kappa_j = |\ker(\chi_j)|$. The characters $\chi_1^{\kappa_2}$ and $\chi_2^{\kappa_1}$ factor through a common quotient of $H_{x|x'}$ as faithful characters. When $H_{x|x'}$ is cyclic, this quotient is $H_{x|x'}$.*

In addition, $\kappa_2 | m_1$ and $\kappa_1 | m_2$.

The cyclicity condition on $H_{x|x'}$ will hold in our application to modular curves, as then even H is cyclic.

Proof. The injectivity of (2.3.3) implies that χ_1 is faithful on $\ker(\chi_2)$ and χ_2 is faithful on $\ker(\chi_1)$. Since $\chi_1^{m_1}\chi_2^{m_2} = 1$, we get $\kappa_2 | m_1$ and $\kappa_1 | m_2$ (even if $m_2 = 0$).

For the proof that the indicated powers of the χ_j's factor as faithful characters of a common quotient of $H_{x|x'}$, it is enough to focus attention on ℓ-primary parts for a prime ℓ dividing $|H_{x|x'}|$ (so $\ell \neq p$). More specifically, if G is an finite ℓ-group that is either cyclic or a product of two cyclic groups, and $\psi_0, \psi_1 : G \to \mathbf{Z}/\ell^n\mathbf{Z}$ are homomorphisms such that $\psi_0 \times \psi_1$ is injective (*i.e.*, $\ker(\psi_0) \cap \ker(\psi_1) = \{1\}$), then we claim that the $\psi_j^{\kappa_{1-j}}$'s factor as faithful characters on a common quotient of G, where $\kappa_j = |\ker(\psi_j)|$. If one of the ψ_j's is faithful (or equivalently, if the ℓ-group G is cyclic), this is clear. This settles the case in which G is cyclic, so we may assume G is a product of two non-trivial cyclic ℓ-groups and that both ψ_j's have non-trivial kernel. Since the ℓ-torsion subgroups $\ker(\psi_j)[\ell]$ must be non-trivial with trivial intersection, these must be distinct lines spanning $G[\ell]$. Passing to group $G/G[\ell]$ and the characters ψ_j^{ℓ} therefore permits us to induct on $|G|$.

□

By the lemma, we conclude that the characters $\chi_1' = \chi_1^{\kappa_2}$ and $\chi_2' = \chi_1^{\kappa_1}$ both factor faithfully through a common (cyclic) quotient $H_{x|x'}'$ of $H_{x|x'}$. Define $t_1' = t_1^{\kappa_2}$ and $t_2' = t_2^{\kappa_1}$. Since formation of $H_{x|x'}$-invariants commutes with passage to quotients on $\widehat{\mathscr{O}_{S,s}^{\mathrm{sh}}}$-modules, Lemma 2.3.4 shows that in order to compute the $H_{x|x'}$-invariants of $\widehat{\mathscr{O}}_{X',x'}^{\mathrm{sh}}$ it suffices to compute invariants on the level of $\widehat{\mathscr{O}_{S,s}^{\mathrm{sh}}}[\![t_1, t_2]\!]$ and then pass to a quotient. The subalgebra of invariants in $\widehat{\mathscr{O}_{S,s}^{\mathrm{sh}}}[\![t_1, t_2]\!]$ under the subgroup generated by $\ker(\chi_1)$ and $\ker(\chi_2)$ is $\widehat{\mathscr{O}_{S,s}^{\mathrm{sh}}}[\![t_1', t_2']\!]$, and $H_{x|x'}$ acts on this subalgebra through the quotient $H_{x|x'}'$ via the characters χ_1' and χ_2'. Letting $m_1' = m_1/\kappa_2$ and $m_2' = m_2/\kappa_1$ (so $m_2' = 0$ in the case of one analytic branch), we obtain the description

$$\widehat{\mathcal{O}^{\rm sh}_{X',x'}} = (\widehat{\mathcal{O}^{\rm sh}_{S,s}}[\![t'_1, t'_2]\!]/({t'_1}^{m'_1}{t'_2}^{m'_2} - \pi_s))^{H'_{x|x'}} \tag{2.3.4}$$

Obviously $\chi'_2 = {\chi'_1}^{r_{x|x'}}$ for a unique $r_{x|x'} \in (\mathbf{Z}/|H'_{x|x'}|\mathbf{Z})^\times$, as the characters χ'_j are both faithful on $H'_{x|x'}$.

Since $|H'_{x|x'}|$ and $r_{x|x'} \in (\mathbf{Z}/|H'_{x|x'}|\mathbf{Z})^\times$ are intrinsic to $x' \in X' = X/H$ and do not depend on x (or on a choice of $k(x)_{\rm sep}$), we may denote these two integers $n_{x'}$ and $r_{x'}$ respectively. We have $m'_1 + m'_2 r'_{x'} \equiv 0 \bmod n_{x'}$ since $1 = {\chi'_1}^{m'_1}{\chi'_2}^{m'_2} = {\chi'_1}^{m'_1+m'_2 r_{x'}}$ with χ'_1 faithful. Theorem 2.3.9 below shows that $n_{x'} > 1$, since x' is the non-regular.

If S were a smooth curve over $\mathbf{C}$, then the setup in (2.3.4) would be the classical cyclic surface quotient-singularity situation whose minimal regular resolution is most readily computed via toric varieties. That case motivates what to expect for minimal regular resolutions with more general S in §2.4, but rather than delve into a relative theory of toric varieties we can just use the classical case as a guide.

To define the class of singularities we shall resolve, let $X'_{/S}$ now be a *normal* (not necessarily connected) curve over a connected Dedekind scheme S. Assume moreover that either S is excellent or that $X'_{/S}$ has smooth generic fiber, so there are only finitely many non-regular points (all closed in closed fibers). Consider a closed point $s \in S$ with residue characteristic $p \geq 0$, and pick a closed point $x' \in X'_s$ such that X'_s has one or two (geometric) analytic branches at x'.

Definition 2.3.6. We say that a closed point x' in a closed fiber X'_s is a *tame cyclic quotient singularity* if there exists a positive integer $n > 1$ not divisible by $p = \operatorname{char}(k(s))$, a unit $r \in (\mathbf{Z}/n\mathbf{Z})^\times$, and integers $m'_1 > 0$ and $m'_2 \geq 0$ satisfying $m'_1 \equiv -rm'_2 \bmod n$ such that $\widehat{\mathcal{O}^{\rm sh}_{X',x'}}$ is isomorphic to the subalgebra of $\mu_n(k(s)_{\rm sep})$-invariants in $\widehat{\mathcal{O}^{\rm sh}_{S,s}}[\![t'_1, t'_2]\!]/({t'_1}^{m'_1}{t'_2}^{m'_2} - \pi_s)$ under the action $t'_1 \mapsto \zeta t'_1$, $t'_2 \mapsto \zeta^r t'_2$.

Remark 2.3.7. Note that when $X'_{/S}$ has a tame cyclic quotient singularity at $x' \in X'_s$, then $k(x')/k(s)$ is separable and x' is non-regular (by Theorem 2.3.9 below). Also, it is easy to check that the exponents m'_1 and m'_2 are necessarily the analytic branch multiplicities at x'. Note that the data of n and r is merely part of a presentation of $\widehat{\mathcal{O}}_{X',x'}$ as a ring of invariants, so it is not clear *a priori* that n and r are intrinsic to $x' \in X'$. The fact that n and r are uniquely determined by x' follows from Theorem 2.4.1 below, where we show that n and r arise from the structure of the minimal regular resolution of X' at x'.

Using notation as in the preceding global considerations, there is a very simple criterion for a nil-semistable $x' \in X/H$ to be a non-regular point: there should not be a line in $T_x(X)$ on which the inertia group $H_{x|x'}$ acts trivially. To prove this, we recall Serre's pseudo-reflection theorem [57, Thm. 1′]. This requires a definition:

Definition 2.3.8. Let V be a finite-dimensional vector space over a field k. An element σ of $\mathrm{Aut}_k(V)$ is called a *pseudo-reflection* if $\mathrm{rank}(1-\sigma) \leq 1$.

Theorem 2.3.9 (Serre). *Let A be a noetherian regular local ring with maximal ideal $\mathfrak{m}$ and residue field k. Let G be a finite subgroup of $\mathrm{Aut}(A)$, and let A^G denote the local ring of G-invariants of A. Suppose that:*

1. *The characteristic of k does not divide the order of G,*
2. *G acts trivially on k, and*
3. *A is a finitely generated A^G-module.*

Then A^G is regular if and only if the image of G in $\mathrm{Aut}_k(\mathfrak{m}/\mathfrak{m}^2)$ is generated by pseudo-reflections.

In fact, the "only if" implication is true without hypotheses on the order of G, provided A^G has residue field k (which is automatic when k is algebraically closed).

Remark 2.3.10. By Theorem 3.7(i) of [44] with $B = A$ and $A = A^G$, hypothesis 3 of Serre's theorem forces A^G to be noetherian. Serre's theorem ensures that x' as in Definition 2.3.6 is necessarily non-regular.

Proof. Since this result is not included in Serre's Collected Works, we note that a proof of the "if and only if" assertion can be found in [68, Cor. 2.13, Prop. 2.15]. The proof of the "only if" implication in [68] works without any conditions on the order of G as long as one knows that A^G has the same residue field as A. Such equality is automatic when k is algebraically closed. Indeed, the case of characteristic 0 is clear, and for positive characteristic we note that k is a priori finite over the residue field of A^G, so if equality were to fail then the residue field of A^G would be of positive characteristic with algebraic closure a finite extension of degree > 1, an impossibility by Artin-Schreier.

To see why everything still works without restriction on the order of G when we assume A^G is regular, note first that regularity of A^G ensures that $A^G \to A$ must be finite free, so even without a Reynolds operator we still have $(A \otimes_{A^G} A)^G = A$, where G acts on the left tensor factor. Hence, the proof of [68, Lemma 2.5] still works. Meanwhile, equality of residue fields for A^G and A makes the proof of [68, Prop. 2.6] still work, and then one easily checks that the proofs of [68, Thm. 2.8, Prop. 2.15(i)⇒(ii)] go through unchanged. □

The point of the preceding study is that in a *global* quotient situation $X' = X/H$ as considered above, one always has a tame cyclic quotient singularity at the image x' of a nil-semistable point $x \in X_s$ when x' is not regular (by Lemma 2.3.3, both $k(x)$ and $k(x')$ are automatically separable over $k(s)$ when such non-regularity holds). Thus, when computing complete local rings at geometric closed points on a coarse modular curve (in residue characteristic

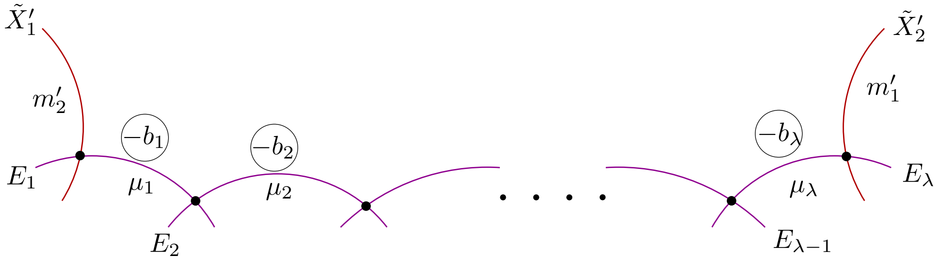

Figure 1: Minimal regular resolution of x'

> 3), we will naturally encounter a situation such as in Definition 2.3.6. The ability to explicitly (minimally) resolve tame cyclic quotient singularities in general will therefore have immediate applications to modular curves.

2.4 Jung–Hirzebruch resolution

As we noted in Remark 2.3.7, it is natural to ask whether the numerical data of n and $r \in (\mathbf{Z}/n\mathbf{Z})^\times$ in Definition 2.3.6 are intrinsic to $x' \in X'$. We shall see in the next theorem that this data is intrinsic, as it can be read off from the minimal regular resolution over x'.

Theorem 2.4.1. *Let $X'_{/S}$ be a normal curve over a local Dedekind base S with closed point s. Assume either that S is excellent or that $X'_{/S}$ has smooth generic fiber. Assume X' has a tame cyclic quotient singularity at a closed point $x' \in X'_s$ with parameters n and r (in the sense of Definition* 2.3.6*), where we represent $r \in (\mathbf{Z}/n\mathbf{Z})^\times$ by the unique integer r satisfying $1 \leq r < n$ and* $\gcd(r,n) = 1$. *Finally, assume either that $k(s)$ is separably closed or that all connected components of the regular compactification $\overline{X}'_K$ of the regular generic-fiber curve X'_K have positive arithmetic genus.*

Consider the Jung–Hirzebruch continued fraction expansion

$$\frac{n}{r} = b_1 - \cfrac{1}{b_2 - \cfrac{1}{\cdots - \cfrac{1}{b_\lambda}}} \tag{2.4.1}$$

with integers $b_j \geq 2$ for all j.

The minimal regular resolution of X' along x' has fiber over $k(x')_{\rm sep}$ whose underlying reduced scheme looks like the chain of E_j's as shown in Figure 1*, where:*

- *all intersections are transverse, with $E_j \simeq \mathbf{P}^1_{k(x')_{\rm sep}}$;*
- *$E_j.E_j = -b_j < -1$ for all j;*

- *E_1 is transverse to the strict transform $\widetilde{X}'_1$ of the global algebraic irreducible component X'_1 through x' with multiplicity m'_2 (along which t'_1 is a cotangent direction), and similarly for E_λ and the component $\widetilde{X}'_2$ with multiplicity m'_1 in the case of two analytic branches.*

Remark 2.4.2. The case $X'_2 = X'_1$ can happen, and there is no $\widetilde{X}'_1$ in case of one analytic branch (*i.e.*, in case $m'_2 = 0$).

We will also need to know the multiplicities μ_j of the components E_j in Figure 1, but this will be easier to give after we have proved Theorem 2.4.1; see Corollary 2.4.3.

The labelling of the E_j's indicates the order in which they arise in the resolution process, with each "new" E_j linking the preceding ones to the rest of the closed fiber in the case of one initial analytic branch. Keeping this picture in mind, we see that it is always the strict transform $\widetilde{X}'_2$ of the initial component with formal parameter t'_2 that occurs at the end of the chain, and this is the component whose multiplicity is m'_1.

Proof. We may assume S is local, and if S is not already excellent then (by hypothesis) X'_K is smooth and all connected components of its regular compactification have positive arithmetic genus. We claim that this positivity assumption is preserved by extension of the fraction field K. That is, if $\overline{C}$ is a connected regular proper curve over a field k with $\mathrm{H}^1(\overline{C}, \mathcal{O}_{\overline{C}}) \neq 0$ and C is a dense open in $\overline{C}$ that is k-smooth, then for any extension k'/k we claim that all connected components C'_i of the regular k'-curve $C' = C_{/k'}$ have compactification $\overline{C}'_i$ with $\mathrm{H}^1(\overline{C}'_i, \mathcal{O}_{\overline{C}'_i}) \neq 0$. Since the field $\mathrm{H}^0(\overline{C}, \mathcal{O}_{\overline{C}})$ is clearly finite separable over k, by using Stein factorization for $\overline{C}$ we may assume $\overline{C}$ is geometrically connected over k. Thus, $\overline{C}' = \overline{C}_{/k'}$ is a connected proper k'-curve with $\mathrm{H}^1(\overline{C}', \mathcal{O}_{\overline{C}'}) \neq 0$ and there is a dense open C' that is k'-smooth, and we want to show that the normalization of $\overline{C}'_{\mathrm{red}}$ has positive arithmetic genus. Since $\overline{C}'$ is generically reduced, the map from $\mathcal{O}_{\overline{C}'}$ to the normalization sheaf of $\mathcal{O}_{\overline{C}'_{\mathrm{red}}}$ has kernel and cokernel supported in dimension 0, and so the map on H^1's is an isomorphism. Thus, the normalization of $\overline{C}'_{\mathrm{red}}$ indeed has positive arithmetic genus.

We conclude that Lemma 2.1.1 and the base-change compatibility of Definition 2.2.3 (via Theorem 2.2.2) permit us to base-change to $\widehat{\mathcal{O}}_{S,s}$ without losing any hypotheses. Thus, we may assume $S = \operatorname{Spec} W$ with W a complete (hence excellent) discrete valuation ring. This brings us to the excellent case with all connected components of the regular compactification of X'_K having positive arithmetic genus when the residue field is not separably closed. If in addition $k(s)$ is not separably closed, then we claim that base-change to $\operatorname{Spec} W^{\mathrm{sh}}$ preserves all hypotheses, and so we can always get to the case of a separably closed residue field (in particular, we get to the case with $k(x')$ separably closed); see [24, p. 17] for a proof that strict henselization preserves excellence. We need to show that base change to W^{sh} commutes with the formation of the minimal regular resolution. This is a refinement on Theorem 2.2.2 because such base change is generally not residually trivial.

From the proof of Theorem 2.2.2 in the excellent case, we see that if $X' \hookrightarrow \overline{X}'$ is a Nagata compactification then the minimal resolution $X \to X'$ of X' is the part of the minimal regular resolution of $\overline{X}'$ that lies over X'. Hence, the base-change problem for $W \to W^{\rm sh}$ is reduced to the proper case. We may assume that X' is connected, so $\widetilde{W} = \mathrm{H}^0(X', \mathcal{O}_{X'})$ is a complete discrete valuation ring finite over W. Hence, $\widetilde{W}^{\rm sh} \simeq \widetilde{W} \otimes_W W^{\rm sh}$, so we may reduce to the case when $X' \to \operatorname{Spec} W$ is its own Stein factorization. In this proper case, the positivity condition on the arithmetic genus of the generic fiber allows us to use [41, 9/3.28] (which rests on a dualizing-sheaf criterion for minimality) to conclude that formation of the minimal regular resolution of X' is compatible with étale localization on W. A standard direct limit argument that chases the property of having a -1-curve in a fiber over X' thereby shows that the formation of the minimal regular resolution is compatible with ind-étale base change (such as $W \to W^{\rm sh}$). Thus, we may finally assume that W is excellent and has a separably closed residue field, and so we no longer need to impose a positivity condition on arithmetic genera of the connected components of the generic-fiber regular compactification.

The intrinsic numerical data for the *unique* minimal resolution (that is, the self-intersection numbers and multiplicities of components in the exceptional divisor for this resolution) may be computed in an étale neighborhood of x', by Corollary 2.2.4 and Remark 2.2.5, and the Artin approximation theorem is the ideal tool for finding a convenient étale neighborhood in which to do such a calculation. We will use the Artin approximation theorem to construct a special case that admits an étale neighborhood that is also an étale neighborhood of our given x', and so it will be enough to carry out the resolution in the special case. The absence of a good theory of minimal regular resolutions for complete 2-dimensional local noetherian rings prevents us from carrying out a proof entirely on $\widehat{\mathcal{O}}_{X',x'}$, and so forces us to use the Artin approximation theorem. It is perhaps worth noting at the outset that the reason we have to use Artin approximation is that the resolution process to be used in the special case will not be intrinsic (we blow up certain codimension-1 subschemes that depend on coordinates).

Here is the special case that we wish to analyze. Let $n > 1$ be a positive integer that is a unit in W, and choose $1 \le r < n$ with $\gcd(r, n) = 1$. Pick integers $m_1 \ge 1$ and $m_2 \ge 0$ satisfying $m_1 \equiv -rm_2 \bmod n$. For technical reasons, we do not require either of the m_j's to be units in W. To motivate things, let us temporarily assume that the residue field k of W contains a full set of nth roots of unity. Let $\mu_n(k)$ act on the *regular domain* $A = W[t_1, t_2]/(t_1^{m_1} t_2^{m_2} - \pi)$ via

$$[\zeta](t_1) = \zeta t_1, \ \ [\zeta](t_2) = \zeta^r t_2. \tag{2.4.2}$$

Since the $\mu_n(k)$-action in (2.4.2) is clearly free away from $t_1 = t_2 = \pi = 0$, the quotient

$$Z = (\mathrm{Spec}(A))/\mu_n(k) = \mathrm{Spec}(B)$$

(with $B = A^{\mu_n(k)}$) is normal and also is regular away from the image point $z \in Z$ of $t_1 = t_2 = \pi = 0$.

To connect up the special situation (Z, z) and the tame cyclic quotient singularity $x' \in X'_{/S}$, note that Lemma 2.3.4 shows that our situation is formally isomorphic to the algebraic $Z = \mathrm{Spec}(B)$ for a suitable such B and $n \in W^\times$. By the Artin approximation theorem, there is a common (residually trivial) connected étale neighborhood (U, u) of (Z, z) and (X', x'). That is, there is a pointed connected affine W-scheme $U = \mathrm{Spec}(A)$ that is a residually-trivial étale neighborhood of x' and of z. In particular, U is a connected normal W-curve. We can assume that u is the only point of U over z, and also the only point of U over x'. Keep in mind (*e.g.*, if $\gcd(m_1, m_2) > 1$) that the field K might not be separably closed in the function fields of U or Z, so the generic fibers of U and $Z = \mathrm{Spec}(B)$ over W might not be geometrically connected and U is certainly not proper over W in general.

The étale-local nature of the minimal regular resolution, as provided by Corollary 2.2.4 and Remark 2.2.5, implies that the minimal regular resolutions of (X', x') and (Z, z) have pullbacks to (U, u) that coincide with the minimal regular resolution of U along $\{u\}$. The fibers over u, x', z are all the same due to residual-triviality, so the geometry of the resolution fiber at x' is the same as that over z. Hence, we shall compute the minimal regular resolution $Z' \to Z$ at z, and will see that the fiber of Z' over z is as in Figure 1.

Let us now study (Z, z). Since n is a unit in W, the normal domain $B = A^{\mu_n(k)}$ is a quotient of $W[t_1, t_2]^{\mu_n(k)}$ via the natural map. Since the action of $\mu_n(k)$ as in (2.4.2) sends each monomial $t_1^{e_1} t_2^{e_2}$ to a constant multiple of itself, the ring of invariants $W[t_1, t_2]^{\mu_n(k)}$ is spanned over W by the invariant monomials. Clearly $t_1^{e_1} t_2^{e_2}$ is $\mu_n(k)$-invariant if and only if $e_1 + re_2 = nf$ for some integer f (so $e_2 \leq (n/r)f$), in which case $t_1^{e_1} t_2^{e_2} = u^f v^{e_2}$, where $u = t_1^n$ and $v = t_2/t_1^r$ are $\mu_n(k)$-invariant elements in the fraction field of $W[t_1, t_2]$. Note that even though v does not lie in $W[t_1, t_2]$, for any pair of integers i, j satisfying $0 \leq j \leq (n/r)i$ we have $u^i v^j \in W[t_1, t_2]$ and

$$W[t_1, t_2]^{\mu_n(k)} = \bigoplus_{0 \leq j \leq (n/r)i} W u^i v^j.$$

We have $t_1^{m_1} t_2^{m_2} = u^\mu v^{m_2}$ with $m_1 + rm_2 = n\mu$ (so $m_2 \leq (n/r)\mu$). Thus,

$$B = \frac{\bigoplus_{0 \leq j \leq (n/r)i} W u^i v^j}{(u^\mu v^{m_2} - \pi)}. \tag{2.4.3}$$

Observe that (2.4.3) makes sense as a definition of finite-type W-algebra, without requiring n to be a unit and without requiring that k contain any non-trivial roots of unity. It is clear that (2.4.3) is W-flat, as it has a W-module basis given by monomials $u^i v^j$ with $0 \leq j \leq (n/r)i$ and either $i < \mu$ or $j < m_2$. It is less evident if (2.4.3) is normal for any n, but we do not need this fact. We will inductively compute certain blow-ups on (2.4.3) *without restriction on* n or on the residue field, and the process will end at a resolution of singularities for $\operatorname{Spec} B$.

Before we get to the blowing-up, we shall show that $\operatorname{Spec} B$ is a W-curve and we will infer some properties of its closed fiber. Note that the map $K(u,v) \to K(t_1,t_2)$ defined by $u \mapsto t_1^n$, $v \mapsto t_2/t_1^r$ induces a W-algebra injection

$$\bigoplus_{0\leq j\leq (n/r)i} Wu^iv^j \to W[t_1,t_2] \tag{2.4.4}$$

that is *finite* because $t_1^n = u$ and $t_2^n = u^rv^n$. Thus, the left side of (2.4.4) is a 3-dimensional noetherian domain and passing to the quotient by $u^\mu v^{m_2} - \pi = t_1^{m_1}t_2^{m_2} - \pi$ yields a finite surjection

$$\operatorname{Spec}(W[t_1,t_2]/(t_1^{m_1}t_2^{m_2} - \pi)) \to \operatorname{Spec}(B). \tag{2.4.5}$$

Passing to the generic fiber and recalling that B is W-flat, we infer that $\operatorname{Spec}(B)$ is a W-curve with irreducible generic fiber, so $\operatorname{Spec}(B)$ is 2-dimensional and connected. We also have a finite surjection modulo π,

$$\operatorname{Spec}(k[t_1,t_2]/(t_1^{m_1}t_2^{m_2})) \to \operatorname{Spec}(B/\pi), \tag{2.4.6}$$

so the closed fiber of $\operatorname{Spec}(B)$ consists of at most two irreducible components (or just one when $m_2 = 0$), to be called the images of the t_1-axis and t_2-axis (where we omit mention of the t_1-axis when $m_2 = 0$). Since the t_2-axis is the preimage of the zero-scheme of $u = t_1^n$ under (2.4.6), we conclude that when $m_2 > 0$ the closed fiber $\operatorname{Spec}(B/\pi)$ does have two distinct irreducible components.

Inspired by the case of toric varieties, we will now compute the blow-up Z' of the W-flat $Z = \operatorname{Spec}(B)$ along the ideal (u, uv). Since

$$\operatorname{Spec}(W[t_1,t_2]/(t_1^{m_1}t_2^{m_2} - \pi, t_1^n, t_1^{n-r}t_2)) \to \operatorname{Spec}(B/(u,uv))$$

is a finite surjection and the source is supported in the t_2-axis of the closed fiber over $\operatorname{Spec}(W)$, it follows that $\operatorname{Spec}(B/(u,uv))$ is supported in the image of the t_2-axis of the closed fiber of $\operatorname{Spec}(B)$ over $\operatorname{Spec}(W)$. In particular, blowing up Z along (u,uv) does not affect the generic fiber of Z over W. Since Z is W-flat, it follows that the proper blow-up map $Z' \to Z$ is surjective.

There are two charts covering Z', $D_+(u)$ and $D_+(uv)$, where we adjoin the ratios $uv/u = v$ and $u/uv = 1/v$ respectively. Thus,

$$D_+(u) = \operatorname{Spec}(B[v]) = \operatorname{Spec}(W[u,v]/(u^\mu v^{m_2} - \pi))$$

is visibly regular and connected, and $D_+(uv) = \operatorname{Spec}(B[1/v])$ with

$$B[1/v] = \frac{\bigoplus_{j\leq(n/r)i,\, 0\leq i} Wu^iv^j}{(u^\mu v^{m_2} - \pi)}.$$

We need to rewrite this latter expression in terms of a more useful set of variables. We begin by writing (as one does when computing the Jung–Hirzebruch continued fraction for n/r)

$$n = b_1 r - r'$$

with $b_1 \geq 2$ and either $r = 1$ with $r' = 0$ or else $r' > 0$ with $\gcd(r, r') = 1$ (since $\gcd(n, r) = 1$). We will first treat the case $r' = 0$ (proving that $B[1/v]$ is also regular) and then we will treat the case $r' > 0$. Note that there is no reason to expect that p cannot divide r or r', even if $p \nmid n$, and it is for this reason that we had to recast the definition of B in a form that avoids the assumption that n is a unit in W. For similar reasons, we must avoid assuming m_1 or m_2 is a unit in W.

Assume $r' = 0$, so $r = 1$, $b_1 = n$, and $b_1\mu - m_2 = m_1$. Let $i' = b_1 i - j$ and $j' = i$, so i' and j' vary precisely over non-negative integers and $u^i v^j = (1/v)^{i'}(uv^{b_1})^{j'}$. Thus, letting $u' = 1/v$ and $v' = uv^{b_1}$ yields

$$B[1/v] = W[u', v']/({u'}^{b_1\mu - m_2}{v'}^{\mu} - \pi) = W[u', v']/({u'}^{m_1}{v'}^{\mu} - \pi),$$

which is regular. In the closed fiber of $Z' = \mathrm{Bl}_{(u,uv)}(Z)$ over $\mathrm{Spec}(W)$, let D_1 denote the v'-axis in $D_+(uv) = \mathrm{Spec}\, B[1/v]$ and when $m_2 > 0$ let D_2 denote the u-axis in $D_+(u)$. The multiplicities of D_1 and D_2 in Z'_k are respectively $m_1 = b_1\mu - m_2$ and m_2 (with multiplicity $m_2 = 0$ being a device for recording that there is no D_2). The exceptional divisor E is a projective line over k (with multiplicity μ and gluing data $u' = 1/v$) and hence the uniformizer π has divisor on $Z' = \mathrm{Bl}_{(u,uv)}(Z)$ given by

$$\mathrm{div}_{Z'}(\pi) = (b_1\mu - m_2)D_1 + \mu E + m_2 D_2 = m_1 D_1 + \mu E + m_2 D_2$$

(when $m_2 = 0$, the final term really is omitted).

It is readily checked that the D_j's each meet E transversally at a single k-rational point (suppressing D_2 when $m_2 = 0$). The intersection product $\mathrm{div}_{Z'}(\pi).E$ makes sense since E is proper over k, even though Z is not proper over W, and it must vanish because $\mathrm{div}_{Z'}(\pi)$ is principal, so by additivity of intersection products in the first variable (restricted to effective Cartier divisors for a fixed proper second variable such as E) we have

$$0 = \mathrm{div}_{Z'}(\pi).E = b_1\mu - m_2 + \mu(E.E) + m_2.$$

Thus, $E.E = -b_1$.

Now assume $r' > 0$. Since $n = b_1 r - r'$, the condition $0 \leq j \leq (n/r)i$ can be rewritten as $0 \leq i \leq (r/r')(b_1 i - j)$. Letting $j' = i$ and $i' = b_1 i - j$, we have $u^i v^j = {u'}^{i'}{v'}^{j'}$ with $u' = 1/v$ and $v' = uv^{b_1}$. In particular, $u^\mu v^{m_2} = {u'}^{b_1\mu - m_2}{v'}^{\mu}$. Thus,

$$B[1/v] = \frac{\bigoplus_{0 \leq j' \leq (r/r')i'} W{u'}^{i'}{v'}^{j'}}{({u'}^{b_1\mu - m_2}{v'}^{\mu} - \pi)}. \tag{2.4.7}$$

Note the similarity between (2.4.3) and (2.4.7) up to modification of parameters: replace (n, r, m_1, m_2, μ) with $(r, r', m_1, \mu, b_1\mu - m_2)$. The blow-up along $(u', u'v')$ therefore has closed fiber over $\mathrm{Spec}(W)$ with the following irreducible components: the v'-axis D_1 in $D_+(uv)$ with multiplicity $b_1\mu - m_2$, the u-axis D_2 in $D_+(u)$ with multiplicity m_2 (so this only shows up when $m_2 > 0$), and the exceptional divisor E that is a projective line (via gluing $u' = 1/v$) having multiplicity μ and meeting D_1 (as well as D_2 when $m_2 > 0$) transversally at a single k-rational point. We will focus our attention on $D_+(uv)$ (as we have already seen that the other chart $D_+(u)$ is regular), and in particular we are interested in the "origin" in the closed fiber of $D_+(uv)$ over $\mathrm{Spec}(W)$ where the projective line E meets D_1; near this origin, $D_+(uv)$ is an affine open that is given by the spectrum of (2.4.7).

If r were also a unit in W then $D_+(uv)$ would be the spectrum of the ring of $\mu_r(k)$-invariants in $W[t'_1, t'_2]/({t'_1}^{m_1}{t'_2}^{\mu} - \pi)$ with the action $[\zeta](t'_1) = \zeta t'_1$ and $[\zeta](t'_1) = \zeta^{r'} t'_2$ (this identification uses the identity $m_1 + r'\mu = r(b_1\mu - m_2)$), and without any restriction on r we at least see that (2.4.7) is an instance of the general (2.4.3) and that there is a natural finite surjection

$$\mathrm{Spec}(k[t'_1, t'_2]/({t'_1}^{m_1}{t'_2}^{\mu})) \to D_+(uv)_k.$$

On $D_+(uv)_k$, the component E of multiplicity μ is the image of the t'_1-axis and the component D_1 with multiplicity m_1 is the image of the t'_2-axis. As a motivation for what follows, note also that if $r \in W^\times$ then since $r > 1$ we see that the "origin" in $D_+(uv)_k$ is necessarily a non-regular point in the total space over $\mathrm{Spec}(W)$ (by Serre's Theorem 2.3.9).

We conclude (without requiring any of our integer parameters to be units in W) that if we make the change of parameters

$$(n, r, m_1, m_2, \mu) \rightsquigarrow (r, r', m_1, \mu, b_1\mu - m_2) \tag{2.4.8}$$

then $D_+(uv)$ is like the original situation (2.4.3) with a revised set of initial parameters. In particular, n is replaced by the strictly smaller $r > 1$, so the process will eventually end. Moreover, since $\mu > 0$ we see that the case $m_2 = 0$ is now "promoted" to the case $m_2 > 0$. When we make the blow-up at the origin in $D_+(uv)_k$, the strict transform E_1 of E plays the same role that D_2 played above, so E_1 is entirely in the regular locus and the new exceptional divisor E' has multiplicity $b_1\mu - m_2$ (this parameter plays the role for the second blow-up that μ played for the first blow-up, as one sees by inspecting our change of parameters in (2.4.8)).

As the process continues, nothing more will change around E_1, so inductively we conclude from the descriptions of the regular charts that the process ends at a regular connected W-curve with closed-fiber Weil divisor

$$\cdots + (b_1\mu - m_2)E' + \mu E_1 + m_2 D_2 + \ldots \tag{2.4.9}$$

(where we have abused notation by writing E' to denote the strict transform of E' in the final resolution, and this strict transform clearly has generic multiplicity $b_1\mu - m_2$). The omitted terms in (2.4.9) do not meet E_1, so we may form the intersection against E_1 to solve

$$0 = (b_1\mu - m_2) + \mu(E_1.E_1) + m_2$$

just as in the case $r' = 0$ (*i.e.*, $r = 1$), so $E_1.E_1 = -b_1$. Since

$$\frac{n}{r} = b_1 - \frac{1}{r/r'},$$

by induction on the length of the continued fraction we reach a regular resolution in the expected manner, with $E_j.E_j = -b_j$ for all j and the final resolution having fiber over $z \in Z$ looking exactly like in Figure 1. Note also that each new blow-up separates all of the previous exceptional lines from the (strict transform of the initial) component through z with multiplicity m_1. Since $-b_j \leq -2 < -1$ for all j, we conclude that at no stage of the blow-up process before the end did we have a regular scheme (otherwise there would be a -1-curve in a fiber over the original base Z). Thus, we have computed the minimal regular resolution at z.

□

We now compute the multiplicity μ_j in the closed fiber of ${X'}^{\mathrm{reg}}$ for each fibral component E_j over $x' \in X'$ in Figure 1. In order to compute the μ_j's, we introduce some notation. Let $n/r > 1$ be a reduced-form fraction with positive integers n and r, so we can write

$$n/r = [b_1, b_2, \ldots, b_\lambda]_{\mathrm{JH}} := b_1 - \cfrac{1}{b_2 - \cfrac{1}{\cdots - \cfrac{1}{b_\lambda}}}$$

as a Jung–Hirzebruch continued fraction, where $b_j \geq 2$ for all j. Define $P_j = P_j(b_1, \ldots, b_\lambda)$ and $Q_j = Q_j(b_1, \ldots, b_\lambda)$ by

$$P_{-1} = 0,\ \ Q_{-1} = -1,\ \ P_0 = 1,\ \ Q_0 = 0,$$

$$P_j = b_j P_{j-1} - P_{j-2},\ \ Q_j = b_j Q_{j-1} - Q_{j-2}$$

for all $j \geq 1$. Clearly P_j and Q_j are universal polynomials in $b_1, \ldots, b_j$, and by induction $P_j Q_{j-1} - Q_j P_{j-1} = -1$ and $Q_j > Q_{j-1}$ for all $j \geq 0$, so in particular $Q_j > 0$ for all $j > 0$. Thus,

$$[b_1, \ldots, b_\lambda]_{\mathrm{JH}} = \frac{P_\lambda(b_1, \ldots, b_\lambda)}{Q_\lambda(b_1, \ldots, b_\lambda)}$$

makes sense and P_λ/Q_λ is in reduced form. Thus, $P_\lambda = n$ and $Q_\lambda = r$ since the Q_j's are necessarily positive.

Corollary 2.4.3. *With hypotheses and notation as in Theorem* 2.4.1, *let* μ_j *denote the multiplicity of* E_j *in the fiber of* ${X'}^{\mathrm{reg}}$ *over* $k(x')_{\mathrm{sep}}$. *The condition* $r = 1$ *happens if and only if* $\lambda = 1$, *in which case* $\mu_1 = (m'_1 + m'_2)/n$.

If $r > 1$ (*so* $\lambda > 1$), *then the* μ_j*'s are the unique solution to the equation*

$$\begin{pmatrix} b_1 & -1 & 0 & 0 & \dots & 0 & 0 & 0 \\ -1 & b_2 & -1 & 0 & \dots & 0 & 0 & 0 \\ 0 & -1 & b_3 & -1 & \dots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & -1 & b_{\lambda-1} & -1 \\ 0 & 0 & 0 & 0 & \dots & 0 & -1 & b_\lambda \end{pmatrix} \begin{pmatrix} \mu_1 \\ \vdots \\ \vdots \\ \mu_\lambda \end{pmatrix} = \begin{pmatrix} m'_2 \\ 0 \\ \vdots \\ 0 \\ m'_1 \end{pmatrix}. \tag{2.4.10}$$

Keeping the condition $r > 1$, *define* $P'_j = P_j(b_{\lambda-j+1}, \dots, b_\lambda)$, *so* $P'_\lambda = n$ *and* $P'_{\lambda-1} = Q_\lambda(b_1, \dots, b_\lambda) = r$. *If we let* $\widetilde{m}_2 = P'_{\lambda-1} m'_2 + m'_1 = r m'_2 + m'_1$, *then the* μ_j*'s are also the unique solution to*

$$\begin{pmatrix} P'_\lambda & 0 & 0 & \dots & 0 & 0 & 0 \\ -P'_{\lambda-2} & P'_{\lambda-1} & 0 & \dots & 0 & 0 & 0 \\ 0 & -P'_{\lambda-3} & P'_{\lambda-2} & \dots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & -P'_1 & P'_2 & 0 \\ 0 & 0 & 0 & \dots & 0 & -1 & P'_1 \end{pmatrix} \begin{pmatrix} \mu_1 \\ \vdots \\ \vdots \\ \mu_\lambda \end{pmatrix} = \begin{pmatrix} \widetilde{m}_2 \\ m'_1 \\ \vdots \\ m'_1 \\ m'_1 \end{pmatrix}. \tag{2.4.11}$$

In particular, $\mu_1 = (r m'_2 + m'_1)/n$.

Note that in the applications with $X' = X/H$ as at the beginning of §2.3, the condition $\chi'_1 \neq \chi'_2$ (*i.e.*, $H'_{x|x'}$ does not act through scalars) is equivalent to the condition $r > 1$ in Corollary 2.4.3.

Proof. The value of μ_1 when $r = 1$ was established in the proof of Theorem 2.4.1, so now assume $r > 1$. On ${X'}^{\mathrm{reg}}$ (or rather, its base change to $\mathcal{O}^{\mathrm{sh}}_{S,s}$) we have

$$\mathrm{div}(\pi_s) = m'_1 \widetilde{X}'_2 + \sum_{j=1}^{\lambda} \mu_j E_j + m'_2 \widetilde{X}'_1 + \dots \tag{2.4.12}$$

where

- the $\widetilde{X}'_1$-term does not appear if there is only one analytic branch through x' (recall we also set $m'_2 = 0$ in this case),
- the $\widetilde{X}'_j$-terms are a single term when there are two analytic branches but only one global irreducible (geometric) component (in which case $m'_1 = m'_2$),
- the omitted terms "$\dots$" on the right side of (2.4.12) are not in the fiber over x' (and in particular do not intersect the E_j's).

Thus, the equations $E_j.\mathrm{div}(\pi_s) = 0$ and the intersection calculations in the proof of Theorem 2.4.1 (as summarized by Figure 1, including transversalities) immediately yield (2.4.10). By solving this system of equations by working up from the bottom row, an easy induction argument yields the reformulation (2.4.11).

□

To prove Theorems 1.1.2 and 1.1.6, the preceding general considerations will provide the necessary intersection-theoretic information on a minimal resolution. To apply Theorem 2.4.1 and Corollary 2.4.3 to the study of singularities at points x' on modular curves, we need to find the value of the parameter $r_{x'}$ in each case. This will be determined by studying universal deformation rings for moduli problems of elliptic curves.

3 The Coarse moduli scheme $X_1(p)$

Let p be a prime number. In this section we review the construction of the coarse moduli scheme $X_1(p)$ attached to $\Gamma_1(p)$ in terms of an auxiliary finite étale level structure which exhibits $X_1(p)$ as the compactification of a quotient of a fine moduli scheme. It is the fine moduli schemes whose completed local rings are well understood through deformation theory (as in [34]), and this will provide the starting point for our subsequent calculations of regular models and component groups.

3.1 Some general nonsense

As in [34, Ch. 4], for a scheme T we let (Ell/T) be the category whose objects are elliptic curves over T-schemes and whose morphisms are cartesian diagrams. The moduli problem $[\Gamma_1(p)]$ is the contravariant functor $(\mathrm{Ell}) \to (\mathrm{Sets})$ that to an elliptic curve $E_{/S}$ attaches the set of $P \in E(S)$ such that the relative effective Cartier divisor

$$[0] + [P] + [2P] + \cdots + [(p-1)P],$$

viewed as a closed subscheme of E, is a closed subgroup scheme. For any moduli problem $\mathcal{P}$ on (Ell/T) and any object $E_{/S}$ over a T-scheme, we define the functor $\mathcal{P}_{E/S}(S') = \mathcal{P}(E_{/S'})$ to classify "$\mathcal{P}$-structures" on base changes of $E_{/S}$. If $\mathcal{P}_{E/S}$ is representable (with some property $\mathbf{P}$ relative to S) for every $E_{/S}$, we say that $\mathcal{P}$ is *relatively representable* (with property $\mathbf{P}$). For example, $[\Gamma_1(p)]$ is relatively representable and finite locally free of degree p^2-1 on (Ell) for every prime p.

For $p \geq 5$, the moduli problem $[\Gamma_1(p)]_{/\mathbf{Z}[1/p]}$ is representable by a smooth affine curve over $\mathbf{Z}[1/p]$ [34, Cor. 2.7.3, Thm. 3.7.1, and Cor. 4.7.1]. For any elliptic curve $E_{/S}$ over an $\mathbf{F}_p$-scheme S, the point $P = 0$ is fixed by the automorphism -1 of $E_{/S}$, and is in $[\Gamma_1(p)](E/S)$ because $[0]+[P]+\cdots+[(p-1)P]$ is the kernel of the relative Frobenius morphism $F\colon E \to E^{(p)}$. Thus, $[\Gamma_1(p)]_{/\mathbf{Z}_{(p)}}$ is not rigid, so it is not representable.

As there is no fine moduli scheme associated to $[\Gamma_1(p)]_{/\mathbf{Z}_{(p)}}$ for any prime p, we let $X_1(p)$ be the compactified coarse moduli scheme $\overline{M}([\Gamma_1(p)]_{/\mathbf{Z}_{(p)}})$, as constructed in [34, Ch. 8]. This is a proper normal $\mathbf{Z}_{(p)}$-model of a smooth and geometrically connected curve $X_1(p)_{/\mathbf{Q}}$, but $X_1(p)$ is usually not regular. Nevertheless, the complete local rings on $X_1(p)$ are computable in terms of abstract deformation theory. Since $(\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ acts on isomorphism classes of $\Gamma_1(p)$-structures via

$$(E, P) \mapsto (E, a \cdot P) \simeq (E, -a \cdot P),$$

we get a natural action of this group on $X_1(p)$ which is readily checked to be a faithful action (*i.e.*, non-identity elements act non-trivially). Thus, for any subgroup $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ we get the modular curve $X_H(p) = X_1(p)/H$ which is a normal proper connected $\mathbf{Z}_{(p)}$-curve with smooth generic fiber $X_H(p)_{/\mathbf{Q}}$. When $p > 3$, the curve $X_H(p)$ has tame cyclic quotient singularities at its non-regular points.

In order to compute a minimal regular model for these normal curves, we need more information than is provided by abstract deformation theory: we need to keep track of *global* irreducible components on the geometric fiber mod p, whereas deformation theory will only tell us about the analytic branches through a point. Fortunately, in the case of modular curves $X_H(p)$, distinct analytic branches through a closed-fiber geometric point always arise from distinct global (geometric) irreducible components through the point. In order to review this fact, as well as to explain the connection between complete local rings on $X_H(p)$ and rings of invariants in universal deformation rings, we need to recall how $X_1(p)$ can be constructed from fine moduli schemes. Let us briefly review the construction process.

Pick a representable moduli problem $\mathcal{P}$ that is finite, étale, and Galois over $(\mathrm{Ell}/\mathbf{Z}_{(p)})$ with Galois group $G_{\mathcal{P}}$, and for which $M(\mathcal{P})$ is affine. For example (cf. [34, §4.5–4.6]) if $\ell \neq p$ is a prime with $\ell \geq 3$, we can take $\mathcal{P}$ to be the moduli problem $[\Gamma(\ell)]_{/\mathbf{Z}_{(p)}}$ that attaches to $E_{/S}$ the set of isomorphisms of S-group schemes

$$\phi\colon (\mathbf{Z}/\ell\mathbf{Z})^2_S \simeq E[\ell];$$

the Galois group $G_{\mathcal{P}}$ is $\mathrm{GL}_2(\mathbf{F}_\ell)$. Let $Y_1(p;\mathcal{P})$ be the fine moduli scheme $M([\Gamma_1(p)]_{/\mathbf{Z}_{(p)}}, \mathcal{P})$ that classifies pairs consisting of a $\Gamma_1(p)$-structure and a $\mathcal{P}$-structure on elliptic curves over variable $\mathbf{Z}_{(p)}$-schemes. The scheme $Y_1(p;\mathcal{P})$ is a flat affine $\mathbf{Z}_{(p)}$-curve. Let $Y_1(p)$ be the quotient of $Y_1(p;\mathcal{P})$ by the $G_{\mathcal{P}}$-action.

We introduce the global $\mathcal{P}$ rather than just use formal deformation theory throughout because on characteristic-p fibers we need to retain a connection between closed fiber irreducible components of global modular curves and closed fiber "analytic" irreducible components of formal deformation rings. The precise connection between global $\mathcal{P}$'s and infinitesimal deformation theory is given by the well-known:

Theorem 3.1.1. *Let k be an algebraically closed field of characteristic p and let $W = W(k)$ be its ring of Witt vectors. Let $z \in Y_1(p)_{/k}$ be a rational point. Let* $\mathrm{Aut}(z)$ *denote the finite group of automorphisms of the (non-canonically unique) $\Gamma_1(p)$-structure over k underlying z. Choose a $\mathcal{P}$-structure on the elliptic curve underlying z, with $\mathcal{P}$ as above, and let $z' \in Y_1(p;\mathcal{P})(k)$ be the corresponding point over z.*

The ring $\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$ is naturally identified with the formal deformation ring of z. Under the resulting natural action of $\mathrm{Aut}(z)$ *on $\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$, the subring of* $\mathrm{Aut}(z)$*-invariants is $\widehat{\mathcal{O}}_{Y_1(p)_W,z}$.*

For any subgroup $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$ equipped with its natural action on $Y_1(p)$, the stabilizer $H_{z'|z}$ of z' in H acts faithfully on the universal deformation ring $\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$ of z in the natural way, with subring of invariants $\widehat{\mathcal{O}}_{Y_H(p)_W,z}$.

Proof. Since $\mathcal{P}$ is étale and $Y_1(p;\mathcal{P})_W$ is a fine moduli scheme, the interpretation of $\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$ as a universal deformation ring is immediate. Since $Y_1(p)_W$ is the quotient of $Y_1(p;\mathcal{P})_W$ by the action of $G_{\mathcal{P}}$, it follows that $\widehat{\mathcal{O}}_{Y_1(p)_W,z}$ is identified with the subring of invariants in $\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$ for the action of the stabilizer of z' for the $G_{\mathcal{P}}$-action on $Y_1(p;\mathcal{P})_W$. We need to compute this stabilizer subgroup.

If $z' = (E_z, P_z, \iota)$ with supplementary $\mathcal{P}$-structure ι, then $g \in G_{\mathcal{P}}$ fixes z' if and only if (E_z, P_z, ι) is isomorphic to $(E_z, P_z, g(\iota))$. This says exactly that there exists an automorphism α_g of (E_z, P_z) carrying ι to $g(\iota)$, and such α_g is clearly unique if it exists. Moreover, any two $\mathcal{P}$-structures on E_z are related by the action of a unique $g \in G_{\mathcal{P}}$ because of the definition of $G_{\mathcal{P}}$ as the Galois group of $\mathcal{P}$ (and the fact that z is a geometric point). Thus, the stabilizer of z in $G_{\mathcal{P}}$ is naturally identified with $\mathrm{Aut}(E_z, P_z) = \mathrm{Aut}(z)$ (*compatibly* with actions on the universal deformation ring of z). The assertion concerning the H-action is clear.

□

Since $Y_1(p;\mathcal{P})$ is a regular $\mathbf{Z}_{(p)}$-curve [34, Thm. 5.5.1], it follows that its quotient $Y_1(p)$ is a normal $\mathbf{Z}_{(p)}$-curve. Moreover, by [34, Prop. 8.2.2] the natural map $j : Y_1(p) \to \mathbf{A}^1_{\mathbf{Z}_{(p)}}$ is finite, and hence it is also *flat* [44, 23.1]. In [34], $X_1(p)$ is *defined* to be the normalization of $Y_1(p)$ over the compactified j-line $\mathbf{P}^1_{\mathbf{Z}_{(p)}}$. Both $X_1(p)$ and $Y_1(p)$ are independent of the auxiliary choice of $\mathcal{P}$. The complex analytic theory shows that $X_1(p)$ has geometrically connected fibers over $\mathbf{Z}_{(p)}$, so the same is true for $Y_1(p)$ since the complete local rings at the cusps are analytically irreducible mod p (by the discussion in §4.2, especially the self-contained Lemma 4.2.4 and Lemma 4.2.5).

3.2 Formal parameters

To do deformation theory computations, we need to recall some canonical formal parameters in deformation rings. Fix an algebraically closed field k of characteristic p and let $W = W(k)$ denote its ring of Witt vectors. Let

$z \in Y_1(p)_{/k}$ be a k-rational point corresponding to an elliptic curve $E_{z/k}$ with $\Gamma_1(p)$-structure P_z.

For later purposes, it is useful to give a conceptual description of the 1-dimensional "reduced" cotangent space $\mathfrak{m}/(p, \mathfrak{m}^2)$ of $\mathcal{R}_z^0$, or equivalently the cotangent space to the equicharacteristic formal deformation functor of E_z:

Theorem 3.2.1. *The cotangent space to the equicharacteristic formal deformation functor of an elliptic curve E over a field k is canonically isomorphic to* $\mathrm{Cot}_0(E)^{\otimes 2}$.

Proof. This is just the dual of the Kodaira-Spencer isomorphism. More specifically, the cotangent space is isomorphic to $\mathrm{H}^1(E, (\Omega^1_{E/k})^\vee)^\vee$, and Serre duality identifies this latter space with

$$\begin{tikzcd} \mathrm{H}^0(E, (\Omega^1_{E/k})^{\otimes 2}) & \mathrm{H}^0(E, \Omega^1_{E/k})^{\otimes 2} \arrow[l, "\simeq"'] \arrow[r, equal] & \mathrm{Cot}_0(E)^{\otimes 2}, \end{tikzcd}$$

the first map being an isomorphism since $\Omega^1_{E/k}$ is (non-canonically) trivial. □

Let

$$\mathbf{E}_z \to \mathrm{Spec}(\mathcal{R}_z^0)$$

denote an algebraization of the universal deformation of E_z, so non-canonically $\mathcal{R}_z^0 \simeq W[\![t]\!]$ and (by Theorem 3.1.1) there is a unique local W-algebra map $\mathcal{R}_z^0 \to \mathcal{R}_z$ to the universal deformation ring $\mathcal{R}_z$ of (E_z, P_z) such that there is a (necessarily unique) isomorphism of deformations between the base change of $\mathbf{E}_z$ over $\mathcal{R}_z$ and the universal elliptic curve underlying the algebraized universal $\Gamma_1(p)$-structure deformation at z.

Now make the additional hypothesis $P_z = 0$, so upon choosing a formal coordinate $\underline{x}$ for the formal group of $\mathbf{E}_z$ it makes sense to consider the coordinate

$$x = \underline{x}(\mathbf{P}_z) \in \mathcal{R}_z$$

of the "point" $\mathbf{P}_z$ in the universal $\Gamma_1(p)$-structure over $\mathcal{R}_z$. We thereby get a natural local W-algebra map

$$W[\![x, t]\!] \to \mathcal{R}_z. \tag{3.2.1}$$

Theorem 3.2.2. *The natural map* (3.2.1) *is a surjection with kernel generated by an element f_z that is part of a regular system of parameters of the regular local ring $W[\![x,t]\!]$. Moreover, x and t span the* 2*-dimensional cotangent space of the target ring.*

Proof. The surjectivity and cotangent-space claims amount to the assertion that an artinian deformation whose $\Gamma_1(p)$-structure vanishes and whose t-parameter vanishes necessarily has $p = 0$ in the base ring (so we then have a constant deformation). The vanishing of p in the base ring is [34, 5.3.2.2]. Since the deformation ring $\mathcal{R}_z$ is a 2-dimensional regular local ring, the kernel of the surjection (3.2.1) is a height-1 prime that must therefore be principal with a generator that is part of a regular system of parameters. □

3.3 Closed-fiber description

For considerations in Section 5, we will need some more refined information, particularly a description of $f_z \bmod p$ in Theorem 3.2.2. To this end, we first need to recall some specialized moduli problems in characteristic p.

Definition 3.3.1. If $E_{/S}$ is an elliptic curve over an $\mathbf{F}_p$-scheme S, and $G \hookrightarrow E$ is a finite locally free closed subgroup scheme of order p, we shall say that G is a $(1,0)$-*subgroup* if G is the kernel of the relative Frobenius map $F_{E/S} : E \to E^{(p)}$ and G is a $(0,1)$-*subgroup* if the order p group scheme $E[p]/G \hookrightarrow E/G$ is the kernel of the relative Frobenius for the quotient elliptic curve E/G over S.

Remark 3.3.2. This is a special case of the more general concept of (a,b)-*cyclic subgroup* which is developed in [34, §13.4] for describing the mod p fibers of modular curves. On an ordinary elliptic curve over a field of characteristic p, an (a,b)-cyclic subgroup has connected-étale sequence with connected part of order p^a and étale part of order p^b.

Let $\mathcal{P}$ be a representable moduli problem over $(\mathrm{Ell}/\mathbf{Z}_{(p)})$ that is finite, étale, and Galois with $M(\mathcal{P})$ affine (as in §3.1). For $(a,b) = (1,0), (0,1)$, it makes sense to consider the subfunctor

$$[[\Gamma_1(p)]\text{-}(a,b)\text{-cyclic}, \mathcal{P}] \tag{3.3.1}$$

of points of $[\Gamma_1(p)_{/\mathbf{F}_p}, \mathcal{P}]$ whose $\Gamma_1(p)$-structure generates an (a,b)-cyclic subgroup. By [34, 13.5.3, 13.5.4], these subfunctors (3.3.1) are represented by closed subschemes of $Y_1(p;\mathcal{P})_{/\mathbf{F}_p}$ that intersect at exactly the supersingular points and have ordinary loci that give a covering of $Y_1(p;\mathcal{P})^{\mathrm{ord}}_{/\mathbf{F}_p}$ by open subschemes. Explicitly, we have an $\mathbf{F}_p$-scheme isomorphism

$$M([\Gamma_1(p)]\text{-}(0,1)\text{-cyclic}, \mathcal{P}) \simeq M([\mathrm{Ig}(p)], \mathcal{P}) \tag{3.3.2}$$

with a smooth (possibly disconnected) Igusa curve, where $[\mathrm{Ig}(p)]$ is the moduli problem that classifies $\mathbf{Z}/p\mathbf{Z}$-generators of the kernel of the relative Verschiebung $V_{E/S} : E^{(p)} \to E$, and the line bundle ω of relative 1-forms on the universal elliptic curve over $M(\mathcal{P})_{/\mathbf{F}_p}$ provides the description

$$M([\Gamma_1(p)]\text{-}(1,0)\text{-cyclic}, \mathcal{P}) \simeq \mathrm{Spec}((\mathrm{Sym}_{M(\mathcal{P})_{/\mathbf{F}_p}}\omega)/\omega^{\otimes(p-1)}) \tag{3.3.3}$$

as the cover obtained by locally requiring a formal coordinate of the level-p structure to have $(p-1)$th power equal to zero. The scheme (3.3.3) has generic multiplicity $p-1$ and has smooth underlying reduced curve $M(\mathcal{P})_{/\mathbf{F}_p}$.

We conclude that $Y_1(p;\mathcal{P})$ is $\mathbf{Z}_{(p)}$-smooth at points in

$$M([\Gamma_1(p)]\text{-}(0,1)\text{-cyclic}, \mathcal{P})^{\mathrm{ord}},$$

and near points in $M([\Gamma_1(p)]\text{-}(1,0)\text{-cyclic}, \mathcal{P})$ we can use a local trivialization of ω to find a nilpotent function X with a moduli-theoretic interpretation as the formal coordinate of the point in the $\Gamma_1(p)$-structure (with X^{p-1} arising as $\Phi_p(X+1) \bmod p$ along the ordinary locus). Thus, we get the "ordinary" part of:

Theorem 3.3.3. *Let k be an algebraically closed field of characteristic p, and $z \in Y_1(p)_{/k}$ a rational point corresponding to a $(1,0)$-subgroup of an elliptic curve E over k. Choose $z' \in Y_1(p;\mathcal{P})_{/k}$ over z. Let f_z be a generator of the kernel of the surjection $W[\![x,t]\!] \twoheadrightarrow \widehat{\mathcal{O}}_{Y_1(p;\mathcal{P}),z'}$ in* (3.2.1).

We can choose f_z so that

$$f_z \bmod p = \begin{cases} x^{p-1} & \text{if } E \text{ is ordinary,} \\ x^{p-1}t' & \text{if } E \text{ is supersingular,} \end{cases}$$

with p, x, t' a regular system of parameters in the supersingular case. In particular, $Y_1(p;\mathcal{P})^{\mathrm{red}}_{/k}$ has smooth irreducible components, ordinary double point singularities at supersingular points, and no other non-smooth points.

The significance of Theorem 3.3.3 for our purposes is that it ensures the regular $\mathbf{Z}_{(p)}$-curve $Y_1(p;\mathcal{P})_{\mathbf{Z}_{(p)}}$ is nil-semistable in the sense of Definition 2.3.1. In particular, for $p > 3$ and any subgroup $H \subseteq (\mathbf{Z}/p\mathbf{Z})^\times/\{\pm 1\}$, the modular curve $X_H(p)$ has tame cyclic quotient singularities away from the cusps.

Proof. The geometric irreducible components of $Y_1(p,\mathcal{P})^{\mathrm{red}}_{/k}$ are smooth curves (3.3.2) and (3.3.3) that intersect at exactly the supersingular points, and (3.3.3) settles the description of $f_z \bmod p$ in the ordinary case. It remains to verify the description of $f_z \bmod p$ at supersingular points z, for once this is checked then the two minimal primes (x) and (t') in the deformation ring at z must correspond to the k-fiber irreducible components of the smooth curves (3.3.2) and $(3.3.3)_{\mathrm{red}}$ through z', and these two primes visibly generate the maximal ideal at z' in the k-fiber so (3.3.2) and $(3.3.3)_{\mathrm{red}}$ intersect transversally at z' as desired.

Consider the supersingular case. The proof of [34, 13.5.4] ensures that we can choose f_z so that

$$f_z \bmod p = g_{(1,0)}g_{(0,1)}, \tag{3.3.4}$$

with $k[\![x,t]\!]/g_{(0,1)}$ the complete local ring at z' on the closed subscheme (3.3.2) and likewise for $k[\![x,t]\!]/g_{(1,0)}$ and (3.3.3). By (3.3.3), we can take $g_{(1,0)} = x^{p-1}$, so by (3.3.4) it suffices to check that the formally smooth ring $k[\![x,t]\!]/g_{(0,1)}$ does not have t as a formal parameter. In the proof of [34, 12.8.2], it is shown that there is a natural isomorphism between the moduli stack of Igusa structures and the moduli stack of $(p-1)$th roots of the Hasse invariant of elliptic curves over $\mathbf{F}_p$-schemes. Since the Hasse invariant commutes with base change and the Hasse invariant on the the universal deformation of a supersingular elliptic curve over $k[\![t]\!]$ has a simple zero [34, 12.4.4], by extracting a $(p-1)$th root we lose the property of t being a formal parameter if $p > 2$. We do not need the theorem for the supersingular case when $p = 2$, so we leave this case as an exercise for the interested reader.

□

4 Determination of non-regular points

Since the quotient $X_H(p)$ of the normal proper $\mathbf{Z}_{(p)}$-curve $X_1(p;\mathcal{P})$ is normal, there is a finite set of non-regular points in codimension-2 on $X_H(p)$ that we have to resolve to get a regular model. We will prove that the non-regular points on the nil-semistable $X_H(p)$ are certain *non-cuspidal* $\mathbf{F}_p$-rational points with j-invariants 0 and 1728, and that these singularities are tame cyclic quotient singularities when $p>3$, so Jung–Hirzebruch resolution in Theorem 2.4.1 will tell us everything we need to know about the minimal regular resolution of $X_H(p)$.

4.1 Analysis away from cusps

The only possible non-regular points on $X_H(p)$ are closed points in the closed fiber. We will first consider those points that lie in $Y_H(p)$, and then we will study the situation at the cusps. The reason for treating these cases separately is that the deformation theory of generalized elliptic curves is a little more subtle than that of elliptic curves. One can also treat the situation at the cusps by using Tate curves instead of formal deformation theory; this is the approach used in [34].

In order to determine the non-regular points on $Y_H(p)$, by Lemma 2.1.1 we only need to consider geometric points. By Theorem 3.1.1, we need a criterion for detecting when a finite group acting on a regular local ring has regular subring of invariants. The criterion is provided by Serre's Theorem 2.3.9 and leads to:

Theorem 4.1.1. *A geometric point $z=(E_z,P_z)\in Y_1(p)$ has non-regular image in $Y_H(p)$ if and only if it is a point in the closed fiber such that $|\mathrm{Aut}(E_z)|>2$, $P_z=0$, and $2|H|\nmid|\mathrm{Aut}(E_z)|$.*

In particular, when $p>3$ there are at most two non-regular points on $Y_H(p)$ and such points are $\mathbf{F}_p$-rational, while for $p\le 3$ (so H is trivial) the unique ($\mathbf{F}_p$-rational) supersingular point is the unique non-regular point.

Proof. Let k be an algebraically closed field of characteristic p and define $W=W(k)$; we may assume that z is a k-rational point. By Lemma 2.1.1, we may consider the situation after base change by $\mathbf{Z}_{(p)}\to W$. A non-regular point z must be a closed point on the closed fiber. Let z' be a point over z in $Y_1(p;\mathcal{P})(k)$. Let (E_z,P_z) be the structure arising from z.

First suppose $p>3$ and H is trivial. The group $\mathrm{Aut}_k(E_z)$ is cyclic of order prime to p, so the automorphism group $\mathrm{Aut}(z)$ of the $\Gamma_1(p)$-structure underlying z is also cyclic of order prime to p. By Theorems 3.1.1 and 2.3.9, the regularity of $\widehat{\mathcal{O}}_{Y_1(p)_W,z}$ is therefore equivalent to the existence of a stable line under the action of $\mathrm{Aut}(z)$ on the 2-dimensional cotangent space to the regular universal deformation ring $\mathcal{R}_z=\widehat{\mathcal{O}}_{Y_1(p;\mathcal{P})_W,z'}$ of the $\Gamma_1(p)$-structure z.

When the $\Gamma_1(p)$-structure z is étale (*i.e.*, $P_z\neq 0$), then the formal deformation theory for z is the same as for the underlying elliptic curve $E_z/\langle P_z\rangle$, whence the universal deformation ring is isomorphic to $W[\![t]\!]$. In such cases, p spans an $\mathrm{Aut}(z)$-invariant line in the cotangent space of the deformation ring. Even when H is not assumed to be trivial, this line is stable under the action of the stabilizer of z' the preimage of H in $(\mathbf{Z}/p\mathbf{Z})^\times$). Hence, we get regularity at z for any H when $p > 3$ and $P_z \neq 0$.

Still assuming $p > 3$, now drop the assumption of triviality on H but suppose that the $\Gamma_1(p)$-structure is not étale, so $z = (E_z, 0)$ and $\mathrm{Aut}(z) = \mathrm{Aut}_k(E_z)$. The preimage $H' \subseteq (\mathbf{Z}/p\mathbf{Z})^\times$ of H acts on the deformation ring $\mathcal{R}_z$ since $P_z = 0$. By Theorem 3.1.1 and Theorem 3.2.2, the cotangent space to $\mathcal{R}_z$ is canonically isomorphic to

$$\mathrm{Cot}_0(E_z) \oplus \mathrm{Cot}_0(E_z)^{\otimes 2}, \tag{4.1.1}$$

where this decomposition corresponds to the lines spanned by the images of x and t respectively. Conceptually, the first line in (4.1.1) arises from equicharacterisitc deformations of the point of order p on constant deformations of the elliptic curve E_z, and the second line arises from deformations of the elliptic curve without deforming the vanishing level structure P_z. These identifications are compatible with the natural actions of $\mathrm{Aut}(z) = \mathrm{Aut}(E_z)$.

Since $p > 3$, the action of $\mathrm{Aut}(E_z) = \mathrm{Aut}(z)$ on the line $\mathrm{Cot}_0(E_z)$ is given by a faithful (non-trivial) character $\overline{\chi}_{\mathrm{id}}$, and the other line in (4.1.1) is acted upon by $\mathrm{Aut}(E_z)$ via the character χ_{id}^2. The resulting representation of $\mathrm{Aut}(z)$ on $\mathrm{Cot}_0(E_z)^{\otimes 2}$ is trivial if and only if $\overline{\chi}_{\mathrm{id}}^2 = 1$, which is to say (by faithfulness) that $\mathrm{Aut}(E_z)$ has order 2 (*i.e.*, $j(E_z) \neq 0, 1728$). Since the H'-action is trivial on the line $\mathrm{Cot}_0(E_z)^{\otimes 2}$ (due to H' only acting on the level structure) and we are passing to invariants by the action of the group $H' \times \mathrm{Aut}(E_{z/k})$, by Serre's theorem we get regularity without restriction on H when $j(E_z) \neq 0, 1728$.

If $j(E_z) \in \{0, 1728\}$ then $|\mathrm{Aut}(E_z)| > 2$ and the cyclic H' acts on (4.1.1) through a representation $\psi \oplus 1$ with ψ a faithful character. The cyclic $\mathrm{Aut}(z)$ acts through a representation $\chi \oplus \chi^2$ with χ a faithful character, so $\chi^2 \neq 1$. The commutative group of actions on (4.1.1) generated by H' and $\mathrm{Aut}(z)$ is generated by pseudo-reflections if and only if the action of the cyclic $\mathrm{Aut}(z)$ on the first line is induced by the action of a subgroup of H'. That is, the order of χ must divide the order of ψ, or equivalently $|\mathrm{Aut}(z)|$ must divide $|H'| = 2|H|$. This yields exactly the desired conditions for non-regularity when $p > 3$.

Now suppose $p \leq 3$, so H is trivial. If $\mathrm{Aut}(E_{z/k}) = \{\pm 1\}$, so z is an ordinary point, then for $p = 3$ we can use the preceding argument to deduce regularity at z. Meanwhile, for $p = 2$ we see that $\mathcal{R}_z$ is formally smooth by Theorem 3.3.3, so the subring of invariants at z is formally smooth (by [34, p. 508]). It remains to check non-regularity at the unique (supersingular) point $z \in Y_1(p)_{/k}$ with $j = 0 = 1728$ in k.

By Serre's theorem, it suffices to check that the action of $\mathrm{Aut}(z) = \mathrm{Aut}(E_z)$ on (4.1.1) is not generated by pseudo-reflections, where E_z is the unique supersingular elliptic curve over k (up to isomorphism). The action of $\mathrm{Aut}(E_z)$ is through 1-dimensional characters, so the p-Sylow subgroup must act trivially. In both cases ($p = 2$ or 3) the group $\mathrm{Aut}(E_z)$ has order divisible by only two primes p and p', with the p'-Sylow of order > 2. This p'-Sylow must act through a faithful character on $\mathrm{Cot}_0(E_z)$ (use [20, Lemma 3.3] or [68, Lemma 2.16]), and hence this group also acts non-trivially on $\mathrm{Cot}_0(E_z)^{\otimes 2}$. It follows that this action is not generated by pseudo-reflections.

□

4.2 Regularity along the cusps

Now we check that $X_H(p)$ is regular along the cusps, so we can focus our attention on $Y_H(p)$ when computing the minimal regular resolution of $X_H(p)$. We will again use deformation theory, but now in the case of generalized elliptic curves. Throughout this section, p is an arbitrary prime.

Recall that a *generalized elliptic curve* over a scheme S is a proper flat map $\pi : E \to S$ of finite presentation equipped with a section $e : S \to E^{\mathrm{sm}}$ into the relative smooth locus and a map

$$+ : E^{\mathrm{sm}} \times_S E \to E$$

such that

- the geometric fibers of π are smooth genus 1 curves or Néron polygons;
- $+$ restricts to a commutative group scheme structure on E^{sm} with identity section e;
- $+$ is an action of E^{sm} on E such that on singular geometric fibers with at least two "sides", the translation action by each rational point in the smooth locus induces a rotation on the graph of irreducible components.

Since the much of the basic theory of Drinfeld structures was developed in [34, Ch. 1] for arbitrary smooth separated commutative group schemes of relative dimension 1, it can be applied (with minor changes in proofs) to the smooth locus of a generalized elliptic curve. In this way, one can merge the "affine" moduli-theoretic $\mathbf{Z}$-theory in [34] with the "proper" moduli-theoretic $\mathbf{Z}[1/N]$-theory in [15]. We refer the reader to [21] for further details on this synthesis.

The main deformation-theoretic fact we need is an analogue of Theorem 3.2.1:

Theorem 4.2.1. *An irreducible generalized elliptic curve C_1 over a perfect field k of characteristic $p > 0$ admits a universal deformation ring that is abstractly isomorphic to $W[\![t]\!]$, and the equicharacteristic cotangent space of this deformation ring is canonically isomorphic to* $\mathrm{Cot}_0(C_1^{\mathrm{sm}})^{\otimes 2}$.

Proof. The existence and abstract structure of the deformation ring are special cases of [15, III, 1.2]. To describe the cotangent space intrinsically, we wish to put ourselves in the context of deformation theory of proper flat curves. Infinitesimal deformations of C_1 admit a unique generalized elliptic curve structure once we fix the identity section [15, II, 2.7], and any two choices of identity section are uniquely related by a translation action. Thus, the deformation theory for C_1 as a generalized elliptic (*i.e.*, marked) curve coincides with its deformation theory as a flat (unmarked) curve. In particular, the tangent space to this deformation functor is canonically identified with $\mathrm{Ext}^1_{C_1}(\Omega^1_{C_1/k}, \mathcal{O}_{C_1})$ [56, §4.1.1].

Since the natural map $\Omega^1_{C_1/k} \to \omega_{C_1/k}$ to the invertible relative dualizing sheaf is injective with finite-length cokernel (supported at the singularity),

$$\mathrm{Ext}^1_{C_1}(\omega_{C_1/k}, \mathcal{O}_{C_1}) \simeq \mathrm{Ext}^1_{C_1}(\omega^{\otimes 2}_{C_1/k}, \omega_{C_1/k}) \simeq \mathrm{H}^0(C_1, \omega^{\otimes 2}_{C_1/k})^\vee,$$

with the final isomorphism provided by Grothendieck duality. Thus, the cotangent space to the deformation functor is identified with $\mathrm{H}^0(C_1, \omega^{\otimes 2}_{C_1/k})$. Since $\omega_{C_1/k}$ is (non-canonically) trivial, just as for elliptic curves, we get a canonical isomorphism

$$\mathrm{H}^0(C_1, \omega^{\otimes 2}_{C_1/k}) \simeq \mathrm{H}^0(C_1, \omega_{C_1/k})^{\otimes 2} \simeq \mathrm{Cot}_0(C_1^{\mathrm{sm}})^{\otimes 2}$$

(the final isomorphism defined via pullback along the identity section).

□

Definition 4.2.2. A $\Gamma_1(N)$*-structure* on a generalized elliptic curve $E \to S$ is an "S-ample" Drinfeld $\mathbf{Z}/N\mathbf{Z}$-structure on E^{sm}; *i.e.*, a section $P \in E^{\mathrm{sm}}[N](S)$ such that the relative effective Cartier divisor

$$D = \sum_{j \in \mathbf{Z}/N\mathbf{Z}} [jP]$$

in E^{sm} is a subgroup scheme which meets all irreducible components of all geometric fibers.

If $E_{/S}$ admits a $\Gamma_1(N)$-structure, then the non-smooth geometric fibers must be d-gons for various $d|N$. In case $N = p$ is prime, this leaves p-gons and 1-gons as the only options. The importance of Definition 4.2.2 is the following analogue of Theorem 3.1.1:

Theorem 4.2.3. *Let k be an algebraically closed field of characteristic $p > 0$, and $W = W(k)$. The points of $X_1(p)_{/k} - Y_1(p)_{/k}$ correspond to isomorphism classes of $\Gamma_1(p)$-structures on degenerate generalized elliptic curves over k with 1 or p sides.*

For $z \in X_1(p)_{/k} - Y_1(p)_{/k}$, there exists a universal deformation ring $\mathcal{S}_z$ for the $\Gamma_1(p)$-structure z, and $\widehat{\mathcal{O}}_{X_1(p)_W, z}$ is the subring of $\mathrm{Aut}(z)$*-invariants in $\mathcal{S}_z$.*

Proof. In general, $\Gamma_1(p)$-structures on generalized elliptic curves form a proper flat Deligne-Mumford stack $\overline{M}_{\Gamma_1(p)}$ over $\mathbf{Z}_{(p)}$ of relative dimension 1, and this stack is smooth over $\mathbf{Q}$ and is normal (as one checks via abstract deformation theory). For our purposes, the important point is that if we choose an odd prime $\ell \neq p$ then we can define an evident $[\Gamma_1(p), \Gamma(\ell)]$-variant on Definition 4.2.2 (imposing an ampleness condition on the combined level structure), and the open locus of points with trivial geometric automorphism group is a scheme (as it is an algebraic space quasi-finite over the j-line). This locus fills up the entire stack $\overline{M}_{[\Gamma_1(p),\Gamma(\ell)]}$ over $\mathbf{Z}_{(p)}$, so this stack is a scheme.

The resulting normal $\mathbf{Z}_{(p)}$-flat proper scheme $\overline{M}_{[\Gamma_1(p),\Gamma(\ell)]}$ is finite over the j-line, whence it must *coincide* with the scheme $X_1(p;[\Gamma(\ell)])$ as constructed in [34] by the *ad hoc* method of normalization of the fine moduli scheme $Y_1(p;[\Gamma(\ell)])$ over the j-line. We therefore get a map

$$\overline{M}_{[\Gamma_1(p),\Gamma(\ell)]} = X_1(p;[\Gamma(\ell)]) \to X_1(p)$$

that *must* be the quotient by the natural $\mathrm{GL}_2(\mathbf{F}_\ell)$-action on the source. Since complete local rings at geometric points on a Deligne-Mumford stack coincide with universal formal deformation rings, we may conclude as in the proof of Theorem 3.1.1.

□

We are now in position to argue just as in the elliptic curve case: we shall work out the deformation rings in the various possible cases and for $p \neq 2$ we will use Serre's pseudo-reflection theorem to deduce regularity of $X_1(p)$ along the cusps on the closed fiber. A variant on the argument will also take care of $p = 2$.

As in the elliptic curve case, it will suffice to consider geometric points. Thus, there will be two types of $\Gamma_1(p)$-structures (E, P) to deform: E is either a p-gon or a 1-gon.

Lemma 4.2.4. *Let E_0 be a p-gon over an algebraically closed field k of characteristic p, and $P_0 \in E_0^{\mathrm{sm}}(k)$ a $\Gamma_1(p)$-structure. The deformation theory of (E_0, P_0) coincides with the deformation theory of the 1-gon generalized elliptic curve $E_0/\langle P_0\rangle$.*

Note that in the p-gon case, the point $P_0 \in E_0^{\mathrm{sm}}(k)$ generates the order-p constant component group of E_0^{sm}, so the group scheme $\langle P_0\rangle$ generated by P_0 is visibly étale and the quotient $E_0/\langle P_0\rangle$ makes sense (as a generalized elliptic curve) and is a 1-gon.

Proof. For any infinitesimal deformation (E, P) of (E_0, P_0), the subgroup scheme H generated by P is finite étale, and it makes sense to form the quotient E/H as a generalized elliptic curve deformation of the 1-gon E_0/H_0 (with $H_0 = \langle P_0\rangle$). Since any finite étale cover of a generalized elliptic curve admits a unique compatible generalized elliptic curve structure once we fix a lift of the identity section and demand geometric connectedness of fibers over the base [15, II, 1.17], we see that the deformation theory of (E_0, H_0) (ignoring P) is equivalent to the deformation theory of the 1-gon E_0/H_0. The deformation theory of a 1-gon is formally smooth of relative dimension 1 [15, III, 1.2], and upon specifying (E, H) deforming (E_0, H_0) the étaleness of H ensures the existence and uniqueness of the choice of $\Gamma_1(p)$-structure P generating H such that

P lifts P_0 on E_0. That is, the universal deformation ring for (E_0, P_0) coincides with that of E_0/H_0.

□

In the 1-gon case, there is only one (geometric) possibility up to isomorphism: the pair $(C_1, 0)$ where C_1 is the standard 1-gon (over an algebraically closed field k of characteristic p). For this, we have an analogue of (4.1.1):

LEMMA 4.2.5. *The universal deformation ring of the $\Gamma_1(p)$-structure $(C_1, 0)$ is isomorphic to the regular local ring $W[\![t]\!][\![X]\!]/\Phi_p(X+1)$, with cotangent space canonically isomorphic to*

$$\mathrm{Cot}_0(C_1^{\mathrm{sm}}) \oplus \mathrm{Cot}_0(C_1^{\mathrm{sm}})^{\otimes 2}.$$

Proof. Since the p-torsion on C_1^{sm} is isomorphic to μ_p, upon fixing an isomorphism $C_1^{\mathrm{sm}}[p] \simeq \mu_p$ there is a unique compatible isomorphism $C^{\mathrm{sm}}[p] \simeq \mu_p$ for any infinitesimal deformation C of C_1. Thus, the deformation problem is that of endowing a $\mathbf{Z}/p\mathbf{Z}$-generator to the μ_p inside of deformations of C_1 (as a generalized elliptic curve). By Theorem 4.2.3, this is the scheme of generators of μ_p over the universal deformation ring $W[\![t]\!]$ of C_1.

The scheme of generators of μ_p over $\mathbf{Z}$ is $\mathbf{Z}[Y]/\Phi_p(Y)$, so we obtain $W[\![t]\!][Y]/\Phi_p(Y)$ as the desired (regular) deformation ring. Now just set $X = Y - 1$. The description of the cotangent space follows from Theorem 4.2.1.

□

Since C_1 has automorphism group (as a generalized elliptic curve) generated by the unique extension $[-1]$ of inversion from C_1^{sm} to all of C_1, we conclude that $\mathrm{Aut}(C_1, 0)$ is generated by $[-1]$. This puts us in position to carry over our earlier elliptic-curve arguments to prove:

THEOREM 4.2.6. *The scheme $X_H(p)$ is regular along its cusps.*

Proof. As usual, we may work after making a base change by $W = W(k)$ for an algebraically closed field k of characteristic $p > 0$. Let $z \in X_1(p)_{/k}$ be a cusp whose image z_H in $X_H(p)_{/k}$ we wish to study. Let H' be the preimage of H in $(\mathbf{Z}/p\mathbf{Z})^\times$, and let H'_z be the maximal subgroup of H' that acts on the deformation space for z (*e.g.*, $H'_z = H'$ if the level structure P_z vanishes). By Theorem 4.2.3, the ring $\widehat{\mathcal{O}}_{X_H(p), z_H}$ is the subring of invariants under the action of $\mathrm{Aut}(z) \times H'_z$ on the formal deformation ring for z. By Theorem 4.2.1 and Lemma 4.2.4 (as well as [34, p. 508]), this deformation ring is regular (even formally smooth) in the p-gon case. In the 1-gon case, Lemma 4.2.5 ensures that the deformation ring is regular (and even formally smooth when $p = 2$). Thus, for $p \neq 2$ we may use Theorem 2.3.9 to reduce the problem for $p \neq 2$ to checking that the action of $\mathrm{Aut}(z) \times H'_z$ on the 2-dimensional cotangent space to the deformation functor has an invariant line.

In the p-gon case, the deformation ring is $W[\![t]\!]$ and the cotangent line spanned by p is invariant. In the 1-gon case, Lemma 4.2.5 provides a functorial description of the cotangent space to the deformation functor and from this it is clear that the involution $[-1]$ acts with an invariant line $\mathrm{Cot}_0(z)^{\otimes 2}$ when $p \neq 2$ and that H'_z also acts trivially on this line.

To take care of $p = 2$ (for which H is trivial), we just have to check that any non-trivial W-algebra involution ι of $W[\![T]\!]$ has regular subring of invariants. In fact, for $T' = T\iota(T)$ the subring of invariants is $W[\![T']\!]$ by [34, p. 508].

□

5 The Minimal resolution

We now are ready to compute the minimal regular resolution $X_H(p)^{\mathrm{reg}}$ of $X_H(p)$. Since $X_H(p)_{/\mathbf{Q}}$ is a projective line when $p \leq 3$, both Theorem 1.1.2 and Theorem 1.1.6 are trivial for $p \leq 3$. Thus, from now on we assume $p > 3$. We have found all of the non-regular points (Theorem 4.1.1): the $\mathbf{F}_p$-rational points of $(1,0)$-type such that $j \in \{0, 1728\}$, provided that $|H|$ is not divisible by 3 (resp. 2) when $j = 0$ (resp. $j = 1728$). Theorem 3.3.3 provides the necessary local description to carry out Jung–Hirzebruch resolution at these points. These are tame cyclic quotient singularities (since $p > 3$). Moreover, the closed fiber of $X_H(p)$ is a nil-semistable curve that consists of two irreducible components that are geometrically irreducible, as one sees by considering the (1,0)-cyclic and (0,1)-cyclic components.

5.1 General considerations

There are four cases, depending on $p \equiv \pm 1, \pm 5 \bmod 12$ as this determines the behavior of the j-invariants 0 and 1728 in characteristic p (*i.e.*, supersingular or ordinary). This dichotomy between ordinary and supersingular cases corresponds to Jung–Hirzebruch resolution with either one or two analytic branches.

Pick a point $z = (E, 0) \in X_1(p)(\mathbf{F}_p)$ with $j = 0$ or 1728 corresponding an elliptic curve E over $\overline{\mathbf{F}}_p$ with automorphism group of order > 2. Let $z_H \in X_H(p)(\mathbf{F}_p)$ be the image of z. By Theorem 4.1.1, we know that z_H is non-regular if and only if $|H|$ is odd for $j(E) = 1728$, and if and only if $|H|$ is not divisible by 3 for $j(E) = 0$.

There is a single irreducible component through z_H in the ordinary case (arising from either (3.3.2) or (3.3.3)), while there are two such (transverse) components in the supersingular case, and to compute the generic multiplicities of these components in $X_H(p)_{/\overline{\mathbf{F}}_p}$ we may work with completions because the irreducible components through z_H are analytically irreducible (even smooth) at z_H.

Let C' and C denote the irreducible components of $X_H(p)_{/\overline{\mathbf{F}}_p}$, with C' corresponding to étale level p-structures. Since the preimage of H in $(\mathbf{Z}/p\mathbf{Z})^\times$ (of order $2|H|$) acts generically freely (resp. trivially) on the preimage of C' (resp. of C) in a fine moduli scheme over $X_H(p)_{/\overline{\mathbf{F}}_p}$ obtained by adjoining some prime-to-p level structure, ramification theory considerations and Theorem 3.3.3 show that the components C' and C in $X_H(p)_{/\overline{\mathbf{F}}_p}$ have respective multiplicities of 1 and $(p-1)/2|H| = [(\mathbf{Z}/p\mathbf{Z})^\times/\{\pm1\} : H]$. Moreover, by Theorem 3.3.3 we see that z_H lies on C when it is an ordinary point.

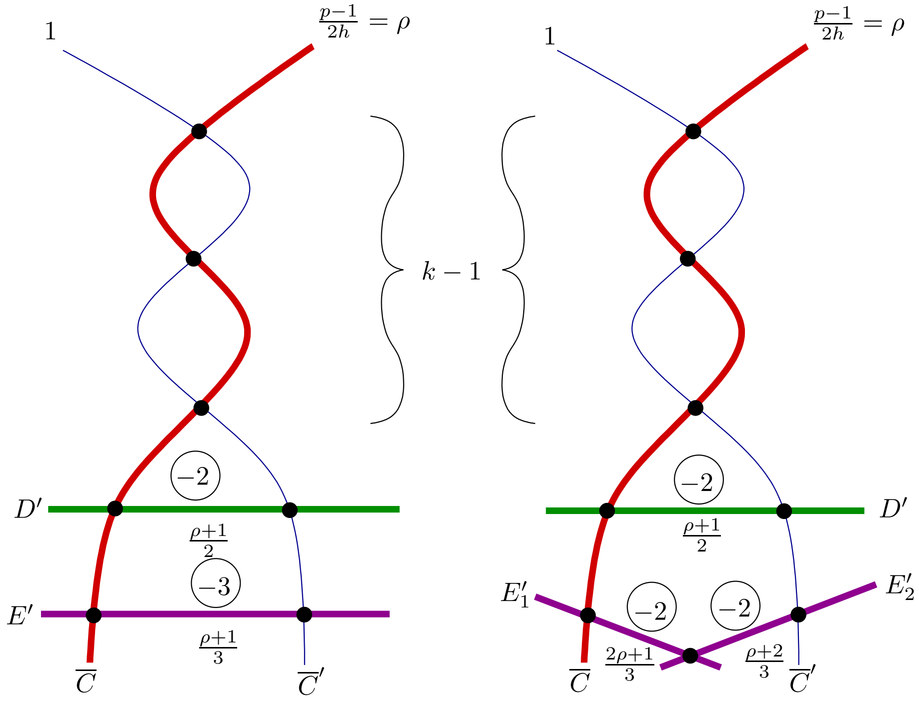
5.2 The case $p \equiv -1 \bmod 12$

We are now ready to resolve the singularities on $X_H(p)_{/W}$ with $W = W(\overline{\mathbf{F}}_p)$. We will first carry out the calculation in the case $p \equiv -1 \pmod{12}$, so 0 and 1728 are supersingular j-values. In this case $(p-1)/2$ is not divisible by 2 or 3, so $|H|$ is automatically not divisible by 2 or 3 (so we have two non-regular points).

Write $p = 12k-1$ with $k \geq 1$. By the Deuring Mass Formula [34, Cor. 12.4.6] the components C and C' meet in $(p-11)/12 = k-1$ geometric points away from the two supersingular points with $j = 0, 1728$. Consider one of the two non-regular supersingular points z_H. The complete local ring at z_H on $X_H(p)_W$ is the subring of invariants for the commuting actions of $\mathrm{Aut}(z)$ and the preimage $H' \subseteq (\mathbf{Z}/p\mathbf{Z})^\times$ of H on the universal deformation ring $\mathcal{R}_z$ of the $\Gamma_1(p)$-structure z. Note that the actions of H' and $\mathrm{Aut}(z)$ on $\mathcal{R}_z$ have a common involution. The action of H' on the tangent space fixes one line and acting through a faithful character on the other line (see the proof of Theorem 4.1.1), so by Serre's Theorem 2.3.9 the subring of H'-invariants in $\mathcal{R}_z$ is regular. By Lemma 2.3.5 and the subsequent discussion there, the subring of H'-invariant has the form $W[\![x', t']\!]/(x'^{(p-1)/|H'|}t' - p)$ with $\mathrm{Aut}(z)/\{\pm1\}$ acting on the tangent space via $\chi^{|H|} \oplus \chi$ for a faithful character χ of $\mathrm{Aut}(z)/\{\pm1\}$. Let $h = |H|$, so $\rho := (p-1)/2h$ is the multiplicity of C in $X_H(p)_{/\overline{\mathbf{F}_p}}$.

When $j(z_H) = 1728$ the character χ is quadratic, so we apply Theorem 2.4.1 and Corollary 2.4.3 with $n = 2$, $r = 1$, $m'_1 = 1$, $m'_2 = \rho$. The resolution has a single exceptional fiber D' that is transverse to the strict transforms $\overline{C}$ and $\overline{C}'$, and D' has self-intersection -2 and multiplicity $(m'_1 + m'_2)/2 = (\rho+1)/2$. When $j(z_H) = 0$ the character χ is cubic, so we apply Theorem 2.4.1 with $n = 3$, $m'_1 = 1$, $m'_2 = \rho$, and $r = h \bmod 3$. That is, $r = 1$ when $h \equiv 1 \bmod 6$ and $r = 2$ when $h \equiv -1 \bmod 6$. In the case $r = 1$ we get a single exceptional fiber E' in the resolution, transverse to $\overline{C}$ and $\overline{C}'$ with self-intersection -3 and multiplicity $(\rho+1)/3$ (by Corollary 2.4.3). This is illustrated in Figure 2(a). In the case $r = 2$ we use the continued fraction $3/2 = 2 - 1/2$ to see that the resolution of z_H has exceptional fiber with two components E'_1 and E'_2, and these have self-intersection -2 and transverse intersections as shown in Figure 2(b) with respective multiplicities $(2\rho+1)/3$ and $(\rho+2)/3$ by Corollary 2.4.3. This completes the computation of the minimal regular resolution $X_H(p)'$ of $X_H(p)$ when $p \equiv -1 \bmod 12$.

To compute the intersection matrix for the closed fiber of $X_H(p)'$, we need to compute some more intersection numbers. For $h \equiv 1 \bmod 6$ we let μ and ν denote the multiplicities of D' and E' in $X_H(p)'$, and for $h \equiv -1 \bmod 6$ we



(a) $h \equiv 1 \bmod 6$

(b) $h \equiv -1 \bmod 6$

Figure 2: Minimal regular resolution $X_H(p)'$ of $X_H(p)$, $p = 12k-1$, $k \geq 1$, $h = |H|$

define μ in the same way and let ν_j denote the multiplicity of E'_j in $X_H(p)'$. In other words,

$$\mu = (\rho+1)/2,\ \nu = (\rho+1)/3,\ \nu_1 = (2\rho+1)/3,\ \nu_2 = (\rho+2)/3.$$

Thus,

$$\overline{C}' + \rho\overline{C} + \mu D' + \nu E' \equiv 0, \tag{5.2.1}$$

so if we intersect (5.2.1) with $\overline{C}$ and use the identities

$$\rho = (6k-1)/h,\ \ \overline{C}'.\overline{C} = k-1 = (h\rho-5)/6,$$

we get

$$\overline{C}.\overline{C} = -1-(h-\varepsilon)/6$$

where $\varepsilon = \pm 1 \equiv h \bmod 6$. In particular, $\overline{C}.\overline{C} < -1$ unless $h=1$ (*i.e.*, unless H is trivial). We can also compute the self-intersection for $\overline{C}'$, but we do not need it.

When H is trivial, so $\overline{C}$ is a -1-curve, we can contract $\overline{C}$ and then by Theorem 2.1.2 and Figure 2 the self-intersection numbers for the components D' and E' drop to -1 and -2 respectively. Then we may contract D', so E' becomes a -1-curve, and finally we end with a single irreducible component (coming from $\overline{C}'$). This proves Theorem 1.1.2 when $p \equiv -1 \bmod 12$.

Returning to the case of general H, let us prove Theorem 1.1.6 for $p \equiv -1 \bmod 12$. Since $\overline{C}'$ has multiplicity 1 in the closed fiber of $X_H(p)'$, we can use the following special case of a result of Lorenzini [9, 9.6/4]:

Lemma 5.2.1 (Lorenzini). *Let X be a regular proper flat curve over a complete discrete valuation ring R with algebraically closed residue field and fraction field K. Assume that $X_{/K}$ is smooth and geometrically connected. Let $X_1, \dots, X_m$ be the irreducible components of the closed fiber $\overline{X}$ and assume that some component X_{i_0} occurs with multiplicity 1 in the closed fiber divisor.*

The component group of the Néron model of the Jacobian $\mathrm{Pic}^0_{X_K/K}$ has order equal to the absolute value of the $(m-1)\times(m-1)$ minor of the intersection matrix $(X_i.X_j)$ obtained by deleting the i_0th row and column.

The intersection submatrices formed by the ordered set $\{\overline{C}, D', E'\}$ for $h \equiv 1 \bmod 6$ and by $\{\overline{C}, D', E'_1, E'_2\}$ for $h \equiv -1 \bmod 6$ are given in Figure 3. The absolute value of the determinant is h in each case, so by Lemma 5.2.1 the order of the component group $\Phi(\mathcal{J}_H(p)_{/\mathbf{F}_p})$ is $h = |H| = |H|/\gcd(|H|, 6)$.

To establish Theorem 1.1.6 for $p \equiv -1 \bmod 12$, it remains to show that the natural Picard map $J_0(p) \to J_H(p)$ induces a surjection on mod-p geometric component groups. We outline a method that works for general p but that we will (for now) carry out only for $p \equiv -1 \bmod 12$, as we have only computed the intersection matrix in this case.

$$\begin{array}{cccc} & \overline{C} & D' & E' \\ \overline{C} & -1-\frac{(h-1)}{6} & 1 & 1 \\ D' & 1 & -2 & 0 \\ E' & 1 & 0 & -3 \end{array}$$

(a) $h \equiv 1 \bmod 6$

$$\begin{array}{ccccc} & \overline{C} & D' & E'_1 & E'_2 \\ \overline{C} & -1-\frac{(h+1)}{6} & 1 & 1 & 0 \\ D' & 1 & -2 & 0 & 0 \\ E'_1 & 1 & 0 & -2 & 1 \\ E'_2 & 0 & 0 & 1 & -2 \end{array}$$

(b) $h \equiv -1 \bmod 6$

Figure 3: Submatrices of intersection matrix for $X_H(p)'$, $p \equiv -1 \bmod 12$

The component group for $J_0(p)$ is generated by $(0)-(\infty)$, where (0) classifies the 1-gon with standard subgroup $\mu_p \hookrightarrow \mathbf{G}_m$ in the smooth locus, and (∞) classifies the p-gon with subgroup $\mathbf{Z}/p\mathbf{Z} \hookrightarrow (\mathbf{Z}/p\mathbf{Z}) \times \mathbf{G}_m$ in the smooth locus. The generic-fiber Picard map induced by the coarse moduli scheme map

$$X_H(p)_{/\mathbf{Z}_{(p)}} \to X_0(p)_{/\mathbf{Z}_{(p)}}$$

pulls $(0)-(\infty)$ back to a divisor

$$P \ - \sum_{j=1}^{(p-1)/2|H|} P'_i \tag{5.2.2}$$

where the P'_i's are $\mathbf{Q}$-rational points whose (cuspidal) reduction lies in the component $\overline{C}'$ classifying étale level-structures and P is a point with residue field $(\mathbf{Q}(\zeta_p)^+)^H$ whose (cuspidal) reduction lies in the component $\overline{C}$ classifying multiplicative level-structures. This description is seen by using the moduli interpretation of cusps (*i.e.*, Néron polygons) and keeping track of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$-actions, and it is valid for any prime p (*e.g.*, the $\Gamma_1(p)$-structures on the standard 1-gon consistute a principal homogenous space for the action of $\mathrm{Gal}(\mathbf{Q}(\mu_p)/\mathbf{Q})$, so they give a single closed point P on $X_H(p)_{/\mathbf{Q}}$ with residue field $(\mathbf{Q}(\zeta_p)^+)^H$).

To apply (5.2.2), we need to recall some general facts (see [9, 9.5/9, 9.6/1]) concerning the relationship between the closed fiber of a regular proper model X of a smooth geometrically connected curve X_η and the component group Φ of (the Néron model of) the Jacobian of X_η, with the base equal to the spectrum of a discrete valuation ring R with algebraically closed residue field. If $\{X_i\}_{i\in I}$ is the set of irreducible components in the closed fiber of X, then we can form a complex

$$\mathbf{Z}^I \xrightarrow{\alpha} \mathbf{Z}^I \xrightarrow{\beta} \mathbf{Z}$$

where $\mathbf{Z}^I$ is the free group on the X_i's, the map α is defined by the intersection matrix $(X_i.X_j)$, and β sends each standard basis vector to the multiplicity of the corresponding component in the closed fiber. The cokernel $\ker(\beta)/\mathrm{im}(\alpha)$

is naturally identified with the component group Φ via the map $\mathrm{Pic}(X) \to \mathbf{Z}^I$ that assigns to each invertible sheaf $\mathcal{L}$ its tuple of partial degrees $\deg_{X_i}(\mathcal{L})$.

By using [9, 9.1/5] to compute such line-bundle degrees, one finds that the Néron-model integral point associated to the pullback divisor in (5.2.2) has reduction whose image in $\Phi(\mathcal{J}_H(p)_{/\overline{\mathbf{F}}_p})$ is represented by

$$\frac{[\mathbf{Q}(P):\mathbf{Q}]}{\mathrm{mult}(\overline{C})}\cdot\overline{C} - \sum_{i=1}^{(p-1)/2|H|}\overline{C}' = \overline{C} - \frac{p-1}{2|H|}\cdot\overline{C}' \tag{5.2.3}$$

when this component group is computed by using the regular model $X_H(p)'$ that we have found for $p \equiv -1 \bmod 12$ (the same calculation will work for all other p's, as we shall see).

The important property emerging from this calculation is that one of the coefficients in (5.2.3) is ±1, so an element in $\ker(\beta)$ that is a $\mathbf{Z}$-linear combination of $\overline{C}$ and $\overline{C}'$ *must* be a multiple of (5.2.3) and hence is in the image of $\Phi(\mathcal{J}_0(p))$ under the Picard map. Thus, to prove that the component group for $J_0(p)$ surjects onto the component group for $J_H(p)$, it suffices to check that any element in $\ker(\beta)$ can be modified modulo $\mathrm{im}(\alpha)$ to lie in the $\mathbf{Z}$-span of $\overline{C}$ and $\overline{C}'$.

Since the matrix for α is the intersection matrix, it suffices (and is even necessary) to check that the submatrix $M_{\overline{C},\overline{C}'}$ of the intersection matrix given by the rows labelled by the irreducible components other than $\overline{C}$ and $\overline{C}'$ is a *surjective* matrix over $\mathbf{Z}$. Indeed, such surjectivity ensures that we can always subtract a suitable element of $\mathrm{im}(\alpha)$ from any element of $\ker\beta$ to kill coefficients away from $\overline{C}$ and $\overline{C}'$ in a representative for an element in $\Phi \simeq \ker(\beta)/\mathrm{im}(\alpha)$. The surjectivity assertion over $\mathbf{Z}$ amounts to requiring that the matrix $M_{\overline{C},\overline{C}'}$ have top-degree minors with gcd equal to 1. It is enough to check that those minors that avoid the column coming from $\overline{C}'$ have gcd equal to 1. Thus, it is enough to check that in Figure 3 the matrix of rows beneath the top row has top-degree minors with gcd equal to 1. This is clear in both cases. In particular, this calculation (especially the analysis of (5.2.3)) yields the following result when $p \equiv -1 \bmod 12$:

Corollary 5.2.2. *Let $\rho = (p-1)/2|H|$. The degree-0 divisor $\overline{C} - \rho\overline{C}'$ represents a generator of the mod-p component group of $J_H(p)$.*

The other cases $p \equiv 1, \pm 5 \bmod 12$ will behave similarly, with Corollary 5.2.2 being true for all such p. The only differences in the arguments are that cases with $|H|$ divisible by 2 or 3 can arise and we will sometimes have to use the "one branch" version of Jung–Hirzebruch resolution to resolve non-regular ordinary points.

5.3 The case $p \equiv 1 \bmod 12$.

We have $p = 12k + 1$ with $k \geq 1$, so $(p-1)/2 = 6k$. In this case 0 and 1728 are both ordinary j-invariants, so the number of supersingular points is

$(p-1)/12 = k$ by the Deuring Mass Formula. The minimal regular resolution $X_H(p)'$ of $X_H(p)$ is illustrated in Figure 4, depending on the congruence class of $h = |H|$ modulo 6. When h is divisible by 6 there are no non-regular points, so $X_H(p)' = X_H(p)_{/W}$ is as in Figure 4(a). When h is even but not divisible by 3 there is only the non-regularity at $j = 0$ to be resolved, as shown in Figures 4(b),(c). The case of odd h is given in Figures 4(d)–(f), and these are all easy applications of Theorem 2.4.1 and Corollary 2.4.3. We illustrate by working out the case $h \equiv 5 \bmod 6$, for which there are two ordinary singularities to resolve.

Arguing much as in the case $p \equiv -1 \bmod 12$, but now with a "one branch" situation at ordinary points, the ring to be resolved is formally isomorphic to the ring of invariants in $W[\![x', t']\!]/(x'^{(p-1)/2|H|} - p)$ under an action of the cyclic $\mathrm{Aut}(z)/\{\pm 1\}$ with a tangent-space action of $\chi^{|H|} \oplus \chi$ for a faithful character χ. At a point with $j = 1728$ we have quadratic χ, $n = 2$, $r = 1$. Using the "one branch" version of Theorem 2.4.1 yields the exceptional divisor D' as illustrated in Figure 4(f), transverse to $\overline{C}$ with self-intersection -2 and multiplicity $\rho/2$. At a point with $j = 0$ we have a cubic χ, so $n = 3$. Since $h \equiv 2 \bmod 3$ when $h \equiv 5 \bmod 6$, we have $r = 2$. Since $3/2 = 2 - 1/2$, we get exceptional divisors E'_1 and E'_2 with transverse intersections as shown and self-intersections of -2. The "outer" component E'_1 has multiplicity $\rho/3$ and the "inner" component E'_2 has multiplicity $2\rho/3$. Once again we will suppress the calculation of $\overline{C}'.\overline{C}'$ since it is not needed.

We now proceed to analyze the component group for each value of $h \bmod 6$. Since $\overline{C}'$ has multiplicity 1 in the closed fiber, we can carry out the same strategy that was used for $p \equiv -1 \bmod 12$, resting on Lemma 5.2.1. When $h \equiv 0 \bmod 6$, there are only the components $\overline{C}$ and $\overline{C}'$ in the closed fiber of $X_H(p)' = X_H(p)$, with $\overline{C}.\overline{C} = -h/6$. Thus, the component group has the expected order $|H|/6$ and since there are no additional components we are done in this case.

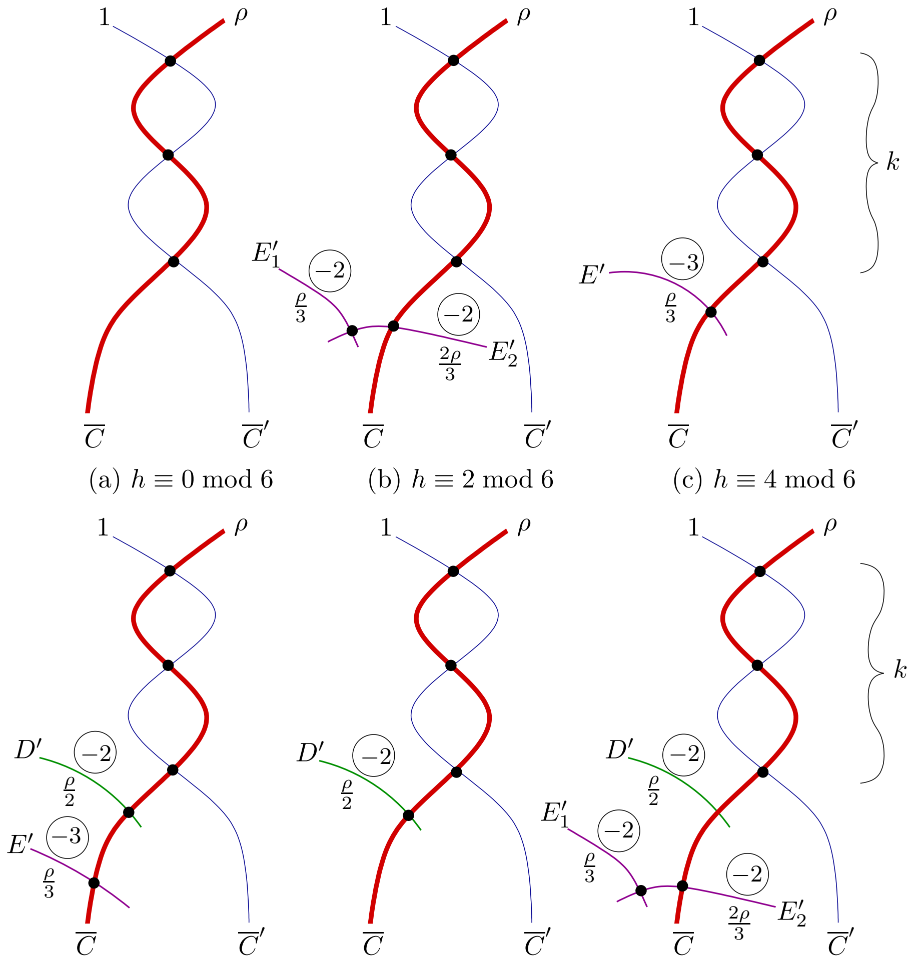
If $h \equiv 1 \bmod 6$, one finds that the submatrix of the intersection matrix corresponding to the ordered set $\{\overline{C}, D', E'\}$ is

$$\begin{pmatrix} -(h+5)/6 & 1 & 1 \\ 1 & -2 & 0 \\ 1 & 0 & -3 \end{pmatrix}$$

with absolute determinant $h = |H|/\gcd(|H|, 6)$ as desired, and the bottom two rows have 2×2 minors with gcd equal to 1. Moreover, in the special case $h = 1$ we see that $\overline{C}$ is a -1-curve, and after contracting this we contract D' and E' in turn, leaving us with only the component $\overline{C}'$. This proves Theorem 1.1.2 for $p \equiv 1 \bmod 12$.

For $h \equiv 2 \bmod 6$, the submatrix indexed by $\{\overline{C}, E'_1, E'_2\}$ is

$$\begin{pmatrix} -(h+4)/6 & 0 & 1 \\ 0 & -2 & 1 \\ 1 & 1 & -2 \end{pmatrix}$$



(a) $h \equiv 0 \bmod 6$

(b) $h \equiv 2 \bmod 6$

(c) $h \equiv 4 \bmod 6$

(d) $h \equiv 1 \bmod 6$

(e) $h \equiv 3 \bmod 6$

(f) $h \equiv 5 \bmod 6$

Figure 4: Minimal regular resolution $X_H(p)'$, $p = 12k + 1$, $k \geq 1$, $h = |H|$, $\rho = (p-1)/2h$

with absolute determinant $h/2 = |H|/\gcd(|H|, 6)$, and the bottom two rows have 2×2 minors with gcd equal to 1. The cases $h \equiv 3, 4 \bmod 6$ are even easier, since there are just two components to deal with, $\{\overline{C}, D'\}$ and $\{\overline{C}, E'\}$ with corresponding matrices

$$\begin{pmatrix} -(h+3)/6 & 1 \\ 1 & -2 \end{pmatrix}, \qquad \begin{pmatrix} -(h+2)/6 & 1 \\ 1 & -3 \end{pmatrix}$$

that yield the expected results.

For the final case $h \equiv -1 \bmod 6$, the submatrix indexed by the ordered set of components $\{\overline{C}, D', E'_1, E'_2\}$ is

$$\begin{pmatrix} -(h+7)/6 & 1 & 0 & 1 \\ 1 & -2 & 0 & 0 \\ 0 & 0 & -2 & 1 \\ 1 & 0 & 1 & -2 \end{pmatrix}$$

with absolute determinant $h = |H|/\gcd(|H|, 6)$ and gcd 1 for the 3×3 minors along the bottom three rows. The case $p \equiv 1 \bmod 12$ is now settled.

5.4 The cases $p \equiv \pm 5 \bmod 12$

With $p = 12k + 5$ for $k \geq 0$, we have $(p-1)/2 = 6k + 2$, so $h = |H|$ is not divisible by 3. Thus, the supersingular $j = 0$ is always non-regular and the ordinary $j = 1728$ is non-regular for even h.

Using Theorem 2.4.1 and Corollary 2.4.3, we obtain a minimal regular resolution depending on the possibilities for $h \bmod 6$ not divisible by 3, as given in Figure 5.

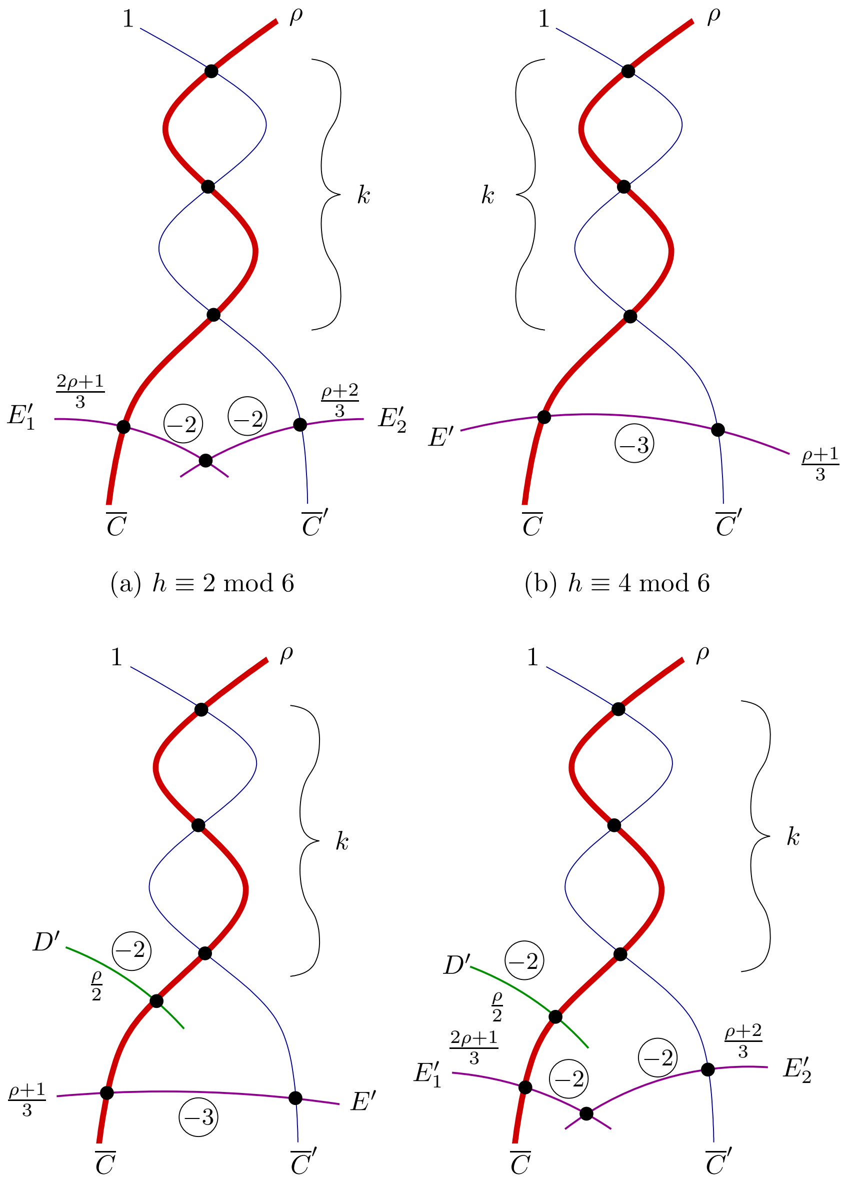
From Figure 5 one easily carries out the computations of the absolute determinant and the gcd of minors from the intersection matrix, just as we have done in earlier cases, and in all cases one gets $|H|/\gcd(|H|, 6)$ for the absolute determinant and the gcd of the relevant minors is 1. Also, the case $h = 1$ has $\overline{C}$ as a -1-curve, and successive contractions end at an integral closed fiber, so we have established Theorems 1.1.2 and 1.1.6 for the case $p \equiv 5 \bmod 12$.

When $p = 12k - 5$ with $k \geq 1$, so $(p-1)/2 = 6k - 3$ is odd, we have that $h = |H|$ is odd. Thus, $j = 1728$ does give rise to a non-regular point, but the behavior at $j = 0$ depends on $h \bmod 6$. The usual applications of Jung–Hirzebruch resolution go through, and the minimal resolution has closed-fiber diagram as in Figure 6, depending on odd $h \bmod 6$, and both Theorem 1.1.2 and Theorem 1.1.6 drop out just as in the preceding cases.

6 The Arithmetic of $J_1(p)$

Our theoretical results concerning component groups inspired us to carry out some arithmetic computations in $J_1(p)$, and this section summarizes this work.

In Section 6.1 we recall the Birch and Swinnerton-Dyer conjecture, as this motivates many of our computations, and then we describe some of the theory



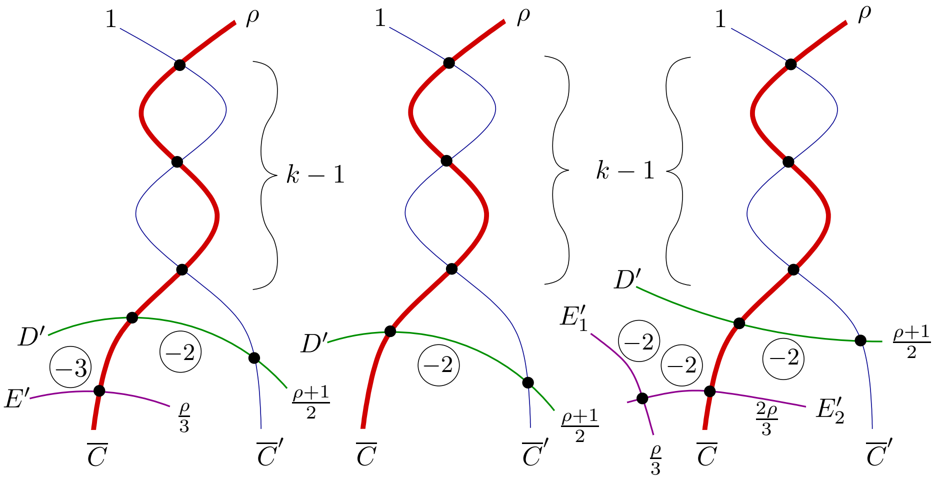
(a) $h \equiv 2 \bmod 6$

(b) $h \equiv 4 \bmod 6$

(c) $h \equiv 1 \bmod 6$

(d) $h \equiv -1 \bmod 6$

Figure 5: Minimal regular resolution $X_H(p)'$, $p = 12k + 5$, $k \geq 0$, $h = |H|$, $\rho = (p-1)/2h$



(a) $h \equiv 1 \bmod 6$ (b) $h \equiv 3 \bmod 6$ (c) $h \equiv 5 \bmod 6$

Figure 6: Minimal regular resolution $X_H(p)'$, $p = 12k-5$, $k \geq 1$, $h = |H|$, $\rho = (p-1)/2h$

behind the computations that went into computing the tables of Section 6.6. In Section 6.2 we find all p such that $J_1(p)$ has rank 0. We next discuss tables of certain arithmetic invariants of $J_1(p)$ and we give a conjectural formula for $|J_1(p)(\mathbf{Q})_{\mathrm{tor}}|$, along with some evidence. In Section 6.3 we investigate Jacobians of intermediate curves $J_H(p)$ associated to subgroups of $(\mathbf{Z}/p\mathbf{Z})^\times$, and in Section 6.4 we consider optimal quotients A_f of $J_1(p)$ attached to newforms. In Section 6.4.1 we describe the lowest-level modular abelian variety that (assuming the Birch and Swinnerton-Dyer conjecture) should have infinite Mordell-Weil group but to which the general theorems of Kato, Kolyvagin, *et al.*, do not apply.

6.1 Computational methodology

We used the third author's modular symbols package for our computations; this package is part of [10] V2.10-6. See Section 6.5 for a description of how to use Magma to compute the tables. For the general theory of computing with modular symbols, see [14] and [63].

Remark 6.1.1. Many of the results of this section assume that a Magma program running on a computer executed correctly. Magma is complicated software that runs on physical hardware that is subject to errors from both programming mistakes and physical processes, such as cosmic radiation. We thus make the running *assumption* for the rest of this section that the computations below were performed correctly. To decrease the chance of hardware errors such as the famous Pentium bug (see [17]), we computed the tables in

Section 6.6 on three separate computers with different CPU architectures (an AMD Athlon 2000MP, a Sun Fire V480 which was donated to the third author by Sun Microsystems, and an Intel Pentium 4-M laptop).

Let A be a modular abelian variety over $\mathbf{Q}$, *i.e.*, a quotient of $J_1(N)$ for some N. We will make frequent reference to the following special case of the general conjectures of Birch and Swinnerton-Dyer:

CONJECTURE 6.1.2 (BSD CONJECTURE). *Let* $Ш(A)$ *be the Shafarevich-Tate group of* A*, let* $c_p = |\Phi_{A,p}(\mathbf{F}_p)|$ *be the Tamagawa number at* p *for* A*, and let* Ω_A *be the volume of* $A(\mathbf{R})$ *with respect to a generator of the invertible sheaf of top-degree relative differentials on the Néron model* $A_{/\mathbf{Z}}$ *of* A *over* $\mathbf{Z}$*. Let* $A^\vee$ *denote the abelian variety dual of* A*. The group* $Ш(A)$ *is finite and*

$$\frac{L(A,1)}{\Omega_A} = \frac{|Ш(A)| \cdot \prod_{p|N} c_p}{|A(\mathbf{Q})| \cdot |A^\vee(\mathbf{Q})|},$$

where we interpret the right side as 0 *in case* $A(\mathbf{Q})$ *is infinite.*

Remark 6.1.3. The hypothesis that A is modular implies that $L(A,s)$ has an analytic continuation to the whole complex plane and a functional equation of a standard type. In particular, $L(A,1)$ makes sense. Also, when $L(A,1) \neq 0$, [32, Cor. 14.3] implies that $Ш(A)$ is finite.

Let $\{f_1,\ldots,f_n\}$ be a set of newforms in $S_2(\Gamma_1(N))$ that is $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$-stable. Let I be the Hecke-algebra annihilator of the subspace generated by $f_1,\ldots,f_n$. *For the rest of Section* 6.1*, we assume that* $A = A_I = J_1(N)/IJ_1(N)$ *for such an* I. Note that A is an *optimal quotient* in the sense that $IJ_1(N) = \ker(J_1(N) \to A)$ is an abelian subvariety of $J_1(N)$.

6.1.1 BOUNDING THE TORSION SUBGROUP

To obtain a multiple of the order of the torsion subgroup $A(\mathbf{Q})_{\mathrm{tor}}$, we proceed as follows. For any prime $\ell \nmid N$, the algorithm of [3, §3.5] computes the characteristic polynomial $f \in \mathbf{Z}[X]$ of Frob_ℓ acting on any p-adic Tate module of A with $p \neq \ell$. To compute $|A(\mathbf{F}_\ell)|$, we observe that

$$|A(\mathbf{F}_\ell)| = \deg(\mathrm{Frob}_\ell - 1) = \det(\mathrm{Frob}_\ell - 1),$$

and this is the value of the characteristic polynomial of Frob_ℓ at 1. For any prime $\ell \nmid 2N$, the reduction map $A(\mathbf{Q})_{\mathrm{tor}} \to A(\mathbf{F}_\ell)$ is injective, so $|A(\mathbf{Q})_{\mathrm{tor}}|$ divides

$$T = \gcd\{|A(\mathbf{F}_\ell)| : \ \ell < 60 \text{ and } \ell \nmid 2N\}.$$

(If N is divisible by all primes up to 60, let $T = 0$. In all of the examples in this paper, N is prime and so $T \neq 0$.) The injectivity of reduction mod ℓ on the finite group $A(\mathbf{Q})_{\mathrm{tor}}$ for any prime $\ell \neq 2$ is well known and follows from the determination of the torsion in a formal group (see, *e.g.*, the appendix to [33] and [59, §IV.6–9]).

The cardinality $|A(\mathbf{F}_\ell)|$ does not change if A is replaced by a $\mathbf{Q}$-isogenous abelian variety B, so we do not expect in general that $|A(\mathbf{Q})_{\mathrm{tor}}| = T$. (For much more on relationships between $|A(\mathbf{Q})_{\mathrm{tor}}|$ and T, see [33, p. 499].) When we refer to an upper bound on torsion, T is the (multiplicative) upper bound that we have in mind.

The number 60 has no special significance; we had to make some choice to do computations, and in practice the sequence of partial gcd's rapidly stabilizes. For example, if $A = J_1(37)$, then the sequence of partial gcd's is:

$$15249085236272475, 802583433488025, 160516686697605, \ldots$$

where the term 160516686697605 repeats for all $\ell < 1000$.

6.1.2 The Manin index

Let p be a prime, let $\Omega_{A/\mathbf{Z}}$ denote the sheaf of relative 1-forms on the Néron model of A over $\mathbf{Z}$, and let I be the annihilator of A in the Hecke algebra $\mathbf{T} \subset \mathrm{End}(J_1(N))$. For a subring $R \subset \mathbf{C}$, let $S_2(\Gamma_1(N), R)$ be the R-module of cusp forms whose Fourier expansion at ∞ lies in $R[\![q]\!]$. The natural surjective Hecke-equivariant morphism $J_1(N) \to J_1(N)/IJ_1(N) = A$ induces (by pullback) a Hecke-equivariant injection $\Psi_A : \mathrm{H}^0(A_{/\mathbf{Z}}, \Omega_{A/\mathbf{Z}}) \hookrightarrow S_2(\Gamma_1(N), \mathbf{Q})$ whose image lies in $S_2(\Gamma_1(N), \mathbf{Q})[I]$. (Here we identify $S_2(\Gamma_1(N), \mathbf{Q})$ with $\mathrm{H}^0(X_1(N), \Omega_{X_1(N)/\mathbf{Q}}) = \mathrm{H}^0(J_1(N), \Omega_{J_1(N)/\mathbf{Q}})$ in the usual manner.)

Definition 6.1.4 (Manin index). The *Manin index of A* is

$$c = [S_2(\Gamma_1(N), \mathbf{Z})[I] : \Psi_A(\mathrm{H}^0(A_{/\mathbf{Z}}, \Omega_{A/\mathbf{Z}}))] \in \mathbf{Q}.$$

Remark 6.1.5. We name c after Manin, since he first studied c, but only in the context of elliptic curves. When $X_0(N) \to A$ is an optimal elliptic-curve quotient attached to a newform f, the usual Manin constant of A is the rational number c such that $\pi^*(\omega_A) = \pm c \cdot f \mathrm{d}q/q$, where ω_A is a basis for the differentials on the Néron model of A. The usual Manin constant equals the Manin index, since $S_2(\Gamma_1(N), \mathbf{Z})[I]$ is generated as a $\mathbf{Z}$-module by f.

A priori, the index in Definition 6.1.4 is only a generalized lattice index in the sense of [12, Ch. 1, §3], which we interpret as follows. In [12], for any Dedekind domain R, the *lattice index* is defined for any two finite free R-modules V and W of the same rank ρ that are embedded in a ρ-dimensional $\mathrm{Frac}(R)$-vector space U. The lattice index is the fractional R-ideal generated by the determinant of any automorphism of U that sends V isomorphically onto W. In Definition 6.1.4, we take $R = \mathbf{Z}$, $U = S_2(\Gamma_1(N), \mathbf{Q})[I]$, $V = S_2(\Gamma_1(N), \mathbf{Z})[I]$, and $W = \Psi_A(\mathrm{H}^0(A_{/\mathbf{Z}}, \Omega_{A/\mathbf{Z}}))$. Thus, c is the absolute value of the determinant of any linear transformation of $S_2(\Gamma_1(N), \mathbf{Q})[I]$ that sends $S_2(\Gamma_1(N), \mathbf{Z})[I]$ onto $\Psi_A(\mathrm{H}^0(A_{/\mathbf{Z}}, \Omega_{A/\mathbf{Z}}))$. In fact, it is not necessary to consider lattice indexes, as the following lemma shows (note we will use lattices indices later in the statement of Proposition 6.1.10).

Lemma 6.1.6. *The Manin index c of A is an integer.*

Proof. Let $X_\mu(N)$ be the coarse moduli scheme over $\mathbf{Z}$ that classifies isomorphism classes of pairs $(E/S, \alpha)$, with $\alpha : \mu_N \hookrightarrow E^{\mathrm{sm}}$ a closed subgroup in the smooth locus of a generalized elliptic curve E with irreducible geometric fibers E_s. This is a smooth $\mathbf{Z}$-curve that is not proper, and it is readily constructed by combining the work of Katz-Mazur and Deligne-Rapoport (see §9.3 and §12.3 of [16]). There is a canonical $\mathbf{Z}$-point $\infty \in X_\mu(N)(\mathbf{Z})$ defined by the standard 1-gon equipped with the canonical embedding of μ_N into the smooth locus $\mathbf{G}_m$, and the theory of the Tate curve provides a canonical isomorphism between $\mathrm{Spf}(\mathbf{Z}[\![q]\!])$ and the formal completion of $X_\mu(N)$ along ∞.

There is an isomorphism between the smooth proper curves $X_1(N)$ and $X_\mu(N)$ over $\mathbf{Z}[1/N]$ because the open modular curves $Y_1(N)$ and $Y_\mu(N)$ coarsely represent moduli problems that may be identified over the category of $\mathbf{Z}[1/N]$-schemes via the map

$$(E, P) \mapsto (E/\langle P\rangle, E[N]/\langle P\rangle),$$

where $E[N]/\langle P\rangle$ is identified with μ_N via the Weil pairing on $E[N]$. For our purposes, the key point (which follows readily from Tate's theory) is that under the moduli-theoretic identification of the analytification of the $\mathbf{C}$-fiber of $X_\mu(N)$ with the analytic modular curve $X_1(N)$ via the trivialization of $\mu_N(\mathbf{C})$ by means of $\zeta_N = e^{\pm 2\pi\sqrt{-1}/N}$, the formal parameter q at the $\mathbf{C}$-point ∞ computes the standard analytic q-expansion for weight-2 cusp forms on $\Gamma_1(N)$. The reason we consider $X_\mu(N)$ rather than $X_1(N)$ is simply because we want a smooth $\mathbf{Z}$-model in which the analytic cusp ∞ descends to a $\mathbf{Z}$-point.

Let $\phi : J_1(N) \to A$ be the Albanese quotient map over $\mathbf{Q}$, and pass to Néron models over $\mathbf{Z}$ (without changing the notation). Since $X_\mu(N)$ is $\mathbf{Z}$-smooth, there is a morphism $X_\mu(N) \to J_1(N)$ over $\mathbf{Z}$ that extends the usual morphism sending ∞ to 0. We have a map $\Psi : \mathrm{H}^0(A, \Omega) \to \mathbf{Z}[\![q]\!]\mathrm{d}q/q$ of $\mathbf{Z}$-modules defined by composition

$$\mathrm{H}^0(A, \Omega) \to \mathrm{H}^0(J_1(N), \Omega) \to \mathrm{H}^0(X_\mu(N), \Omega) \xrightarrow{q-\exp} \mathbf{Z}[\![q]\!]\frac{\mathrm{d}q}{q}.$$

The map Ψ is injective, since it is injective after base extension to $\mathbf{Q}$ and each group above is torsion free. The image of Ψ in $\mathbf{Z}[\![q]\!]\mathrm{d}q/q$ is a finite free $\mathbf{Z}$-module, contained in the image of $S = S_2(\Gamma_1(N), \mathbf{Z})$, the sub-$\mathbf{Z}$-module of $S_2(\Gamma_1(N), \mathbf{C})$ of those elements whose analytic q-expansion at ∞ has coefficients in $\mathbf{Z}$. Since Ψ respects the action of Hecke operators, the image of Ψ is contained in $S[I]$, so the lattice index c is an integer. □

We make the following conjecture:

Conjecture 6.1.7. *If $A = A_f$ is a quotient of $J_1(N)$ attached to a single Galois-conjugacy class of newforms, then $c = 1$.*

Manin made this conjecture for one-dimensional optimal quotients of $J_0(N)$. Mazur bounded c in some cases in [46], Stevens considered c for one-dimensional quotients of $J_1(N)$ in [65], González and Lario considered c for $\mathbf{Q}$-curves in [26], Agashe and Stein considered c for quotients of $J_0(N)$ of dimension bigger than 1 in [4], and Edixhoven proved integrality results in [19, Prop. 2] and [22, §2].

Remark 6.1.8. We only make Conjecture 6.1.7 when A is attached to a *single* Galois-conjugacy class of newforms, since the more general conjecture is false. Adam Joyce [31] has recently used failure of multiplicity one for $J_0(p)$ to produce examples of optimal quotients A of $J_1(p)$, for $p = 431$, 503, and 2089, whose Manin indices are divisible by 2. Here, A is isogenous to a product of two elliptic curves, so A is not attached to a single Galois-orbit of newforms.

Remark 6.1.9. The question of whether or not c is an isogeny-invariant is not meaningful in the context of this paper because we only define the Manin index for optimal quotients.

6.1.3 Computing L-ratios

There is a formula for $L(A_f,1)/\Omega_{A_f}$ in [3, §4.2] when A_f is an optimal quotient of $J_0(N)$ attached to a single Galois conjugacy class of newforms. In this section we describe that formula; it applies to our quotient A of $J_1(N)$.

Recall our running hypothesis that $A = A_I$ is an optimal (new) quotient of $J_1(N)$ attached to a Galois conjugacy class of newforms $\{f_1, \ldots, f_n\}$. Let

$$\Psi : \mathrm{H}_1(X_1(N), \mathbf{Q}) \to \mathrm{Hom}(S_2(\Gamma_1(N))[I], \mathbf{C})$$

be the linear map that sends a rational homology class γ to the functional $\int_\gamma$ on the subspace $S_2(\Gamma_1(N))[I]$ in the space of holomorphic 1-forms on $X_1(N)$.

Let $\mathbf{T} \subset \mathrm{End}(\mathrm{H}_1(X_1(N), \mathbf{Q}))$ be the ring generated by all Hecke operators. Since the $\mathbf{T}$-module $H = \mathrm{Hom}(S_2(\Gamma_1(N))[I], \mathbf{C})$ has a natural $\mathbf{R}$-structure (and even a natural $\mathbf{Q}$-structure), it admits a natural $\mathbf{T}$-linear and $\mathbf{C}$-semilinear action by complex conjugation. If M is a $\mathbf{T}$-submodule of H, let M^+ denote the $\mathbf{T}$-submodule of M fixed by complex conjugation.

Let c be the Manin index of A as in Section 6.1.2, let c_∞ be the number of connected components of $A(\mathbf{R})$, let Ω_A be the volume of $A(\mathbf{R})$ as in Conjecture 6.1.2, and let $\{0, \infty\} \in \mathrm{H}_1(X_1(N), \mathbf{Q})$ be the rational homology class whose integration functional is integration from 0 to $i\infty$ along the i-axis (for the precise definition of $\{0, \infty\}$ and a proof that it lies in the rational homology see [38, Ch. IV §1–2]).

Proposition 6.1.10. *Let $A = A_I$ be an optimal quotient of $J_1(N)$ attached to a Galois-stable collection of newforms. With notation as above, we have*

$$c_\infty \cdot c \cdot \frac{L(A,1)}{\Omega_A} = [\Psi(\mathrm{H}_1(X_1(N), \mathbf{Z}))^+ : \Psi(\mathbf{T}\{0, \infty\})], \tag{6.1.1}$$

where the index is a lattice index as discussed in Section 6.1.7 (*in particular, $L(A,1) = 0$ if and only if $\Psi(\mathbf{T}\{0,\infty\})$ has smaller rank than $\mathrm{H}_1(X_1(N), \mathbf{Z})^+$*).

Proof. It is straightforward to adapt the argument of [3, §4.2] with $J_0(N)$ replaced by $J_1(N)$ (or even $J_H(N)$), but one must be careful when replacing A_f with A. The key observation is that if $f_1, \ldots, f_n$ is the unique basis of normalized newforms corresponding to A, then $L(A, s) = L(f_1, s) \cdots L(f_n, s)$. □

Remark 6.1.11. This equality (6.1.1) need not hold if oldforms are involved, even in the $\Gamma_0(N)$ case. For example, if $A = J_0(22)$, then $L(A, s) = L(J_0(11), s)^2$, but two copies of the newform corresponding to $J_0(11)$ do not form a basis for $S_2(\Gamma_0(22))$.

We finish this section with some brief remarks on how to compute the rational number $c \cdot L(A, 1)/\Omega_A$ using (6.1.1) and a computer. Using modular symbols, one can explicitly compute with $\mathrm{H}_1(X_1(N), \mathbf{Z})$. Though the above lattice index involves two lattices in a complex vector space, the index is unchanged if we replace Ψ with any linear map to a $\mathbf{Q}$-vector space such that the kernel is unchanged (see [3, §4.2]). Such a map may be computed via standard linear algebra by finding a basis for $\mathrm{Hom}(\mathrm{H}_1(X_1(N), \mathbf{Q}), \mathbf{Q})[I]$.

To compute c_∞, use the following well-known proposition; we include a proof for lack of an adequate published reference.

Proposition 6.1.12. *For an abelian variety A over $\mathbf{R}$,*

$$c_\infty = 2^{\dim_{\mathbf{F}_2} A[2](\mathbf{R}) - d},$$

where $d = \dim A$ and $c_\infty := |A(\mathbf{R})/A^0(\mathbf{R})|$.

Proof. Let $\Lambda = \mathrm{H}_1(A(\mathbf{C}), \mathbf{Z})$, so the exponential uniformization of $A(\mathbf{C})$ provides a short exact sequence

$$0 \to \Lambda \to \mathrm{Lie}(A(\mathbf{C})) \to A(\mathbf{C}) \to 0.$$

There is an evident action of $\mathrm{Gal}(\mathbf{C}/\mathbf{R})$ on all terms via the action on $A(\mathbf{C})$, and this short exact sequence is Galois-equivariant because A is defined over $\mathbf{R}$. Let Λ^+ be the subgroup of Galois-invariants in Λ, so we get an exact cohomology sequence

$$0 \to \Lambda^+ \to \mathrm{Lie}(A(\mathbf{R})) \to A(\mathbf{R}) \to \mathrm{H}^1(\mathrm{Gal}(\mathbf{C}/\mathbf{R}), \Lambda) \to 0$$

because higher group cohomology for a finite group vanishes on a $\mathbf{Q}$-vector space (such as the Lie algebra of $A(\mathbf{C})$). The map $\mathrm{Lie}(A(\mathbf{R})) \to A(\mathbf{R})$ is the exponential map for $A(\mathbf{R})$, and so its image is $A(\mathbf{R})^0$. Thus, Λ^+ has $\mathbf{Z}$-rank equal to $\dim A$ and

$$A(\mathbf{R})/A(\mathbf{R})^0 \simeq \mathrm{H}^1(\mathrm{Gal}(\mathbf{C}/\mathbf{R}), \Lambda).$$

To compute the size of this H^1, consider the short exact sequence

$$0 \to \Lambda \overset{2}{\to} \Lambda \to \Lambda/2\Lambda \to 0$$

of Galois-modules. Since $\Lambda/n\Lambda \simeq A[n](\mathbf{C})$ as Galois-modules for any $n \neq 0$, the long-exact cohomology sequence gives an isomorphism

$$A[2](\mathbf{R})/(\Lambda^+/2\Lambda^+) \simeq \mathrm{H}^1(\mathrm{Gal}(\mathbf{C}/\mathbf{R}), \Lambda).$$

□

Remark 6.1.13. Since the canonical isomorphism

$$A[n](\mathbf{C}) \simeq \mathrm{H}_1(A(\mathbf{C}), \mathbf{Z})/n\mathrm{H}_1(A(\mathbf{C}), \mathbf{Z})$$

is $\mathrm{Gal}(\mathbf{C}/\mathbf{R})$-equivariant, we can identify $A[2](\mathbf{R})$ with the kernel of $\overline{\tau} - 1$ where $\overline{\tau}$ is the mod-2 reduction of the involution on $\mathrm{H}_1(A(\mathbf{C}), \mathbf{Z})$ induced by the action τ of complex conjugation on $A(\mathbf{C})$. In the special case when A is a quotient of some $J_1(N)$, and we choose a connected component of $\mathbf{C} - \mathbf{R}$ to uniformize $Y_1(N)$ in the usual manner, then via the $\mathrm{Gal}(\mathbf{C}/\mathbf{R})$-equivariant isomorphism $\mathrm{H}_1(J_1(N)(\mathbf{C}), \mathbf{Z}) \simeq \mathrm{H}_1(X_1(N)(\mathbf{C}), \mathbf{Z})$ we see that $\mathrm{H}_1(A(\mathbf{C}), \mathbf{Z})$ may be computed by modular symbols and that the action of τ on the modular symbol is $\{\alpha, \beta\} \mapsto \{-\alpha, -\beta\}$. This makes $A[2](\mathbf{R})$, and hence c_∞, readily computable via modular symbols.

6.2 Arithmetic of $J_1(p)$

6.2.1 The Tables

For $p \leq 71$, the first part of Table 1 (on page 393) lists the dimension of $J_1(p)$ and the rational number $L = c \cdot L(J_1(p), 1)/\Omega_{J_1(p)}$. Table 1 also gives an upper bound T (in the sense of divisibility) on $|J_1(p)(\mathbf{Q})_{\mathrm{tor}}|$ for $p \leq 71$, as discussed in §6.1.1.

When $L \neq 0$, Conjecture 6.1.2 and the assumption that $c = 1$ imply that the numerator of L divides $c_p \cdot |Ш(A)|$, that in turn divides T^2L. For every $p \neq 29$ with $p \leq 71$, we found that $T^2L = 1$. For $p = 29$, we have $T^2L = 2^{12}$; it would be interesting if the isogeny-invariant T overestimates the order of $J_1(29)(\mathbf{Q})_{\mathrm{tor}}$ or if $Ш(J_1(29))$ is nontrivial.

6.2.2 Determination of positive rank

Proposition 6.2.1. *The primes p such that $J_1(p)$ has positive rank are the same as the primes for which $J_0(p)$ has positive rank:*

$$p = 37, 43, 53, 61, 67, \textit{ and all } p \geq 73.$$

Proof. Proposition 2.8 of [45, §III.2.2, p. 147] says: "Suppose $g^+ > 0$ (which is the case for all $N > 73$, as well as $N = 37, 43, 53, 61, 67$). Then the Mordell-Weil group of J_+ is a torsion-free group of infinite order (*i.e.* of positive rank)." Here, N is a prime, g^+ is the genus of the Atkin-Lehner quotient $X_0(N)^+$ of $X_0(N)$, and J_+ is isogenous to the Jacobian of $X_0(N)^+$. This is essentially correct, except for the minor oversight that $g^+ > 0$ also when $N = 73$ (this is stated correctly on page 34 of [45]).

By Mazur's proposition $J_0(p)$ has positive algebraic rank for all $p \geq 73$ and for $p = 37, 43, 53, 61, 67$. The sign in the functional equation for $L(J_+, s)$ is -1, so

$$L(J, 1) = L(J_+, 1)L(J_-, 1) = 0 \cdot L(J_-, 1) = 0$$

for all p such that $g^+ > 0$. Using (6.1.1) we see that $L(J, 1) \neq 0$ for all p such that $g^+ = 0$, which by Kato (see [32, Cor. 14.3]) or Kolyvagin–Logachev (see [36]) implies that J has rank 0 whenever $g^+ = 0$. Thus $L(J_0(p), 1) = 0$ if and only if $J_0(p)$ has positive rank.

Work of Kato (see [32, Cor. 14.3]) implies that if $J_1(p)$ has analytic rank 0, then $J_1(p)$ has algebraic rank 0. It thus suffices to check that $L(J_1(p), 1) \neq 0$ for the primes p such that $J_0(p)$ has rank 0. We verify this by computing $c \cdot L(J_1(p), 1)/\Omega_{J_1(p)}$ using (6.1.1), as illustrated in Table 1.

□

If we instead consider composite level, it is not true that $J_0(N)$ has positive analytic rank if and only if $J_1(N)$ has positive analytic rank. For example, using (6.1.1) we find that $J_0(63)$ has analytic rank 0, but $J_1(63)$ has positive analytic rank. Closer inspection using Magma (see the program below) shows that there is a two-dimensional new quotient A_f with positive analytic rank, where $f = q + (\omega - 1)q^2 + (-\omega - 2)q^3 + \cdots$, and $\omega^3 = 1$. It would be interesting to prove that that the algebraic rank of A_f is positive.

```
> M := ModularSymbols(63,2);
> S := CuspidalSubspace(M);
> LRatio(S,1);        // So J_0(63) has rank 0
1/384

> G<a,b> := DirichletGroup(63,CyclotomicField(6));

> D := NewformDecomposition(S);
> LRatio(D[1],1);
0
> qEigenform(D[1],5);
q + (-2*zeta_6 + 1)*q^2 + (-2*zeta_6 + 1)*q^3 - q^4 + O(q^5)
```

6.2.3 Conjectural order of $J_1(\mathbf{Q})_{\mathrm{tor}}$

For any Dirichlet character ε modulo N, define Bernoulli numbers $B_{2,\varepsilon}$ by

$$\sum_{a=1}^{N} \frac{\varepsilon(a) t e^{at}}{e^{Nt}-1} = \sum_{k=0}^{\infty} \frac{B_{k,\varepsilon}}{k!} t^k.$$

We make the following conjecture.

Conjecture 6.2.2. *Let $p \geq 5$ be prime. The rational torsion subgroup $J_1(p)(\mathbf{Q})_{\mathrm{tor}}$ is generated by the differences of $\mathbf{Q}$-rational cusps on $X_1(p)$. Equivalently* (*see below*), *for any prime $p \geq 5$,*

$$|J_1(p)(\mathbf{Q})_{\mathrm{tor}}| = \frac{p}{2^{p-3}} \cdot \prod_{\varepsilon \neq 1} B_{2,\varepsilon} \tag{6.2.1}$$

where the product is over the nontrivial even Dirichlet characters ε of conductor dividing p.

Due to how we defined $X_1(p)$, its $\mathbf{Q}$-rational cusps are exactly its cusps lying over the cusp $\infty \in X_0(p)(\mathbf{Q})$ (corresponding to the standard 1-gon equipped with the subgroup μ_p in its smooth locus $\mathbf{G}_m$) via the second standard degeneracy map

$$(E, P) \mapsto (E/\langle P\rangle, E[p]/\langle P\rangle).$$

In [49] Ogg showed that $|J_1(13)(\mathbf{Q})| = 19$, verifying Conjecture 6.2.2 for $p = 13$. The results of [37] are also relevant to Conjecture 6.2.2, and suggest that the rational torsion of $J_1(p)$ is cuspidal. Let $C(p)$ be the conjectural order of $J_1(p)(\mathbf{Q})_{\mathrm{tor}}$ on the right side of (6.2.1). In [37, p. 153], Kubert and Lang prove that $C(p)$ is equal to the order of the group generated by the differences of $\mathbf{Q}$-rational cusps on $X_1(p)$ (in their language, these are viewed as the cusps that lie over $0 \in X_0(p)(\mathbf{Q})$ via the first standard degeneracy map

$$(E, P) \mapsto (E, \langle P\rangle)),$$

and so $C(p)$ is *a priori* an integer that moreover divides $|J_1(p)(\mathbf{Q})_{\mathrm{tor}}|$.

Table 1 provides evidence for Conjecture 6.2.2. Let $T(p)$ be the upper bound on $J_1(p)(\mathbf{Q})_{\mathrm{tor}}$ (see Table 1). For all $p \leq 157$, we have $C(p) = T(p)$ except for $p = 29$, 97, 101, 109, and 113, where $T(p)/C(p)$ is 2^6, 17, 2^4, 3^7, and $2^{12} \cdot 3^2$, respectively. Thus Conjecture 6.2.2 is true for $p \leq 157$, except possibly in these five cases, where the deviation is consistent with the possibility that $T(p)$ is a nontrivial multiple of the true order of the torsion subgroup (recall that $T(p)$ is an isogeny-invariant, and so it is not surprising that it may be too large).

6.3 Arithmetic of $J_H(p)$

For each divisor d of $p-1$, let $H = H_d$ denote the unique subgroup of $(\mathbf{Z}/p\mathbf{Z})^\times$ of order $(p-1)/d$. The group of characters whose kernel contains H_d is exactly the group of characters of order dividing d. Since the linear fractional transformation associated to $\left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ acts trivially on the upper half plane, we lose nothing (for the computations that we will do in this section) if we assume that $-1 \in H$, and so $|H|$ is even.

For any subgroup H of $(\mathbf{Z}/p\mathbf{Z})^\times$ as above, let J_H be the Jacobian of $X_H(p)$, as in Section 1. For each $p \leq 71$, Table 2 lists the dimension of $J_H = J_H(p)$, the rational number $L = c \cdot L(J_H, 1)/\Omega_{J_H}$, an upper bound T on $|J_H(\mathbf{Q})_{\mathrm{tor}}|$, the conjectural multiple T^2L of $|\text{Ш}(J_H)| \cdot c_p$, and $c_p = |\Phi(J_H)|$. We compute $|\Phi(J_H)(\mathbf{F}_p)| = |\Phi(J_H)(\overline{\mathbf{F}}_p)|$ using Theorem 1.1.3. Note that Table 2 omits the data for $d = (p-1)/2$, since $J_H = J_1(p)$ for such d, so the corresponding data is therefore already contained in Table 1.

When $L \neq 0$, we have $T^2L = |\Phi(J_H)|$ in all but one case. The exceptional case is $p = 29$ and $d = 7$, where $T^2L = 2^6$, but $|\Phi(J_H)| = 1$; probably T overestimates the torsion in this case. In the following proposition we use this observation to deduce that $|\text{Ш}(J_H)| = c = 1$ in some cases.

Proposition 6.3.1. *Suppose that $p \leq 71$ is a prime and $d \mid (p-1)$ with $(p-1)/d$ even. Let J_H be the Jacobian of $X_H(p)$, where H is the subgroup of $(\mathbf{Z}/p\mathbf{Z})^\times$ of order $(p-1)/d$. Assume that Conjecture* 6.1.2 *is true, and if $p = 29$ then assume that $d \neq 7, 14$. If $L(J_H, 1) \neq 0$, then $|\text{Ш}(J_H)| = 1$ and $c = 1$.*

It is not interesting to remove the condition $p \leq 71$ in the statement of the proposition, since when $p > 71$ the quantity $L(J_H, 1)$ automatically vanishes (see Proposition 6.2.1). It is probably not always the case that $|\text{Ш}(J_H)| = 1$; for example, Conjecture 6.1.2 and the main result of [1] imply that 7^2 divides $|\text{Ш}(J_0(1091))|$.

Proof. We deduce the proposition from Tables 1–3 as follows. Using Conjecture 6.1.2 we have

$$c \cdot |\text{Ш}(J_H)| = c \cdot \frac{L(J_H, 1)}{\Omega_{J_H} \cdot |\Phi(J_H)|} \cdot |J_H(\mathbf{Q})_{\mathrm{tor}}|^2. \tag{6.3.1}$$

Let T denote the torsion bound on $J_H(\mathbf{Q})_{\mathrm{tor}}$ as in Section 6.1.1 and let $L = c \cdot L(J_H, 1)/\Omega_{J_H}$, so the right side of (6.3.1) divides $T^2L/|\Phi(J_H)|$. An inspection of the tables shows that $T^2L/|\Phi(J_H)| = 1$ for J_H satisfying the hypothesis of the proposition (in the excluded cases $p = 29$ and $d = 7, 14$, the quotient equals 2^6 and 2^{12}, respectively). Since $c \in \mathbf{Z}$, we conclude that $c = |\text{Ш}(J_H)| = 1$.

□

Remark 6.3.2. Theorem 1.1.3 is an essential ingredient in the proof of Proposition 6.3.1 because we used Theorem 1.1.3 to compute the Tamagawa factor c_p.

6.4 Arithmetic of newform quotients

Tables 4–5 at the end of this paper contain arithmetic information about each newform abelian variety quotient A_f of $J_1(p)$ with $p \leq 71$.

The first column gives a label determining a Galois-conjugacy class of newforms $\{f, \ldots\}$, where **A** corresponds to the first class, **B** to the second, *etc.*, and the classes are ordered first by dimension and then in lexicographical order by the sequence of nonegative integers $|\operatorname{tr}(a_2(f))|, |\operatorname{tr}(a_3(f))|, |\operatorname{tr}(a_5(f))|, \ldots$. (WARNING: This ordering does not agree with the one used by Cremona in [14]; for example, our **37A** is Cremona's **37B**.) The next two columns list the dimension of A_f and the order of the Nebentypus character of f, respectively. The fourth column lists the rational number $L = L(A_f, 1)/\Omega_{A_f}$, and the fifth lists the product T^2L, where T is an upper bound (as in Section 6.1.1) on the order of $A_f(\mathbf{Q})_{\mathrm{tor}}$. The sixth column, labeled "modular kernel", lists invariants of the group of $\overline{\mathbf{Q}}$-points of the kernel of the polarization $A_f^\vee \hookrightarrow J_1(p) \to A_f$; this kernel is computed by using an algorithm based on Proposition 6.4.1 below. The elementary divisors of the kernel are denoted with notation such as $[2^2 14^2]$ to denote

$$\mathbf{Z}/2\mathbf{Z} \times \mathbf{Z}/2\mathbf{Z} \times \mathbf{Z}/14\mathbf{Z} \times \mathbf{Z}/14\mathbf{Z}.$$

Proposition 6.4.1. *Suppose $A = A_I$ is an optimal quotient of $J = J_1(N)$ attached to the annihilator I of a Galois-stable collection of newforms. The group of $\overline{\mathbf{Q}}$-points of the kernel of the natural map $A^\vee \hookrightarrow J \to A$ is isomorphic to the cokernel of the natural map*

$$\operatorname{Hom}(\mathrm{H}_1(X_1(N), \mathbf{Z}), \mathbf{Z})[I] \to \operatorname{Hom}(\mathrm{H}_1(X_1(N), \mathbf{Z})[I], \mathbf{Z}).$$

Proof. The proof is the same as [35, Prop. 1].

□

It is possible to compute the modular kernel by using the formula in this proposition, together with modular symbols and standard algorithms for computing with finitely generated abelian groups.

We do not give T in Tables 4–5, since in all but six cases $T^2L \neq 0$, hence T^2L and L determine T. The remaining six cases are **37B**, **43A**, **53A**, **61A**, **61B**, and **67C**, and in all these cases $T = 1$.

Remark 6.4.2. If $A = A_f$ is an optimal quotient of $J_1(p)$ attached to a newform, then the tables do not include the toric, additive, and abelian ranks of the closed fiber of the Néron model of A over $\mathbf{F}_p$, since they are easy to determine from other data about A as follows. If $\varepsilon(f) = 1$, then the toric rank is $\dim(A)$, since A is isogenous to an abelian subvariety of $J_0(p)$ and so A has purely toric reduction over $\mathbf{Z}_p$. Now suppose that $\varepsilon(f)$ is nontrivial, so A is isogenous to an abelian subvariety of the abelian variety $J_1(p)/J_0(p)$ that has potentially good reduction at p. Hence the toric rank of A is zero, and inertia $I_p \subset G_p = \operatorname{Gal}(\overline{\mathbf{Q}}_p/\mathbf{Q}_p)$ acts with finite image on the $\mathbf{Q}_\ell$-adic Tate module V_ℓ of A for any $\ell \neq p$. Hence V_ℓ splits as a nontrivial direct sum of simple representations of I_p. Let V' be a factor of V_ℓ corresponding to a simple summand K

of $\mathbf{T} \otimes \mathbf{Q}_\ell$, where $\mathbf{T}$ is the Hecke algebra. Since the Artin conductor of the 2-dimensional K-representation V'_ℓ is p, the $\overline{\mathbf{Q}}_\ell[I_p]$-module $\overline{\mathbf{Q}}_\ell \otimes_{\mathbf{Q}_\ell} V'$ is the direct sum of the trivial representation and the character $\varepsilon(f) : (\mathbf{Z}/p\mathbf{Z})^\times \to \overline{\mathbf{Q}}_\ell^\times$ viewed as a character of G_p via the identification $\mathrm{Gal}(\mathbf{Q}_p(\zeta_p)/\mathbf{Q}_p) = (\mathbf{Z}/p\mathbf{Z})^\times$. This implies that the abelian rank as well as the additive rank are both equal to half of the dimension of A.

6.4.1 The Simplest example not covered by general theory

The prime $p = 61$ is the only prime $p \leq 71$ such that the maximal quotient of $J_1(p)$ with positive analytic rank is not a quotient of $J_0(p)$. Let ε be a Dirichlet character of conductor 61 and order 6. Consider the abelian variety A_f attached to the newform

$$f = q + (e^{2\pi i/3} - 1)q^2 - 2q^3 + \cdots$$

that lies in the 6-dimensional $\mathbf{C}$-vector space $S_2(\Gamma_1(61), \varepsilon)$. Using Proposition 6.1.10, we see that $L(f, 1) = 0$.

It would be interesting to show that A_f has positive algebraic rank, since A_f is not covered by the general theorems of Kolyvagin, Logachev, and Kato concerning Conjecture 6.1.2. This example is the simplest example in the following sense: every elliptic curve over $\mathbf{Q}$ is a quotient of some $J_0(N)$, and an inspection of Tables 4–5 for any integer $N < 61$ shows that the maximal quotient of $J_1(N)$ with positive analytic rank is also a quotient of $J_0(N)$.

The following observation puts this question in the context of $\mathbf{Q}$-curves, and may be of some use in a direct computation to show that A_f has positive algebraic rank. Since $\overline{f} = f \otimes \varepsilon^{-1}$, Shimura's theory (see [62, Prop. 8]) supplies an isogeny $\varphi : A_f \to A_f$ defined over the degree-6 abelian extension of $\mathbf{Q}$ cut out by $\ker(\varepsilon)$. Using φ, one sees that A_f is isogenous to a product of two elliptic curves. According to Enrique Gonzalez-Jimenez (personal communication) and Jordi Quer, if $t^6 + t^5 - 25t^4 + 8t^3 + 123t^2 - 126t + 27 = 0$, so t generates the degree 6 subfield of $\mathbf{Q}(\zeta_{61})$ corresponding to ε, then one of the elliptic-curve factors of A_f has equation $y^2 = x^3 + c_4 x + c_6$, where

$$\begin{aligned} c_4 &= \frac{1}{3}(-321 + 738t - 305t^2 - 196t^3 + 47t^4 + 13t^5), \\ c_6 &= \frac{1}{3}(-4647 + 6300t + 996t^2 - 1783t^3 - 432t^4 - 14t^5). \end{aligned}$$

6.4.2 Can Optimal Quotients Have Nontrivial Component Group?

Let p be a prime. Component groups of optimal quotients of $J_0(p)$ are well-understood in the sense of the following theorem of Emerton [23]:

Theorem 6.4.3 (Emerton). *If $A_1, \ldots, A_n$ are the distinct optimal quotients of $J_0(p)$ attached the Galois-orbits of newforms, then the product of the orders of the component groups of the A_i's equals the order of the component* *group of* $J_0(p)$*,* i.e.*, the numerator of* $(p-1)/12$*. Moreover, the natural maps* $\Phi(J_0(p)) \to \Phi(A_i)$ *are surjective.*

Shuzo Takehashi asked a related question about $J_1(p)$:

Question 6.4.4 (Takehashi). Suppose $A = A_f$ is an optimal quotient of $J_1(p)$ attached to a newform. What can be said about the component group of A? In particular, is the component group of A necessarily trivial?

Since $J_1(p)$ has trivial component group (see Theorem 1.1.1), the triviality of the component group of A is equivalent to the surjectivity of the natural map from $\Phi(J_1(p))$ to $\Phi(A_f)$.

The data in Tables 4–5 sheds little light on Question 6.4.4. The following are the A_f's that have nonzero $L = c \cdot L(A_f, 1)/\Omega$ with numerator divisible by an odd prime: **37D**, **37F**, **43C**, **43F**, **53D**, **61E**, **61F**, **61G**, **61J**, **67D**, **67E**, and **67G**. For each of these, Conjecture 6.1.2 implies that $c \cdot Ш(A_f) \cdot c_p$ is divisible by an odd prime. However, it seems difficult to deduce which factors in the product are not equal to 1. We remark that for each A_f listed above such that the numerator of L is exactly divisible by p, there is a rank-1 elliptic curve E over $\mathbf{Q}$ such that $E[p] \subset A$, so methods as in [2] may shed light on this problem.

6.5 Using Magma to compute the tables

In this section, we describe how to use Magma V2.10-6 (or later) to compute the entries in Tables 1–5 at the end of this paper.

6.5.1 Computing Table 1: Arithmetic of $J_1(p)$

Let p be a prime. The following Magma code illustrates how to compute the two rows in Table 1 corresponding to p $(=19)$. Note that the space of cuspidal modular symbols has dimension $2\dim J_1(p)$.

```
> p := 19;
> M := ModularSymbols(Gamma1(p));
> S := CuspidalSubspace(M);
> S;
Modular symbols space of level 19, weight 2, and dimension
14 over Rational Field (multi-character)
> LRatio(S,1);
1/19210689
> Factorization(19210689);
[ <3, 4>, <487, 2> ]
> TorsionBound(S,60);
4383
```

Remark 6.5.1. It takes less time and memory to compute $c \cdot L(J_1(p), 1)/\Omega$ in $\mathbf{Q}^\times/2^{\mathbf{Z}}$, and this is done by replacing `M:=ModularSymbols(Gamma1(p))` with

`M:=ModularSymbols(Gamma1(p),2,+1)`. A similar remark applies to all computations of L-ratios in the sections below.

6.5.2 Computing Tables 2–3: Arithmetic of $J_H(p)$

Let p be a prime, d a divisor of $p-1$ such that $(p-1)/d$ is even, and H the subgroup of $(\mathbf{Z}/N\mathbf{Z})^{\times}$ of order $(p-1)/d$. We use Theorem 1.1.3 and commands similar to the ones in Section 6.5.1 to fill in the entries in Tables 2–3. The following code illustrates computation of the second row of Table 2 for $p = 19$.

```
> p := 19;
> [d : d in Divisors(p-1) | IsEven((p-1) div d)];
[ 1, 3, 9 ]
> d := 3;
> M := ModularSymbolsH(p,(p-1) div d, 2, 0);
> S := CuspidalSubspace(M);
> S;
Modular symbols space of level 19, weight 2, and dimension 2
over Rational Field (multi-character)
> L := LRatio(S,1); L;
1/9
> T := TorsionBound(S,60); T;
3
> T^2*L;
1
> Phi := d / GCD(d,6);  Phi;
1
```

It takes about ten minutes to compute all entries in Table 2–3 using an Athlon 2000MP-based computer.

6.5.3 Computing Tables 4–5

Let p be a prime number. To compute the modular symbols factors corresponding to the newform optimal quotients A_f of $J_1(p)$, we use the `NewformDecomposition` command. To compute the modular kernel, we use the command `ModularKernel`. The following code illustrates computation of the second row of Table 4 corresponding to $p = 19$.

```
> p := 19;
> M := ModularSymbols(Gamma1(19));
> S := CuspidalSubspace(M);
> D := NewformDecomposition(S);
> D;
[
    Modular symbols space for Gamma_0(19) of weight 2 and
    dimension 2 over Rational Field,
    Modular symbols space of level 19, weight 2, and
    dimension 12 over Rational Field (multi-character)
]
> A := D[2];
> Dimension(A) div 2;
6
> Order(DirichletCharacter(A));
9
> L := LRatio(A,1); L;
1/2134521
> T := TorsionBound(A,60);
> T^2*L;
1
> Invariants(ModularKernel(A));
[ 3, 3 ]
```

It takes about 2.5 hours to compute all entries in Tables 4–5, except that the entries corresponding to $p = 71$, using an Athlon 2000MP-based computer. The $p = 71$ entry takes about 3 hours.

6.6 Arithmetic tables

The notation in Tables 1–5 below is explained in Section 6.

Table 1: Arithmetic of $J_1(p)$

$J_1(p)$	dim	$c \cdot L(J_1(p),1)/\Omega$
11	1	$1/5^2$
13	2	$1/19^2$
17	5	$1/2^6 \cdot 73^2$
19	7	$1/3^4 \cdot 487^2$
23	12	$1/11^2 \cdot 37181^2$

15 Approximation of Eigenforms of Infinite Slope by Eigenforms of Finite Slope, with R. Coleman

Approximation of Eigenforms of Infinite Slope by Eigenforms of Finite Slope

Robert F. Coleman William A. Stein

April 21, 2003

Contents

1 Introduction

Fix a prime p. Consider a classical newform

$$F = \sum_{n\geq 1} a_n q^n \in S_k\left(\Gamma_1(Np^t), \overline{\mathbf{Q}}_p\right)$$

where k and N are positive integers and $p \nmid N$ is a prime (by a *newform* we mean a Hecke eigenform that lies in the new subspace and is normalized so that $a_1 = 1$). The *slope* of F is $\mathrm{ord}_p(a_p)$, where $\mathrm{ord}_p(p) = 1$. By [Shi94, Prop. 3.64], the twist

$$F^\chi = \sum \chi(n) a_n q^n$$

of F by any Dirichlet character χ of conductor dividing p is an eigenform on $\Gamma_1(Np^{\max\{t+1,2\}})$. This twist has infinite slope.

In Section 2, we prove that if F has finite slope then it is possible to approximate F^χ arbitrarily closely by (classical) finite slope *eigenforms*. Assuming refinements of standard conjectures, the best estimate we obtain for the smallest weight of an approximating eigenforms is exponential in the approximating modulus p^A. Section 4 contains computations that suggest that the best estimates should have weight that is linear in p^A.

One motivation for the question of approximation of infinite slope eigenforms by finite slope eigenforms is the desire to understand the versal deformation space of a residual modular representation [Maz89] (the deformation space of an irreducible representation is universal [Maz89] as is the deformation space of a residual pseudo-representation [CM98]). In [GM98] (see also [Maz97], and [Böc01] for a generalization), it was shown that the Zariski closure of the locus of finite slope modular deformations of an absolutely irreducible "totally unobstructed" residual modular representation is Zariski dense in the associated representation space but very little is known about the topological closure of this locus. For example, it is not known if it contains any nonempty open sets. Our result implies that it contains tamely ramified twists of modular deformations. We also show in Section 3.1 that a result of Hatada implies that in at least one (albeit not irreducible) case it does not contain all modular deformations.

Our investigation began with with our answer in Section 2 to a question of Jochnowitz. The idea of studying the p-adic variation of modular forms began with Serre [Ser73] and was since developed by Katz [Kat75] and Hida [Hid86] (see also [Gou88] for a sketch of the theory). It follows, in particular, from their work, that one can approximate all forms on $X_0(p^n)$ with forms on the j-line $X_0(1)$, but *not* necessarily with *eigenforms*.

We prove the above result about twists in Section 2, then state some questions about approximation by finite slope forms in Section 2.1. We explain how to reinterpret Hatada's result in Section 3.1, then present the results of our computations in Section 4.

Based on the results and computations discussed in this article, Mazur has suggested that it may be the case that an infinite slope eigenform can be approximated by finite slope eigenforms only if the corresponding representation is what he calls *tamely semistable* (i.e., semistable, in the sense of [CF00], after a tame extension).

Acknowledgments. The authors thank Naomi Jochnowitz for provoking this line of thought and for interesting conversations, Barry Mazur for helpful comments and questions, Frank Calegari for conversations, Loïc Merel for his comments on an early draft of this paper, and the referee for a brilliant report.

2 Approximating Teichmüller Twists of Finite Slope Eigenforms

This section is the theoretical heart of the paper. We prove that the infinite slope eigenforms obtained as twists of finite slope eigenforms by powers of the Teichmüller character can always be approximated by finite slope eigenforms. We first show that certain overconvergent eigenforms of sufficiently close weight are congruent and have the same slope. Then we use the θ operator on overconvergent forms to deduce the main result (Theorem 2.1) below.

Let p be a prime. All eigenforms in this section will be cusp forms with coefficients in $\overline{\mathbf{Q}}_p$ normalized so that $a_1 = 1$. Suppose $F = \sum_{n\geq 1} a_n q^n$ is an eigenform and $\chi : (\mathbf{Z}/M\mathbf{Z})^* \to \mathbf{C}_p^*$ is a Dirichlet character with modulus M, which we extend to $\mathbf{Z}/M\mathbf{Z}$ by setting $\chi(n) = 0$ if $(n, M) \neq 1$. Then the twist of F by χ is the eigenform

$$F^{\chi} = \sum_{n\geq 1} \chi(n) a_n q^n.$$

Let $\omega\colon (\mathbf{Z}/p\mathbf{Z})^* \to \mathbf{Z}_p^*$ be the Teichmüller character (so $\omega(n) \equiv n \pmod{p}$). The following theorem concerns finite slope approximations of twists of F by powers of ω. For example, it concerns the twist

$$F^{\omega^0} = \sum_{(n,p)=1} a_n(F) q^n$$

of F by the trivial character mod p, which we call the "p-deprivation" of F and which has infinite slope.

Theorem 2.1. *Suppose F is a classical eigenform on $X_1(Np^t)$, $t \geq 1$, over $\overline{\mathbf{Q}}_p$ of weight k, character ψ, and finite slope at p. Let $A \in \mathbf{Z}_{>0}$ and $r, s \in \mathbf{Z}_{\geq 0}$ with $r, s < p-1$. Then there exists a classical finite slope eigenform G on $X_1(Np^t)$ with $G(q) \equiv F^{\omega^r}(q) \pmod{p^A}$ such that G has weight congruent to $k + 2r - s$ modulo $p-1$ and character $\psi \cdot \omega^s$.*

(The slope of G will be at least A, since the pth Fourier coefficient of F^{ω^r} is 0.)

Let $\mathbf{q} = 4$ if $p = 2$ and p otherwise. Let $\tau : \mathbf{Z}_p^* \to \mathbf{C}_p^*$ be the character of finite order such that $a \equiv \tau(a) \pmod{\mathbf{q}}$. We only need to assume that $F = \sum_{n\geq 1} a_n q^n$ is an overconvergent eigenform of tame level N of finite slope with arithmetic weight-character $\kappa\colon a \to \chi(a)\langle\langle a\rangle\rangle^k$, where χ is a character of finite order whose conductor divides Np^t, k is a possibly negative integer, and $\langle\langle a\rangle\rangle = a/\tau(a)$. (For example, if F is a classical eigenform of weight k and character ψ, then $\chi = \psi\omega^k$.) Recall that the collection of continuous characters on $\mathbf{Z}_p^*$ is a metric space, with

$$d(\rho, \psi) = \max\{|\rho(a) - \psi(a)| : a \in \mathbf{Z}_p^*\},$$

where $|\,|$ is the absolute value on $\mathbf{C}_p$ normalized so that $|p| = 1/p$. We need,

Proposition 2.2. *Suppose $L \in \mathbf{Z}_{\geq 0}$ and H is an overconvergent eigenform of tame level N, finite slope and weight-character κ. Then if γ is a weight-character sufficiently close to κ there exists an overconvergent eigenform R of weight-character γ with the same slope as H such that*

$$H(q) \equiv R(q) \pmod{p^L}.$$

Proof. We will use the notation of the "*R-families*" section (in §B5) of [Col97b]. In particular, B is an affinoid disk in weight space containing κ and X is an affinoid finite over B such that $A(X)$ is generated by the images of the "Hecke operators" $T(n)$. Moreover, if $x \in X$ and $\eta_x\colon A(X) \to \mathbf{C}_p$ is the corresponding homomorphism, then

$$F_x(q) = \sum_{n \geq 1} \eta_x(T(n))q^n$$

is the q-expansion of an overconvergent finite slope eigenform and finally there is a point $y \in X$ such that $F_y(q) = H(q)$. Note that X is a subdomain of the eigencurve of tame level N (although the eigencurves of level $N > 1$ are not yet defined in the literature).

The ring $A^0(X)$ is finite over $A^0(B)$ by Corollary 6.4.1/5 of [BGR84]. Let $f_1, \ldots, f_n$ be generators. Let f_0 be a uniformizing parameter on B so that $A(B) = \mathbf{C}_p\langle f_0\rangle$, where $\mathbf{C}_p\langle f_0\rangle$ is the ring of power series in f_0 whose coefficients tend to 0 with their degree. Let $Z_L(y)$ be the following Weiersträss subdomain of X:

$$\{x \in X\colon |f_i(x) - f_i(y)| \leq p^{-L}, 0 \leq i \leq n\}.$$

Since the functions $x \to \eta_x(T(n))$ lie in $A^0(X)$, it follows that if $x \in Z_L(y)$, then

$$F_x(q) \equiv H(q) \pmod{p^L}.$$

Finally, since $Z_L(y)$ is a subdomain of X and X is finite over B, the map from $Z_L(y)$ to B is quasi-finite. It follows from Proposition A5.5 of [Col97b] that its image in B is a subdomain. Since κ is the image of y, its image contains a disk around y. □

Proof of Theorem 2.1. Let α be the slope of F. It follows from Proposition 2.2 that if $m \in \mathbf{Z}$ is sufficiently small p-adically there exists an overconvergent eigenform K of tame level N, weight-character $\chi \cdot \langle\langle\ \rangle\rangle^{k-m}$ and slope α such that $K(q) \equiv F(q)$ (mod p^A). Suppose $m \geq k$. Then, by Proposition 4.3 of [Col96] (see also [Col97a]) if $F_1 = \theta^{m-k+1}K$, then F_1 is an overconvergent eigenform of weight-character

$$\kappa_1 := \omega^{2(m-k+1)} \cdot \chi \cdot \langle\langle\ \rangle\rangle^{k_1},$$

where $k_1 = m - k + 2$, and F_1 has finite slope $\alpha_1 = \alpha + m - k + 1$. Applying this same process to F_1, for $\ell \in \mathbf{Z}$ sufficiently small p-adically such that $\ell \geq k_1$, we obtain an overconvergent finite slope eigenform F_2 of weight-character κ_2, where $\kappa_2 = \omega^{2\ell} \cdot \chi \cdot \langle\langle\ \rangle\rangle^{k_2}$ and where $k_2 = \ell - k_1 + 2 = k + \ell - m$, such that if $F_2(q) = \sum_{n\geq 1} b_n q^n$, then

$$\begin{aligned} b_n &\equiv n^{\ell-k_1+1} n^{m-k+1} a_n \\ &\equiv n^\ell a_n \pmod{p^A}. \end{aligned}$$

The latter is congruent to $\omega^r(n)a_n \pmod{p^A}$ if $\ell \equiv r \pmod{\varphi(p^A)}$ and $\ell + v(a_p) \geq A$. It follows from [Col96, §8], [Col97a], and [Col97b] that if c is an integer sufficiently small p-adically, such that $c + k_2 > v(b_p) + 1$ (note that $v(b_p)$ is the slope of F_2 so is finite) there exists a classical eigenform G on $X_1(Np^t)$ of weight $k_2 + c = k + \ell - m + c$, slope $v(b_p)$ and character $\omega^{m+r-c} \cdot \psi$ such that $G(q) \equiv F_2(q) \equiv F^{\omega^r}(q) \pmod{p^A}$. We can choose c so that $m + r - c \equiv s \pmod{p-1}$ and then $k_2 + c \equiv k + 2r - s \mod (p-1)$. □

The following corollary addresses a question of Jochnowitz, which motivated this entire investigation:

Corollary 2.3. *Suppose R is a classical eigenform of weight k on $X_1(N)$, let $A \in \mathbf{Z}_{>0}$, and let $r \in \mathbf{Z}_{\geq 0}$ with $r < p - 1$. Then there exists a classical eigenform S on $X_1(N)$ of weight congruent to $k + 2r$ modulo $p - 1$ such that $S(q) \equiv R^{\omega^r}(q)$ $\pmod{p^A}$.*

Proof. Suppose the F in Theorem 2.1 is one of the old eigenforms associated to R on $X_1(Np)$ and $s = 0$. Let G be a classical eigenform of weight $c + k_2$ as mentioned in the proof of the theorem, but suppose $c + k_2 > 2v(b_p) + 1$. Then G is old of weight congruent to $k \mod (p-1)$ and G is congruent to an eigenform S of the same weight on $X_1(N)$ modulo $p^{v(b_p)}$. Since $b_p \equiv 0 \pmod{p^A}$, we obtain the corollary. □

Remark 2.4. Assuming a natural refinement of the Gouvêa-Mazur conjectures, the best estimate we obtain for the weight of H in the above proof is exponential in p^A. Computational evidence suggests that the best estimates should have weights that are linear in p^A (see Section 4).

Remark 2.5. Jochnowitz and Mazur have independently observed that the above argument can be used to prove the following result: *Suppose F is an overconvergent eigenform of arithmetic weight-character κ, which is a limit of overconvergent eigenforms of finite slope. If $\iota \colon \mathbf{Z}_p^* \to \mathbf{Z}_p^*$ is the identity character, then the twist $F^{\iota/\kappa}(q)$ of F by ι/κ, which is the q-expansion of a convergent eigenform of weight-character ι^2/κ, is the limit of overconvergent eigenforms of finite slope.*

Remark 2.6. One can also approach the p-deprivation (the twist by the 0th power of Teichmüller) of a finite slope eigenform F by using the evil twins of eigenforms approaching F.

2.1 Questions

Some natural questions arise:

1. Is every p-adic convergent eigenform which is the limit of finite slope overconvergent eigenforms an overconvergent eigenform? (We can show the twist of an overconvergent eigenform by a Dirichlet character is overconvergent.)

2. Which infinite slope eigenforms are limits of finite slope eigenforms?

3. If $F(q)$ is the q-expansion of an overconvergent eigenform of weight-character κ, is $F^{\iota/\kappa}(q)$ the q-expansion of an overconvergent eigenform of weight-character

ι^2/κ (recall that ι is the identity character $\mathbf{Z}_p^* \xrightarrow{\sim} \mathbf{Z}_p^*$)? Another closely related question is as follows: Suppose ρ is the representation of the absolute Galois group of $\mathbf{Q}$ attached to an overconvergent eigenform and let χ denote the cyclotomic character. Then is the representation $\rho \otimes \chi \cdot \det(\rho)^{-1}$ attached to an overconvergent eigenform?

3 An Infinite Slope Eigenform that is Not Approximable

In Section 3.1, we prove an extension to higher level of a theorem of Hatada about the possibilities for systems of Hecke eigenvalues modulo 8. We use this result to deduce that the normalized weight 2 cusp form on $X_0(32)$ is not 2-adically approximable by normalized eigenforms of tame level 1 and finite slope. In Section 3.2 we give an example of an infinite slope eigenform of level 27 that computer computations suggest cannot be approximated by finite slope forms. For related investigations, see [CE03].

3.1 An Extension of a Theorem of Hatada

Theorem 3.1. *If $F = \sum a_n q^n$ is a normalized cuspidal newform over $\mathbf{C}_2$ of finite slope on $X_0(2^n)$, then $a_2 \equiv 0 \pmod 8$ and $a_p \equiv p+1 \pmod 8$ for all odd primes p.*

Proof. Suppose F has weight k and finite slope α. The assumption that F has finite slope implies $n \leq 1$. If $n = 0$ the assertion of Theorem 3.1 was proved by Hatada in [Hat79], so we may assume that $n = 1$ and $\alpha = (k-2)/2$ (in general, the slope of a newform on $\Gamma_0(p)$ of weight k is $(k-2)/2$). Note that $\alpha \geq 3$ since there are no newforms on $X_0(2)$ of weight < 8. It follows from Theorems A of [Col97b] (see §B2 of [Col97b] for the extension to $p = 2$) and Theorem B5.7 of [Col97b] that if j is an integer sufficiently close 2-adically to k, then there exists a classical normalized cuspidal eigenform G on $X_0(2)$ of weight j and slope α such that

$$G(q) \equiv F(q) \pmod 8.$$

If in addition we assume that $j > 2(\alpha + 1)$, then G must be old (since the slope of a newform of weight j is $(j-2)/2 \neq \alpha$). Thus there is a cuspidal eigenform $H = \sum b_n q^n$ of level 1 such that G is a linear combination of $H(q)$ and $H(q^2)$. More precisely,

$$G(q) = H(q) - \rho H(q^2)$$

where ρ is a root of $P(X) = X^2 - b_2 X + 2^{j-1}$. By Hatada's theorem $\mathrm{ord}_2(b_2) \geq 3$, and $j \geq 12$, so the slopes of the Newton polygon of $P(X)$ at 2 are both at least 3. Thus $G(q) \equiv H(q) \pmod 8$, which proves the theorem because H has level 1. □

Corollary 3.2. *Let G be the normalized weight 2 cusp form on $X_0(32)$. Then G is not 2-adically approximable by normalized eigenforms of tame level 1 and finite slope.*

Proof. If F_{32} were approximable there would have to be a normalized eigenform F on $X_0(2)$ such that $F_{32}(q) \equiv F(q) \pmod 8$. However, $F_{32}(q) = \sum_{n=1}^{\infty} a_n q^n$ where,

$$a_p = \begin{cases} 2x & \text{if } p = x^2 + y^2, \quad \text{written so } x + y \equiv x^2 \pmod 4 \\ 0 & \text{otherwise.} \end{cases}$$

As $a_3 = 0 \not\equiv 4 \pmod 8$, we see from Theorem 3.1 that F does not exist. □

Remark 3.3. If $p \equiv 1 \pmod 4$ then the coefficient of a_p in F_{32} agrees modulo 8 with $p + 1$. If p is 3 mod 4 it does not because for F_{32} the coefficient vanishes. What is happening is that there is a reducible mod 8 pseudo-representation (namely the trivial one-dimensional representation plus the cyclotomic character) such that any finite slope level 2^n form gives this pseudo-representation mod 8. Conversely the mod 8 representation associated to F_{32} is the direct sum of the quadratic character associated to $\mathbf{Q}(i)$ and the cyclotomic character. Hence the congruence works when $p = 1 \mod 4$ but not otherwise.

3.2 Another Eigenform that Conjecturally Cannot be Approximated

In this section we consider an infinite slope eigenform that is not a Teichmüller twist of a finite slope eigenform. We conjecture that this eigenform cannot be approximated arbitrarily closely by finite slope eigenforms.

Conjecture 3.4. *There are exactly five residue classes in* $(\mathbf{Z}/9\mathbf{Z})[[q]]$ *of normalized eigenforms in* $S_k(\Gamma_0(N))$ *where* $k \geq 1$ *and* $N = 1, 3, 9$. *They are given in the following table, where the indicated weight is the smallest weight where that system of eigenvalues occurs (the level is* 1 *in each case):*

Weight	[$a_2, a_3, \ldots, a_{43}$ mod 9]
12	[3, 0, 6, 5, 3, 8, 0, 2, 6, 3, 8, 2, 6, 5]
16	[0, 0, 0, 2, 0, 2, 0, 2, 0, 0, 2, 2, 0, 2]
20	[6, 0, 3, 8, 6, 5, 0, 2, 3, 6, 5, 2, 3, 8]
24	[6, 0, 3, 5, 6, 8, 0, 2, 3, 6, 8, 2, 3, 5]
32	[3, 0, 6, 8, 3, 5, 0, 2, 6, 3, 5, 2, 6, 8]

The system of eigenvalues mod 9 *associated to the weight* 2 *form* F *on* $X_0(27)$ *is*

```
[ 0, 0, 0, 8, 0, 5, 0, 2, 0, 0, 5, 2, 0, 8 ],
```

so we conjecture that there is no eigenform f *on* $\Gamma_0(N)$ *with* $N \mid 9$ *such that* $f \equiv F \pmod 9$.

As evidence, we verified that each of the mod 9 reductions of each newform of level 1 and weight $k \leq 74$ has one of the five systems of Hecke eigenvalues listed in the table. We also verified that all newforms of levels 3 and 9 and weight $k \leq 40$ have corresponding system of eigenvalues mod 9 in the above table. We checked using the method described in Section 4 that there is no newform of level 1 with weight $k \leq 300$ that approximates the weight 2 form on $X_0(27)$ modulo 9.

We now make some remarks about pseudo-representations when $p = 3$. Let

$$\chi : \mathbf{Z}/27\mathbf{Z} \to \mathbf{Z}/9\mathbf{Z}$$

be the mod 9 cyclotomic character, so χ has order 6 and if $\gcd(n, 3) = 1$ then $\chi(n) = n \in \mathbf{Z}/9\mathbf{Z}$. The pseudo-representation corresponding to a form of weight k giving the system of eigenvalues in the table in Conjecture 3.4 are

Weight	Pseudo-representation
12	$\chi^2 \oplus \chi^3$
16	$1 \oplus \chi^3$
20	$\chi^3 \oplus \chi^4$
24	$1 \oplus \chi^5$
32	$1 \oplus \chi$
$S_2(\Gamma_0(27))$	$\chi^2 \oplus \chi^5$

Note that the square of any pseudo-representation of level 1 in the above table has 1 as an eigenvalue, but the square of the pseudo-representation attached to $S_2(\Gamma_0(27))$ does not have 1 as an eigenvalue. Also,

$$F \equiv f_{16} \otimes \chi^2 \pmod{9},$$

where f_{16} is of weight 16. The order of χ^2 is 3, so χ^2 is not a power of the Teichmüller character (which has order 2) and Theorem 2.1 does not apply.

Further computations *suggest* that the pseudo-representations attached to forms of level 1 with coefficients in $\mathbf{Z}_9$ are

Weight	Pseudo-representations
$k \equiv 0 \pmod{6}$	$1 \oplus \chi^5, \quad \chi^2 \oplus \chi^3$
$k \equiv 2 \pmod{6}$	$1 \oplus \chi, \quad \chi^3 \oplus \chi^4$
$k \equiv 4 \pmod{6}$	$1 \oplus \chi^3$

The pseudo-representations attached to forms of level 27 with coefficients in $\mathbf{Z}_9$ seem to be

Weight	Pseudo-representations
$k \equiv 0 \pmod{6}$	$\chi \oplus \chi^4$
$k \equiv 2 \pmod{6}$	$\chi^2 \oplus \chi^5$
$k \equiv 4 \pmod{6}$	$\chi \oplus \chi^2, \quad \chi^4 \oplus \chi^5$

Also note that if $\chi^i \oplus \chi^j$ is one of the pseudo-representations of level 27 in the table, then the sum of the orders of χ^i and χ^j is 9, whereas at level 1 the sum of the orders is at most 7.

4 Computations About Approximating Infinite Slope Eigenforms

In this section, we investigate computationally how well certain infinite slope form can be approximated by finite slope eigenforms.

4.1 A Question About Families

The following question is an analogue of [GM92, §8] but for eigenforms of infinite slope. Fix a prime p and an integer N with $(N,p)=1$.

Question 4.1. Suppose $f \in S_{k_0}(\Gamma_0(Np^r))$ is an eigenform having infinite slope (note that f need not be a newform). Is there a "family" of eigenforms $\{f_k\}$, with $f_k \in S_k(\Gamma_0(Np))$, where the weights k run through an arithmetic progression

$$k \in \mathcal{K} = \{k_0 + mp^{\nu}(p-1) \text{ for } m = 1,2,\ldots\}$$

for some integer ν, such that

$$f_k \equiv f \pmod{p^n},$$

where $n = \mathrm{ord}_p(k-k_0)+1$? (When $p=2$ set $n=\mathrm{ord}_2(k-k_0)+2$.)

Our question differs from the one in [GM92, §8] because there the form being approximated has finite slope, whereas our form f does not. We know, as discussed in the previous section, that our question sometimes has a negative answer since it might not be possible to approximate f at all.

4.2 An Approximation Bound

Let

$$f = \sum_{n\geq 1} a_n q^n \in K[[q]]$$

be a q-expansion with coefficients that generate a number field K. Fix a prime p and an even integer $k \geq 2$. In order to gather some data about Question 4.1, we now define a reasonably easy to compute upper bound on how well f can be approximated by an eigenform in $S_k(\Gamma_0(p))$. Suppose $\ell \geq 1$, let F be the characteristic polynomial of T_ℓ acting on the space $S_k(\Gamma_0(p))$ of classical cusp forms of weight k and tame level 1, and let H be the characteristic polynomial of $a_\ell \in K$. Let G be the resultant of $F(Y)$ and $H(X+Y)$ with respect to the variable Y, normalized so that G is monic. Thus the roots of G are the differences $\alpha - \beta$ where α runs through the roots of F and β runs through the $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$-conjugates of a_ℓ. We can easily compute the p-valuations of the roots of G without finding the roots, because the p-valuations of the roots are the slopes of the newton polygon of G. Let $m_\ell \in \mathbf{Q}\cup\{\infty\}$ be the *maximum* of the slopes of the Newton polygon of G. Let

$$c_k(f,r) = \min\{m_\ell : \ \ell \leq r \text{ is prime}\}.$$

We note that computing $c_k(f,r)$ requires knowing only the characteristic polynomials of Hecke operators T_ℓ on $S_k(\Gamma_0(p))$ and of a_ℓ for primes $\ell \leq r$.

Proposition 4.2. *If there is a normalized eigenform $g \in S_k(\Gamma_0(p))$ such that $f \equiv g \pmod{p^A}$, then $A \leq c_k(f,r)$ for any r.*

Proof. To see this observe that $c_k(f,r)$ is the minimum of the

$$\mathrm{ord}_p(a_n(f) - a_n(g))$$

where $1 \leq n \leq r$ and g runs through all normalized eigenforms in $S_k(\Gamma_0(p))$, and we run through all possible embeddings of f and g into $\overline{\mathbf{Z}}_p[[q]]$. □

The motivation for our definition of $c_k(f,r)$ is that it is straightforward to compute from characteristic polynomials of Hecke operators, even when the coefficients of f lie in a complicated number field. The number $c_k(f,r)$ could overestimate the true extent to which f is approximated by an eigenform in $S_k(\Gamma_0(p))$ in at least two ways:

1. There is an $r' > r$ such that $c_k(f,r') < c_k(f,r)$.

2. No *single* eigenform g is congruent to f, but each coefficient of f is congruent to some coefficient of some eigenform g.

4.3 Some Data About Approximations

Let p be a prime and $f \in S_{k_0}(\Gamma_0(p^r))$ be a newform of infinite slope. Suppose that the answer to Question 4.1 for f is yes. If k is a weight (in the arithmetic progression) then there should be an eigenform $f_k \in S_k(\Gamma_0(p))$ such that $f_k \equiv f \pmod{p^{n+1}}$ where $n = \mathrm{ord}_p(k-k_0)$. Thus we should have

$$\mathrm{ord}_p(k-k_0) + 1 \leq c_k(f,r)$$

for all $r > 1$ and all k in an arithmetic progression $\mathcal{K} = \{k_0 + mp^\nu(p-1) \text{ for } m = 0, 1, 2, \ldots\}$. (When $p = 2$ we should have $\mathrm{ord}_2(k-k_0) + 2 \leq c_k(f,r)$.)

The following or the results of some computations of $c_k(f,r)$.

$\mathbf{p = 2}$:

1. For $k_0 = 6, 10, 12, 14, 16, 20$ let $f \in S_{k_0}(\Gamma_0(4))$ be the unique newform. Then for all k with $k_0 < k \leq 100$ we have $c_k(f, 47) = \mathrm{ord}_2(k-k_0) + 2$.

2. For $k_0 = 18, 22$ let $f \in S_{k_0}(\Gamma_0(4))$ be the unique, up to Galois conjugacy, newform. Then for all k with $k_0 < k \leq 100$ we have $c_k(f,7) = \mathrm{ord}_2(k-k_0)+2$.

3. Let $f \in S_4(\Gamma_0(8))$ be the unique newform. For most $4 < k \leq 100$ we have $c_k(f, 47) = \mathrm{ord}_2(k-k_0) + 2$. However, in this range if $\mathrm{ord}_2(k-k_0) \geq 4$ then $c_k(f, 47) = 5$ Since $\mathrm{ord}_2(68-4) + 2 = 8$, this is a problem; perhaps this form is not approximated. Very similar behavior occurs for the newforms in $S_6(\Gamma_0(8))$, $S_8(\Gamma_0(8))$, and $S_4(\Gamma_0(16))$.

4. For the two newforms $f \in S_6(\Gamma_0(16))$, we have $c_k(f, 47) \leq 3$ for all $k < 100$, so these f probably can not be approximated by finite slope forms.

5. Let f be the 2-deprivation of the unique normalized eigenform in $S_{k_0}(\Gamma_0(1))$ for $k_0 = 12, 16, 18, 20, 22, 26$. Then $c_k(f, 47) = \mathrm{ord}_2(k - k_0) + 2$ for $12 < k \leq 100$. Same statement for $k_0 = 24, 28$ for the 2-deprivation of one of the Galois conjugates and $c_k(f, 47)$ replaced by $c_k(f, 7)$.

$\mathbf{p = 3}$:

1. Suppose f is a newform in $S_{k_0}(\Gamma_0(9))$ for $k_0 \leq 12$. Then for $k_0 < k \leq 100$ we have $c_k(f, 47) = \mathrm{ord}_3(k - k_0) + 1$, except possibly for the nonrational form of weight 8, where we have only checked that $c_k(f, 7) \geq \mathrm{ord}_3(k - k_0) + 1$.

2. Let f be the twist of a newform in $S_{k_0}(\Gamma_0(1))$ by ω_3 for $k_0 \leq 32$. Then $c_k(f, 7) \geq \mathrm{ord}_3(k - k_0) + 1$ for $k_0 < k \leq 100$, with equality usually.

3. Let f be the newform in $S_2(\Gamma_0(45))$ of tame level 5. Then $c_{2+(3-1)3^n}(f, 7) = n+1$ for $n = 0, 1, 2, 3$ (here we are testing congruences with forms in $S_k(\Gamma_0(15))$).

$\mathbf{p = 5}$:

1. Let $f = q + q^2 + \cdots \in S_4(\Gamma_0(25))$ be a newform. Then $c_{4+4}(f, 7) = 1$, $c_{4+4\cdot 5}(f, 7) = 2$, and $c_{4+4\cdot 5^2}(f, 7) = 3$. Same result for the newform $f = q + 4q^2 + \cdots \in S_4(\Gamma_0(25))$.

2. Let $f = q - q^2 + \cdots \in S_2(\Gamma_0(2 \cdot 25))$. Then $c_{2+4}(f, 7) = 1$ and $c_{2+4\cdot 5}(f, 7) = 2$, where we are testing congruences with forms in $S_k(\Gamma_0(10))$.

3. Let f be one of the newforms in $S_2(\Gamma_0(5^3))$ defined over a quadratic extension of $\mathbf{Q}$. Then $c_{2+4}(f, 7) = c_{2+4\cdot 5}(f, 7) = c_{2+4\cdot 5^2}(f, 2) = 1/2$. Thus it seems unlikely that f can be approximated by forms of finite slope.

$\mathbf{p = 7}$:

1. Let $f \in S_2(\Gamma_0(49))$ be the newform. Then $c_{2+6}(f, 7) = 1$ and $c_{2+6\cdot 7}(f, 7) = 2$. Same statement for the form $f = q - q^2 \in S_4(\Gamma_0(49))$ at weights $4 + 6$ and $4 + 6 \cdot 7$.

The data and results of this paper suggests the following:

Guess 4.3. Let p be a prime and N an integer coprime to p. Then the eigenforms on $X_0(Np^t)$ that can be approximated by finite-slope eigenforms are exactly the eigenforms on $X_0(Np^2)$. Suppose f is an infinite slope eigenform that can be approximated by finite slope eigenforms and f has weight k_0. Then for any $k > k_0$ with $k \equiv k_0 \pmod{p-1}$, there is an eigenform f_k on $X_0(Np)$ of weight k such that $f \equiv f_k \pmod{p^n}$ where $n = \mathrm{ord}_p(k - k_0) + 1$ (or $+2$ if $p = 2$). (In general one might have to restrict to n sufficiently large.)

16 ShafarevichTate Groups of Nonsquare Order

Shafarevich–Tate Groups of Nonsquare Order

William A. Stein

Abstract. Let A denote an abelian variety over $\mathbb{Q}$. We give the first known examples in which $\#Ш(A/\mathbb{Q})$ is neither a square nor twice a square. For example, let E be the elliptic curve $y^2 + y = x^3 - x$ of conductor 37. We prove that for every odd prime $p < 25000$ (with $p \neq 37$), there is a twist A of $E \times \cdots \times E$ ($p-1$ copies) such that $\#Ш(A/\mathbb{Q}) = pn^2$ for some integer n. We prove this by showing under certain hypothesis on E and p that there is an exact sequence

$$0 \to E(\mathbb{Q})/pE(\mathbb{Q}) \to Ш(A/\mathbb{Q})[p^\infty] \to Ш(E/K)[p^\infty] \to Ш(E/\mathbb{Q})[p^\infty] \to 0,$$

where K is a certain abelian extension of $\mathbb{Q}$ of degree p.

1. Introduction

The Shafarevich–Tate group of an abelian variety A over a number field F is

$$Ш(A/F) := \operatorname{Ker}\left(H^1(F, A) \to \bigoplus_{\text{all } v} H^1(F_v, A)\right).$$

What are the possibilities for the group structure of $Ш(A/F)$? It is conjectured that $Ш(A/F)$ is finite and this is known in some cases.

Theorem 1.1 (Kato, Kolyvagin, Wiles, et al.)**.** *Suppose A is an elliptic curve over $\mathbb{Q}$. (1) If $\operatorname{ord}_{s=1} L(A, s) \leq 1$, then $Ш(A/\mathbb{Q})$ is finite. (2) If χ is a character of the Galois group of an abelian extension K of $\mathbb{Q}$ and $L(A, \chi, 1) \neq 0$, then the χ-component of $Ш(A/K) \otimes_{\mathbb{Z}} \mathbb{Z}[\chi]$ is finite. (Here $\mathbb{Z}[\chi]$ is generated by the image of χ.)*

The Cassels–Tate pairing $Ш(A/F) \times Ш(A^\vee/F) \to \mathbb{Q}/\mathbb{Z}$ imposes strong constraints on the structure of $Ш(A/F)$.

Theorem 1.2 (Tate, Flach)**.** *Let p be a prime and suppose that there is a polarization $\lambda : A \to A^\vee$ of degree coprime to p. If $p = 2$ assume also that λ arises from an F-rational divisor on A (this hypothesis is automatic if A is an elliptic curve, but can fail in general). If $Ш(A/F)[p^\infty]$ is finite then $\#Ш(A/F)[p^\infty]$ is a perfect square.*

Proof. If λ is F-rational, the Cassels–Tate pairing on $Ш(A/F)[p^\infty]$ (induced by λ) is nondegenerate and alternating (see [Tat63]), so $\#Ш(A/F)[p^\infty]$ is a perfect square. Even when λ is not F-rational, the Cassels–Tate pairing is nondegenerate and antisymmetric (see [Fla90]), which when p is odd implies that $\#Ш(A/F)[p^\infty]$ is a perfect square. □

It is tempting to conjecture that $\#Ш(A/F)$ is always a perfect square. Perhaps squareness is a fundamental property of Shafarevich–Tate groups? While implementing algorithms based on [PS97] for computing with Jacobians of hyperelliptic curves, M. Stoll was shocked to discover an example of an abelian variety of dimension two such that $\#Ш(A/F)[2^\infty] = 2$. This was surprising because, for example, one finds in the literature [SD67, pg.149] the following statement: "[The group $Ш(A/F)$] is conjectured to be finite, and Tate [26] has shown that if it is finite its order is a perfect square." Stoll and B. Poonen discovered what hid behind this and other similar examples in which $\#Ш(A/F)$ is twice a perfect square.

An algebraic curve X of genus g over a local field k is *deficient* if X has no k-rational divisor of degree $g-1$.

Theorem 1.3 (Poonen-Stoll [PS99])**.** *Suppose A is the Jacobian of an algebraic curve over F that is deficient at an odd number of places. If $\#Ш(A/F)$ is finite, then $\#Ш(A/F)$ is twice a square.*

For example, they prove that the Jacobian J of the nonsingular projective curve defined by

$$y^2 = -3(x^2+1)(x^2-6x+1)(x^2+6x+1)$$

has Shafarevich–Tate group of order 2 (to see that $\#Ш(J) \mid 2$ they observe that J is isogenous to a product of CM elliptic curves and apply a theorem of Rubin; see [PS99, Prop. 27] for details). Also, Jordan and Livné [JL99] give an infinite family of Atkin–Lehner quotients of Shimura curves which are deficient at an odd number of places.

Though $\#Ш(A/F)$ need not be square, one might still be tempted to conjecture that $Ш(A/F)$ must have order either a square or twice a square. Let p be an odd prime. In this paper, we construct (under certain hypotheses that are satisfied for $p < 25000$) abelian varieties A such that $\#Ш(A/\mathbb{Q}) = pn^2$ for some integer n. For example (see Section 3):

Theorem 1.4. *Let E be the elliptic curve $y^2 + y = x^3 - x$ of conductor 37. For every odd prime $p < 25000$ (with $p \neq 37$), there is a twist A of $E^{\times(p-1)}$ such that $\#Ш(A/\mathbb{Q}) = pn^2$ for some integer n.*

This paper was originally motivated by the problem of relating the conjecture of Birch and Swinnerton-Dyer about the ranks of elliptic curves E to the Birch and Swinnerton-Dyer formula for the orders $\#Ш(A)$ for abelian varieties A of analytic rank 0.

Let p be a prime. Under suitable hypotheses, we construct an abelian variety A and a natural map $E(\mathbb{Q})/pE(\mathbb{Q}) \hookrightarrow Ш(A/\mathbb{Q})$. Thus if $E(\mathbb{Q}) \cong \mathbb{Z}$ then $Ш(A/\mathbb{Q})$ has a natural subgroup of order p, and no other natural subgroup of order p presents itself. Moreover, when E is defined by $y^2 + y = x^3 - x$, the Birch and Swinnerton-Dyer formula predicts that $Ш(A/\mathbb{Q})[3]$ is of order 3. Further investigation led to the results of this paper.

Acknowledgement: It is a pleasure to thank Kevin Buzzard, Frank Calegari, Sol Friedberg, Benedict Gross, Emmanuel Kowalski, Barry Mazur, Bjorn Poonen, and David Rohrlich for their helpful comments, and in particular Michael Stoll for Lemma 2.10 and Cristian González for carefully reading this paper, making many comments, and sending me a proof of Proposition 2.13.

1.1. Notation

If G is an abelian group and n is an integer, then $G[n]$ denotes the subgroup of elements of order n and $G[n^\infty]$ is the subgroup of elements of order any power of n. We refer to elliptic curves using the notation of [C97].

2. Construction of Nonsquare Shafarevich–Tate Groups

For the rest of this paper we will work with an elliptic curve E over $\mathbb{Q}$. Aside from the significant use of known cases of the Birch and Swinnerton-Dyer conjecture below, much of the construction should generalize to the situation when E is replaced by a principally polarized abelian variety over a global field.

For the rest of this section, fix an elliptic curve E over $\mathbb{Q}$. By [BCDT01], E is modular so there is a newform $f = \sum_{n=1}^{\infty} a_n q^n$ of level equal to the conductor $N = N_E$ of E such that $L(E,s) = L(f,s)$. For each prime $q \mid N$, the Tamagawa number c_q of E at q is the order of the group of rational components of the special fiber of the Néron model of E at q.

2.1. Twisting By Characters of Prime Order

Let p be a prime number. For any prime $\ell \equiv 1 \pmod{p}$, let

$$\chi_{p,\ell} : (\mathbb{Z}/\ell\mathbb{Z})^* \to \mu_p \subset \mathbb{C}^*$$

be one of the $p-1$ Galois-conjugate Dirichlet characters of order p and conductor ℓ.

Conjecture 2.1. *Suppose p is a prime such that $\rho_{E,p} : \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathrm{Aut}(E[p])$ is surjective. Then there exists a prime $\ell \nmid N$ such that $L(E,\chi_{p,\ell},1) \neq 0$, $\ell \equiv 1 \pmod{p}$ and $a_\ell \not\equiv \ell + 1 \pmod{p}$.*

Remarks 2.2.

1. Formulas involving modular symbols imply that $L(E,\chi_{p,\ell},1) \neq 0$ if and only if $L(E,\chi_{p,\ell}^\sigma,1) \neq 0$ for any $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugate $\chi_{p,\ell}^\sigma$ of $\chi_{p,\ell}$.
2. J. Fearnley proved related nonvanishing results when $L(E,1) \neq 0$ in [Fea01].
3. If E is the elliptic curve $y^2 + y = x^3 - x$ of conductor 37 and rank 1, then $\ell = 41$ is the only $\ell \equiv 1 \pmod{5}$ with $\ell < 1000$ for which $L(E,\chi_{5,\ell},1) = 0$.

The following proposition gives evidence for Conjecture 2.1 for the lowest-conductor elliptic curves of ranks 1, 2, and 3.

Proposition 2.3. *Conjecture 2.1 is true for the rank* 1 *elliptic curve* **37A** *for every odd* $p < 25000$ *(with* $p \neq 37$*). The conjecture is true for the rank* 2 *curve* **389A** *for every odd* $p < 1000$ *(with* $p \neq 389$*). The conjecture is true for the rank* 3 *curve* **5077A** *for every odd* $p < 1000$.

Proof. Consider the modular symbol

$$e_{p,\ell} = \sum_{a\in(\mathbb{Z}/\ell\mathbb{Z})^*} \chi_{p,\ell}(a)\cdot\left\{0,\ \frac{a}{\ell}\right\} \in H_1(X_0(N),\mathbb{Q}(\zeta_p)).$$

Then $L(E,\chi_{p,\ell},1)\neq 0$ if and only if the image of $e_{p,\ell}$ under

$$H_1(X_0(N),\mathbb{Q}(\zeta_p)) \to H_1(E,\mathbb{Q}(\zeta_p))$$

is nonzero. In any particular case, we can use modular symbols to determine whether or not this image is nonzero.

When p is large, it is difficult to compute in the field $\mathbb{Q}(\zeta_p)$, so instead we compute in the residue class field $\mathbb{F}_\ell = \mathbb{Z}[\zeta_p]/\mathfrak{m} \cong Z/\ell\mathbb{Z}$, where $\mathfrak{m}$ is one of the maximal ideals of $\mathbb{Z}[\zeta_p]$ that lies over ℓ. (Note that ℓ splits completely in $\mathbb{Z}[\zeta_p]$ because $\ell \equiv 1 \pmod{p}$.) After reducing modulo $\mathfrak{m}$, we compute the image of

$$\overline{e}_{p,\ell} = \sum_{a\in(\mathbb{Z}/\ell\mathbb{Z})^*} a^{(\ell-1)/p}\cdot\left\{0,\ \frac{a}{\ell}\right\} \in H_1(X_0(N),\mathbb{F}_\ell)$$

in $H_1(E,\mathbb{F}_\ell)$. If it is nonzero, then the image of $e_{p,\ell}$ in $H_1(E,\mathbb{Q}(\zeta_p))$ is nonzero.

A big computation (that takes hundreds of hours using Magma [BCP97]) shows that the image of $\overline{e}_{p,\ell}$ is nonzero in the cases asserted by the proposition. So the reader can carry out similar computations, we include the following Magma V2.10-6 code, which illustrates verification of the proposition for **37A** for $p < 100$:

```
procedure VerifyConjecture(E, p)
   assert Type(E) eq CrvEll;
   assert Type(p) eq RngIntElt and IsPrime(p) and IsOdd(p);
   N := Conductor(E);
   assert N mod p ne 0;
   M := ModularSymbols(E,+1);  // takes a long time if N large!
   ell := 3; t := Cputime();
   printf "p=%o: ", p;
   while true do
      while (ell mod p ne 1)  or  (N mod ell eq 0) or
       TraceOfFrobenius(ChangeRing(E,GF(ell))) mod p eq (ell+1) do
         ell := NextPrime(ell);
      end while;
      k := FiniteField(ell);
      printf "trying ell=%o...",ell;
      psi := DirichletGroup(ell,k).1;
      eps := psi^(Order(psi) div p);  // order p character
      M_k := BaseExtend(M,k);
      phi := RationalMapping(M_k);
      e := TwistedWindingElement(M_k,1,eps);
      if phi(e) ne 0 then
         printf " success! (%o seconds)\n", Cputime(t);
         return;
      end if;
      printf "failed. ";
      ell := NextPrime(ell);
   end while;
end procedure;

E := EllipticCurve([0,0,1,-1,0]);  // 37A
for p in [q : q in [3..100] | IsPrime(q) and q ne 37] do
   VerifyConjecture(E,p);
end for;
```

The above input results in the following abbreviated output:

```
p=3: trying ell=7... success! (0.021 seconds)
p=5: trying ell=11... success! (0.039 seconds)
p=7: trying ell=29... success! (0.121 seconds)
...
p=89: trying ell=179... success! (0.739 seconds)
p=97: trying ell=389... success! (1.491 seconds)
```

□

2.2. A Restriction of Scalars Exact Sequence

As above, E is an elliptic curve over $\mathbb{Q}$. Let p be any prime (note that $p = 2$ is allowed). Suppose $\ell \equiv 1 \pmod{p}$ is another prime and that $\ell \nmid N_E$. Let $K \subset \mathbb{Q}(\mu_\ell)$ be the abelian extension of $\mathbb{Q}$ that corresponds to $\chi_{p,\ell}$ (thus K is the unique subfield of $\mathbb{Q}(\mu_\ell)$ of degree p).

Let $R = \mathrm{Res}_{K/\mathbb{Q}}(E_K)$ be the restriction of scalars down to $\mathbb{Q}$ of E viewed as an elliptic curve over K. Thus R is an abelian variety over $\mathbb{Q}$ of dimension $p = [K : \mathbb{Q}]$. It is characterized by the fact that it represents the following functor on $\mathbb{Q}$-schemes S:

$$S \mapsto E_K(S_K).$$

As a Galois module,

$$R(\overline{\mathbb{Q}}) = E(\overline{\mathbb{Q}}) \otimes_{\mathbb{Z}} \mathbb{Z}[\mathrm{Gal}(K/\mathbb{Q})],$$

where $\tau \in \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts on $\sum P_\sigma \otimes \sigma$ by

$$\tau\left(\sum P_\sigma \otimes \sigma\right) = \sum \tau(P_\sigma) \otimes \tau_{|K} \cdot \sigma,$$

where $\tau_{|K}$ is the image of τ in $\mathrm{Gal}(K/\mathbb{Q})$.

Proposition 2.4. *The identity map induces a closed immerion $\iota : E \hookrightarrow R$, and the trace* $\mathrm{Tr} : K \to \mathbb{Q}$ *induces a surjection* $\mathrm{Tr} : R \to E$ *whose kernel is geometrically connected. Thus we have an exact sequence of abelian varieties*

$$0 \to A \to R \xrightarrow{\mathrm{Tr}} E \to 0. \tag{1}$$

Proof. The existence of ι and Tr follows from Yoneda's lemma. The map ι is induced by the functorial inclusion $E(S) \hookrightarrow E_K(S_K) = R(S)$, so ι is injective. The Tr map is induced by the functorial trace map on points $R(S) = E_K(S_K) \xrightarrow{\mathrm{Tr}} E(S)$.

To verify that Ker(Tr) is geometrically connected, we base extend the exact sequence (1) to $\overline{\mathbb{Q}}$. First, note that there is an isomorphism

$$R_{\overline{\mathbb{Q}}} \cong E_{\overline{\mathbb{Q}}} \times \cdots \times E_{\overline{\mathbb{Q}}}.$$

After base extension, we identify the trace map with the summation map

$$+ : E_{\overline{\mathbb{Q}}} \times \cdots \times E_{\overline{\mathbb{Q}}} \longrightarrow E_{\overline{\mathbb{Q}}}.$$

Let $n = [K : \mathbb{Q}]$. The map defined by

$$(a_1, \ldots, a_{n-1}) \mapsto \left(a_1, a_2, \ldots, a_{n-1}, -\sum_{i=1}^{n-1} a_i \right),$$

is an isomorphism from $E_{\overline{\mathbb{Q}}}^{\times(n-1)}$ to $\mathrm{Ker}(+) = \mathrm{Ker}(\mathrm{Tr}_{\overline{\mathbb{Q}}})$. Thus $\mathrm{Ker}(\mathrm{Tr}_{\overline{\mathbb{Q}}})$ is isomorphic to a product of copies of $E_{\overline{\mathbb{Q}}}$, and hence is connected. □

Corollary 2.5. $\iota(E) \cap \mathrm{Ker}(\mathrm{Tr}) = \iota(E)[p]$.

Proof. The composition $\mathbb{Q} \hookrightarrow K \xrightarrow{\mathrm{Tr}} \mathbb{Q}$ is multiplication by p, so the composition $E \xrightarrow{\iota} R \xrightarrow{\mathrm{Tr}} E$ is also multiplication by p. Since $\iota(E) \cap \mathrm{Ker}(\mathrm{Tr})$ is the kernel of $\mathrm{Tr} \circ \iota = [p]$, it equals $E[p]$. □

Lemma 2.6. *The abelian varieties A_K, R_K, and $(R/\iota(E))_K$ are all isomorphic to a product of copies of E_K.*

Proposition 2.7. *The exact sequence* $0 \to A \to R \to E \to 0$ *of Proposition 2.4 extends to an exact sequence* $0 \to \mathcal{A} \to \mathcal{R} \to \mathcal{E} \to 0$ *of Néron models over* $\mathbb{Z}$.

Proof. We use results of [BLR90, Ch. 7] and the fact that formation of Néron models commutes with unramified base change (see [BLR90, §1.2, Prop. 2]) to prove that for every prime q, the complex

$$0 \to \mathcal{A}_{\mathbb{Z}_q} \to \mathcal{R}_{\mathbb{Z}_q} \to \mathcal{E}_{\mathbb{Z}_q} \to 0 \tag{2}$$

is exact.

First suppose that $q \neq \ell$, and let $\mathfrak{q}$ be a prime of K lying over q. We use the fact that formation of Néron models commutes with unramified base extension and check exactness of (2) after base extension to the unramified extension $\mathcal{O}_{K,\mathfrak{q}}$ of $\mathbb{Z}_q$. By Lemma 2.6, the generic fiber of the base extension of (2) to $\mathcal{O}_{K,\mathfrak{q}}$ is

$$0 \to E_{K,\mathfrak{q}}^{\oplus(n-1)} \to E_{K,\mathfrak{q}}^{\oplus n} \xrightarrow{\Sigma} E_{K,\mathfrak{q}} \to 0.$$

Thus the corresponding complex of Néron models over $\mathcal{O}_{K,\mathfrak{q}}$ is

$$0 \to \mathcal{E}_{\mathcal{O}_{K,\mathfrak{q}}}^{\oplus(n-1)} \to \mathcal{E}_{\mathcal{O}_{K,\mathfrak{q}}}^{\oplus n} \xrightarrow{\Sigma} \mathcal{E}_{\mathcal{O}_{K,\mathfrak{q}}} \to 0,$$

which is exact, since it is exact on S-points for *any* ring S.

Suppose that $q = \ell$. Since $p \neq \ell$, [BLR90, Prop. 7.5.3 (a)] asserts that the sequence $0 \to \mathcal{A}_{\mathbb{Z}_q} \to \mathcal{R}_{\mathbb{Z}_q} \to \mathcal{E}_{\mathbb{Z}_q}$ is exact. Since $p \neq q$, the map $[p] : \mathcal{E}_{\mathbb{Z}_q} \to \mathcal{E}_{\mathbb{Z}_q}$ is an étale morphism of smooth schemes. Since E has good reduction at q, we also know that the fibers of $\mathcal{E}_{\mathbb{Z}_q}$ are geometrically connected, so $[p]$ is surjective (for more details, see the proof of [AS02, Lem. 3.2]). It follows that $\mathcal{R}_{\mathbb{Z}_q} \to \mathcal{E}_{\mathbb{Z}_q}$ is surjective.

□

2.3. The Cokernel of Trace

Let ℓ be a prime as in Conjecture 2.1. This section is devoted to computing the cokernel of the trace map $R(\mathbb{Q}) \to E(\mathbb{Q})$. Note that $R(\mathbb{Q}) = E(K)$, so this cokernel is also $E(\mathbb{Q})/\operatorname{Tr}_{K/\mathbb{Q}}(E(K))$.

Lemma 2.8. *Let K_ℓ denote the completion of K at the totally ramified prime of K lying over ℓ. Then $E(K)[p] = E(K_\ell)[p] = 0$.*

Proof. The characteristic polynomial of $\mathrm{Frob}_\ell \in \mathrm{Gal}(\mathbb{Q}_\ell^{\mathrm{ur}}/\mathbb{Q}_\ell)$ on $E[p] = E(\mathbb{Q}_\ell^{\mathrm{ur}})[p]$ is $x^2 - a_\ell x + \ell \in \mathbb{F}_p[x]$. By hypothesis $a_\ell \not\equiv \ell + 1 \pmod{p}$, so $+1$ is not a root of $x^2 - a_\ell x + \ell$ hence

$$E(\mathbb{Q}_\ell)[p] = E(\mathbb{Q}_\ell^{\mathrm{ur}})[p]^{\mathrm{Frob}_\ell - 1} = 0.$$

Since K is totally ramified at ℓ and E has good reduction at ℓ, $E(K_\ell)[p] = 0$ as well, so $E(K)[p] = 0$, as required. □

Proposition 2.9. $\mathrm{Coker}(R(\mathbb{Q}) \to E(\mathbb{Q})) \cong E(\mathbb{Q})/pE(\mathbb{Q})$.

Proof. By Corollary 2.5 the the image of $\iota(E(\mathbb{Q})) \subset R(\mathbb{Q})$ in $E(\mathbb{Q})$ is $pE(\mathbb{Q})$, so the cokernel of $R(\mathbb{Q}) \to E(\mathbb{Q})$ is a quotient of $E(\mathbb{Q})/pE(\mathbb{Q})$. Thus it suffices to prove that $R(\mathbb{Q})/\iota(E(\mathbb{Q}))$ is *finite* of order coprime to p.

We have an exact sequence $0 \to E \to R \to A' \to 0$, with A' an abelian variety that is isogenous to A (in fact, A' is the abelian variety dual of A since R is self dual, but we will not use this fact.) The L-series of A' is $\prod_{i=1}^{p-1} L(E, \chi_{p,\ell}^i, s)$, so by hypothesis $L(A', 1) \neq 0$ and it follows from Kato's theorem (see [Rub98, §8.1]) that $A'(\mathbb{Q})$ is finite. Thus $R(\mathbb{Q})/\iota(E(\mathbb{Q}))$ is finite since $R(\mathbb{Q})/\iota(E(\mathbb{Q})) \subset A'(\mathbb{Q})$. By Lemma 2.6, $A'_K \approx E_K^{\times(p-1)}$ and by Lemma 2.8 $E(K)[p] = 0$, so $A'(\mathbb{Q})[p] = 0$, which proves the proposition. □

2.4. Étale Cohomology and Shafarevich–Tate Groups

Fix an elliptic curve E over $\mathbb{Q}$ and a prime $p \nmid \prod c_{E,q}$.

In this section, we use results mostly due to Mazur to relate the Shafarevich–Tate groups of A, R, and E to certain étale cohomology groups. We maintain the notation and assumptions of the previous sections, except that we abuse notation slightly and let $\mathcal{A}$, $\mathcal{R}$, and $\mathcal{E}$ also denote the étale sheaves on $\mathrm{Spec}(\mathbb{Z})$ defined by the Néron models $\mathcal{A}$, $\mathcal{R}$, and $\mathcal{E}$. Let $\mathcal{B}$ be either $\mathcal{A}$, $\mathcal{R}$, or $\mathcal{E}$ and let $B = \mathcal{B}_{\mathbb{Q}}$ be the corresponding abelian variety. Let $H^q(\mathbb{Z}, \mathcal{B})$ be the qth étale cohomology group of $\mathcal{B}$.

Lemma 2.10. *There is an isomorphism* $B(\mathbb{Q}_\ell)[p] \cong \mathcal{B}(\mathbb{F}_\ell)[p]$.

Proof. This follows from [ST68, Lem. 2, pg. 495], but we sketch a proof for the convenience of the reader. Let $B^1(\mathbb{Q}_\ell)$ denote the kernel of the natural reduction map $r : B(\mathbb{Q}_\ell) \to \mathcal{B}(\mathbb{F}_\ell)$. Using formal groups and that $p \neq \ell$, one sees that $[p] : B^1(\mathbb{Q}_\ell) \to B^1(\mathbb{Q}_\ell)$ is an isomorphism. Since $\mathcal{B}$ is smooth over $\mathbb{Q}_\ell$, Hensel's lemma (see [BLR90, §2.3 Prop. 5]) implies that the reduction map is surjective, so we obtain an exact sequence

$$0 \to B^1(\mathbb{Q}_\ell) \to B(\mathbb{Q}_\ell) \to \mathcal{B}(\mathbb{F}_\ell) \to 0.$$

The snake lemma applied to the multiplication-by-p diagram attached to this exact sequence yields the exact sequence

$$0 \to B(\mathbb{Q}_\ell)[p] \to \mathcal{B}(\mathbb{F}_\ell)[p] \to 0 \to B(\mathbb{Q}_\ell)/pB(\mathbb{Q}_\ell) \to \mathcal{B}(\mathbb{F}_\ell)/p\mathcal{B}(\mathbb{F}_\ell) \to 0,$$

which proves the lemma. □

The *Tamagawa number* of B at a prime q is $c_{B,q} = \#\Phi_{B,q}(\mathbb{F}_q)$, where $\Phi_{B,q}$ is the component group of the closed fiber of the Néron model of B at q.

Lemma 2.11. $p \nmid c_{B,q}$.

Proof. First suppose $q = \ell$. The cokernel of $\mathcal{B}(\mathbb{F}_\ell) \to \Phi_{B,\ell}(\mathbb{F}_\ell)$ is contained in $H^1(\mathbb{F}_\ell, \mathcal{B}^0)$, which is 0 by Lang's theorem (see [Lan56] or [Ser88, §VI.4]), so if $\Phi_{B,\ell}(\mathbb{F}_\ell)[p] \neq 0$ then $\mathcal{B}(\mathbb{F}_\ell)[p] \neq 0$. But by Lemmas 2.6, 2.8, and 2.10,

$$\mathcal{B}(\mathbb{F}_\ell)[p] \cong \mathcal{B}(\mathbb{Q}_\ell)[p] \subset \mathcal{B}(K_\ell)[p] \cong E(K_\ell)[p] \times \cdots \times E(K_\ell)[p] = 0.$$

Next suppose that $q \neq \ell$. Since formation of Néron models commutes with unramified base extension, we have

$$\Phi_{B,q}(\overline{\mathbb{F}}_q)[p] \cong \Phi_{E,q}(\overline{\mathbb{F}}_q)[p] \times \cdots \times \Phi_{E,q}(\overline{\mathbb{F}}_q)[p] = 0,$$

by our hypotheses on p. □

Following the appendix to [Maz72], let

$$\Sigma(B/\mathbb{Q}) = \ker\left(H^1(\mathbb{Q}, B) \to \bigoplus_{\text{all finite } q} H^1(\mathbb{Q}_q, B) \right),$$

where the sum is over all finite primes q of $\mathbb{Q}$. If p is an odd prime, then $\Sigma(B/\mathbb{Q})[p^\infty] = Ш(B/\mathbb{Q})[p^\infty]$; also one can see easily using Tate cohomology for the cyclic group $\mathrm{Gal}(\mathbb{C}/\mathbb{R})$ that

$$\Sigma(B/\mathbb{Q})[2]/Ш(B/\mathbb{Q})[2] \subset H^1(\mathbb{R}, B(\mathbb{C})) \cong B(\mathbb{R})/B(\mathbb{R})^0,$$

where $B(\mathbb{R})/B(\mathbb{R})^0$ has order 2^e for some $e \leq \dim B$.

Proposition 2.12 (Mazur)**.** *Suppose that* $a_\ell \not\equiv \ell + 1 \pmod{p}$*. If* p *is odd, then*

$$H^1(\mathbb{Z}, \mathcal{B})[p^\infty] \cong Ш(B/\mathbb{Q})[p^\infty].$$

Also, $\#H^1(\mathbb{Z}, \mathcal{B})[2^\infty]/Ш(B/\mathbb{Q})[2^\infty]$ *divides* $\#(B(\mathbb{R})/B(\mathbb{R})^0)$*.*

Proof. It follows from the appendix to [Maz72] that there is an exact sequence

$$0 \to \Sigma(B)[p^\infty] \to H^1(\mathbb{Z}, \mathcal{B})[p^\infty] \to \bigoplus_{\text{all finite } q} H^1\left(\mathbb{F}_q, \Phi_{B,q}(\overline{\mathbb{F}}_q)\right)[p^\infty], \tag{3}$$

where $\Phi_{B,q}$ is the component group of the fiber of $\mathcal{B}$ at q. By [Ser79, VIII.4.8],

$$\#H^1(\mathbb{F}_q, \Phi_{B,q}(\overline{\mathbb{F}}_q)) = \#\Phi_{B,q}(\mathbb{F}_q) = c_{B,q},$$

so the proposition follows from Lemma 2.11. □

Proposition 2.13. $H^2(\mathbb{Z}, \mathcal{A})[p] = 0$*.*

Proof. We apply the lemmas in [Sch83, §III.6]. Note that A has good reduction at p by [Mil72, Prop. 1], and $H^1(\mathbb{Z}, \mathcal{A})[p^\infty]$ is finite by Kato's theorem (see [Rub98, §8.1]) and Proposition 2.12. In the proof of Proposition 2.9, we showed that $A'(\mathbb{Q})$ is finite of order coprime to p, where A' is the abelian variety dual of A. We now use[1] Lemma 7 of [Sch83, §III.6], which because $A'(\mathbb{Q})[p] = 0$ implies that $H^2(\mathbb{Z}, \mathcal{A}[p^\infty]) = 0$ (Schneider uses H^q_{fpqf}, but this is not a problem since étale and fpqf cohomology agree on the smooth scheme $\mathcal{A}$.) It is easy to see (see, e.g., the proof of Lemma 6 of [Sch83, §III.6]) that the natural map $H^q(\mathbb{Z}, \mathcal{A}[p^\infty]) \to H^q(\mathbb{Z}, \mathcal{A})[p^\infty]$ is surjective for any $q > 0$, in particular, for $q = 2$, so $H^2(\mathbb{Z}, \mathcal{A})[p^\infty] = 0$ which proves the proposition. □

2.5. The Main Theorem

Fix an elliptic curve E over $\mathbb{Q}$ and a prime $p \nmid \prod c_{E,q}$ such that $\rho_{E,p} : G_\mathbb{Q} \to \mathrm{Aut}(E[p])$ is surjective. If $p = 2$ assume also that $E(\mathbb{R})$ is connected. Assume that ℓ is one of the primes whose existence is predicted by Conjecture 2.1. Let A and R be the corresponding abelian varieties, which fit into an exact sequence $0 \to A \to R \to E \to 0$, and recall that $L(A, 1) \neq 0$ so $A(\mathbb{Q})$ and $Ш(A/\mathbb{Q})$ are both finite (by [Rub98, §8.1] and [Kat, Cor. 14.3]).

[1] Note that the proof of Lemma 7 of [Sch83, §III.6] relies on a theorem of Artin and Mazur whose proof they never published; generalizations of this theorem have been published by McCallum [McC86, §5] and Milne [Mil86, §III.3.4], and Mazur assures the author that he and Milne both know the proof of Artin-Mazur duality well.

Theorem 2.14. *There is an exact sequence*

$$0 \to E(\mathbb{Q})/pE(\mathbb{Q}) \to Ш(A/\mathbb{Q})[p^\infty] \to Ш(E/K)[p^\infty] \to Ш(E/\mathbb{Q})[p^\infty] \to 0.$$

In particular, if E has odd rank and $Ш(E/\mathbb{Q})[p^\infty]$ is finite, then $\#Ш(A/\mathbb{Q})[p^\infty]$ is not a perfect square.

Proof. By Proposition 2.7 we have an exact sequence of étale sheaves

$$0 \to \mathcal{A} \to \mathcal{R} \to \mathcal{E} \to 0,$$

which gives rise to an exact sequence of étale cohomology groups

$$H^0(\mathbb{Z}, \mathcal{R}) \to H^0(\mathbb{Z}, \mathcal{E}) \to H^1(\mathbb{Z}, \mathcal{A}) \to H^1(\mathbb{Z}, \mathcal{R}) \to H^1(\mathbb{Z}, \mathcal{E}) \to H^2(\mathbb{Z}, \mathcal{A}).$$

We have

$$H^0(\mathbb{Z}, \mathcal{R}) = \mathcal{R}(\mathbb{Z}) = R(\mathbb{Q})$$

and likewise for $\mathcal{E}$, so by Propositions 2.9, 2.12, and 2.13 we obtain an exact sequence

$$0 \to E(\mathbb{Q})/pE(\mathbb{Q}) \to Ш(A/\mathbb{Q})[p^\infty] \to Ш(R/\mathbb{Q})[p^\infty] \to Ш(E/\mathbb{Q})[p^\infty] \to 0.$$

By Shapiro's lemma, there is an isomorphism $Ш(R/\mathbb{Q}) \cong Ш(E/K)$ (see [AS02, §1.3]), which yields the claimed exact sequence.

Kato's theorem ([Rub98, §8.1] and [Kat, Cor. 14.3]) implies that $Ш(E/K)[p^\infty]$ is finite (for the trivial character use our hypothesis that $Ш(E/\mathbb{Q})[p^\infty]$ is finite, and for the nontrivial characters use our hypothesis that $L(E, \chi_{p,\ell}, 1) \neq 0$). Theorem 1.2 then implies that $\#Ш(E/K)[p^\infty]$ is a perfect square. If $E(\mathbb{Q})$ has odd rank then $\#(E(\mathbb{Q})/pE(\mathbb{Q}))$ is an odd power of p (since $E[p]$ is irreducible), so $\#Ш(A/\mathbb{Q})[p^\infty]$ cannot be a perfect square. □

Remark 2.15. In the language of visibility of Shafarevich-Tate groups (see [CM00]), Theorem 2.14 asserts that the visible subgroup of $Ш(A)$ with respect to the embedding $A \hookrightarrow R$ is canonically isomorphic to the Mordell-Weil quotient $E(\mathbb{Q})/pE(\mathbb{Q})$.

Proposition 2.16. *If $q \neq p$ is a prime, then*

$$Ш(E/K)[q^\infty] \cong Ш(E/\mathbb{Q})[q^\infty] \oplus Ш(A/\mathbb{Q})[q^\infty]. \tag{4}$$

In particular, if $Ш(E/\mathbb{Q})[q^\infty]$ is finite, then $Ш(A/\mathbb{Q})[q^\infty]$ has order a perfect square.

Proof. The intersection of E and A in R is $E[p]$, so the summation map $E \times A \to R$ is an isogeny with kernel $E[p]$. Considering the long exact sequence associated to $0 \to E[p] \to E \times A \to R \to 0$, we see that

$$H^1(\mathbb{Q}, E \times A)[q^\infty] \cong H^1(\mathbb{Q}, R)[q^\infty], \tag{5}$$

and likewise for any completion $\mathbb{Q}_v$ of $\mathbb{Q}$. We then obtain (4) by combining (5) with the fact that cohomology commutes with products and that $H^1(\mathbb{Q}, R) \cong H^1(K, E)$.

If $Ш(E/\mathbb{Q})[q^\infty]$ is finite, then since $Ш(A/\mathbb{Q})[q^\infty]$ is finite (since $L(A, 1) \neq 0$, by construction), it follows from (4) that $Ш(E/K)[q^\infty]$ is finite. We have by Theorem 1.2 that both $Ш(E/K)[q^\infty]$ and $Ш(E/\mathbb{Q})[q^\infty]$ have order a perfect square, so (4) implies that $Ш(A/\mathbb{Q})[q^\infty]$ has order a perfect square. □

3. An Example

Combining Proposition 2.3, Theorem 2.14, and Proposition 2.16 yields the following theorem.

Theorem 3.1. *Let E be the elliptic curve $y^2 + y = x^3 - x$ of conductor 37. For every odd prime $p < 25000$ (with $p \neq 37$), there is a twist A of $E^{\times(p-1)}$ such that $\#\text{Ш}(A/\mathbb{Q}) = pn^2$ for some integer n.*

Remark 3.2. Using the elliptic curve of conductor 43 in place of E one can construct an abelian variety A with $\text{Ш}(A/\mathbb{Q}) = 37n^2$ for some integer n.

Though unnecessary for Theorem 3.1, we prove below that $\text{Ш}(E/\mathbb{Q}) = 0$, which removes our dependence on Proposition 2.13. We show that $\text{Ш}(E/\mathbb{Q})[p^\infty] = 0$ for all odd p using [Kol90, Thm. A], and we use a 2-descent (with [CrB]) to see that $\text{Ш}(E/\mathbb{Q})[2] = 0$.

Theorem 3.3 (Kolyvagin)**.** *Let E be an elliptic curve and let $L = \mathbb{Q}(\sqrt{-D})$ be an imaginary quadratic field of odd discriminant $-D$, where all primes dividing the conductor of E split, and assume that $D \neq 3, 4$. If the Heegner point $y_L \in E(L)$ has infinite order (equivalently, by* [GZ86]*, $L'(E/L, 1) \neq 0$), then $\#\text{Ш}(E/L) \mid t \cdot [E(L) : \mathbb{Z}y_L]^2$, where the only primes that divide t are 2 or primes where $\rho_{E,p}$ is not surjective.*

By [C97], E is isolated in its isogeny class, so $\rho : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \text{Aut}(E[p])$ is surjective for all primes p (see [RS01, §1.4]) hence t is a power of 2. Let $L = \mathbb{Q}(\sqrt{-7})$. To compute $[E(L) : \mathbb{Z}y_L]$ up to a power of 2 we use the Gross-Zagier formula and the fact that $[E(L) : E(\mathbb{Q}) + E^D(\mathbb{Q})]$ is a power of 2. By [GZ86, Thm. 6.3],

$$h(y_L) = \frac{u^2|D|^{\frac{1}{2}}}{\|\omega_f\|} L'(E,1)L(E^D,1),$$

where $D = -7$, $u = 1$, and $\|\omega_f\|$ is the Peterson norm of the newform f corresponding to E. Generators for the period lattice of E are $\omega_1 \sim 2.993459$ and $\omega_2 \sim 2.451389i$, so $\|\omega_f\| \sim 7.338133$. The quadratic twist E^D is the curve **1813B1** in [CrA], and $E^D(\mathbb{Q}) = 0$. From [CrA] we find that $L'(E,1) \sim 0.306000$ and $L(E^D,1) \sim 1.853076$, so $h(y_L) \sim 0.204446$. The height of a generator of $E(\mathbb{Q})$ is $\sim 0.051111 \sim h(y_L)/4$, so $[E(L) : \mathbb{Z}y_L]$ is a power of 2. (As a double check, and to avoid dependence on the Gross-Zagier formula, we wrote a program using [BCP97] to compute Heegner points and found that $y_L = (0,0)$, which is a generator for $E(\mathbb{Q})$.) Thus $\#\text{Ш}(E/L)$ is a power of 2.

To connect $\text{Ш}(E/L)$ with $\text{Ш}(E/\mathbb{Q})$, use the inflation-restriction exact sequence

$$0 \to H^1(L/\mathbb{Q}, E(L)) \to H^1(\mathbb{Q}, E(\overline{\mathbb{Q}})) \to H^1(L, E(\overline{\mathbb{Q}})).$$

Let p be an odd prime. Since $H^1(L/\mathbb{Q}, E(L))$ is a 2-group, the above sequence leads to an injective map

$$H^1(\mathbb{Q}, E(\overline{\mathbb{Q}}))[p] \hookrightarrow H^1(L, E(\overline{\mathbb{Q}}))[p],$$

which induces an inclusion

$$Ш(E/\mathbb{Q})[p] \hookrightarrow Ш(E/L)[p] = 0.$$

17 Constructing Elements In Shafarevich-Tate Groups Of Modular Motives, with N. Dummigan and M. Watkins

CONSTRUCTING ELEMENTS IN SHAFAREVICH-TATE GROUPS OF MODULAR MOTIVES

NEIL DUMMIGAN, WILLIAM STEIN, AND MARK WATKINS

Abstract. We study Shafarevich-Tate groups of motives attached to modular forms on $\Gamma_0(N)$ of weight bigger than 2. We deduce a criterion for the existence of nontrivial elements of these Shafarevich-Tate groups, and give 16 examples in which a strong form of the Beilinson-Bloch conjecture implies the existence of such elements. We also use modular symbols and observations about Tamagawa numbers to compute nontrivial conjectural lower bounds on the orders of the Shafarevich-Tate groups of modular motives of low level and weight at most 12. Our methods build upon the idea of visibility due to Cremona and Mazur, but in the context of motives instead of abelian varieties.

1. Introduction

Let E be an elliptic curve defined over $\mathbb{Q}$ and let $L(E,s)$ be the associated L-function. The conjecture of Birch and Swinnerton-Dyer [BS-D] predicts that the order of vanishing of $L(E,s)$ at $s = 1$ is the rank of the group $E(\mathbb{Q})$ of rational points, and also gives an interpretation of the leading term in the Taylor expansion in terms of various quantities, including the order of the Shafarevich-Tate group of E.

Cremona and Mazur [CM1] look, among all strong Weil elliptic curves over $\mathbb{Q}$ of conductor $N \leq 5500$, at those with nontrivial Shafarevich-Tate group (according to the Birch and Swinnerton-Dyer conjecture). Suppose that the Shafarevich-Tate group has predicted elements of prime order p. In most cases they find another elliptic curve, often of the same conductor, whose p-torsion is Galois-isomorphic to that of the first one, and which has positive rank. The rational points on the second elliptic curve produce classes in the common $H^1(\mathbb{Q}, E[p])$. They show [CM2] that these lie in the Shafarevich-Tate group of the first curve, so rational points on one curve explain elements of the Shafarevich-Tate group of the other curve.

The Bloch-Kato conjecture [BK] is the generalisation to arbitrary motives of the leading term part of the Birch and Swinnerton-Dyer conjecture. The Beilinson-Bloch conjecture [B, Be] generalises the part about the order of vanishing at the central point, identifying it with the rank of a certain Chow group.

This paper is a partial generalisation of [CM1] and [AS] from abelian varieties over $\mathbb{Q}$ associated to modular forms of weight 2 to the motives attached to modular forms of higher weight. It also does for congruences between modular forms of equal weight what [Du2] did for congruences between modular forms of different weights.

Date: 28 January 2003.

1991 *Mathematics Subject Classification.* 11F33, 11F67, 11G40.

Key words and phrases. modular form, L-function, visibility, Bloch-Kato conjecture, Shafarevich-Tate group.

We consider the situation where two newforms f and g, both of even weight $k > 2$ and level N, are congruent modulo a maximal ideal $\mathfrak{q}$ of odd residue characteristic, and $L(g, k/2) = 0$ but $L(f, k/2) \neq 0$. It turns out that this forces $L(g, s)$ to vanish to order at least 2 at $s = k/2$. In Section 7, we give sixteen such examples (all with $k = 4$ and $k = 6$), and in each example, we find that $\mathfrak{q}$ divides the numerator of the algebraic number $L(f, k/2)/\operatorname{vol}_\infty$, where $\operatorname{vol}_\infty$ is a certain canonical period.

In fact, we show how this divisibility may be deduced from the vanishing of $L(g, k/2)$ using recent work of Vatsal [V]. The point is, the congruence between$f$ and g leads to a congruence between suitable "algebraic parts" of the special values $L(f, k/2)$ and $L(g, k/2)$. In slightly more detail, a multiplicity one result of Faltings and Jordan shows that the congruence of Fourier expansions leads to a congruence of certain associated cohomology classes. These are then identified with the modular symbols which give rise to the algebraic parts of special values. If $L(g, k/2)$ vanishes then the congruence implies that $L(f, k/2)/\operatorname{vol}_\infty$ must be divisible by $\mathfrak{q}$.

The Bloch-Kato conjecture sometimes then implies that the Shafarevich-Tate group Ш attached to f has nonzero $\mathfrak{q}$-torsion. Under certain hypotheses and assumptions, the most substantial of which is the Beilinson-Bloch conjecture relating the vanishing of $L(g, k/2)$ to the existence of algebraic cycles, we are able to construct some of the predicted elements of Ш using the Galois-theoretic interpretation of the congruence to transfer elements from a Selmer group for g to a Selmer group for f. One might say that algebraic cycles for one motive explain elements of Ш for the other, or that we use the congruence to link the Beilinson-Bloch conjecture for one motive with the Bloch-Kato conjecture for the other.

We also compute data which, assuming the Bloch-Kato conjecture, provides lower bounds for the orders of numerous Shafarevich-Tate groups (see Section 7.3). We thank the referee for many constructive comments.

2. Motives and Galois representations

This section and the next provide definitions of some of the quantities appearing later in the Bloch-Kato conjecture. Let $f = \sum a_n q^n$ be a newform of weight $k \geq 2$ for $\Gamma_0(N)$, with coefficients in an algebraic number field E, which is necessarily totally real. Let λ be any finite prime of E, and let ℓ denote its residue characteristic. A theorem of Deligne [De1] implies the existence of a two-dimensional vector space V_λ over E_λ, and a continuous representation

$$\rho_\lambda : \operatorname{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \operatorname{Aut}(V_\lambda),$$

such that

(1) ρ_λ is unramified at p for all primes p not dividing ℓN, and
(2) if Frob_p is an arithmetic Frobenius element at such a p then the characteristic polynomial of $\operatorname{Frob}_p^{-1}$ acting on V_λ is $x^2 - a_p x + p^{k-1}$.

Following Scholl [Sc], V_λ may be constructed as the λ-adic realisation of a Grothendieck motive M_f. There are also Betti and de Rham realisations V_B and V_{dR}, both 2-dimensional E-vector spaces. For details of the construction see [Sc]. The de Rham realisation has a Hodge filtration $V_{\mathrm{dR}} = F^0 \supset F^1 = \cdots = F^{k-1} \supset F^k = \{0\}$. The Betti realisation V_B comes from singular cohomology, while V_λ comes from étale ℓ-adic cohomology. For each prime λ, there is a natural isomorphism $V_B \otimes E_\lambda \simeq V_\lambda$. We may choose a $\operatorname{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-stable O_λ-module T_λ inside each V_λ. Define $A_\lambda = V_\lambda/T_\lambda$. Let $A[\lambda]$ denote the λ-torsion in A_λ. There is the Tate twist $V_\lambda(j)$ (for any integer j), which amounts to multiplying the action of Frob_p by p^j.

Following [BK] (Section 3), for $p \neq \ell$ (including $p = \infty$) let

$$H^1_f(\mathbb{Q}_p, V_\lambda(j)) = \ker(H^1(D_p, V_\lambda(j)) \to H^1(I_p, V_\lambda(j))).$$

The subscript f stands for "finite part", D_p is a decomposition subgroup at a prime above p, I_p is the inertia subgroup, and the cohomology is for continuous cocycles and coboundaries. For $p = \ell$ let

$$H^1_f(\mathbb{Q}_\ell, V_\lambda(j)) = \ker(H^1(D_\ell, V_\lambda(j)) \to H^1(D_\ell, V_\lambda(j) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}))$$

(see Section 1 of [BK] for definitions of Fontaine's rings B_{cris} and B_{dR}). Let $H^1_f(\mathbb{Q}, V_\lambda(j))$ be the subspace of elements of $H^1(\mathbb{Q}, V_\lambda(j))$ whose local restrictions lie in $H^1_f(\mathbb{Q}_p, V_\lambda(j))$ for all primes p.

There is a natural exact sequence

$$\begin{tikzcd} 0 \arrow[r] & T_\lambda(j) \arrow[r] & V_\lambda(j) \arrow[r, "\pi"] & A_\lambda(j) \arrow[r] & 0. \end{tikzcd}$$

Let $H^1_f(\mathbb{Q}_p, A_\lambda(j)) = \pi_* H^1_f(\mathbb{Q}_p, V_\lambda(j))$. Define the λ-Selmer group $H^1_f(\mathbb{Q}, A_\lambda(j))$ to be the subgroup of elements of $H^1(\mathbb{Q}, A_\lambda(j))$ whose local restrictions lie in $H^1_f(\mathbb{Q}_p, A_\lambda(j))$ for all primes p. Note that the condition at $p = \infty$ is superfluous unless $\ell = 2$. Define the Shafarevich-Tate group

$$Ш(j) = \oplus_\lambda H^1_f(\mathbb{Q}, A_\lambda(j))/\pi_* H^1_f(\mathbb{Q}, V_\lambda(j)).$$

Define an ideal $\#Ш(j)$ of O_E, in which the exponent of any prime ideal λ is the length of the λ-component of $Ш(j)$. We shall only concern ourselves with the case $j = k/2$, and write Ш for $Ш(k/2)$. It depends on the choice of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-stable O_λ-module T_λ inside each V_λ. But if $A[\lambda]$ is irreducible then T_λ is unique up to scaling and the λ-part of Ш is independent of choices.

In the case $k = 2$ the motive comes from a (self-dual) isogeny class of abelian varieties over $\mathbb{Q}$, with endomorphism algebra containing E. Choose an abelian variety B in the isogeny class in such a way that the endomorphism ring of B contains the full ring of integers O_E. If one takes all the $T_\lambda(1)$ to be λ-adic Tate modules, then what we have defined above coincides with the usual Shafarevich-Tate group of B (assuming finiteness of the latter, or just taking the quotient by its maximal divisible subgroup). To see this one uses 3.11 of [BK], for $\ell = p$. For $\ell \neq p$, $H^1_f(\mathbb{Q}_p, V_\ell) = 0$. Considering the formal group, every class in $B(\mathbb{Q}_p)/\ell B(\mathbb{Q}_p)$ is represented by an ℓ-power torsion point in $B(\mathbb{Q}_p)$, so maps to zero in $H^1(\mathbb{Q}_p, A_\ell)$.

Define the group of global torsion points

$$\Gamma_{\mathbb{Q}} = \oplus_\lambda H^0(\mathbb{Q}, A_\lambda(k/2)).$$

This is analogous to the group of rational torsion points on an elliptic curve. Define an ideal $\#\Gamma_{\mathbb{Q}}$ of O_E, in which the exponent of any prime ideal λ is the length of the λ-component of $\Gamma_{\mathbb{Q}}$.

3. Canonical periods

We assume from now on for convenience that $N \geq 3$. We need to choose convenient O_E-lattices T_B and T_{dR} in the Betti and de Rham realisations V_B and V_{dR} of M_f. We do this in a way such that T_B and $T_{\mathrm{dR}} \otimes_{O_E} O_E[1/Nk!]$ agree with (respectively) the O_E-lattice $\mathfrak{M}_{f,B}$ and the $O_E[1/Nk!]$-lattice $\mathfrak{M}_{f,\mathrm{dR}}$ defined in [DFG1] using cohomology, with non-constant coefficients, of modular curves. (In [DFG1], see especially Sections 2.2 and 5.4, and the paragraph preceding Lemma 2.3.)

For any finite prime λ of O_E define the O_λ module T_λ inside V_λ to be the image of $T_B \otimes O_\lambda$ under the natural isomorphism $V_B \otimes E_\lambda \simeq V_\lambda$. Then the O_λ-module T_λ is $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-stable.

Let $M(N)$ be the modular curve over $\mathbb{Z}[1/N]$ parametrising generalised elliptic curves with full level-N structure. Let $\mathfrak{E}$ be the universal generalised elliptic curve over $M(N)$. Let $\mathfrak{E}^{k-2}$ be the $(k-2)$-fold fibre product of $\mathfrak{E}$ over $M(N)$. (The motive M_f is constructed using a projector on the cohomology of a desingularisation of $\mathfrak{E}^{k-2}$). Realising $M(N)(\mathbb{C})$ as the disjoint union of $\phi(N)$ copies of the quotient $\Gamma(N)\backslash\mathfrak{H}^*$ (where $\mathfrak{H}^*$ is the completed upper half plane), and letting τ be a variable on $\mathfrak{H}$, the fibre $\mathfrak{E}_\tau$ is isomorphic to the elliptic curve with period lattice generated by 1 and τ. Let $z_i \in \mathbb{C}/\langle 1, \tau\rangle$ be a variable on the i^{th} copy of $\mathfrak{E}_\tau$ in the fibre product. Then $2\pi i f(\tau)\, d\tau \wedge dz_1 \wedge \ldots \wedge dz_{k-2}$ is a well-defined differential form on (a desingularisation of) $\mathfrak{E}^{k-2}$ and naturally represents a generating element of $F^{k-1}T_{\mathrm{dR}}$. (At least we can make our choices locally at primes dividing $Nk!$ so that this is the case.) We shall call this element $e(f)$.

Under the de Rham isomorphism between $V_{\mathrm{dR}} \otimes \mathbb{C}$ and $V_B \otimes \mathbb{C}$, $e(f)$ maps to some element ω_f. There is a natural action of complex conjugation on V_B, breaking it up into one-dimensional E-vector spaces V_B^+ and V_B^-. Let ω_f^+ and ω_f^- be the projections of ω_f to $V_B^+ \otimes \mathbb{C}$ and $V_B^- \otimes \mathbb{C}$, respectively. Let $T_B^\pm$ be the intersections of $V_B^\pm$ with T_B. These are rank one O_E-modules, but not necessarily free, since the class number of O_E may be greater than one. Choose nonzero elements $\delta_f^\pm$ of $T_B^\pm$ and let $\mathfrak{a}^\pm$ be the ideals $[T_B^\pm : O_E\delta_f^\pm]$. Define complex numbers $\Omega_f^\pm$ by $\omega_f^\pm = \Omega_f^\pm \delta_f^\pm$.

4. The Bloch-Kato conjecture

In this section we extract from the Bloch-Kato conjecture for $L(f, k/2)$ a prediction about the order of the Shafarevich-Tate group, by analysing the other terms in the formula.

Let $L(f,s)$ be the L-function attached to f. For $\Re(s) > \frac{k+1}{2}$ it is defined by the Dirichlet series with Euler product $\sum_{n=1}^{\infty} a_n n^{-s} = \prod_p (P_p(p^{-s}))^{-1}$, but there is an analytic continuation given by an integral, as described in the next section. Suppose that $L(f, k/2) \neq 0$. The Bloch-Kato conjecture for the motive $M_f(k/2)$ predicts the following equality of fractional ideals of E:

$$\frac{L(f,k/2)}{\mathrm{vol}_\infty} = \left(\prod_p c_p(k/2)\right) \frac{\#\text{Ш}}{\mathfrak{a}^\pm(\#\Gamma_\mathbb{Q})^2}.$$

Here, **and from this point onwards,** ± represents the parity of $(k/2) - 1$. The quantity vol_∞ is equal to $(2\pi i)^{k/2}$ multiplied by the determinant of the isomorphism $V_B^\pm \otimes \mathbb{C} \simeq (V_{\mathrm{dR}}/F^{k/2}) \otimes \mathbb{C}$, calculated with respect to the lattices $O_E\delta_f^\pm$ and the image of T_{dR}. For $l \neq p$, $\mathrm{ord}_\lambda(c_p(j))$ is defined to be

$$\begin{aligned} &\text{length } H^1_f(\mathbb{Q}_p, T_\lambda(j))_{\mathrm{tors}} - \mathrm{ord}_\lambda(P_p(p^{-j})) \\ &\quad = \text{length } \left(H^0(\mathbb{Q}_p, A_\lambda(j))/H^0\left(\mathbb{Q}_p, V_\lambda(j)^{I_p}/T_\lambda(j)^{I_p}\right)\right). \end{aligned}$$

We omit the definition of $\mathrm{ord}_\lambda(c_p(j))$ for $\lambda \mid p$, which requires one to assume Fontaine's de Rham conjecture ([Fo1], Appendix A6), and depends on the choices of T_{dR} and T_B, locally at λ. (We shall mainly be concerned with the q-part of the

Bloch-Kato conjecture, where q is a prime of good reduction. For such primes, the de Rham conjecture follows from Theorem 5.6 of [Fa].)

Strictly speaking, the conjecture in [BK] is only given for $E = \mathbb{Q}$. We have taken here the obvious generalisation of a slight rearrangement of (5.15.1) of [BK]. The Bloch-Kato conjecture has been reformulated and generalised by Fontaine and Perrin-Riou, who work with general E, though that is not really the point of their work. In Section 11 of [Fo2] it is sketched how to deduce the original conjecture from theirs, in the case $E = \mathbb{Q}$.

Lemma 4.1. $\mathrm{vol}_\infty / \mathfrak{a}^\pm = c(2\pi i)^{k/2}\mathfrak{a}^\pm\Omega_\pm$, *with* $c \in E$ *and* $\mathrm{ord}_\lambda(c) = 0$ *for* $\lambda \nmid Nk!$.

Proof. We note that vol_∞ is equal to $(2\pi i)^{k/2}$ times the determinant of the period map from $F^{k/2}V_{\mathrm{dR}} \otimes \mathbb{C}$ to $V_B^\pm \otimes \mathbb{C}$, with respect to lattices dual to those we used above in the definition of vol_∞ (c.f. the last paragraph of 1.7 of [De2]). We are using here natural pairings. Meanwhile, $\Omega_\pm$ is the determinant of the same map with respect to the lattices $F^{k/2}T_{\mathrm{dR}}$ and $O_E\delta_f^\pm$. Recall that the index of $O_E\delta_f^\pm$ in $T_B^\pm$ is the ideal $\mathfrak{a}^\pm$. Then the proof is completed by noting that, locally away from primes dividing $Nk!$, the index of T_{dR} in its dual is equal to the index of T_B in its dual, both being equal to the ideal denoted η in [DFG2]. □

Remark 4.2. Note that the "quantities" $\mathfrak{a}^\pm\Omega_\pm$ and $\mathrm{vol}_\infty / \mathfrak{a}^\pm$ are independent of the choice of $\delta_f^\pm$.

Lemma 4.3. *Let* $p \nmid N$ *be a prime and* j *an integer. Then the fractional ideal* $c_p(j)$ *is supported at most on divisors of* p.

Proof. As on p. 30 of [Fl2], for odd $l \neq p$, $\mathrm{ord}_\lambda(c_p(j))$ is the length of the finite O_λ-module $H^0(\mathbb{Q}_p, H^1(I_p, T_\lambda(j))_{\mathrm{tors}})$, where I_p is an inertia group at p. But $T_\lambda(j)$ is a trivial I_p-module, so $H^1(I_p, T_\lambda(j))$ is torsion free. □

Lemma 4.4. *Let* $q \nmid N$ *be a prime satisfying* $q > k$. *Suppose that* $A[\mathfrak{q}]$ *is an irreducible representation of* $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, *where* $\mathfrak{q} \mid q$. *Let* $p \mid N$ *be a prime, and if* $p^2 \mid N$ *suppose that* $p \not\equiv -1 \pmod{q}$. *Suppose also that* f *is not congruent modulo* $\mathfrak{q}$ *(for Fourier coefficients of index coprime to* Nq*) to any newform of weight* k*, trivial character, and level dividing* N/p. *Then* $\mathrm{ord}_\mathfrak{q}(c_p(j)) = 0$ *for all integers* j.

Proof. There is a natural injective map from $V_\mathfrak{q}(j)^{I_p}/T_\mathfrak{q}(j)^{I_p}$ to $H^0(I_p, A_\mathfrak{q}(j))$ (i.e., $A_\mathfrak{q}(j)^{I_p}$). Consideration of $\mathfrak{q}$-torsion shows that

$$\dim_{O_E/\mathfrak{q}} H^0(I_p, A[\mathfrak{q}](j)) \geq \dim_{E_\mathfrak{q}} H^0(I_p, V_\mathfrak{q}(j)).$$

To prove the lemma it suffices to show that

$$\dim_{O_E/\mathfrak{q}} H^0(I_p, A[\mathfrak{q}](j)) = \dim_{E_\mathfrak{q}} H^0(I_p, V_\mathfrak{q}(j)),$$

since this ensures that $H^0(I_p, A_\mathfrak{q}(j)) = V_\mathfrak{q}(j)^{I_p}/T_\mathfrak{q}(j)^{I_p}$, hence that $H^0(\mathbb{Q}_p, A_\mathfrak{q}(j)) = H^0(\mathbb{Q}_p, V_\mathfrak{q}(j)^{I_p}/T_\mathfrak{q}(j)^{I_p})$. If the dimensions differ then, given that f is not congruent modulo $\mathfrak{q}$ to a newform of level dividing N/p, Condition (b) of Proposition 2.3 of [L] is satisfied. If Condition (a) was not satisfied then Proposition 2.2 of [L] would imply that f was congruent modulo $\mathfrak{q}$ to a twist of level dividing N/p. Since Condition (c) is clearly also satisfied, we are in a situation covered by one of the three cases in Proposition 2.3 of [L]. Since $p \not\equiv -1 \pmod{q}$ if $p^2 \mid N$, Case 3 is excluded, so $A[\mathfrak{q}](j)$ is unramified at p and $\mathrm{ord}_p(N) = 1$. (Here we are using Carayol's result that N is the prime-to-q part of the conductor of $V_\mathfrak{q}$ [Ca1].) But then Theorem 1 of [JL] (which uses the condition $q > k$) implies the existence of a newform of weight k, trivial character and level dividing N/p, congruent to g modulo $\mathfrak{q}$, for Fourier coefficients of index coprime to Nq. This contradicts our hypotheses. □

Remark 4.5. For an example of what can be done when f is congruent to a form of lower level, see the first example in Section 7.4 below.

Lemma 4.6. *If* $\mathfrak{q} \mid q$ *is a prime of* E *such that* $q \nmid Nk!$*, then* $\mathrm{ord}_{\mathfrak{q}}(c_q) = 0$.

Proof. It follows from Lemma 5.7 of [DFG1] (whose proof relies on an application, at the end of Section 2.2, of the results of [Fa]) that $T_{\mathfrak{q}}$ is the $O_{\mathfrak{q}}[\mathrm{Gal}(\overline{\mathbb{Q}}_q/\mathbb{Q}_q)]$-module associated to the filtered module $T_{\mathrm{dR}} \otimes O_{\mathfrak{q}}$ by the functor they call $\mathbb{V}$. (This property is part of the definition of an S-integral premotivic structure given in Section 1.2 of [DFG1].) Given this, the lemma follows from Theorem 4.1(iii) of [BK]. (That $\mathbb{V}$ is the same as the functor used in Theorem 4.1 of [BK] follows from the first paragraph of 2(h) of [Fa].) □

Lemma 4.7. *If* $A[\lambda]$ *is an irreducible representation of* $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$*, then*

$$\mathrm{ord}_{\lambda}(\#\Gamma_{\mathbb{Q}}) = 0.$$

Proof. This follows trivially from the definition. □

Putting together the above lemmas we arrive at the following:

Proposition 4.8. *Let* $q \nmid N$ *be a prime satisfying* $q > k$ *and suppose that* $A[\mathfrak{q}]$ *is an irreducible representation of* $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$*, where* $\mathfrak{q} \mid q$*. Assume the same hypotheses as in Lemma 4.4 for all* $p \mid N$*. Choose* T_{dR} *and* T_B *which locally at* $\mathfrak{q}$ *are as in the previous section. If* $L(f, k/2)\mathfrak{a}^{\pm}/\mathrm{vol}_{\infty} \neq 0$ *then the Bloch-Kato conjecture predicts that*

$$\mathrm{ord}_{\mathfrak{q}}(\#Ш) = \mathrm{ord}_{\mathfrak{q}}(L(f, k/2)\mathfrak{a}^{\pm}/\mathrm{vol}_{\infty}).$$

5. Congruences of special values

Let $f = \sum a_n q^n$ and $g = \sum b_n q^n$ be newforms of equal weight $k \geq 2$ for $\Gamma_0(N)$. Let E be a number field large enough to contain all the coefficients a_n and b_n. Suppose that $\mathfrak{q} \mid q$ is a prime of E such that $f \equiv g \pmod{\mathfrak{q}}$, i.e. $a_n \equiv b_n \pmod{\mathfrak{q}}$ for all n. Assume that $A[\mathfrak{q}]$ is an irreducible representation of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, and that $q \nmid N\phi(N)k!$. Choose $\delta_f^{\pm} \in T_B^{\pm}$ in such a way that $\mathrm{ord}_{\mathfrak{q}}(\mathfrak{a}^{\pm}) = 0$, i.e., $\delta_f^{\pm}$ generates $T_B^{\pm}$ locally at $\mathfrak{q}$. Make two further assumptions:

$$L(f, k/2) \neq 0 \qquad \text{and} \qquad L(g, k/2) = 0.$$

Proposition 5.1. *With assumptions as above,* $\mathrm{ord}_{\mathfrak{q}}(L(f, k/2)/\mathrm{vol}_{\infty}) > 0$.

Proof. This is based on some of the ideas used in Section 1 of [V]. Note the apparent typo in Theorem 1.13 of [V], which presumably should refer to “Condition 2”. Since $\mathrm{ord}_{\mathfrak{q}}(\mathfrak{a}^{\pm}) = 0$, we just need to show that $\mathrm{ord}_{\mathfrak{q}}(L(f, k/2)/((2\pi i)^{k/2}\Omega_{\pm})) > 0$, where $\pm 1 = (-1)^{(k/2)-1}$. It is well known, and easy to prove, that

$$\int_0^{\infty} f(iy) y^{s-1} dy = (2\pi)^{-s}\Gamma(s)L(f, s).$$

Hence, if for $0 \leq j \leq k-2$ we define the j^{th} period

$$r_j(f) = \int_0^{i\infty} f(z) z^j dz,$$

where the integral is taken along the positive imaginary axis, then

$$r_j(f) = j!(-2\pi i)^{-(j+1)} L_f(j+1).$$

Thus we are reduced to showing that $\mathrm{ord}_{\mathfrak{q}}(r_{(k/2)-1}(f)/\Omega_{\pm}) > 0$.

Let $\mathcal{D}_0$ be the group of divisors of degree zero supported on $\mathbb{P}^1(\mathbb{Q})$. For a $\mathbb{Z}$-algebra R and integer $r \geq 0$, let $P_r(R)$ be the additive group of homogeneous polynomials of degree r in $R[X,Y]$. Both these groups have a natural action of $\Gamma_1(N)$. Let $S_{\Gamma_1(N)}(k,R) := \mathrm{Hom}_{\Gamma_1(N)}(\mathcal{D}_0, P_{k-2}(R))$ be the R-module of weight k modular symbols for $\Gamma_1(N)$.

Via the isomorphism (8) in Section 1.5 of [V], combined with the argument in 1.7 of [V], the cohomology class $\omega_f^{\pm}$ corresponds to a modular symbol $\Phi_f^{\pm} \in S_{\Gamma_1(N)}(k,\mathbb{C})$, and $\delta_f^{\pm}$ corresponds to an element $\Delta_f^{\pm} \in S_{\Gamma_1(N)}(k, O_{E,\mathfrak{q}})$. We are now dealing with cohomology over $X_1(N)$ rather than $M(N)$, which is why we insist that $q \nmid \phi(N)$. It follows from the last line of Section 4.2 of [St] that, up to some small factorials which do not matter locally at $\mathfrak{q}$,

$$\Phi_f^{\pm}([\infty]-[0]) = \sum_{j=0, j\equiv (k/2)-1 \pmod 2}^{k-2} r_f(j) X^j Y^{k-2-j}.$$

Since $\omega_f^{\pm} = \Omega_f^{\pm}\delta_f^{\pm}$, we see that

$$\Delta_f^{\pm}([\infty]-[0]) = \sum_{j=0, j\equiv (k/2)-1 \pmod 2}^{k-2} (r_f(j)/\Omega_f^{\pm}) X^j Y^{k-2-j}.$$

The coefficient of $X^{(k/2)-1}Y^{(k/2)-1}$ is what we would like to show is divisible by $\mathfrak{q}$. Similarly

$$\Phi_g^{\pm}([\infty]-[0]) = \sum_{j=0, j\equiv (k/2)-1 \pmod 2}^{k-2} r_g(j) X^j Y^{k-2-j}.$$

The coefficient of $X^{(k/2)-1}Y^{(k/2)-1}$ in this is 0, since $L(g,k/2)=0$. Therefore it would suffice to show that, for some $\mu \in O_E$, the element $\Delta_f^{\pm} - \mu\Delta_g^{\pm}$ is divisible by $\mathfrak{q}$ in $S_{\Gamma_1(N)}(k, O_{E,\mathfrak{q}})$. It suffices to show that, for some $\mu \in O_E$, the element $\delta_f^{\pm} - \mu\delta_g^{\pm}$ is divisible by $\mathfrak{q}$, considered as an element of $\mathfrak{q}$-adic cohomology of $X_1(N)$ with non-constant coefficients. This would be the case if $\delta_f^{\pm}$ and $\delta_g^{\pm}$ generate the same one-dimensional subspace upon reduction modulo $\mathfrak{q}$. But this is a consequence of Theorem 2.1(1) of [FJ] (for which we need the irreducibility of $A[\mathfrak{q}]$). □

Remark 5.2. The signs in the functional equations of $L(f,s)$ and $L(g,s)$ are equal. They are determined by the eigenvalue of the Atkin-Lehner involution W_N, which is determined by a_N and b_N modulo $\mathfrak{q}$, because a_N and b_N are each $N^{k/2-1}$ times this sign and $\mathfrak{q}$ has residue characteristic coprime to $2N$. The common sign in the functional equation is $(-1)^{k/2}w_N$, where w_N is the common eigenvalue of W_N acting on f and g.

This is analogous to the remark at the end of Section 3 of [CM1], which shows that if $\mathfrak{q}$ has odd residue characteristic and $L(f,k/2)\neq 0$ but $L(g,k/2)=0$ then $L(g,s)$ must vanish to order at least two at $s=k/2$. Note that Maeda's conjecture implies that there are no examples of g of level one with positive sign in their functional equation such that $L(g,k/2)=0$ (see [CF]).

6. Constructing elements of the Shafarevich-Tate group

Let f, g and $\mathfrak{q}$ be as in the first paragraph of the previous section. In the previous section we showed how the congruence between f and g relates the vanishing of $L(g,k/2)$ to the divisibility by $\mathfrak{q}$ of an "algebraic part" of $L(f,k/2)$. Conjecturally the former is associated with the existence of certain algebraic cycles (for M_g) while the latter is associated with the existence of certain elements of the Shafarevich-Tate group (for M_f, as we saw in §4). In this section we show how the congruence, interpreted in terms of Galois representations, provides a direct link between algebraic cycles and the Shafarevich-Tate group.

For f we have defined V_λ, T_λ and A_λ. Let V'_λ, T'_λ and A'_λ be the corresponding objects for g. Since a_p is the trace of Frob_p^{-1} on V_λ, it follows from the Cebotarev Density Theorem that $A[\mathfrak{q}]$ and $A'[\mathfrak{q}]$, if irreducible, are isomorphic as $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-modules.

Recall that $L(g,k/2)=0$ and $L(f,k/2)\neq 0$. Since the sign in the functional equation for $L(g,s)$ is positive (this follows from $L(f,k/2)\neq 0$, see Remark 5.2), the order of vanishing of $L(g,s)$ at $s=k/2$ is at least 2. According to the Beilinson-Bloch conjecture [B, Be], the order of vanishing of $L(g,s)$ at $s=k/2$ is the rank of the group $\mathrm{CH}_0^{k/2}(M_g)(\mathbb{Q})$ of $\mathbb{Q}$-rational rational equivalence classes of null-homologous, algebraic cycles of codimension $k/2$ on the motive M_g. (This generalises the part of the Birch–Swinnerton-Dyer conjecture which says that for an elliptic curve $E/\mathbb{Q}$, the order of vanishing of $L(E,s)$ at $s=1$ is equal to the rank of the Mordell-Weil group $E(\mathbb{Q})$.)

Via the $\mathfrak{q}$-adic Abel-Jacobi map, $\mathrm{CH}_0^{k/2}(M_g)(\mathbb{Q})$ maps to $H^1(\mathbb{Q},V'_{\mathfrak{q}}(k/2))$, and its image is contained in the subspace $H^1_f(\mathbb{Q},V'_{\mathfrak{q}}(k/2))$, by 3.1 and 3.2 of [Ne]. If, as expected, the $\mathfrak{q}$-adic Abel-Jacobi map is injective, we get (assuming also the Beilinson-Bloch conjecture) a subspace of $H^1_f(\mathbb{Q},V'_{\mathfrak{q}}(k/2))$ of dimension equal to the order of vanishing of $L(g,s)$ at $s=k/2$. In fact, one could simply conjecture that the dimension of $H^1_f(\mathbb{Q},V'_{\mathfrak{q}}(k/2))$ is equal to the order of vanishing of $L(g,s)$ at $s=k/2$. This would follow from the "conjectures" $C_r(M)$ and $C^i_\lambda(M)$ in Sections 1 and 6.5 of [Fo2]. We shall call it the "strong" Beilinson-Bloch conjecture.

Similarly, if $L(f,k/2)\neq 0$ then we expect that $H^1_f(\mathbb{Q},V_{\mathfrak{q}}(k/2))=0$, so that $H^1_f(\mathbb{Q},A_{\mathfrak{q}}(k/2))$ coincides with the $\mathfrak{q}$-part of Ш.

Theorem 6.1. *Let $q\nmid N$ be a prime satisfying $q>k$. Let r be the dimension of $H^1_f(\mathbb{Q},V'_{\mathfrak{q}}(k/2))$. Suppose that $A[\mathfrak{q}]$ is an irreducible representation of* $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ *and that for no prime $p\mid N$ is f congruent modulo $\mathfrak{q}$ (for Fourier coefficients of index coprime to Nq) to a newform of weight k, trivial character and level dividing N/p. Suppose that, for all primes $p\mid N$, $p\not\equiv -w_p \pmod{q}$, with $p\not\equiv -1 \pmod{q}$ if $p^2\mid N$. (Here w_p is the common eigenvalue of the Atkin-Lehner involution W_p acting on f and g.) Then the $\mathfrak{q}$-torsion subgroup of $H^1_f(\mathbb{Q},A_{\mathfrak{q}}(k/2))$ has $\mathbb{F}_{\mathfrak{q}}$-rank at least r.*

Proof. The theorem is trivially true if $r = 0$, so we assume that $r > 0$. It follows easily from our hypothesis that the rank of the free part of $H^1_f(\mathbb{Q}, T'_{\mathfrak{q}}(k/2))$ is r. The natural map from $H^1_f(\mathbb{Q}, T'_{\mathfrak{q}}(k/2))/\mathfrak{q}H^1_f(\mathbb{Q}, T'_{\mathfrak{q}}(k/2))$ to $H^1(\mathbb{Q}, A'[\mathfrak{q}](k/2))$ is injective. Take a nonzero class c in the image, which has $\mathbb{F}_{\mathfrak{q}}$-rank r. Choose $d \in H^1_f(\mathbb{Q}, T'_{\mathfrak{q}}(k/2))$ mapping to c. Consider the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-cohomology of the short exact sequence

$$0 \longrightarrow A'[\mathfrak{q}](k/2) \longrightarrow A'_{\mathfrak{q}}(k/2) \xrightarrow{\pi} A'_{\mathfrak{q}}(k/2) \longrightarrow 0,$$

where π is multiplication by a uniformising element of $O_{\mathfrak{q}}$. By irreducibility, $H^0(\mathbb{Q}, A[\mathfrak{q}](k/2))$ is trivial. Hence $H^0(\mathbb{Q}, A_{\mathfrak{q}}(k/2))$ is trivial, so $H^1(\mathbb{Q}, A[\mathfrak{q}](k/2))$ injects into $H^1(\mathbb{Q}, A_{\mathfrak{q}}(k/2))$, and we get a nonzero, $\mathfrak{q}$-torsion class $\gamma \in H^1(\mathbb{Q}, A_{\mathfrak{q}}(k/2))$.

Our aim is to show that $\mathrm{res}_p(\gamma) \in H^1_f(\mathbb{Q}_p, A_{\mathfrak{q}}(k/2))$, for all (finite) primes p. We consider separately the cases $p \nmid qN$, $p \mid N$ and $p = q$.

Case (1) $p \nmid qN$:

Consider the I_p-cohomology of the short exact sequence above. Since in this case $A'_{\mathfrak{q}}(k/2)$ is unramified at p, $H^0(I_p, A'_{\mathfrak{q}}(k/2)) = A'_{\mathfrak{q}}(k/2)$, which is $\mathfrak{q}$-divisible. Therefore $H^1(I_p, A'[\mathfrak{q}](k/2))$ (which, remember, is the same as $H^1(I_p, A[\mathfrak{q}](k/2))$) injects into $H^1(I_p, A'_{\mathfrak{q}}(k/2))$. It follows from the fact that $d \in H^1_f(\mathbb{Q}, T'_{\mathfrak{q}}(k/2))$ that the image in $H^1(I_p, A'_{\mathfrak{q}}(k/2))$ of the restriction of c is zero, hence that the restriction of c to $H^1(I_p, A'[\mathfrak{q}](k/2)) \simeq H^1(I_p, A[\mathfrak{q}](k/2))$ is zero. Hence the restriction of γ to $H^1(I_p, A_{\mathfrak{q}}(k/2))$ is also zero. By line 3 of p. 125 of [Fl1], $H^1_f(\mathbb{Q}_p, A_{\mathfrak{q}}(k/2))$ is equal to (not just contained in) the kernel of the map from $H^1(\mathbb{Q}_p, A_{\mathfrak{q}}(k/2))$ to $H^1(I_p, A_{\mathfrak{q}}(k/2))$, so we have shown that $\mathrm{res}_p(\gamma) \in H^1_f(\mathbb{Q}_p, A_{\mathfrak{q}}(k/2))$.

Case (2) $p \mid N$:

First we show that $H^0(I_p, A'_{\mathfrak{q}}(k/2))$ is $\mathfrak{q}$-divisible. It suffices to show that

$$\dim H^0(I_p, A'[\mathfrak{q}](k/2)) = \dim H^0(I_p, V'_{\mathfrak{q}}(k/2)),$$

since then the natural map from $H^0(I_p, V'_{\mathfrak{q}}(k/2))$ to $H^0(I_p, A'_{\mathfrak{q}}(k/2))$ is surjective; this may be done as in the proof of Lemma 4.4. It follows as above that the image of $c \in H^1(\mathbb{Q}, A[\mathfrak{q}](k/2))$ in $H^1(I_p, A[\mathfrak{q}](k/2))$ is zero. Then $\mathrm{res}_p(c)$ comes from $H^1(D_p/I_p, H^0(I_p, A[\mathfrak{q}](k/2)))$, by inflation-restriction. The order of this group is the same as the order of the group $H^0(\mathbb{Q}_p, A[\mathfrak{q}](k/2))$ (this is Lemma 1 of [W]), which we claim is trivial. By the work of Carayol [Ca1], the level N is the conductor of $V_{\mathfrak{q}}(k/2)$, so $p \mid N$ implies that $V_{\mathfrak{q}}(k/2)$ is ramified at p, hence $\dim H^0(I_p, V_{\mathfrak{q}}(k/2)) = 0$ or 1. As above, we see that $\dim H^0(I_p, V_{\mathfrak{q}}(k/2)) = \dim H^0(I_p, A[\mathfrak{q}](k/2))$, so we need only consider the case where this common dimension is 1. The (motivic) Euler factor at p for M_f is $(1 - \alpha p^{-s})^{-1}$, where Frob_p^{-1} acts as multiplication by α on the one-dimensional space $H^0(I_p, V_{\mathfrak{q}})$. It follows from Theoréme A of [Ca1] that this is the same as the Euler factor at p of $L(f, s)$. By Theorems 3(ii) and 5 of [AL], it then follows that $p^2 \nmid N$ and $\alpha = -w_p p^{(k/2)-1}$, where $w_p = \pm 1$ is such that $W_p f = w_p f$. Twisting by $k/2$, Frob_p^{-1} acts on $H^0(I_p, V_{\mathfrak{q}}(k/2))$ (hence also on $H^0(I_p, A[\mathfrak{q}](k/2))$) as $-w_p p^{-1}$. Since $p \not\equiv -w_p \pmod{q}$, we see that $H^0(\mathbb{Q}_p, A[\mathfrak{q}](k/2))$ is trivial. Hence $\mathrm{res}_p(c) = 0$ so $\mathrm{res}_p(\gamma) = 0$ and certainly lies in $H^1_f(\mathbb{Q}_p, A_{\mathfrak{q}}(k/2))$.

Case (3) $p = q$:

Since $q \nmid N$ is a prime of good reduction for the motive M_g, $V'_{\mathfrak{q}}$ is a crystalline representation of $\mathrm{Gal}(\overline{\mathbb{Q}}_q/\mathbb{Q}_q)$, meaning $D_{\mathrm{cris}}(V'_{\mathfrak{q}})$ and $V'_{\mathfrak{q}}$ have the same dimension, where $D_{\mathrm{cris}}(V'_{\mathfrak{q}}) := H^0(\mathbb{Q}_q, V'_{\mathfrak{q}} \otimes_{\mathbb{Q}_q} B_{\mathrm{cris}})$. (This is a consequence of Theorem 5.6 of [Fa].) As already noted in the proof of Lemma 4.6, $T_{\mathfrak{q}}$ is the $O_{\mathfrak{q}}[\mathrm{Gal}(\overline{\mathbb{Q}}_q/\mathbb{Q}_q)]$-module associated to the filtered module $T_{\mathrm{dR}} \otimes O_{\mathfrak{q}}$. Since also $q > k$, we may now prove, in the same manner as Proposition 9.2 of [Du1], that $\mathrm{res}_q(\gamma) \in H^1_f(\mathbb{Q}_q, A_{\mathfrak{q}}(k/2))$. For the convenience of the reader, we give some details.

In Lemma 4.4 of [BK], a cohomological functor $\{h^i\}_{i\geq 0}$ is constructed on the Fontaine-Lafaille category of filtered Dieudonné modules over $\mathbb{Z}_q$. $h^i(D) = 0$ for all $i \geq 2$ and all D, and $h^i(D) = \mathrm{Ext}^i(1_{FD}, D)$ for all i and D, where 1_{FD} is the "unit" filtered Dieudonné module.

Now let $D = T_{\mathrm{dR}} \otimes O_{\mathfrak{q}}$ and $D' = T'_{\mathrm{dR}} \otimes O_{\mathfrak{q}}$. By Lemma 4.5 (c) of [BK],

$$h^1(D) \simeq H^1_e(\mathbb{Q}_q, T_{\mathfrak{q}}),$$

where

$$H^1_e(\mathbb{Q}_q, T_{\mathfrak{q}}) = \ker(H^1(\mathbb{Q}_q, T_{\mathfrak{q}}) \to H^1(\mathbb{Q}_q, V_{\mathfrak{q}})/H^1_e(\mathbb{Q}_q, V_{\mathfrak{q}}))$$

and

$$H^1_e(\mathbb{Q}_q, V_{\mathfrak{q}}) = \ker(H^1(\mathbb{Q}_q, V_{\mathfrak{q}}) \to H^1(\mathbb{Q}_q, B^{f=1}_{\mathrm{cris}} \otimes_{\mathbb{Q}_q} V_{\mathfrak{q}})).$$

Likewise $h^1(D') \simeq H^1_e(\mathbb{Q}_q, T'_{\mathfrak{q}})$. When applying results of [BK] we view D, $T_{\mathfrak{q}}$ etc. simply as $\mathbb{Z}_q$-modules, forgetting the $O_{\mathfrak{q}}$-structure.

For an integer j let $D(j)$ be D with the Hodge filtration shifted by j. Then

$$h^1(D(j)) \simeq H^1_e(\mathbb{Q}_q, T_{\mathfrak{q}}(j))$$

(as long as $k - p + 1 < j < p - 1$, so that $D(j)$ satisfies the hypotheses of Lemma 4.5 of [BK]). By Corollary 3.8.4 of [BK],

$$H^1_f(\mathbb{Q}_q, V_{\mathfrak{q}}(j))/H^1_e(\mathbb{Q}_q, V_{\mathfrak{q}}(j)) \simeq (D(j) \otimes_{\mathbb{Z}_q} \mathbb{Q}_q)/(1-f)(D(j) \otimes_{\mathbb{Z}_q} \mathbb{Q}_q),$$

where f is the Frobenius operator on crystalline cohomology. By 1.2.4(ii) of [Sc], and the Weil conjectures, $H^1_e(\mathbb{Q}_q, V_{\mathfrak{q}}(j)) = H^1_f(\mathbb{Q}_q, V_{\mathfrak{q}}(j))$, since $j \neq (k-1)/2$. Similarly $H^1_e(\mathbb{Q}_q, V'_{\mathfrak{q}}(j)) = H^1_f(\mathbb{Q}_q, V'_{\mathfrak{q}}(j))$.

We have

$$h^1(D(k/2)) \simeq H^1_f(\mathbb{Q}_q, T_{\mathfrak{q}}(k/2)) \quad \text{and} \quad h^1(D'(k/2)) \simeq H^1_f(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2)).$$

The exact sequence in the middle of page 366 of [BK] gives us a commutative diagram.

$$\begin{tikzcd}
h^1(D'(k/2)) \arrow[r, "\pi"] \arrow[d] & h^1(D'(k/2)) \arrow[r] \arrow[d] & h^1(D'(k/2)/\mathfrak{q}D'(k/2)) \arrow[d] \\
H^1(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2)) \arrow[r, "\pi"] & H^1(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2)) \arrow[r] & H^1(\mathbb{Q}_q, A'[\mathfrak{q}](k/2)).
\end{tikzcd}$$

The vertical arrows are all inclusions and we know that the image of $h^1(D'(k/2))$ in $H^1(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2))$ is exactly $H^1_f(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2))$. The top right horizontal map is surjective since $h^2(D'(k/2)) = 0$.

The class $\mathrm{res}_q(c) \in H^1(\mathbb{Q}_q, A'[\mathfrak{q}](k/2))$ is in the image of $H^1_f(\mathbb{Q}_q, T'_{\mathfrak{q}}(k/2))$, by construction, and therefore is in the image of $h^1(D'(k/2)/\mathfrak{q}D'(k/2))$. By the fullness and exactness of the Fontaine-Lafaille functor [FL] (see Theorem 4.3 of [BK]), $D'(k/2)/\mathfrak{q}D'(k/2)$ is isomorphic to $D(k/2)/\mathfrak{q}D(k/2)$.

It follows that the class $\mathrm{res}_q(c) \in H^1(\mathbb{Q}_q, A[\mathfrak{q}](k/2))$ is in the image of $h^1(D(k/2)/\mathfrak{q}D(k/2))$ by the vertical map in the exact sequence analogous to the above. Since the map from $h^1(D(k/2))$ to $h^1(D(k/2)/\mathfrak{q}D(k/2))$ is surjective, $\mathrm{res}_q(c)$ lies in the image of $H^1_f(\mathbb{Q}_q, T_{\mathfrak{q}}(k/2))$. From this it follows that $\mathrm{res}_q(\gamma) \in H^1_f(\mathbb{Q}_q, A_{\mathfrak{q}}(k/2))$, as desired. □

Theorem 2.7 of [AS] is concerned with verifying local conditions in the case $k = 2$, where f and g are associated with abelian varieties A and B. (Their theorem also applies to abelian varieties over number fields.) Our restriction outlawing congruences modulo $\mathfrak{q}$ with cusp forms of lower level is analogous to theirs forbidding q from dividing Tamagawa factors $c_{A,l}$ and $c_{B,l}$. (In the case where A is an elliptic curve with $\mathrm{ord}_l(j(A)) < 0$, consideration of a Tate parametrisation shows that if $q \mid c_{A,l}$, i.e., if $q \mid \mathrm{ord}_l(j(A))$, then it is possible that $A[q]$ is unramified at l.)

In this paper we have encountered two technical problems which we dealt with in quite similar ways:

(1) dealing with the $\mathfrak{q}$-part of c_p for $p \mid N$;
(2) proving local conditions at primes $p \mid N$, for an element of $\mathfrak{q}$-torsion.

If our only interest was in testing the Bloch-Kato conjecture at $\mathfrak{q}$, we could have made these problems cancel out, as in Lemma 8.11 of [DFG1], by weakening the local conditions. However, we have chosen not to do so, since we are also interested in the Shafarevich-Tate group, and since the hypotheses we had to assume are not particularly strong. Note that, since $A[\mathfrak{q}]$ is irreducible, the $\mathfrak{q}$-part of Ш does not depend on the choice of $T_{\mathfrak{q}}$.

7. Examples and Experiments

This section contains tables and numerical examples that illustrate the main themes of this paper. In Section 7.1, we explain Table 1, which contains 16 examples of pairs f, g such that the strong Beilinson-Bloch conjecture and Theorem 6.1 together imply the existence of nontrivial elements of the Shafarevich-Tate group of the motive attached to f. Section 7.2 outlines the higher-weight modular symbol computations that were used in making Table 1. Section 7.3 discusses Table 2, which summarizes the results of an extensive computation of conjectural orders of Shafarevich-Tate groups for modular motives of low level and weight. Section 7.4 gives specific examples in which various hypotheses fail. Note that in §7 "modular symbol" has a different meaning from in §5, being related to homology rather than cohomology. For precise definitions see [SV].

7.1. **Visible Ш Table 1.** Table 1 on page 11 lists sixteen pairs of newforms f and g (of equal weights and levels) along with at least one prime q such that there is a prime $\mathfrak{q} \mid q$ with $f \equiv g \pmod{\mathfrak{q}}$. In each case, $\mathrm{ord}_{s=k/2} L(g, k/2) \geq 2$ while $L(f, k/2) \neq 0$. The notation is as follows. The first column contains a label whose structure is

[Level]k[Weight][GaloisOrbit]

This label determines a newform $g = \sum a_n q^n$, up to Galois conjugacy. For example, **127k4C** denotes a newform in the third Galois orbit of newforms in $S_4(\Gamma_0(127))$. The Galois orbits are ordered first by the degree of $\mathbb{Q}(\ldots, a_n, \ldots)$, then by the sequence of absolute values $|\mathrm{Tr}(a_p(g))|$ for p not dividing the level, with positive trace being first in the event that the two absolute values are equal, and the first

Table 1. Visible Ш

Galois orbit is denoted **A**, the second **B**, and so on. The second column contains the degree of the field $\mathbb{Q}(\ldots, a_n, \ldots)$. The third and fourth columns contain f and its degree, respectively. The fifth column contains at least one prime q such that there is a prime $\mathfrak{q} \mid q$ with $f \equiv g \pmod{\mathfrak{q}}$, and such that the hypotheses of Theorem 6.1 (except possibly $r > 0$) are satisfied for f, g, and $\mathfrak{q}$.

For the two examples **581k4E** and **684k4K**, the square of a prime q appears in the q-column, meaning q^2 divides the order of the group $S_k(\Gamma_0(N), \mathbb{Z})/(W + W^{\perp})$, defined at the end of 7.3 below.

We describe the first line of Table 1 in more detail. See the next section for further details on how the computations were performed.

Using modular symbols, we find that there is a newform

$$g = q - q^2 - 8q^3 - 7q^4 - 15q^5 + 8q^6 - 25q^7 + \cdots \in S_4(\Gamma_0(127))$$

with $L(g, 2) = 0$. Because $W_{127}(g) = g$, the functional equation has sign $+1$, so $L'(g, 2) = 0$ as well. We also find a newform $f \in S_4(\Gamma_0(127))$ whose Fourier coefficients generate a number field K of degree 17, and by computing the image of the modular symbol $XY\{0, \infty\}$ under the period mapping, we find that $L(f, 2) \neq 0$. The newforms f and g are congruent modulo a prime $\mathfrak{q}$ of K of residue characteristic 43. The mod $\mathfrak{q}$ reductions of f and g are both equal to

$$\overline{f} = q + 42q^2 + 35q^3 + 36q^4 + 28q^5 + 8q^6 + 18q^7 + \cdots \in \mathbb{F}_{43}[[q]].$$

There is no form in the Eisenstein subspaces of $M_4(\Gamma_0(127))$ whose Fourier coefficients of index n, with $(n, 127) = 1$, are congruent modulo 43 to those of $\overline{f}$, so $\rho_{f,\mathfrak{q}} \approx \rho_{g,\mathfrak{q}}$ is irreducible. Since 127 is prime and $S_4(\mathrm{SL}_2(\mathbb{Z})) = 0$, $\overline{f}$ does not arise from a level 1 form of weight 4. Thus we have checked the hypotheses of Theorem 6.1, so if r is the dimension of $H^1_f(\mathbb{Q}, V'_{\mathfrak{q}}(k/2))$ then the $\mathfrak{q}$-torsion subgroup of $H^1_f(\mathbb{Q}, A_{\mathfrak{q}}(k/2))$ has $\mathbb{F}_{\mathfrak{q}}$-rank at least r.

Recall that since $\operatorname{ord}_{s=k/2} L(g,s) \geq 2$, we expect that $r \geq 2$. Then, since $L(f,k/2) \neq 0$, we expect that the $\mathfrak{q}$-torsion subgroup of $H^1_f(\mathbb{Q}, A_{\mathfrak{q}}(k/2))$ is equal to the $\mathfrak{q}$-torsion subgroup of Ш. Admitting these assumptions, we have constructed the $\mathfrak{q}$-torsion in Ш predicted by the Bloch-Kato conjecture.

For particular examples of elliptic curves one can often find and write down rational points predicted by the Birch and Swinnerton-Dyer conjecture. It would be nice if likewise one could explicitly produce algebraic cycles predicted by the Beilinson-Bloch conjecture in the above examples. Since $L'(g,k/2) = 0$, Heegner cycles have height zero (see Corollary 0.3.2 of [Z]), so ought to be trivial in $\mathrm{CH}_0^{k/2}(M_g) \otimes \mathbb{Q}$.

7.2. **How the computation was performed.** We give a brief summary of how the computation was performed. The algorithms that we used were implemented by the second author, and most are a standard part of MAGMA (see [BCP]).

Let g, f, and q be some data from a line of Table 1 and let N denote the level of g. We verified the existence of a congruence modulo q, that $L(g, \frac{k}{2}) = L'(g, \frac{k}{2}) = 0$ and $L(f, \frac{k}{2}) \neq 0$, and that $\rho_{f,\mathfrak{q}} = \rho_{g,\mathfrak{q}}$ is irreducible and does not arise from any $S_k(\Gamma_0(N/p))$, as follows:

To prove there is a congruence, we showed that the corresponding *integral* spaces of modular symbols satisfy an appropriate congruence, which forces the existence of a congruence on the level of Fourier expansions. We showed that $\rho_{g,\mathfrak{q}}$ is irreducible by computing a set that contains all possible residue characteristics of congruences between g and any Eisenstein series of level dividing N, where by congruence, we mean a congruence for all Fourier coefficients of index n with $(n,N) = 1$. Similarly, we checked that g is not congruent to any form h of level N/p for any p that exactly divides N by listing a basis of such h and finding the possible congruences, where again we disregard the Fourier coefficients of index not coprime to N.

To verify that $L(g, \frac{k}{2}) = 0$, we computed the image of the modular symbol $\mathbf{e} = X^{\frac{k}{2}-1}Y^{\frac{k}{2}-1}\{0,\infty\}$ under a map with the same kernel as the period mapping, and found that the image was 0. The period mapping sends the modular symbol $\mathbf{e}$ to a nonzero multiple of $L(g, \frac{k}{2})$, so that $\mathbf{e}$ maps to 0 implies that $L(g, \frac{k}{2}) = 0$. In a similar way, we verified that $L(f, \frac{k}{2}) \neq 0$. Next, we checked that $W_N(g) = (-1)^{k/2} g$ which, because of the functional equation, implies that $L'(g, \frac{k}{2}) = 0$. Table 1 is of independent interest because it includes examples of modular forms of even weight > 2 with a zero at $\frac{k}{2}$ that is not forced by the functional equation. We found no such examples of weights ≥ 8.

7.3. **Conjecturally nontrivial Ш.** In this section we apply some of the results of Section 4 to compute lower bounds on conjectural orders of Shafarevich-Tate groups of many modular motives. The results of this section suggest that Ш of a modular motive is usually not "visible at level N", i.e., explained by congruences at level N, which agrees with the observations of [CM1] and [AS]. For example, when $k > 6$ we find many examples of conjecturally nontrivial Ш but no examples of nontrivial visible Ш.

For any newform f, let $L(M_f/\mathbb{Q}, s) = \prod_{i=1}^{d} L(f^{(i)}, s)$ where $f^{(i)}$ runs over the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f. Let T be the complex torus $\mathbb{C}^d/(2\pi i)^{k/2}\mathcal{L}$, where the lattice $\mathcal{L}$ is defined by integrating integral cuspidal modular symbols (for $\Gamma_0(N)$) against the conjugates of f. Let $\Omega_{M_f/\mathbb{Q}}$ denote the volume of the $(-1)^{(k/2)-1}$ eigenspace $T^{\pm} = \{z \in T : \overline{z} = (-1)^{(k/2)-1} z\}$ for complex conjugation on T.

Lemma 7.1. *Suppose that $p \nmid Nk!$ is such that f is not congruent to any of its Galois conjugates modulo a prime dividing p. Then the p-parts of*

$$\frac{L(M_f/\mathbb{Q}, k/2)}{\Omega_{M_f/\mathbb{Q}}} \qquad \textit{and} \qquad \mathrm{Norm}\left(\frac{L(f,k/2)}{\mathrm{vol}_\infty}\mathfrak{a}^{\pm}\right)$$

are equal, where vol_∞ *is as in Section 4.*

Proof. Let H be the $\mathbb{Z}$-module of all integral cuspidal modular symbols for $\Gamma_0(N)$. Let I be the image of H under projection into the submodule of $H \otimes \mathbb{Q}$ corresponding to f and its Galois conjugates. Note that I is not necessarily contained in H, but it is contained in $H \otimes \mathbb{Z}[\frac{1}{m}]$ where m is divisible by the residue characteristics of any primes of congruence between f and cuspforms of weight k for $\Gamma_0(N)$ which are not Galois conjugate to f.

The lattice $\mathcal{L}$ defined in the paragraph before the lemma is (up to divisors of $Nk!$) obtained by pairing the cohomology modular symbols $\Phi^{\pm}_{f^{(i)}}$ (as in §5) with the homology modular symbols in H; equivalently, since the pairing factors through the map $H \to I$, the lattice $\mathcal{L}$ is obtained by pairing with the elements of I. For $1 \leq i \leq d$ let I_i be the O_E-module generated by the image of the projection of I into $I \otimes E$ corresponding to $f^{(i)}$. The finite index of $I \otimes O_E$ in $\oplus_{i=1}^{d} I_i$ is divisible only by primes of congruence between f and its Galois conjugates. Up to these primes, $\Omega_{M_f/\mathbb{Q}}/(2\pi i)^{((k/2)-1)d}$ is then a product of the d quantities obtained by pairing $\Phi^{\pm}_{f^{(i)}}$ with I_i, for $1 \leq i \leq d$. (These quantities inhabit a kind of tensor product of $\mathbb{C}^*$ over E^* with the group of fractional ideals of E.) Bearing in mind the last line of §3, we see that these quantities are the $\mathfrak{a}^{\pm}\Omega^{\pm}_{f^{(i)}}$, up to divisors of $Nk!$. Now we may apply Lemma 4.1. We have then a factorisation of the left hand side which shows it to be equal to the right hand side, to the extent claimed by the lemma. Note that $\frac{L(f,k/2)}{\mathrm{vol}_\infty}\mathfrak{a}^{\pm}$ has an interpretation in terms of integral modular symbols, as in §5, and just gets Galois-conjugated when one replaces f by some $f^{(i)}$. □

Remark 7.2. The newform $f =$ **319k4C** is congruent to one of its Galois conjugates modulo 17 and $17 \mid \frac{L(M_f/\mathbb{Q},k/2)}{\Omega_{M_f/\mathbb{Q}}}$ so the lemma and our computations say nothing about whether or not 17 divides $\mathrm{Norm}\left(\frac{L(f,k/2)}{\mathrm{vol}_\infty}\mathfrak{a}^{\pm}\right)$.

Let $\mathcal{S}$ be the set of newforms with level N and weight k satisfying either $k = 4$ and $N \leq 321$, or $k = 6$ and $N \leq 199$, or $k = 8$ and $N \leq 149$, or $k = 10$ and $N \leq 72$, or $k = 12$ and $N \leq 49$. Given $f \in \mathcal{S}$, let B be defined as follows:

1. Let L_1 be the numerator of the rational number $L(M_f/\mathbb{Q}, k/2)/\Omega_{M_f/\mathbb{Q}}$. If $L_1 = 0$ let $B = 1$ and terminate.
2. Let L_2 be the part of L_1 that is coprime to $Nk!$.
3. Let L_3 be the part of L_2 that is coprime to $p + 1$ for every prime p such that $p^2 \mid N$.
4. Let L_4 be the part of L_3 coprime to the residue characteristic of any prime of congruence between f and a form of weight k and lower level. (By congruence here, we mean a congruence for coefficients a_n with n coprime to the level of f.)
5. Let L_5 be the part of L_4 coprime to the residue characteristic of any prime of congruence between f and an Eisenstein series. (This eliminates residue characteristics of reducible representations.)

(6) Let B be the part of L_5 coprime to the residue characteristic of any prime of congruence between f and any one of its Galois conjugates.

Proposition 4.8 and Lemma 7.1 imply that if $\mathrm{ord}_p(B) > 0$ then, according to the Bloch-Kato conjecture, $\mathrm{ord}_p(\#Ш) = \mathrm{ord}_p(B) > 0$.

We computed B for every newform in $\mathcal{S}$. There are many examples in which L_3 is large, but B is not, and this is because of Tamagawa factors. For example, **39k4C** has $L_3 = 19$, but $B = 1$ because of a 19-congruence with a form of level 13; in this case we must have $19 \mid c_3(2)$, where $c_3(2)$ is as in Section 4. See Section 7.4 for more details. Also note that in every example B is a perfect square, which, away from congruence primes, is as predicted by the existence of Flach's generalised Cassels-Tate pairing [Fl1]. (Note that if $A[\lambda]$ is irreducible then the lattice T_λ is at worst a scalar multiple of its dual, so the pairing shows that the order of the λ-part of Ш, if finite, is a square.) That our computed value of B should be a square is not *a priori* obvious.

For simplicity, we discard residue characteristics instead of primes of rings of integers, so our definition of B is overly conservative. For example, 5 occurs in row 2 of Table 1 but not in Table 2, because **159k4E** is Eisenstein at some prime above 5, but the prime of congruences of characteristic 5 between **159k4B** and **159k4E** is not Eisenstein.

The newforms for which $B > 1$ are given in Table 2. The second column of the table records the degree of the field generated by the Fourier coefficients of f. The third contains B. Let W be the intersection of the span of all conjugates of f with $S_k(\Gamma_0(N), \mathbb{Z})$ and $W^\perp$ the Petersson orthogonal complement of W in $S_k(\Gamma_0(N), \mathbb{Z})$. The fourth column contains the odd prime divisors of $\#(S_k(\Gamma_0(N), \mathbb{Z})/(W + W^\perp))$, which are exactly the possible primes of congruence between f and non-conjugate cusp forms of the same weight and level. We place a $*$ next to the four entries of Table 2 that also occur in Table 1.

7.4. **Examples in which hypotheses fail.** We have some other examples where forms of different levels are congruent (for Fourier coefficients of index coprime to the levels). However, Remark 5.2 does not apply, so that one of the forms could have an odd functional equation, and the other could have an even functional equation. For instance, we have a 19-congruence between the newforms g = **13k4A** and f = **39k4C** of Fourier coefficients of index coprime to 39. Here $L(f, 2) \neq 0$, while $L(g, 2) = 0$ since $L(g, s)$ has *odd* functional equation. Here f fails the condition about not being congruent to a form of lower level, so in Lemma 4.4 it is possible that $\mathrm{ord}_{\mathfrak{q}}(c_3(2)) > 0$. In fact this does happen. Because $V'_{\mathfrak{q}}$ (attached to g of level 13) is unramified at $p = 3$, $H^0(I_p, A[\mathfrak{q}])$ (the same as $H^0(I_p, A'[\mathfrak{q}])$) is two-dimensional. As in (2) of the proof of Theorem 6.1, one of the eigenvalues of Frob_p^{-1} acting on this two-dimensional space is $\alpha = -w_p p^{(k/2)-1}$, where $W_p f = w_p f$. The other must be $\beta = -w_p p^{k/2}$, so that $\alpha\beta = p^{k-1}$. Twisting by $k/2$, we see that Frob_p^{-1} acts as $-w_p$ on the quotient of $H^0(I_p, A[\mathfrak{q}](k/2))$ by the image of $H^0(I_p, V_{\mathfrak{q}}(k/2))$. Hence $\mathrm{ord}_{\mathfrak{q}}(c_p(k/2)) > 0$ when $w_p = -1$, which is the case in our example here with $p = 3$. Likewise $H^0(\mathbb{Q}_p, A[\mathfrak{q}](k/2))$ is nontrivial when $w_p = -1$, so (2) of the proof of Theorem 6.1 does not work. This is just as well, since had it worked we would have expected $\mathrm{ord}_{\mathfrak{q}}(L(f, k/2)/\mathrm{vol}_\infty) \geq 3$, which computation shows not to be the case.

In the following example, the divisibility between the levels is the other way round. There is a 7-congruence between g = **122k6A** and f = **61k6B**, both L-functions have even functional equation, and $L(g, 3) = 0$. In the proof of Theorem 6.1, there is a problem with the local condition at $p = 2$. The map from $H^1(I_2, A'[\mathfrak{q}](3))$ to $H^1(I_2, A'_{\mathfrak{q}}(3))$ is not necessarily injective, but its kernel is at most one dimensional, so we still get the $\mathfrak{q}$-torsion subgroup of $H^1_f(\mathbb{Q}, A_{\mathfrak{q}}(2))$ having $\mathbb{F}_{\mathfrak{q}}$-rank at least 1 (assuming $r \geq 2$), and thus get elements of Ш for **61k6B** (assuming all along the strong Beilinson-Bloch conjecture). In particular, these elements of Ш are *invisible* at level 61. When the levels are different we are no longer able to apply Theorem 2.1 of [FJ]. However, we still have the congruences of integral modular symbols required to make the proof of Proposition 5.1 go through. Indeed, as noted above, the congruences of modular forms were found by producing congruences of modular symbols. Despite these congruences of modular symbols, Remark 5.2 does not apply, since there is no reason to suppose that $w_N = w_{N'}$, where N and N' are the distinct levels.

Finally, there are two examples where we have a form g with even functional equation such that $L(g, k/2) = 0$, and a congruent form f which has odd functional equation; these are a 23-congruence between $g =$ **453k4A** and $f =$ **151k4A**, and a 43-congruence between $g =$ **681k4A** and $f =$ **227k4A**. If $\mathrm{ord}_{s=2} L(f, s) = 1$, it ought to be the case that $\dim(H^1_f(\mathbb{Q}, V_{\mathfrak{q}}(2))) = 1$. If we assume this is so, and similarly that $r = \mathrm{ord}_{s=2}(L(g, s)) \geq 2$, then unfortunately the appropriate modification of Theorem 6.1 (with strong Beilinson-Bloch conjecture) does not necessarily provide us with nontrivial $\mathfrak{q}$-torsion in Ш. It only tells us that the $\mathfrak{q}$-torsion subgroup of $H^1_f(\mathbb{Q}, A_{\mathfrak{q}}(2))$ has $\mathbb{F}_{\mathfrak{q}}$-rank at least 1. It could all be in the image of $H^1_f(\mathbb{Q}, V_{\mathfrak{q}}(2))$. Ш appears in the conjectural formula for the first derivative of the complex L function, evaluated at $s = k/2$, but in combination with a regulator that we have no way of calculating.

Let $L_q(f, s)$ and $L_q(g, s)$ be the q-adic L functions associated with f and g by the construction of Mazur, Tate and Teitelbaum [MTT], each divided by a suitable canonical period. We may show that $\mathfrak{q} \mid L'_q(f, k/2)$, though it is not quite clear what to make of this. This divisibility may be proved as follows. The measures $d\mu_{f,\alpha}$ and (a q-adic unit times) $d\mu_{g,\alpha'}$ in [MTT] (again, suitably normalised) are congruent mod $\mathfrak{q}$, as a result of the congruence between the modular symbols out of which they are constructed. Integrating an appropriate function against these measures, we find that $L'_q(f, k/2)$ is congruent mod $\mathfrak{q}$ to $L'_q(g, k/2)$. It remains to observe that $L'_q(g, k/2) = 0$, since $L(g, k/2) = 0$ forces $L_q(g, k/2) = 0$, but we are in a case where the signs in the functional equations of $L(g, s)$ and $L_q(g, s)$ are the same, positive in this instance. (According to the proposition in Section 18 of [MTT], the signs differ precisely when $L_q(g, s)$ has a "trivial zero" at $s = k/2$.)

We also found some examples for which the conditions of Theorem 6.1 were not met. For example, we have a 7-congruence between **639k4B** and **639k4H**, but $w_{71} = -1$, so that $71 \equiv -w_{71} \pmod 7$. There is a similar problem with a 7-congruence between **260k6A** and **260k6E** — here $w_{13} = 1$ so that $13 \equiv -w_{13} \pmod 7$. According to Propositions 5.1 and 4.8, Bloch-Kato still predicts that the $\mathfrak{q}$-part of Ш is non-trivial in these examples. Finally, there is a 5-congruence between **116k6A** and **116k6D**, but here the prime 5 is less than the weight 6 so Propositions 5.1 and 4.8 (and even Lemma 7.1) do not apply.

1 Introduction

In the late 1980s, Brumer and McGuinness [2] undertook the construction of a database of elliptic curves whose discriminant Δ was both prime and satisfied $|\Delta| \leq 10^8$. While the restriction to primality was nice for many reasons, there are still many curves of interest lacking this property. As ten years have passed since the original experiment, we decided to undertake an extension of it, simultaneously extending the range for the type of curves they considered, and also including curves with composite discriminant. Our database can be crudely described as being the curves with $|\Delta| \leq 10^{12}$ which either have conductor smaller than 10^8 or have prime conductor less than 10^{10}—but there are a few caveats concerning issues like quadratic twists and isogenous curves. For each curve in our database, we have undertaken to compute various invariants (as did Brumer and McGuinness), such as the Birch–Swinnerton-Dyer L-ratio, generators, and the modular degree. We did not compute the latter two of these for every curve. The database currently contains about 44 million curves; the end goal is find as many curves with conductor less than 10^8 as possible, and we comment on this direction of growth of the database below. Of these 44 million curves, we have started a first stage of processing (computation of analytic rank data), with point searching to be carried out in a later second stage of computation.

Our general frame of mind is that computation of many of the invariants is rather trivial, for instance, the discriminant, conductor, and even the isogeny structure. We do not even save these data, expecting them to be recomputable quite easily in real time. For instance, for each isogeny class, we store only one representative (the one of minimal Faltings height), as we view the construction of isogenous curves as a “fast” process. It is only information like analytic ranks, modular degrees (both of which use computation of the Frobenius traces a_p), and coordinates of generators that we save; saving the a_p would take too much storage space. It might be seen that our database could be used a "seed" for other more specialised databases, as we can quickly calculate the less time-consuming information and append it to the saved data.

2 Generating the Curves.

While Brumer and McGuinness fixed the a_1, a_2, a_3 invariants of the elliptic curve (12 total possibilities) and then searched for a_4 and a_6 which made $|\Delta|$ small, we instead decided to break the c_4 and c_6 invariants into congruence classes, and then find small solutions to $c_4^3 - c_6^2 = 1728\Delta$. We write $c_4^\star$ for the least nonnegative residue of c_4 modulo 576, and $c_6^\star$ for the least nonnegative residue of c_6 modulo 1728. The work of Connell [3] gives necessary and sufficient conditions on c_4 and c_6 for an elliptic curve with such invariants to exist. We first need that $c_6 \equiv 3 \pmod 4$ (when it follows that c_4 is odd), or $2^4 \mid c_4$ and $c_6 \equiv 0, 8 \pmod{32}$, and secondly we require a local condition at the prime 3, namely that $c_6 \not\equiv \pm 9 \pmod{27}$. Using this information and the fact that $1728 \mid (c_4^3 - c_6^2)$, this leads to 288 possible $(c_4^\star, c_6^\star)$ pairs.

For each fixed such $(c_4^\star, c_6^\star)$ pair, we can simply loop over c_4 and c_6, finding the curves with $|\Delta| \le 10^{12}$. Of course, it is only under the ABC-conjecture that we would have an upper bound on c_4 to ensure that we would have found all such curves, and even then the bound would be too large. Our method was to take $c_4 \le 1.44 \cdot 10^{12}$ in this first step; in any case, curves with larger c_4 are most likely found more easily using the method of Elkies [5].

2.1 Minimal Twists

In the sequel, we shall write E_d for the quadratic twist of E by d. For each (c_4, c_6) pair (again with $c_4 \le 1.44 \cdot 10^{12}$) which satisfies the $|\Delta| \le 10^{12}$ condition, we then determine whether this curve is minimal—not only in the traditional sense for its minimal discriminant, but also whether it is has the minimal discriminant in its family of quadratic twists. For $p \ge 5$, this is rather easy to determine; unless $p^6 \mid \Delta$ and $p \mid c_4$, the curve is minimal for quadratic twists (the only difference between this and the standard notion of minimality is that the exponent here is 6 instead of 12). If both the above conditions hold, then we throw the curve out, as $E_{\tilde{p}}$, where $\tilde{p} = \left(\frac{-1}{p}\right)p$, is a curve with lesser discriminant (which will be found by our search procedure). Given that the curve is minimal at a prime divisor $p \geq 5$ of $\varDelta$, the local conductor at p is p^2 if $p \mid c_4$ and p^1 otherwise.

The case with $p = 3$ is a bit harder. By Connell's conditions, we see that if $3^9 \mid (c_4^3 - c_6^2)$ while $3 \mid c_6$ but 3^5 does not exactly divide c_6, then E_{-3} is a curve with invariants $(c_4/9, -c_6/27)$ which has the discriminant reduced by 3^6. This is the only prohibition against the curve being the minimal twist at 3. If $3 \mid\mid c_4$, the curve has good reduction (at 3), while if c_4 is not divisible by 3, the curve has either good or multiplicative reduction. In both cases, the local conductor can be computed readily, it being 3^0 for good reduction and 3^1 for multiplicative. To compute the conductor in the remaining cases, let $\tilde{c}_4$ be the the least nonnegative residue of $(c_4/9)$ modulo 3, and $\tilde{c}_6$ be the the least nonnegative residue of $(c_6/27)$ modulo 9. Table 1 then gives us the exponent of the local conductor. Here $e = 5$ if $3^4 \mid c_4$ and $e = 4$ if $3^3 \mid\mid c_4$ (note that we must have $3^5 \mid\mid c_6$ in this case for the curve to be twist-minimal).

Table 1. Local Conductors at 3

$\tilde{c}_4 \backslash \tilde{c}_6$	0	1	2	3	4	5	6	7	8
0	e	3	3	5	2	2	5	3	3
1	2	3	4	3	4	4	3	4	3
2	2	3	2	3	3	3	3	2	3

For $p = 2$, the minimality test and conductor computation is much more complicated. We include the prime at infinity (twisting by -1) in the test for $p = 2$. By Connell's conditions, if $2^6 \mid c_4$ and $2^8 \mid c_6$, we see that E_2 is a curve with invariants $(c_4/4, c_6/8)$, and has a lesser discriminant. Also if $2^6 \mid c_4$ and $2^6 \mid\mid c_6$, then one of the twists $E_{\pm 2}$ (the sign depending on whether $c_6/8$ is 8 mod 32) has lesser discriminant. And finally if we have $2^4 \mid\mid c_4$ and $2^6 \mid\mid c_6$ and $2^{18} \mid (c_4^3 - c_6^2)$, then one of $E_{\pm 1}$ (depending on whether $c_6/64$ is 3 mod 4) is nonminimal (in the standard sense) at 2, and hence can be ignored. If none of these events happens, then the curve is twist-minimal at $p = 2$ and the infinite prime. We next describe how to compute the local conductor at $p = 2$ in terms of congruence conditions. If c_4 is odd, then the local conductor is 2^0 or 2^1, depending on whether 2 divides $\varDelta$. If c_4 is even, then it is divisible by 16. In this case, if c_6 is 8 mod 32, there is good reduction at 2, and again the local conductor is 2^0. So we are left to consider the cases of additive reduction where $2^4 \mid c_4$ and $2^5 \mid c_6$. Let $\tilde{c}_4$ be the the least nonnegative residue of

$(c_4/16)$ modulo 8, and $\tilde{c}_6$ be the the least nonnegative residue of $(c_6/32)$ modulo 8. Table 2 then gives the exponent of the local conductor at 2. In this, the dashed entries simply do not occur. For the entries marked by e, let $\tilde{c}_4$ be the the least nonnegative residue of $(c_4/16)$ modulo 16, and $\tilde{c}_6$ be the the least nonnegative residue of $(c_6/32)$ modulo 16. We then use the further Table 3. All the conductor computations are exercises with Tate's algorithm [9].

Table 2. Local Conductors at 2

$\tilde{c}_4 \backslash \tilde{c}_6$	0	1	2	3	4	5	6	7
1,5	6	4	e	3	6	4	e	3
2,6	8	3	6	4	7	3	6	4
3,7	5	2	7	2	5	2	7	4
4	6	2	-	4	3	2	-	4
0	6	2	-	4	2	2	-	4

Table 3. More of the Same

$\tilde{c}_4 \backslash \tilde{c}_6$	2	6	10	14
1	4	5	5	3
5	3	2	4	4
9	5	3	4	5
13	4	4	3	2

A curve which has minimal discriminant at $p = 2$ will be of minimal conductor at $p = 2$ unless $2^4 \mid\mid N$ or $2^6 \mid\mid N$; we can throw out the curve in the first case, since E_{-1} will be found in the search process (and it has lesser conductor). But in the latter case, we cannot immediately discard the curve, as E_2 will have conductor smaller by a factor of 2, but the discriminant rises by a factor of 64. So only if $|\Delta| \leq 10^{12}/64$ do we discard the curve; in the alternative case we replace the curve by E_2, so that we have the twist of minimal conductor. Finally, if we have $2^5 \mid\mid N$ (possibly after the above twisting by 2), or $2^7 \mid N$, we make the arbitrary decision to discard the curve if $c_6 < 0$, as we will also find E_{-1} in the search, which will have the same conductor and discriminant.

Using the above method, we can rid ourselves of all curves which are not minimal twists, and simultaneously compute the conductor. If $N > 10^{10}$, we simply ignore the curve; if $N > 10^8$ (and $N \leq 10^{10}$), we check whether N is a strong pseudoprime for 2, 13, 23, and 1662803, this being sufficient to prove primality [6]. At this point, we have a list of curves which meet our size conditions on the discriminant, and which have the minimal conductor in a family of quadratic twists, and minimal discriminant at primes other than $p = 2$.

2.2 Isogenous Curves

The next step will be to get rid of isogenous curves. The process of finding all curves isogenous to a given one is described in [4]. This is a fairly fast process, as most curves will have no nontrivial isogenies. Amongst the isogenous curves, we then take the curve of largest fundamental volume, that is, minimal Faltings height (which is unique by [8], as our representative. Note that this curve might not have the minimal discriminant in the isogeny class. Our final set of curves is then: the set of elliptic curves E such that E has minimal height in its isogeny class, and has some isogenous curve F for which we have $c_4 \leq 1.44 \cdot 10^{12}$ and either $N \leq 10^{10}$ with $|\Delta|$ prime, or $N \leq 10^8$ with $|\Delta| \leq 10^{12}$ for either the curve F or F_2.

2.3 Future Extension of the Database

As stated above, we would desire to have all minimal twists which have conductor less than 10^8. There are three ways of enlarging the database. The first is extending the range on c_4 by using the algorithm of [5]. The second is to incorporate the data from the exhaustive methods of Cremona. The third is to find families in which we expect the conductor to be substantially less than the discriminant; for instance, curves with a rational point of order 5 often have some prime to the 5th power dividing the discriminant. In the same vein, curves with (say) a 5-isogeny are parametrised from $X_0(5)$, and in such a parametrised family we again expect a large difference between the conductor and discriminant. We could also extend the discriminant limit to (say) 10^{13} for certain $(c_4^\star, c_6^\star)$ pairs, especially those for which we know ahead of time that we will save significant powers of 2 and 3 in the conductor compared to the discriminant.

3 Data Computed for Each Curve

One object of interest for an elliptic curve is its algebraic rank. This is hard to compute; indeed, there is no known algorithm to do this, only ones which work conditionally. By the process given in [4], we can try to determine the **analytic rank** of the curve, which is the degree of vanishing of its L-series at the central point. Of course, as there is no way to determine if a computed number is exactly zero, we can only give a good guess as to the analytic rank. The conjecture of Birch and Swinnerton-Dyer asserts that the algebraic rank and the analytic rank are equal, and that the first nonzero derivative of the L-function at the central point has arithmetic significance. For each curve in the database, we computed the suspected analytic rank and first nonzero derivative for both the curve itself and some of its quadratic twists.

Each curve in our database is the curve of minimal Faltings height in its isogeny class. A conjecture of Stevens [8] asserts that this curve should be the **optimal** curve for parametrisations from $X_1(N)$, in the sense that the parametrisations to the isogenous curves factor through the parametrisation to the strong curve (the existence of a modular parametrisation from $X_1(N)$ was proved in [1] following the methods initiated by Wiles [11]). It is sometimes the case that the optimal curve for parametrisations from $X_0(N)$ differs from the curve we find; in [10], a process is given to find the $X_0(N)$-optimal curve, assuming a technical condition, namely that the Manin constant of the optimal curve is 1 (this is similar to the Stevens conjecture). As many of the Frobenius traces were already computed for the analytic rank computation, these can be re-used at this stage. In a section below, we discuss the data obtained.

In the aforementioned paper [10], a process is given to compute the modular degree of an elliptic curve, again assuming that the Manin constant is 1. Compared to the computation of the analytic rank, which requires about the first $\sqrt{N}$ of the Frobenius traces, this method requires on the order of N of these (actually $\tilde{N}$, the symmetric-square conductor; see below). Thus for $N \geq 300000$ or so, it becomes rather time-consuming to compute the modular degree. We therefore compromised, computing the modular degree only if the symmetric-square conductor of the elliptic curve was sufficiently small (if we write $N = \prod_p p^{f_p}$ as a product of local conductors, then the symmetric-square conductor is simply $\tilde{N} = \prod_p p^{\lceil f_p/2 \rceil}$, except possibly when $f_2 = 8$, when the local symmetric-square conductor at 2 might be either 2^3 or 2^4; see [10] for details). We also computed the modular degree in some other interesting cases, for instance, when the rank is large.

4 Differing Optimal Curves

Here we discuss the question of differing optimal curves for parametrisations from $X_0(N)$ and $X_1(N)$. Note that we do not compute the actual optimal curve for the latter, relying instead on the Stevens conjecture, and compute the optimal curve for $X_0(N)$ only under the assumption that the Manin constant is 1. But the results are still interesting.

There appear to be three major cases when the optimal curves differ by a 2-isogeny. One of these, the so-called Setzer-Neumann curves, was considered in [7]. These curves are parametrised by $c_4 = u^2 + 48$ and $c_6 = -u\left(u^2 + 72\right)$, with the discriminant $u^2 + 64$ being a prime and u being taken to be congruent to 1 mod 4. The second family corresponds to taking $c_4 = 16\left(u^2 + 3\right)$ and $c_6 = -32u\left(2u^2 + 9\right)$ with u again being 1 mod 4 and $p = u^2 + 4$ being prime. Here the conductor is $4p$ and the discriminant is $16p$; the differing optimal curves property appears to be preserved upon twisting by -1.

The third family we found is obtained by taking $c_4 = p\,(p + 16) + 16$ and $c_6 = (p + 8)\left(p^2 + 16p - 8\right)$ of discriminant $p\,(p + 16)$ with both p and $p + 16$ primes congruent to 3 mod 4. A similar thing occurs if p and $p + 16$ are more generally powers of primes, but at least one of the two must be a power of a prime which is congruent to 3 mod 4 (i.e. $p = 11$ or $p = 2401$ works, but $p = 625$ does not). If p is congruent to 1 mod 4, then the sign of c_6 must be switched. Finally, p can be taken to be negative, for instance $p = -5$. Note that $p = 9$ leads to 15A, in which the optimal curves differ by a 4-isogeny; also, 17A might be thrown into consideration here with $p = 1$, which also has the optimal curves differing by a 4-isogeny.

With these considerations, there are but a couple of outstanding cases of optimal curves differing by a 2-isogeny (though proofs of this classification are lacking), those being the isogeny classes 24A/48A, 40A/80A, 32A/64A, and 128B/128D, though this last case can be seen as the $p = 8$ case of the second family. Ignoring the 5-isogeny example of 11A as being spurious, this leaves just the occasions of the optimal curves differing by a 3-isogeny. Here, all known examples are parametrised by

$$c_4 = (n + 3)\left(n^3 + 9n^2 + 27n + 3\right)$$

and

$$c_6 = -\left(n^6 + 18n^5 + 135n^4 + 504n^3 + 891n^2 + 486n - 27\right)$$

with the discriminant being $n\left(n^2 + 9n + 27\right)$. The n's for which the optimal curves differ are (experimentally) precisely those for which $n^2{+}9n{+}27$

is a prime power and n has no prime factors congruent to 1 mod 6; else the optimal curves are the same. We have no theoretical justification of this observation.

5 Data Obtained

This may seem strange for a comprehensive database project, but we do not dwell on large-scale phemonemon; indeed, the Brumer–McGuinness work is probably already sufficient in this manner, at least for prime conductor. As noted there, telling the difference between a small power of 10^8 (or whatever the upper limit of consideration may be) and a large power of its logarithm is rather hopeless—extending their data by a factor of 5/4 on the logarithmic scale does not help matters much. We mention that there are 11386955 isogeny classes of curves with prime conductor less than 10^{10} in our database (this should grow slightly when curves with $c_4 \geq 1.44 \cdot 10^{12}$ are added). Of these curves with prime conductor, of the ones we have processed, we have that 62.5% of the curves with even functional equation possess rank 0, compared to about 60% for Brumer–McGuinness. It is conjectured that asymptotically this percentage should be 100%. Similarly, 92.5% of the curves with odd functional equation have rank 1, slightly more than the previous results; there is no real reason to think that our numbers will change drastically upon extending the rank computation to all the prime conductor curves we have. The least conductor for a rank 5 curve we have found is 48012824 for $[0, 1, 0, -625, 6099]$, and for rank 6 we have $[0, 0, 1, -277, 4566]$ of conductor 7647224363. These respectively fall short to the best-known (to the authors) examples of $[0, 0, 1, -79, 342]$ of conductor 19047851 and $[0, 0, 1, -7077, 235516]$ of conductor 5258110041.

Instead of concentrating on large-scale behavior, we see our database as more of a tool to be used by other mathematicians. For instance, Neil Dummigan queried us concerning examples of strong Weil curves with rank 2 and a rational point of order 5 for which the conductor is not divisible by 5, and we were able to provide him with the example $[0, 1, 1, -840, 39800]$ of conductor 13881 (and modular degree 52000), among other examples which were beyond the range of Cremona's tables (which include $[1, 1, 1, -2365, 43251]$ of conductor 5302). Though we would likely be better able to answer the question after extending our database with parametrisations from $X_0(5)$, the efficacy of our database was evinced. As another example, the second author has conjectured in [10] that 2^r divides the modular degree for any curve (where r is the rank), and perhaps higher powers of 2 should divide the modular degree when the conductor is composite, due to factorisation through Atkin–Lehner involutions. For many large-rank curves in the Brumer–McGuinness database, we verified this. With our extension to curves of composite conductor, we are able to give more evidence for this conjecture. Also, the third 2-isogeny family in the previous section was discovered after looking at our data, as was the parametrisation of the 3-isogeny family, and finally our analytic rank data concerning quadratic twists could be of use.

6 Acknowledgements

The authors would like to thank Neil Dummigan for the question mentioned in Section V, Noam Elkies for many useful observations, especially concerning Section IV, and Blair Kelly III and Wayne Whitney for providing computing power.

19 Studying the Birch and Swinnerton-Dyer Conjecture for Modular Abelian Varieties Using Magma

Studying the Birch and Swinnerton-Dyer Conjecture for Modular Abelian Varieties Using MAGMA

William Stein

Harvard University, Cambridge, Massachusetts, USA

1 Introduction

In this paper we describe the Birch and Swinnerton-Dyer conjecture in the case of modular abelian varieties and how to use MAGMA to do computations with some of the quantities that appear in the conjecture. We assume the reader has some experience with algebraic varieties and number theory, but do not assume the reader has proficiency working with elliptic curves, abelian varieties, modular forms, or modular symbols.

In Section 2 we quickly survey abelian varieties, modular forms, Hecke algebras, modular curves, and modular Jacobians, then discuss Shimura's construction of abelian varieties attached to modular forms. In Section 3 we survey many quantities associated to an abelian variety, including the Mordell-Weil group, torsion subgroup, regulator, Tamagawa numbers, real volume, and Shafarevich-Tate group, and use these to state the full Birch and Swinnerton-Dyer conjecture for modular abelian varieties. Section 4 contains some computational results from other papers about the Birch and Swinnerton-Dyer conjecture.

The rest of the paper is about how to use the package that I wrote for MAGMA to carry out an explicit computational study of modular abelian varieties. Section 5 is about modular symbols and how to compute with them in MAGMA. In Section 6 we state a theorem that allows us to use MAGMA to compute subgroups of Shafarevich-Tate groups of abelian varieties. In Section 7 we discuss computation of special values of L-functions. Section 8 is about computing Tamagawa numbers, and in Section 9 we describe how to compute a divisor and multiple of the order of the torsion subgroup. All these computations are pulled together in Section 10 to obtain a conjectural divisor and multiple of the order of the Shafarevich-Tate group of a modular abelian variety of dimension 20. We finish with Section 11, which contains an example in which the level is composite and elements of the Shafarevich-Tate group only becomes "visible" at higher level.

Taken together, these computations give evidence for the Birch and Swinnerton-Dyer conjecture and increase our explicit understanding of modular abelian varieties.

2 Modular Abelian Varieties

An elliptic curve E over the rational numbers $\mathbf{Q}$ is a one-dimensional commutative compact algebraic group. Such a curve is usually given as the projective closure of an affine curve $y^2 = x^3 + ax + b$, with a and b in $\mathbf{Q}$. The points over the real numbers $\mathbf{R}$ of $y^2 = x^3 - x + 1$ are illustrated in Figure 1. If P and Q are two distinct points on E, we find their sum as follows: draw the unique line through them and let (x, y) be the third point of intersection of this line with E. Then the sum of P and Q is $R = (x, -y)$, as illustrated in Figure 1. For more about elliptic curves, see [33, 34].

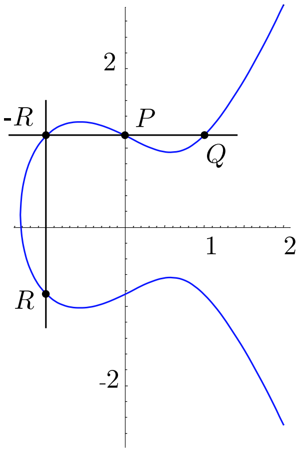

Fig. 1. Adding $P = (0, 1)$ to $Q = (1, 1)$ to get $R = (-1, -1)$ on $y^2 = x^3 - x + 1$

This paper is about abelian varieties, which are compact (commutative) algebraic groups of dimension possibly greater than 1. For example, the Cartesian product of two elliptic curves is an abelian variety of dimension 2.

Explicit equations for abelian varieties are vastly more complicated than for elliptic curves, so algorithms for computing with abelian varieties without recourse to explicit algebraic equations are of great value. In this paper we focus on such algorithms in the case when the abelian variety is endowed with extra structure coming from modular forms.

A cuspidal modular form of weight 2 for

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbf{Z}) : N \mid c \right\}$$

is a holomorphic function $f(z)$ on the upper half plane such that for all $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$ we have

$$f\left(\frac{az+b}{cz+d}\right) = (cz+d)^2 f(z),$$

and which satisfies certain vanishing conditions at the cusps (see [13, pg. 42] for a precise definition). We denote the finite dimensional complex vector space of all cuspidal modular forms of weight 2 for $\Gamma_0(N)$ by $S_2(\Gamma_0(N))$. Because $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \Gamma_0(N)$, cuspidal modular forms have a Fourier series representation

$$f(z) = \sum_{n=1}^{\infty} a_n q^n = \sum_{n=1}^{\infty} a_n e^{2\pi i n z}.$$

The Hecke algebra

$$\mathbf{T} = \mathbf{Z}[T_1, T_2, T_3, \ldots] \subset \mathrm{End}(S_2(\Gamma_0(N)))$$

is a commutative ring that is free of rank equal to $\dim_{\mathbf{C}} S_2(\Gamma_0(N))$ (for the definition and basic properties of the Hecke operators T_n, see [13, §3] and the references therein).

A newform is a modular form

$$f = q + \sum_{n \geq 2} a_n q^n$$

that is a simultaneous eigenvector for every element of the Hecke algebra and such that the coefficients $\{a_p : p \nmid N\}$ are not the prime-index coefficients of another eigenform of some level that strictly divides N.

The group $\Gamma_0(N)$ acts as a discrete group of linear fractional transformations on the upper half plane; the quotient of the upper half plane by this action is a non-compact Riemann surface. Its compactification has the structure of algebraic curve over $\mathbf{Q}$, i.e., the compactification is the set of complex points of an algebraic curve $X_0(N)$ defined by polynomial equations with coefficients in $\mathbf{Q}$.

A divisor on an algebraic curve X is an element of the free abelian group generated by the points of X. For example, if f is a rational function on X then

$$(f) = (\text{formal sum of poles of } f) - (\text{formal sum of zeros of } f)$$

is a divisor on X, where the sums are with multiplicity. Two divisors D_1 and D_2 are linearly equivalent if there is a rational function f on X such that

$D_1 - D_2 = (f)$. The Jacobian J of an algebraic curve X is an abelian variety of dimension equal to the genus (number of holes in the Riemann surface $X(\mathbf{C})$) of X such that the underlying group of J is naturally isomorphic to the group of divisor classes of degree 0 on X. Let $J_0(N)$ denote the Jacobian of $X_0(N)$.

Similarly, let

$$\Gamma_1(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbf{Z}) : N \mid c \text{ and } a \equiv 1 \pmod{N} \right\},$$

define $X_1(N)$ similarly, and let $J_1(N)$ be the Jacobian of $X_1(N)$.

A modular abelian variety is an abelian variety A for which there exists a surjective morphism $J_1(N) \to A$. Modular abelian varieties are appealing objects to study. For example, it is a deep theorem that every elliptic curve over $\mathbf{Q}$ is modular (see [7, 40, 41]), and this implies Fermat's Last Theorem (see [25, Cor. 1.2]). In [27], Ken Ribet conjectured that the simple abelian varieties over $\mathbf{Q}$ of "GL_2-type" are exactly the simple modular abelian varieties. A closely related conjecture of Serre (see [29, pg. 179] and [28]) asserts that every odd irreducible Galois representation

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_2(\overline{\mathbf{F}}_p)$$

is "modular"; this conjecture is equivalent to the assertion that ρ can be realized (up to twist) as the action of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ on a subgroup of the points on some $J_1(N)$ (see [28, §3.3.1] for a partial explanation). Though Serre's conjecture is still far from proved, it implies Ribet's conjecture (see [27, Thm. 4.4]).

We now return to considering $\Gamma_0(N)$, though we could consider $\Gamma_1(N)$ for everything in the rest of this section. The Hecke algebra $\mathbf{T}$, which we introduced above as a ring of linear transformations on $S_2(\Gamma_0(N))$, also acts via endomophisms on $J_0(N)$.

In order to construct Galois representations attached to modular forms, Goro Shimura (see [31, §1] and [32, §7.14]) associated to each newform $f = \sum a_n q^n$ a simple abelian variety A_f defined over $\mathbf{Q}$. Let I_f be the ideal of elements of $\mathbf{T}$ that annihilate f. Then

$$A_f = J_0(N)/I_f J_0(N).$$

The dimension of A_f equals the degree of the field generated over $\mathbf{Q}$ by the coefficients a_n of f. Note that A_f need not be simple over $\overline{\mathbf{Q}}$.

We will frequently mention the dual $A_f^\vee$ below. The dual can be considered as an abelian subvariety of $J_0(N)$, by using that Jacobians are canonically self dual and the dual of the quotient map $J_0(N) \to A_f$ is an inclusion $A_f^\vee \hookrightarrow J_0(N)$. Note that $A_f^\vee$ is the connected component of the intersection of the kernels of all elements of I_f.

We say that a newform g is a Galois conjugate of f if there is σ in $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ such that $g = \sum \sigma(a_n) q^n$. If g is a Galois conjugate of f, then

$A_f = A_g$; if g is not a conjugate of f then the only homomorphism from A_f to A_g is the zero map. (A nonzero homomorphism $A_f \to A_g$ would induce an isogeny of Tate modules, from which one could deduce that f and g are Galois conjugate.)

We will concern ourselves almost entirely with these modular abelian varieties attached to newforms, because, as mentioned above, there are a number of algorithms for computing with them that do not require explicit algebraic equations (see [2, 3, 9, 10, 15, 19, 37, 35]). Also, it follows from standard results about constructing spaces of cusp forms from newforms, which can be found in [4, 22], that every modular abelian variety is isogenous to a product of abelian varieties of the form A_f. (An isogeny of abelian varieties is a surjective homomorphism with finite kernel.)

3 The Birch and Swinnerton-Dyer Conjecture

In the 1960s Bryan Birch and Peter Swinnerton-Dyer did computations with elliptic curves at Cambridge University on the EDSAC computer (see, e.g., [5]). These computations led to earth-shattering conjectures about the arithmetic of elliptic curves over $\mathbf{Q}$. Tate [39] formulated their conjectures in a more functorial way that generalized them to abelian varieties over global fields (such as the rational numbers). We now state their conjectures below for modular abelian varieties over $\mathbf{Q}$.

Let A_f be a modular abelian variety. Mordell and Weil proved that the abelian group $A_f(\mathbf{Q})$ of rational points on A_f is finitely generated, so it is isomorphic to $\mathbf{Z}^r \times T$ where T is the finite group $A_f(\mathbf{Q})_{\mathrm{tor}}$ of all elements of finite order in $A_f(\mathbf{Q})$. The exponent r is called the Mordell-Weil rank of A_f.

If f is a newform, the L-function of f is defined by the Dirichlet series $L(f,s) = \sum_{n\geq 1} a_n n^{-s}$. Hasse showed that $L(f,s)$ has an analytic continuation to a holomorphic function on the whole complex plane. The Hasse-Weil L-function of A_f is

$$L(A_f, s) = \prod L(g, s)$$

where the product is over the Galois conjugates g of f. The analytic rank of A_f is $\mathrm{ord}_{s=1} L(A_f, s)$.

We are now ready to state the first part of the conjecture.

Conjecture 3.1 (Birch and Swinnerton-Dyer) *The analytic rank of A_f is equal to the Mordell-Weil rank of A_f.*

Remark 1.

1. It is an open problem to give, with proof, an example of an elliptic curve with analytic rank at least 4. No examples with analytic rank at least 3 were known until the deep theorem of [16, Prop. 7.4].

2. When A_f is an elliptic curve, Conjecture 3.1 is the Clay Mathematics Institute Millennium Prize Problem from arithmetic geometry [17], so it has received much publicity.

In order to explain the conjecture of Birch and Swinnerton-Dyer about the leading coefficient of $L(A_f, s)$ at $s = 1$, we introduce the regulator, real volume, Tamagawa numbers, and Shafarevich-Tate group of A_f. Most of what we say below is true for a general abelian variety over a global field; the notable exceptions are that we do not know that the L-function is defined on the whole complex plane, and there are hardly any cases in general when the Shafarevich-Tate group is known to be finite.

Let $A_f(\mathbf{Q})_{/\mathrm{tor}}$ denote the quotient of $A_f(\mathbf{Q})$ by its torsion subgroup, so $A_f(\mathbf{Q})_{/\mathrm{tor}}$ is isomorphic to $\mathbf{Z}^r$, where r is the Mordell-Weil rank of A_f. The height pairing is a nondegenerate bilinear pairing h on $A_f(\mathbf{Q})_{/\mathrm{tor}}$. The regulator Reg_{A_f} of A_f is the absolute value of the determinant of a matrix who entries are $h(P_i, P_j)$, where $P_1, \ldots, P_r$ are a basis for $A_f(\mathbf{Q})_{/\mathrm{tor}}$. When $A_f(\mathbf{Q})$ has rank zero, the regulator is 1.

We use a certain integral model of A_f to define the real volume and Tamagawa numbers of A_f. The Néron model $\mathcal{A}$ of A_f, whose existence was established by Néron in [24] (see also [6, Ch. 1]), is a canonical object associated to A_f that is defined over $\mathbf{Z}$. The Néron model can be reduced modulo p for every prime p, and when base extended to $\mathbf{Q}$, the Néron model is isomorphic to A_f. The Néron model $\mathcal{A}$ is determined, up to unique isomorphism, by the following properties, which the reader unfamiliar with schemes can safely ignore: $\mathcal{A}$ is a smooth commutative group scheme over $\mathbf{Z}$ such that whenever S is a smooth scheme over $\mathbf{Z}$ the restriction map

$$\mathrm{Hom}(S, \mathcal{A}) \to \mathrm{Hom}_{\mathbf{Q}}(S_{\mathbf{Q}}, A)$$

is a bijection.

The real volume Ω_{A_f} of A_f is the absolute value of the integral over $A_f(\mathbf{R})$ of $h_1 \wedge \cdots \wedge h_d$ where $h_1, \ldots, h_d$ are a basis for the holomorphic 1-forms on $\mathcal{A}$. Using various identifications as in [1, §2.2.2] one sees that the $\mathbf{Z}$-span M of $h_1, \ldots, h_d$ can be viewed as a submodule of

$$W = S_2(\Gamma_0(N), \mathbf{Z}) \cap (\mathbf{C}f_1 \oplus \cdots \oplus \mathbf{C}f_d)$$

where $f_1, \ldots, f_d$ are the $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ conjugates of f. We call the index of M in W the Manin constant of A_f, and conjecture (see [1]) that the Manin constant is 1. This conjecture would imply that a basis $h_1, \ldots, h_d$ can be computed, since W can be computed.

The reduction modulo p of $\mathcal{A}$ is an algebraic group $\mathcal{A}_{\mathbf{F}_p}$ over the finite field $\mathbf{F}_p$ with p elements. If p does not divide N, then this group is connected, but when p divides N, the reduction $\mathcal{A}_{\mathbf{F}_p}$ need not be connected. Let

$$\Phi_{A,p} = \mathcal{A}_{\mathbf{F}_p} / \mathcal{A}^0_{\mathbf{F}_p}$$

be the finite group of components. The Tamagawa number of A_f at p, denoted c_p, is the number of $\mathbf{F}_p$-rational components of the reduction of $\mathcal{A}$ modulo p, so $c_p = \#\Phi_{A,p}(\mathbf{F}_p)$.

The only object left to define before we state the second part of the Birch and Swinnerton-Dyer conjecture is the Shafarevich-Tate group of A_f. This is a group that measures the failure of a certain local-to-global principle for A_f. To give an exact description, we let $\mathrm{H}^1(\mathbf{Q}, A_f)$ be the first Galois cohomology group of A_f, which is a torsion group with infinitely many elements of any order bigger than 1 (see [30] for a proof in the case when A_f is an elliptic curve; the top of page 278 of [8] also purports to contain a proof). More precisely, $\mathrm{H}^1(\mathbf{Q}, A_f)$ is the set of equivalence classes of maps $c : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to A_f(\overline{\mathbf{Q}})$, with finite image, such that $c(\sigma\tau) = c(\sigma) + \sigma c(\tau)$, and two classes c_1 and c_2 are equivalent if there exists P in $A_f(\overline{\mathbf{Q}})$ such that $c_1(\sigma) - c_2(\sigma) = \sigma(P) - P$ for all $\sigma \in \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$. For each prime p we define $\mathrm{H}^1(\mathbf{Q}_p, A_f)$ analogously, but with the rational numbers $\mathbf{Q}$ replaced by the p-adic numbers $\mathbf{Q}_p$. Also, we allow $p = \infty$, in which case $\mathbf{Q}_p = \mathbf{R}$. Then

$$Ш(A_f) = \ker\left(\mathrm{H}^1(\mathbf{Q}, A_f) \longrightarrow \bigoplus_{\text{primes } p \leq \infty} \mathrm{H}^1(\mathbf{Q}_p, A_f)\right).$$

We are now ready to state the full Birch and Swinnerton-Dyer conjecture for modular abelian varieties A_f.

Conjecture 3.2 *Let $A = A_f$ be a modular abelian variety attached to a newform, and let $r = \mathrm{ord}_{s=1}L(A, s)$ be the analytic rank of A. Then*

$$\frac{L^{(r)}(A,1)}{r!} = \frac{\prod c_p \cdot \Omega_A \cdot \mathrm{Reg}_A}{\#A(\mathbf{Q})_{\mathrm{tor}} \cdot \#A^\vee(\mathbf{Q})_{\mathrm{tor}}} \cdot \#Ш(A).$$

Recall that $L^{(r)}(A_f, 1)$ makes sense at $s = 1$ because A_f is attached to a modular form. Also Kato established in [18, Cor. 14.3] that if $L(A_f, 1) \neq 0$ then $Ш(A_f)$ is finite, and Kolyvagin-Logachev ([20, Thm. 0.3]) proved that if f is a modular form in $S_2(\Gamma_0(N))$ and $\mathrm{ord}_{s=1}L(f, s) \leq 1$, then $Ш(A_f)$ is finite. When the theorems of Kato, Kolyvagin, and Logachev do not apply, we do not know even one example of a modular abelian variety A_f for which $Ш(A_f)$ is provably finite. John Tate once remarked that Conjecture 3.2 (for arbitrary abelian varieties) relates the value of a function where it is not known to be defined to the order of a group that is not known to be finite.

The rest of this paper is about how to use Magma to gather computational evidence for Conjecture 3.2, a task well worth pursuing. Elliptic curves are naturally surrounded by modular abelian varieties, so we want to understand modular abelian varieties well in order to say something about Conjectures 3.1–3.2 for elliptic curves. Doing explicit computations about these conjectures results in stimulating tables of data about modular abelian varieties, which could never be obtained except by direct computation. Until [2, 15] there were very few nontrivial computational examples of Conjecture 3.2 for abelian varieties in the literature, so it is important to test the conjecture since we might find a counterexample. Trying to compute information about a conjecture stimulates development of algorithms and theorems about that conjecture. Finally, our computations may lead to refinements of Conjecture 3.2 in the special case of modular abelian varieties; for example, most objects in Conjecture 3.2 are modules over the Hecke algebra so there should be more precise module-theoretic versions of the conjecture.

4 Some Computational Results

In [2] we use Magma to compute some of the arithmetic invariants of the 19608 abelian variety quotients A_f of $J_0(N)$ with $N \leq 2333$. Over half of these A_f have analytic rank 0, and for these we compute a divisor and a multiple of the order of $Ш(A_f)$ predicted by Conjecture 3.2. We find that there are at least 168 abelian varieties A_f such that the Birch and Swinnerton-Dyer Conjecture implies that $\#Ш(A_f)$ is divisible by an odd prime, and we use Magma to show that for 37 of these the odd part of the conjectural order of $Ш(A_f)$ divides $\#Ш(A_f)$ by constructing nontrivial elements of $Ш(A_f)$ using visibility theory. The challenge remains to show that the remaining 131 abelian varieties A_f have odd part of $Ш(A_f)$ divisible by the odd part of the conjectural order of $Ш(A_f)$ (we successfully take up this challenge for one example of level 551 in Section 11 of the present paper).

In [9, §2 and §7] we investigate Conjecture 3.1–3.2 when A_f is a quotient of $J_1(p)$ with p prime. In particular, we compute some of the invariants of every A_f for $p \leq 71$.

It was once thought by some mathematicians that Shafarevich-Tate groups of abelian varieties would have order a perfect square (or at least twice a perfect square). This is false, as we showed in the paper [36], where we use Magma to prove that for every odd prime $p < 25000$ there is an abelian variety whose Shafarevich-Tate group has order pn^2 with n an integer.

Much of the data mentioned above is of interest even if the full Birch and Swinnerton-Dyer conjecture were known since this data could probably never be discovered without considerable computation, even assuming the conjectures were true.

The rest of this paper is about how to use Magma to do computations with newform quotients A_f of $J_0(N)$ as in [2]. These computations involve modular symbols, which underly most algorithms for working with modular abelian varieties. (I hope to add functionality to a future release of Magma for computing directly with modular abelian varieties, so that no explicit mention of modular symbols is required.)

Remark 2. From a computational point of view, it is difficult to give evidence for Conjecture 3.1 when the dimension is greater than 1 in cases not covered by the general theorems of Kato, Kolyvagin, and Logachev. To give new evidence we would have to consider a modular abelian variety A_f with either f a newform in $S_2(\Gamma_0(N))$ and $\mathrm{ord}_{s=1}L(f,s) > 1$, or f a newform in $S_2(\Gamma_1(N))$ but not in $S_2(\Gamma_0(N))$ and $\mathrm{ord}_{s=1}L(f,s) > 0$. We would then show that $A_f(\mathbf{Q})$ is infinite, and more precisely that it has the rank predicted by Conjecture 3.1. In the above 2 cases the only known way to show that $A_f(\mathbf{Q})$ is infinite is to exhibit a point of infinite order in $A_f(\mathbf{Q})$, and this seems to require knowing equations for A_f. Also when $L(A_f,1) = 0$, Conjecture 3.2 involves a regulator term, which we do not know how to compute without explicitly finding the points on a model for A_f. Thus we will focus on giving evidence for Conjecture 3.2 in the case when $L(f,1) \neq 0$.

5 Modular Symbols

In this section we describe how modular symbols are related to homology of modular curves, and illustrate how to compute with modular symbols in Magma. We also discuss computing decomposition of modular symbols spaces and, for efficiency reasons, computing in the +1 quotient.

Let N be a positive integer. The integral homology $\mathrm{H}_1(X_0(N),\mathbf{Z})$ of the modular curve $X_0(N)$ is a free abelian group of rank equal to the genus of $X_0(N)$. The Hecke algebra $\mathbf{T} = \mathbf{Z}[T_1, T_2, T_3, \ldots]$ acts on a $\mathrm{H}_1(X_0(N),\mathbf{Z})$ as a ring of homomorphisms and makes $\mathrm{H}_1(X_0(N),\mathbf{Z})$ into a $\mathbf{T}$-module. This section is concerned with how to compute with this module using Magma. Section 12 contains a complete log of all Magma computations given below.

Modular symbols provide a finite computable presentation for the homology of $X_0(N)$ along with the action of the Hecke algebra $\mathbf{T}$ on this homology. The relative rational homology $\mathrm{H}_1(X_0(N),\mathbf{Q},\text{cusps})$ is the rational homology of $X_0(N)$ relative to the cusps; it is the finitely generated free abelian group of homology equivalence classes of geodesic paths from α to β, where α and β lie in $\mathbf{P}^1(\mathbf{Q}) = \mathbf{Q} \cup \{\infty\}$. A finite presentation for $\mathrm{H}_1(X_0(N),\mathbf{Q},\text{cusps})$ can be found in [23]. For simplicity, we typically compute $\mathrm{H}_1(X_0(N),\mathbf{Q},\text{cusps})$ first, then find $\mathrm{H}_1(X_0(N),\mathbf{Z})$ inside $\mathrm{H}_1(X_0(N),\mathbf{Q},\text{cusps})$ if it is needed. By definition, We now illustrate how Magma can compute a basis for $\mathrm{H}_1(X_0(N),\mathbf{Q},\text{cusps})$, and, given arbitrary α and β in $\mathbf{P}^1(\mathbf{Q})$, find an equivalent linear combination of basis elements.

```
M := ModularSymbols(389);
Basis(M);
```

The output of Basis(M) begins with the symbol $\{-1/337, 0\}$. Figure 2 on page 10 illustrates how the expression $\{-1/337, 0\}$ represents the relative rational homology class determined by a geodesic path from $-1/337$ to 0 in the upper half plane. The cusps determined by $-1/337$ and 0 are equivalent by an element of $\Gamma_0(389)$, so the image of the geodesic path in the 32 holed torus $X_0(389)(\mathbf{C})$ is a closed loop.

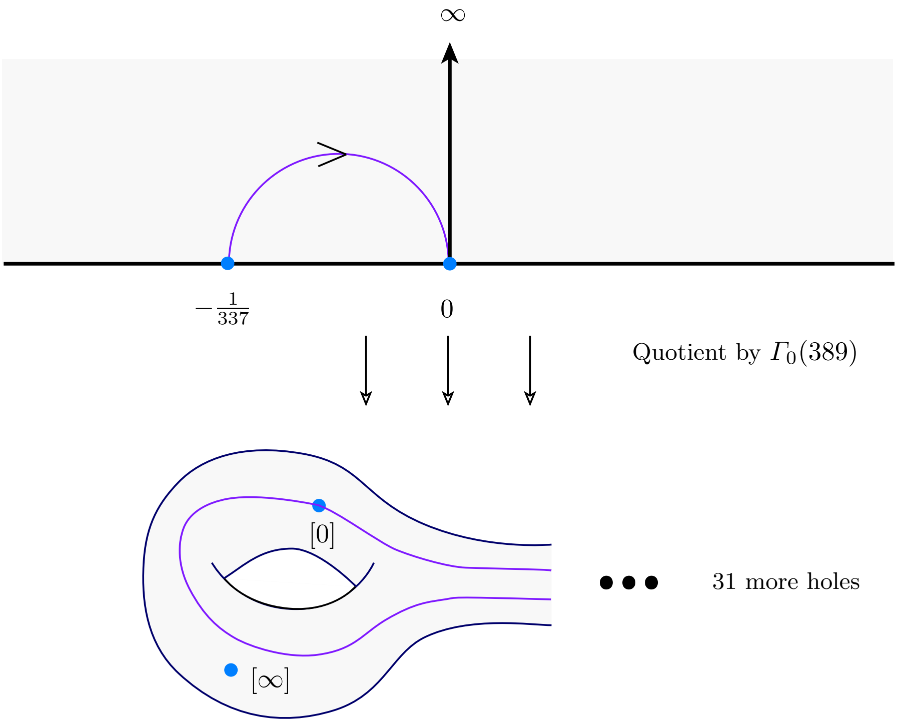

Fig. 2. The Modular Symbol $\{-1/337, 0\}$

The following Magma code illustrates how to find the image in the relative homology of an arbitrary path between cusps. The extra < and > are needed because we are considering modular symbols of weight $k = 2$; in general there is a coefficient which is a homogenous polynomial of degree $k - 2$, which is the first argument to the coercion. The Cusps()| part of the expression is needed so that the sequence is a sequence of cusps (this is not required if both cusps are rational numbers).

```
M ! <1, [Cusps() | −1/337, Infinity()] > ;
```

For more about computing with modular symbols, see [11, 12, 23, 37, 35].

Precise relationships between $\mathrm{H}_1(X_0(N), \mathbf{Q})$ and $S_2(\Gamma_0(N))$, along with some linear algebra, make it possible for us to compute a basis of $S_2(\Gamma_0(N))$

from knowledge about $\mathrm{H}_1(X_0(N), \mathbf{Q})$ as a $\mathbf{T}$-module. The following code, which computes a basis for $S_2(\Gamma_0(389))$, computes $\mathrm{H}_1(X_0(389), \mathbf{Q})$ and uses it to deduce the basis.

```
S := CuspForms(389);
SetPrecision(S,40);
Basis(S);
```

The SetPrecision command sets the output precision for q-expansions. The computed basis consists of q-expansions with coefficients in $\mathbf{Z}$.

Using NewformDecomposition, we find the submodules of $\mathrm{H}_1(X_0(389), \mathbf{Q})$ that correspond to Galois-conjugacy classes of newforms. These in turn correspond to the modular abelian varieties A_f attached to newforms. Magma excels at dense linear algebra over $\mathbf{Q}$ and is highly optimized for computing these decompositions. The following commands compute a decomposition of the new subspace of $\mathrm{H}_1(X_0(389), \mathbf{Q})$ corresponding to newforms.

```
M := ModularSymbols(389);
N := NewSubspace(CuspidalSubspace(M));
NewformDecomposition(N);
```

Since 389 is prime, the NewSubspace command is not necessary since everything is automatically new (there are no nonzero cusp forms of level 1 and weight 2). The decomposition consists of five factors of dimensions 2, 4, 6, 12, and 40; these correspond to newforms defined over fields of degrees 1, 2, 3, 6, and 20, respectively, which in turn correspond to abelian varieties over $\mathbf{Q}$ of dimensions 1, 2, 3, 6, and 20, respectively.

Remark 3. When information about the powers of 2 appearing in Conjecture 3.2 is not needed, we can instead do all computations in the "+1 quotient" of the space of modular symbols, which has half the dimension.

```
M := ModularSymbols(389,2,+1);    // the plus one quotient
```

6 Visibility Theory

Mazur introduced the notion of visibility to unify diverse ideas for constructing elements of Shafarevich-Tate groups. In this section we define what it means for an element of the Shafarevich-Tate group to be visible, state a theorem that allows us to compute pieces of this visible subgroup in some cases, and illustrate the theorem with a 20 dimensional abelian variety of level 389.

Suppose $i : A \to J$ is an injective morphism of abelian varieties over $\mathbf{Q}$. Then the visible subgroup of $\text{Ш}(A)$ is the kernel of the induced map $\text{Ш}(A) \to \text{Ш}(J)$.

Our interest in visibility in the present paper is that it allows us to obtain a provable divisor of $\#\text{Ш}(A)$, which is useful in giving evidence for Conjecture 3.2. The following theorem is proved in [3, Thm. 3.1] for abelian varieties over number fields.

Theorem 6.1 *Let A and B be abelian subvarieties of an abelian variety J over $\mathbf{Q}$ such that $A(\overline{\mathbf{Q}}) \cap B(\overline{\mathbf{Q}})$ is finite. (Note that J need not be a Jacobian.) Let N be an integer divisible by the residue characteristics of primes of bad reduction for B (so if A and B are modular then N is the level). Suppose p is an odd prime and that*

$$p \nmid N \cdot \#(J/B)(\mathbf{Q})_{\mathrm{tor}} \cdot \#B(\mathbf{Q})_{\mathrm{tor}} \cdot \prod_{p} c_{A,p} \cdot c_{B,p},$$

where $c_{A,p} = \#\Phi_{A,p}(\mathbf{F}_p)$ (resp., $c_{B,p}$) is the Tamagawa number of A (resp., B) at p. Suppose furthermore that $B(\overline{\mathbf{Q}})[p] \subset A(\overline{\mathbf{Q}})$, where both are viewed as subgroups of $J(\overline{\mathbf{Q}})$. Then there is a natural map

$$\varphi : B(\mathbf{Q})/pB(\mathbf{Q}) \to \text{Ш}(A)[p]$$

such that

$$\dim_{\mathbf{F}_p} \ker(\varphi) \leq \dim_{\mathbf{Q}} A(\mathbf{Q}) \otimes \mathbf{Q}.$$

In particular, if A has Mordell-Weil rank 0, then φ is injective.

Let A be the 20 dimensional quotient of $J_0(389)$ attached to a newform and B the elliptic curve quotient of $J_0(389)$. We use Magma to verify the hypothesis of Theorem 6.1 for $J = A^\vee + B^\vee \subset J_0(389)$ with $p = 5$, and hence deduce that $B(\mathbf{Q})/5B(\mathbf{Q}) = (\mathbf{Z}/5\mathbf{Z}) \times (\mathbf{Z}/5\mathbf{Z})$ injects into $\text{Ш}(A)$.

Since A and B are quotients of $J_0(389)$, we have $N = 389$. Next we construct the corresponding spaces A and B of modular symbols.

```
M := ModularSymbols(389);
N := NewSubspace(CuspidalSubspace(M));
D := SortDecomposition(NewformDecomposition(N));
A := D[5]; B := D[1];
```

The command IntersectionGroup computes the group structure of the intersection of two abelian subvarieties. In our case these are the abelian varieties $A^\vee$ and $B^\vee$, and we find that $A^\vee \cap B^\vee = (\mathbf{Z}/20\mathbf{Z}) \times (\mathbf{Z}/20\mathbf{Z})$. In particular, $B^\vee[5] = (\mathbf{Z}/5\mathbf{Z}) \times (\mathbf{Z}/5\mathbf{Z})$ is contained in $A^\vee$ as abelian subvarieties of $J_0(389)$.

```
IntersectionGroup(A,B);
```

Using the TorsionBound command (see Section 9 below), we obtain a multiple of the order of the torsion subgroup of B (it is 1) and of J/B (it is 97).

```
TorsionBound(A,7);
TorsionBound(B,7);
```

Neither torsion subgroup has order divisible by 5, as required to apply Theorem 6.1. The reason that TorsionBound(A,7) is a multiple of the order of the torsion subgroup of J/B is because TorsionBound is an isogeny invariant and A is isogenous to J/B. (The kernel of the natural map from A to J/B is $A \cap B = (\mathbf{Z}/20\mathbf{Z}) \times (\mathbf{Z}/20\mathbf{Z})$, which is finite.)

Finally, we compute the Tamagawa numbers of A and B and obtain 97 and 1, respectively (see Section 8 below).

```
TamagawaNumber(A, 389);
TamagawaNumber(B, 389);
```

Putting everything together we see that $B(\mathbf{Q})/5B(\mathbf{Q})$ is a subgroup of $\text{Ш}(A)$. Finally, using the Rank command on the elliptic curve attached to B, we see that $B(\mathbf{Q})/5B(\mathbf{Q}) = (\mathbf{Z}/5\mathbf{Z}) \times (\mathbf{Z}/5\mathbf{Z})$.

```
E := EllipticCurve(B);
Rank(E);
```

Thus 25 divides $\#\text{Ш}(A)$, which gives evidence for Conjecture 3.2, as we will see in Section 10.

Frequently not all of $\text{Ш}(A)$ can be constructed using Theorem 6.1 and abelian subvarieties B of $J_0(N)$. One obstruction to visibility arises from a canonical homomorphism from $A^\vee$ to A. Jacobians of curves are canonically isomorphic to their dual abelian variety and the composition $A^\vee \to J_0(389)^\vee \cong J_0(389) \to A$ defines a homomorphism from $A^\vee$ to A. According to [3, §5.3], if p does not divide the kernel of $A^\vee \to A$, then no element of order p in $\text{Ш}(A)$ is visible in $J_0(N)$. The command ModularKernel computes the group structure of the kernel of $A^\vee \to A$.

```
G := ModularKernel(A);
Factorization(#G);
```

We find that the modular kernel has order $2^{24}5^2$, so any element of $\text{Ш}(A^\vee)$ that is visible in $J_0(389)$ has order divisible only by 2 and 5.

7 Computing Special Values of Modular L-function

This section is about computing the quotient $L(A_f, 1)/\Omega_{A_f}$. We discuss the Manin constant and the LRatio command.

Let $A = A_f$ for some newform f and assume that $L(A, 1) \neq 0$. We can then rewrite Conjecture 3.2 as follows:

$$\frac{L(A,1)}{\Omega_A} = \frac{\prod c_p \cdot \#\text{Ш}(A)}{\#A(\mathbf{Q})_{\mathrm{tor}} \cdot \#A^\vee(\mathbf{Q})_{\mathrm{tor}}}.$$

We do not know an algorithm, in general, to compute $L(A, 1)/\Omega_A$. However, we can compute $c_A \cdot L(A, 1)/\Omega_A$, where c_A is the Manin constant, which is defined in [1, §2.2]. We conjecture that $c_A = 1$, and prove in [1, §2.2.2] that if f is a newform on $\Gamma_0(N)$ then c_A is an integer divisible only by primes whose square divides $4N$. Moreover, if N is odd then $2^{\dim A}$ is the largest power of 2 that can divide c_A. See also [14] for results when A has dimension 1, and [9, §6.1.2] for a proof that c_A is an integer when $\Gamma_0(N)$ is replaced by $\Gamma_1(N)$.

The algorithm described in [9, §2.1.3], [2, §4] and [37, §3.10] to compute $c_A \cdot L(A,1)/\mathit{\Omega}_A$ is implemented in MAGMA via the LRATIO command. For example, if A is as in Section 6, then $c_A \cdot L(A,1)/\mathit{\Omega}_A = 2^{11} \cdot 5^2/97$.

```
LRatio(A, 1)
```

8 Computing Tamagawa Numbers

In this section we discuss computing Tamagawa numbers when $p \mid\mid N$ and some bounds when $p^2 \mid N$. We also discuss issues that arise in going from the order of the component group to the Tamagawa number when $p \mid\mid N$.

Let $A = A_f$ be a modular abelian variety attached to a newform $f \in S_2(\mathit{\Gamma}_0(N))$. When $p \mid\mid N$, [10, §2.1] contains a computable formula for $\#\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$ and for $c_p = \#\mathit{\Phi}_{A,p}(\mathbf{F}_p)$, where the latter formula is in some cases only valid up to a bounded power of 2. Also [19] is about how to compute these orders. Note that the Tamagawa number of A at p is the same as the Tamagawa number of $A^\vee$ at p.

When $p^2 \mid N$ the authors do not know an algorithm to compute c_p. However, in this case Lenstra and Oort proved in [21, Cor. 1.15] that

$$\sum_{\ell \neq p} (\ell - 1)\mathrm{ord}_\ell(\#\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)) \leq 2\dim(A_f),$$

so if $\ell \mid \#\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$ then $\ell \leq 2 \cdot \dim(A_f) + 1$ or $\ell = p$. (Here $\mathrm{ord}_\ell(x)$ denotes the exponent of the largest power of ℓ that divides x.)

Using [10], when $p \mid\mid N$ we know how to compute the order of the component group over the algebraic closure, but not its structure as a group. The command COMPONENTGROUPORDER computes the order of $\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$. The command TAMAGAWANUMBER computes $c_p = \#\mathit{\Phi}_{A,p}(\mathbf{F}_p)$ when the subgroup of elements of $\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$ fixed by the Galois group has order that does not depend on the underlying group structure. By computing the Atkin-Lehner involution on modular symbols, we can decide whether the Galois group acts trivially or by -1 on $\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$ since the Atkin-Lehner involution acts as the negative of the canonical generator Frobenius of $\mathrm{Gal}(\overline{\mathbf{F}}_p/\mathbf{F}_p)$. We can thus compute $\#\mathit{\Phi}_{A,p}(\mathbf{F}_p)$ when the Galois group acts trivially. When the Galois group acts nontrivially, $\mathit{\Phi}_{A,p}(\mathbf{F}_p)$ is the 2-torsion subgroup of $\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$, whose order we know as long as 4 does not divide $\#\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$. It is an open problem to given an algorithm to compute the group structure of $\mathit{\Phi}_{A,p}(\overline{\mathbf{F}}_p)$ or the order of $\mathit{\Phi}_{A,p}(\mathbf{F}_p)$ in general.

Section 11 contains an example of an abelian variety of dimension 18 in which the author is only able to find the Tamagawa number up to a controlled power of 2.

9 Computing the Torsion Subgroup

In this section we describe how to compute a divisor and multiple of the order of the torsion subgroup and explain how knowing a divisor of $\#A_f(\mathbf{Q})_{\mathrm{tor}}$ yields a divisor of $\#A_f^\vee(\mathbf{Q})_{\mathrm{tor}}$.

The papers [2, §3.5–3.6] and [9, §2.1.1] contain discussions of how to compute a divisor and multiple of the order of the torsion subgroup $A_f(\mathbf{Q})_{\mathrm{tor}}$ of $A_f(\mathbf{Q})$, and likewise for $A_f^\vee(\mathbf{Q})_{\mathrm{tor}}$. (The multiple of $\#A_f^\vee(\mathbf{Q})_{\mathrm{tor}}$ is the same as for $A_f(\mathbf{Q})_{\mathrm{tor}}$, and the divisor can be computed as described below.) We compute the multiple by using that $A_f(\mathbf{Q})_{\mathrm{tor}}$ injects into $A_f(\mathbf{F}_p)$ for all p not dividing $2N$, and that $\#A_f(\mathbf{F}_p)$ is fairly easy to compute, though we do not know how to compute the group structure. We compute the lower bound by considering the subgroup of elements of $J_0(N)(\mathbf{Q})_{\mathrm{tor}}$ generated by rational cusps on $X_0(N)$ (see [38, §1.3]), and taking its image in $A_f(\mathbf{Q})_{\mathrm{tor}}$ or intersecting its image with $A_f^\vee(\mathbf{Q})_{\mathrm{tor}} \subset J_0(N)(\mathbf{Q})_{\mathrm{tor}}$. Note that there is no reason for the subgroup generated by rational cusps to equal the rational subgroup of the group generated by all cusps, and one might want to compute and work with this possibly larger group instead.

Let A and B be as in Section 6, where we showed that the torsion subgroup of B is trivial and the order of $B(\mathbf{Q})$ and $B^\vee(\mathbf{Q})$ divides 97. In Section 10, we give an example in which the divisor and multiple of the order of the torsion subgroup differ by a power of 2.

```
RationalCuspidalSubgroup(A);    // subgroup of $A(\mathbf{Q})$
```

As mentioned in Section 6, there is a homomorphism $A^\vee \to A$ of degree $2^{24} \cdot 5^2$, which implies that 97 also divides $\#A_f^\vee(\mathbf{Q})_{\mathrm{tor}}$. Thus $\#A_f(\mathbf{Q})_{\mathrm{tor}} = \#A_f^\vee(\mathbf{Q})_{\mathrm{tor}} = 97$.

Remark 4. Computation of a nontrivial divisor of $\#A_f^\vee(\mathbf{Q})_{\mathrm{tor}}$ directly using rational cusps is not yet implemented in Magma, though in principle this should not be difficult to implement.

10 A Divisor and Multiple of the Order of the Shafarevich-Tate Group

In this section we substitute the values computed above into Conjecture 3.2 to obtain a conjectural divisor and multiple of the order of a Shafarevich-Tate group. We then remark that the visibility computation of Section 6 gives evidence for Conjecture 3.2. This example is also discussed in [3, §4.2].

To obtain evidence for Conjecture 3.2, we consider an abelian variety A_f with $L(A_f, 1) \neq 0$ and combine the invariants whose computation is described above with Conjecture 3.2 to obtain a conjectural divisor and multiple of the order of $\text{Ш}(A_f)$. We then observe that this divisor and multiple is consistent with Conjecture 3.2.

We now combine the computations from the previous sections for the 20 dimensional quotient A of $J_0(389)$. Recall that Conjecture 3.2 asserts that

$$\frac{L(A,1)}{\Omega_A} = \frac{\prod c_p \cdot \#Ш(A)}{\#A(\mathbf{Q})_{\mathrm{tor}} \cdot \#A^{\vee}(\mathbf{Q})_{\mathrm{tor}}}.$$

This equation becomes

$$\frac{2^n \cdot 2^{11} \cdot 5^2}{97} = \frac{97 \cdot \#Ш(A)}{97^2}$$

where $0 \leq n \leq 20$ (using the bound from [1, Thm. 2.7]). Thus the conjecture asserts that $\#Ш(A) = 5^2 \cdot 2^{11+n}$, and we have computed a conjectural divisor $5^2 \cdot 2^{11}$ and a conjectural multiple $5^2 \cdot 2^{31}$ of $\#Ш(A)$. Using visibility theory from Section 6 we have proved that $5^2 \mid \#Ш(A)$, which provides evidence for Conjecture 3.2.

11 An Element of the Shafarevich-Tate Group that Becomes Visible at Higher Level

We finish this paper by considering the 18-dimensional newform quotient A of $J_0(551)$. In this example, the level $551 = 19 \cdot 29$ is composite, the Shafarevich-Tate group is conjecturally nontrivial, and the methods of Section 6 do not produce nontrivial elements of the Shafarevich-Tate group at level 551.

This example is striking because it is, in some sense, the simplest known example of "visibility only at a higher level"; more precisely, the methods of Section 6 do produce a nontrivial element at the rather small level 1102. For a similar example, see [3, §4.3], where the levels involved are much larger.

We first compute the space of modular symbols corresponding to A:

```
M := ModularSymbols(551);
N := NewSubspace(CuspidalSubspace(M));
D := SortDecomposition(NewformDecomposition(N));
A := D[8];
```

Next we compute a divisor and a multiple of the order of the torsion subgroup of $A(\mathbf{Q})$ and $A^{\vee}(\mathbf{Q})$. Using odd primes $p \leq 7$ we obtain the multiple 160, and using the rational cuspidal subgroup we obtain the divisor 40.

```
TorsionBound(A, 7);
RationalCuspidalSubgroup(A);
```

Since the divisor and multiple are different, we try more finite fields. For $p \leq 29$ the multiple we obtain is still 160; however, for $p = 31$ the multiple is 80, which is where it appears to stabilize.

```
TorsionBound(A, 31);
```

We conclude that $40 \mid \#A(\mathbf{Q})_{\mathrm{tor}} \mid 80$ and $5 \mid \#A^{\vee}(\mathbf{Q})_{\mathrm{tor}} \mid 80$. We know that 5 divides $\#A^{\vee}(\mathbf{Q})_{\mathrm{tor}}$ because, as we will see below, there is a homomorphism $A^{\vee} \to A$ of degree not divisible by 5.

Next we compute the modular kernel, which is of order $2^{44} \cdot 13^4$.

```
Factorization(#ModularKernel(A));
```

The only possible elements of $Ш(A)$ that we can construct using Theorem 6.1 at level 551 are of order 13.

The level 551 is not prime, so computation of the Tamagawa numbers involves certain relatively slow algorithms (a minute rather than seconds) that involve arithmetic in quaternion algebras. Also, in this example, we are unable to determine the exact power of 2 that divides the Tamagawa number at 19.

```
TamagawaNumber(A, 19);    // takes over a minute; gives an error
TamagawaNumber(A, 29);
```

We find that $c_{29} = 40$. We also deduce that $c_{19} = 2$ or 4 by noting that the component group over $\overline{\mathbf{F}}_{19}$ has order $2^2 \cdot 13^2$ by using the command

```
ComponentGroupOrder(A, 19);
```

and noting that the Galois generator Frobenius acts as -1 because

```
AtkinLehnerOperator(A, 19)[1, 1];
```

returns 1. Finally note that the 2 torsion in any group of order $2^2 \cdot 13^2$ is a subgroup of order either 2 or 4.

Next we find that $L(A, 1)/\Omega_A = 2^n \cdot 2^2 \cdot 3^2/5$, with $0 \leq n \leq 18$, using the command

```
LRatio(A, 1)
```

and the fact that the Manin constant divides $2^{\dim A}$ (see [1, Thm. 2.7]).

Putting these computations together we find that Conjecture 3.2 asserts that

$$\frac{2^n \cdot 2^2 \cdot 3^2}{5} = \frac{2^m \cdot 40 \cdot \#Ш(A)}{40 \cdot 2^r \cdot 5 \cdot 2^s},$$

where $0 \leq n \leq 18$, $1 \leq m \leq 2$, $0 \leq r \leq 1$, and $0 \leq s \leq 4$. Solving for $\#Ш(A)$, we see that Conjecture 3.2 predicts that

$$\#Ш(A) = 2^t \cdot 3^2$$

with $2 \leq t \leq 24$.

Theorem 6.1 does not construct elements of order 2 (yet), so we do not consider the factor 2^t further. As mentioned above, we cannot construct any elements of $Ш(A)$ of order 3 using visibility at level 551. We can, however, consider the images of A in $J_0(2 \cdot 551)$ under various natural maps. These natural maps are the degeneracy maps δ_1 and δ_2, which correspond to the maps $f(q) \mapsto f(q)$ and $f(q) \mapsto f(q^2)$ from $S_2(\Gamma_0(551))$ to $S_2(\Gamma_0(2 \cdot 551))$.

We next compute the space of modular symbols that corresponds to the sum $C = \delta_1(A)+\delta_2(A)$ of the images of A at level $2\cdot551$ by the two degeneracy maps δ_1 and δ_2.

```
M := ModularSymbols(2*551,2);
N := NewSubspace(CuspidalSubspace(M));
D := SortDecomposition(NewformDecomposition(N));
M551 := ModularSymbols(M,551);
N551 := NewSubspace(CuspidalSubspace(M551));
D551 := SortDecomposition(NewformDecomposition(N551));
A551 := D551[#D551];
C := M !! A551;    // sum of images under degeneracy maps
```

The sum C contains the 3-torsion of the rank 2 elliptic curve B defined by $y^2 + xy = x^3 + x^2 - 29x + 61$, as the following computation shows.

```
IntersectionGroup(C,D[1]);
B := EllipticCurve(D[1]); B;
```

It follows that $B[3]$ is contained in C. The following computation shows that the Tamagawa numbers of B are 2, 2, and 1 and $B(\mathbf{Q}) \equiv \mathbf{Z} \times \mathbf{Z}$:

```
TamagawaNumber(B,2);
TamagawaNumber(B,19);
TamagawaNumber(B,29);
MordellWeilGroup(B);
```

Theorem 6.1 implies that $B(\mathbf{Q})/3B(\mathbf{Q}) = \mathbf{Z}/3\mathbf{Z} \times \mathbf{Z}/3\mathbf{Z}$ is a subgroup of $\text{Ш}(C)$. By [26, §2], there is an isogeny φ from $A \times A$ to C whose kernel is isomorphic to the intersection of A with the Shimura subgroup of $J_0(551)$. The Shimura subgroup Σ is a subgroup of $J_0(N)$ that, according to [26, Prop. 2], is annihilated by $T_p - (p + 1)$ for all primes $p \nmid 551$. Using Magma we find that $3 \nmid \det(T_3|_A - 4) = 12625812402998886400$, so the degree of φ is coprime to 3.

```
T3 := HeckeOperator(A,3);
d := Determinant(T3-4);
Valuation(d,3);
```

Since $3 \mid \#\text{Ш}(C)$ it follows that $3 \mid \#\text{Ш}(A)$. By [2, §5.3] the power of 3 that divides $\#\text{Ш}(A)$ is even, so $9 \mid \#\text{Ш}(A)$, as predicted by the Birch and Swinnerton-Dyer conjecture.

12 Complete Magma Log

This is a complete log of using MAGMA V2.10-6 to do all of the computations discussed in this paper. The output has been edited slightly to save space.

20 Modular Parametrizations Of NeumannSetzer Elliptic Curves, with M. Watkins

MODULAR PARAMETRIZATIONS OF NEUMANN–SETZER ELLIPTIC CURVES

WILLIAM STEIN AND MARK WATKINS

Abstract. Suppose p is a prime of the form $u^2 + 64$ for some integer u, which we take to be 3 mod 4. Then there are two Neumann–Setzer elliptic curves E_0 and E_1 of prime conductor p, and both have Mordell–Weil group $\mathbf{Z}/2\mathbf{Z}$. There is a surjective map $X_0(p) \xrightarrow{\pi} E_0$ that does not factor through any other elliptic curve (i.e., π is optimal), where $X_0(p)$ is the modular curve of level p. Our main result is that the degree of π is odd if and only if $u \equiv 3 \pmod 8$. We also prove the prime-conductor case of a conjecture of Glenn Stevens, namely that that if E is an elliptic curve of prime conductor p then the optimal quotient of $X_1(p)$ in the isogeny class of E is the curve with minimal Faltings height. Finally we discuss some conjectures and data about modular degrees and orders of Shafarevich–Tate groups of Neumann–Setzer curves.

1. Introduction

Let p be a prime of the form $u^2 + 64$ for some integer u, which we take to be 3 modulo 4. Neumann and Setzer [Neu71, Set75] considered the following two elliptic curves of conductor p (note that Setzer chose $u \equiv 1 \pmod 4$ instead):

$$E_0: \quad y^2 + xy = x^3 - \frac{u+1}{4}x^2 + 4x - u, \tag{1.1}$$

$$E_1: \quad y^2 + xy = x^3 - \frac{u+1}{4}x^2 - x. \tag{1.2}$$

For E_1 we have $c_4 = p - 16$ and $c_6 = u(p+8)$ with $\Delta = p = u^2 + 64$, while for E_0 we have $c_4 = p - 256$ and $c_6 = u(p + 512)$ with $\Delta = -p^2$. Thus each E_i is isomorphic to a curve of the form $y^2 = x^3 - 27c_4x - 54c_6$ for the indicated values of c_4 and c_6. The curves E_0 and E_1 are 2-isogenous and one can show using Lutz-Nagell and descent via 2-isogeny that

$$E_0(\mathbf{Q}) = E_1(\mathbf{Q}) = \mathbf{Z}/2\mathbf{Z}.$$

Moreover, if E is *any* elliptic curve over $\mathbf{Q}$ of prime conductor with a rational point of order 2 then E is a Neumann–Setzer curve or has conductor 17 (see [Set75]).

Let $X_0(p)$ be the modular curve of level p. By [Wil95] there is a surjective map $\pi : X_0(p) \to E_0$, and by [MO89, §5, Lem. 3] we may choose π to be optimal, in the sense that π does not factor through any other elliptic curve. The *modular degree* of E_0 is $\deg(\pi)$.

We prove in Section 2 that the modular degree of E_0 is odd if and only if $u \equiv 3 \pmod 8$. Our proof relies mostly on results from [Maz77]. In Section 3 we show that E_1 is the curve of minimal Faltings height in the isogeny class $\{E_0, E_1\}$ of E_1 and prove that E_1 is an optimal quotient of $X_1(p)$, which is enough to prove the prime-conductor case of a conjecture of [Ste89] (this case is not covered by the results of [Vat03]). Finally, in Section 4 we give evidence for our conjecture that there are infinitely many elliptic curves with odd modular degree, and give a conjectural refinement of

Date: December 2003.

Theorem 2.1. We also present some data about p-divisibility of conjectural orders of Shafarevich–Tate groups of Neumann–Setzer curves.

1.1. Notation.

Let p be a prime and n be the numerator of $(p-1)/12$.

We use standard notation for modular forms, modular curves, and Hecke algebras, as in [DI95] and [Maz77]. In particular, let $X_0(p)$ be the compactified coarse moduli space of elliptic curves with a cyclic subgroup of order p. Then $X_0(p)$ is an algebraic curve defined over $\mathbf{Q}$. Let $J = J_0(p)$ be the Jacobian of $X_0(p)$, and let $\mathbf{T} = \mathbf{Z}[T_2, T_3, \ldots] \subset \mathrm{End}(J)$ be the Hecke algebra. Also, let $X_1(p)$ be the modular curve the classifies isomorphism classes of pairs (E, P), where $P \in E$ is a point of order p.

To each newform $f \in S_2(\Gamma_0(p))$, there is an associated abelian subvariety $A = A_f \subset J_0(p)$. We call the kernel Ψ_A of the natural map $A \hookrightarrow J \to A^\vee$ the *modular kernel*. For example, when A is an elliptic curve, this map is induced by pullback followed by push forward on divisors and Ψ_A is multiplication by $\deg(X_0(p) \to A)$. The *modular degree* of A is the square root of the degree of Ψ_A. This definition makes sense even when $\dim(A) > 1$, since the degree of a polarization is the square of its Euler characteristic, hence a perfect square (see [Mum70, §16, pg. 150]). If $I \subset \mathbf{T}$ is an ideal, let

$$A[I] = \{x \in A(\overline{\mathbf{Q}}) : Ix = 0\} \qquad \text{and} \qquad A[I^\infty] = \bigcup_{n>0} A[I^n].$$

2. Determination of the Parity of the Modular Degree

Let p, E_0, J and n be as in Section 1, and fix notation as in Section 1.1. In this section we prove the following theorem.

Theorem 2.1. *The modular degree of E_0 is odd if and only if $u \equiv 3 \pmod 8$.*

In order to prove the theorem we deduce seven lemmas using techniques and results from [Maz77].

Let m be the modular degree of E_0, and let

$$B = \ker(J \xrightarrow{\pi} E_0).$$

Lemma 2.2. *We have $m^2 = \#(B \cap E_0)$.*

Proof. As mentioned in Section 1.1, the composition $E_0 \to J \to E_0$ is multiplication by the degree of $X_0(p) \to E_0$, i.e., multiplication by the modular degree of E_0. The lemma follows since multiplication by m on E_0 has degree m^2. □

The *Eisenstein ideal* $\mathcal{I}$ of $\mathbf{T}$ is the ideal generated by $T_\ell - (\ell + 1)$ for $\ell \neq p$ and $T_p - 1$. By hypothesis, there is a Neumann–Setzer curve of conductor p, which implies that the numerator n of $(p-1)/12$ is even (we do the elementary verification that this numerator is even in the proof of Theorem 2.1 below). As discussed in [Maz77, Prop. II.9], the 2-*Eisenstein prime* $\mathfrak{m} = (2) + \mathcal{I}$ of $\mathbf{T}$ is a maximal ideal of $\mathbf{T}$, with $\mathbf{T}/\mathfrak{m} \cong \mathbf{Z}/2\mathbf{Z}$.

Lemma 2.3. *We have $E_0[\mathfrak{m}] = E_0[2]$.*

Proof. By [Maz77, Prop. II.11.1, Thm. III.1.2], the Eisenstein ideal $\mathcal{I}$ annihilates $J(\mathbf{Q})_{\mathrm{tor}}$, so $\mathfrak{m}$ annihilates $J(\mathbf{Q})_{\mathrm{tor}}[2]$. Since $J(\mathbf{Q})_{\mathrm{tor}}$ is cyclic of order n (by [Maz77, Thm. III.1.2]), $J(\mathbf{Q})_{\mathrm{tor}}[2]$ has order 2, so $J(\mathbf{Q})_{\mathrm{tor}}[2] = E_0(\mathbf{Q})_{\mathrm{tor}}[2]$, hence $E_0(\mathbf{Q})[\mathfrak{m}] \neq 0$. The Hecke algebra $\mathbf{T}$ acts on E_0 through $\mathrm{End}(E_0) \cong \mathbf{Z}$, so each element of $\mathbf{T}$ acts on E_0 as an integer; in particular, the elements of $\mathfrak{m}$ all act as multiples of 2 (since $E_0[\mathfrak{m}] \neq 0$ and $2 \in \mathfrak{m}$), so $E_0[\mathfrak{m}] = E_0[2]$ since $2 \in \mathfrak{m}$. □

Lemma 2.4. *Suppose $A \subset J_0(p)$ is a $\mathbf{T}$-stable abelian subvariety and $\wp \subset \mathbf{T}$ is a maximal ideal such that $A[\wp^\infty] \neq 0$. Then $A[\wp] \neq 0$. Also $A[\wp^\infty]$ is infinite.*

Proof. Arguing as in [Maz77, §II.14, pg. 112], we see that for any r, $A[\wp^r]/A[\wp^{r+1}]$ is isomorphic to a direct sum of copies of $A[\wp]$. If $A[\wp] = 0$, then since $A[\wp^\infty] \neq 0$, there must exist an r such that $A[\wp^r]/A[\wp^{r+1}] \neq 0$. But $A[\wp^r]/A[\wp^{r+1}]$ is contained in a direct sum of copies of $A[\wp] = 0$, which is a contradiction.

To see that $A[\wp^\infty]$ is infinite, note that if ℓ is the residue characteristic of $\wp$ and $\mathrm{Tate}_\ell(A)$ is the Tate module of A at ℓ, then

$$\mathrm{Tate}_\wp(A) = \varprojlim_r A[\wp^r] = \mathrm{Tate}_\ell(A) \otimes_{\mathbf{T}} \mathbf{T}_\wp$$

is infinite. (For more details, see the proof of [RS01, Prop. 3.2].) □

The analogues of Lemmas 2.5–2.7 below are true, with the same proofs, for $\mathfrak{m}$ any Eisenstein prime. We state and prove them for the 2-Eisenstein prime, since that is the main case of interest to us. Let $\tilde{J}^{(2)}$ be the 2-*Eisenstein quotient of* J, where $\tilde{J}^{(2)}$ is as defined in [Maz77, §II.10]. More precisely, we have the following:

Lemma 2.5. *The simple factors of $\tilde{J}^{(2)}$ correspond to the $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$-conjugacy classes of newforms f such that $A_f[\mathfrak{m}] \neq 0$ (or equivalently, $A_f^\vee[\mathfrak{m}] \neq 0$).*

Proof. On page 97 of [Maz77] we find that the $\mathbf{C}$-simple factors of $\tilde{J}^{(2)}$ are in bijection with the irreducible components $\mathrm{Spec}(I_f)$ of $\mathrm{Spec}(\mathbf{T})$ which meet the support of the ideal $\mathfrak{m}$, so the I_f are the newform ideals contained in $\mathfrak{m}$. We have for any I_f,

$$I_f \subset \mathfrak{m} \iff \mathbf{T}_m/(I_f)_\mathfrak{m} \neq 0 \iff \mathrm{Tate}_\mathfrak{m}(A_f) \neq 0 \iff A_f[\mathfrak{m}] \neq 0.$$

Note that the same argument applies to $A_f^\vee$. □

Lemma 2.6. *Suppose A and B are abelian varieties equipped with an action of the Hecke ring $\mathbf{T}$ and that $\varphi : A \to B$ is a $\mathbf{T}$-module isogeny. If $\wp \subset \mathbf{T}$ is a maximal ideal and $B[\wp] \neq 0$, then also $A[\wp] \neq 0$.*

Proof. Let $\psi : B \to A$ be the isogeny complementary to φ, so ψ is the unique isogeny such that $\psi \circ \varphi$ is multiplication by $\deg(\varphi)$. Then ψ is also a $\mathbf{T}$-module homomorphism (one can see this in various ways; one way is to use the rational representation on homology to view the endomorphisms as matrices acting on lattices, and to note that if matrices M and N commute, then M^{-1} and N also commute). By Lemma 2.4, the union $B[\wp^\infty]$ is infinite, so $\psi(B[\wp^\infty]) \neq 0$. Since $\psi(B[\wp^\infty]) \subset A[\wp^\infty]$, Lemma 2.4 implies that $A[\wp] \neq 0$, as claimed. □

Lemma 2.7. *Suppose $B \subset J_0(p)$ is a sum of abelian subvarieties A_f attached to newforms. If $B[\mathfrak{m}] \neq 0$, then there is some $A_f \subset B$ such that $A_f[\mathfrak{m}] \neq 0$.*

Proof. There is something to be proved because if $x \in B[\mathfrak{m}]$ it could be the case that $x = y + z$ with $y \in A_f$ and $z \in A_g$, but $x \notin A_h$ for any h. Let $C = \oplus A_f$, where the $A_f \subset J_0(p)$ are simple abelian subvarieties of B corresponding to conjugacy classes of newforms. Then there is an isogeny $\varphi : C \to B$ given by

$$\varphi(x_1, \ldots, x_n) = x_1 + \cdots + x_n,$$

where the sum is in $B \subset J_0(p)$. By Lemma 2.6, $C[\mathfrak{m}] \neq 0$. Since $C[\mathfrak{m}] \cong \oplus A_f[\mathfrak{m}]$, it follows that $A_f[\mathfrak{m}] \neq 0$ for some $A_f \subset B$. □

Lemma 2.8. *If* $4 \mid n$, *then* $\dim \tilde{J}^{(2)} > 1$.

Proof. This follows from the remark on page 163 of [Maz77]. Since the proof is only sketched there, we give further details for the convenience of the reader. Because $4 \mid n$, the cuspidal subgroup C, which is generated in $J_0(p)$ by $(0) - (\infty)$ and is cyclic of order n, contains an element of order 4. Let $C(2)$ be the 2-primary part of C, and let $D = \ker(J_0(p) \to \tilde{J}^{(2)})$. If there is a nonzero element in the kernel of the homomorphism $C(2) \to \tilde{J}^{(2)}$, then $D[\mathfrak{m}] \neq 0$, where $\mathfrak{m}$ is the 2-Eisenstein prime. But then by Lemma 2.7, there is an $A_f \subset D$ such that $A_f[\mathfrak{m}] \neq 0$. By Lemma 2.5, $A_f^\vee$ is a quotient of $\tilde{J}^{(2)}$, so $A_f \subset (\tilde{J}^{(2)})^\vee$ so A_f cannot be in D. This contradiction shows that the map $C(2) \to \tilde{J}^{(2)}$ is injective, so $\tilde{J}^{(2)}$ contains a rational point of order 4. However, as mentioned in the introduction, $E_0(\mathbf{Q})$ has order 2, so $\tilde{J}^{(2)} \neq E_0$. Thus $\tilde{J}^{(2)}$ has dimension bigger than 1. □

Having established the above lemmas, we are now ready to deduce the theorem.

Proof of Theorem 2.1. It seems more straightforward to prove the equivalent statement that the modular degree is even if and only if $u \equiv 7 \pmod 8$, so we will prove this instead.

($\Longrightarrow$) $u \equiv 7 \pmod 8$ *implies that the modular degree is even:* Writing $u = 8k + 7$ we see that $p = (8k+7)^2 + 64 \equiv 1 \pmod{16}$, so $16 \mid (p-1)$ hence $4 \mid n$. By Lemma 2.3 and Lemma 2.5, E_0 is a factor of $\tilde{J}^{(2)}$. By Lemma 2.8, the dimension of $\tilde{J}^{(2)}$ is bigger than 1, so by Lemma 2.5 there is an A_f distinct from E_0 such that $A_f[\mathfrak{m}] \neq 0$. Since $A_f \subset B = \ker(J_0(p) \to E_0)$, it follows that $B[\mathfrak{m}] \neq 0$. As discussed on page 38 of [Maz77], $J[\mathfrak{m}]$ has dimension 2 over $\mathbf{F}_2$ so $E_0[\mathfrak{m}] = J[\mathfrak{m}]$, hence $B[\mathfrak{m}] \subset E_0[\mathfrak{m}]$. It follows that $2 \mid \#(B \cap E_0)$, so E_0 has even modular degree.

($\Longleftarrow$) *Modular degree even implies that* $u \equiv 7 \pmod 8$*:* Suppose that the modular degree m of E_0 is even. Letting $B = \ker(J_0(p) \to E_0)$, we have

$$E_0 \cap B \cong \ker(E_0 \to J_0(p) \to E_0),$$

so $\Psi := E_0 \cap B = E_0[m]$. Lemma 2.3 and our assumption that m is even imply that

$$E_0[\mathfrak{m}] = E_0[2] \subset E_0[m] = \Psi,$$

so $\Psi[\mathfrak{m}] \neq 0$. Since $\Psi[\mathfrak{m}] \neq 0$, and $\Psi \subset B$, we have $B[\mathfrak{m}] \neq 0$. By Lemma 2.7, there is some $A_f \subset B$ such that $A_f[\mathfrak{m}] \neq 0$. Then by Lemma 2.5 we see that A_f is an isogeny factor of $\tilde{J}^{(2)}$. Thus $\tilde{J}^{(2)}$ has dimension bigger than 1. If $u = 8k+3$, then $p = (8k+3)^2 + 64 \equiv 9 \pmod{16}$, so that $2 \mid\mid n$. However, when $2 \mid\mid n$, [Maz77, Prop. III.7.5] implies that $\tilde{J}^{(2)} = E_0$, which is false, so $u \equiv 7 \pmod 8$. □

Remark 2.9. Frank Calegari observed that Lemma 2.8 and its converse also follow from conditions (i) and (v) of Théorème 3 of [Mer96].

3. The Stevens Conjecture for Neumann–Setzer Curves is True

Let E be an arbitrary elliptic curve over $\mathbf{Q}$ of conductor N. Stevens conjectured in [Ste89] that the optimal quotient of $X_1(N)$ in the isogeny class of E is the curve in the isogeny class of E with minimal Faltings height. In this section we explain why this conjecture is true when N is prime.

Let $p = u^2 + 64$ be prime and E_1 and E_0 be as in Section 1. In this section we verify that the curve E_1 has smaller Faltings height than E_0, then show that E_1 is $X_1(p)$-optimal. The Stevens conjecture asserts that the $X_1(p)$-optimal curve is the curve of minimal Faltings height in an isogeny class, so our results verify the conjecture for Neumann–Setzer curves. In fact, the Stevens conjecture is true for all isogeny classes of elliptic curves of prime conductor. For if E is an elliptic curve of prime conductor, then by [Set75] there is only one curve in the isogeny class of E, unless E is a Neumann–Setzer curve or the conductor of E is 11, 17, 19, or 37. When the isogeny class of E contains only one curve, that curve is obviously both X_1-optimal and of minimal Faltings height. The conjecture is also well-known to be true for curves of conductor 11, 17, 19, or 37 (see [Ste89]). We note that Vatsal [Vat03] has recently extended results of Tang [Tan97] that make considerable progress toward the Stevens conjecture, but his work is not applicable to Neumann–Setzer curves.

Lemma 3.1. *The curve E_1 has smaller Faltings height than E_0.*

Proof. By [Ste89, Thm. 2.3, pg. 84] it is enough to exhibit an isogeny from E_1 to E_0 whose extension to Néron models is étale. Let φ be the isogeny $E_0 \to E_1$ of degree 2 whose kernel is the subgroup generated by the point whose coordinates are $(u/4, -u/8)$ in terms of the Weierstrass equation (1.1) for E_0, which is a global minimal model for E_0. The kernel of φ does not extend to an étale group scheme over $\mathbf{Z}$, since its special fiber at 2 is not étale (it has only one $\overline{\mathbf{F}}_2$-point), so the morphism on Néron models induced by $E_0 \to E_1$ cannot be étale, since kernels of étale morphisms are étale. By [Ste89, Lemma 2.5] the dual isogeny $E_1 \to E_0$ extends to an étale morphism of Néron models. □

Proposition 3.2. *The curve E_1 is $X_1(p)$-optimal.*

Proof. By [MO89, §5, Lem. 3], E_0 is an optimal quotient of $X_0(p)$, so we have an injection $E_0 \hookrightarrow J_0(p)$. As in [Maz77, pg. 100], let Σ be the kernel of the functorial map $J_0(p) \to J_1(p)$ induced by the cover $X_1(p) \to X_0(p)$. By [Maz77, Prop. II.11.6], Σ is the Cartier dual of the constant subgroup scheme U, which turns out to equal $J_0(p)(\mathbf{Q})_{\mathrm{tor}}$. Because $\#(E_0 \cap U) = 2$ and $E_0[2]$ is self dual, we have $\#(E_0 \cap \Sigma) = 2$. Thus the image of E_0 in $J_1(p)$ is the quotient of E_0 by the subgroup generated by the rational point of order 2 (note that the Cartier dual of $\mathbf{Z}/2\mathbf{Z}$ is $\mu_2 = \mathbf{Z}/2\mathbf{Z}$). This quotient is E_1, so $E_1 \subset J_1(p)$, which implies that E_1 is an optimal quotient of $X_1(p)$, as claimed. □

Remark 3.3. The above proposition could also be proved in a slightly different manner. The Faltings height of an elliptic curve is $\sqrt{2\pi/\Omega}$ where Ω is the volume of the fundamental parallelogram associated to the curve. When the conductor is prime, we have by [AL96] that the Manin constants for $X_0(p)$ and $X_1(p)$ are 1; this says that for a G-optimal curve E, the period lattice generated by G has covolume equal to Ω_E. Since the lattice generated by $\Gamma_1(p)$ is contained in the lattice generated by $\Gamma_0(p)$ (and thus has larger covolume), the Faltings height of the $X_1(p)$-optimal curve must be less than or equal to that of the $X_0(p)$-optimal curve. So if these two curves differ, the $X_1(p)$-optimal curve must have smaller Faltings height.

Remark 3.4. On page 12 of [Maz98], there is a "To be removed from the final draft" comment that asks (in our notation) whether E_0 is $X_0(p)$-optimal when $p \equiv 1 \pmod{16}$. This is already answered by [MO89], whereas here we go further and show additionally that E_1 is $X_1(p)$-optimal.

4. Conjectures

4.1. **Refinement of Theorem 2.1.** The following conjectural refinement of Theorem 2.1 is supported by the experimental data of [Wat02]. It is unclear whether the method of proof of Theorem 2.1 can be extended to prove this conjecture.

Conjecture 4.1. *If $u \equiv 7 \pmod 8$, then 2 exactly divides the modular degree of E_0 if and only if $u \equiv 7 \pmod{16}$.*

We can note that the pattern seems to end here; for curves with $u \equiv 15 \pmod{16}$ the data give no further information about the 2-valuation of the modular degree. For instance, with $u = -17$ we have that $[1, 1, 1, -2, 16]$ has modular degree $2^3 \cdot 3$, while with $u = 175$ the curve $[1, 1, 1, -634, -6484]$ has modular degree $2^2 \cdot 3^3 \cdot 5 \cdot 23$. Similarly, we have that $u = -33$ gives the curve $[1, -1, 1, -19, 68]$ with modular degree $2^5 \cdot 3$, while $u = 127$ gives the curve $[1, 1, 1, -332, -2594]$ of modular degree $2^2 \cdot 3^2 \cdot 5 \cdot 43$.

4.2. **The Parity of the Modular Degree.** According to Cremona's tables [Cre], of the 29755 new optimal elliptic curve quotients of $J_0(N)$ with $N < 8000$, a mere 89 have odd modular degree, which is less than 0.3%. There are 52878 non Neumann–Setzer curves in the database of [BM90] with prime conductor $N \leq 10^7$; of these curves 4592, or 8%, have odd modular degree (see [Wat02]). One reason that curves tend to have even modular degree is that for many curves the modular parametrization factors through an Atkin-Lehner quotient. Note that the method of [Wat02] used to compute the modular degree is rigourous when the level is prime because by [AL96] the Manin constant is 1 when the level is odd and square-free.

If $f(x) = (8x + 3)^2 + 64$, then it is a well-known conjecture (see [HL22] and e.g., [Guy94, §A1]) that there are infinitely many primes of the form $f(n)$ for some integer n, thus we make the following conjecture.

Conjecture 4.2. *There are infinitely many elliptic curves over* $\mathbf{Q}$ *with odd modular degree.*

Our data suggest the following conjecture:

Conjecture 4.3. *If E is an optimal elliptic curve quotient of $J_0(p)$ with $p \not\equiv 3 \pmod 8$ and E is not a Neumann–Setzer curve then the modular degree of E is even or $p = 17$.*

There are 23442 Brumer-McGuinness (see [BM90]) curves of conductor $37 \leq p \leq 10^7$ with $p \equiv 3 \pmod 8$, of which 11815 have even functional equation, of which 7322 have rank 0, and 4589 have odd modular degree. The significance of the data concerning the rank is that the second author has conjectured that 2^r divides the modular degree, where r is the rank.

Remark 4.4. Instead of asking about divisibility by 2, one could ask about divisibility by p. The first author and Frank Calegari make a conjecture about discriminants of Hecke algebras in [CS03] that implies that the modular degree of an elliptic curve of prime conductor p is not divisible by p. This conjecture agrees with our data.

4.3. **Shafarevich–Tate Groups of Neumann–Setzer Curves.** We consider the distribution of Ш in the Neumann–Setzer family (and note that similar phenomena occur in the related families listed in [SW02]). We look at u with $u^2 + 64$ prime and less than $2 \cdot 10^{12}$. We now take u to be positive, which thus replaces the restriction that u be 3 mod 4. The heuristics of [Del01] would seem to give us an idea of how

Table 1. Frequency of a prime dividing Ш

restriction	number	$p = 3$	$p = 5$	$p = 7$	$p = 11$
$u \equiv 1 \pmod 8$	25559	33.2%	16.9%	9.2%	3.0%
$u \equiv 3 \pmod 8$	25557	39.7%	20.3%	14.3%	8.4%
$u \equiv 5 \pmod 8$	25584	36.2%	18.5%	11.5%	5.0%
$u \equiv 7 \pmod 8$	25612	34.3%	20.3%	14.3%	8.2%
$u \equiv 0 \pmod 3$	34009	36.0%	18.7%	12.1%	6.0%
$u \equiv 1 \pmod 3$	34032	35.2%	18.6%	11.5%	5.6%
$u \equiv 2 \pmod 3$	34271	36.3%	19.7%	13.3%	6.9%
$u \equiv 0 \pmod 5$	34208	33.1%	18.0%	11.4%	5.4%
$u \equiv 2 \pmod 5$	33879	37.1%	19.5%	12.8%	6.5%
$u \equiv 3 \pmod 5$	34225	37.3%	19.5%	12.7%	6.5%
total	102312	35.8%	19.0%	12.3%	6.2%
Delaunay		36.1%	20.7%	14.5%	9.2%

often we expect a given prime to divide Ш. For instance, since Neumann–Setzer curves have rank 0, the prime 3 should divide Ш about 36.1% of the time. However, Table 1 gives a slightly different story with effects seen that depend on the various congruential properties of u.

Abstract. In this paper, we study p-divisibility of discriminants of Hecke algebras associated to spaces of cusp forms of prime level. By considering cusp forms of weight bigger than 2, we are are led to make a precise conjecture about indexes of Hecke algebras in their normalisation which implies (if true) the surprising conjecture that there are no mod p congruences between non-conjugate newforms in $S_2(\Gamma_0(p))$, but there are almost always many such congruences when the weight is bigger than 2.

1 Basic Definitions

We first recall some commutative algebra related to discriminants, then introduce Hecke algebras of spaces of cusp forms.

1.1 Commutative Algebra

In this section we recall the definition of discriminant of a finite algebra and note that the discriminant is nonzero if and only if no base extension of the algebra contains nilpotents.

Let R be a ring and let A be an R-algebra that is free of finite rank as an R-module. The *trace* of $x \in A$ is the trace, in the sense of linear algebra, of left multiplication by x.

Definition 1 (Discriminant). *Let $\omega_1, \ldots, \omega_n$ be an R-basis for A. Then the* discriminant $\mathrm{disc}(A)$ *of A is the determinant of the $n \times n$ matrix $(\mathrm{tr}(\omega_i\omega_j))$.*

⋆⋆⋆ Supported in part by the American Institute of Mathematics

† Supported in part by a National Science Foundation Postdoctoral Fellowship

The discriminant is only well-defined modulo squares of units in R. When $R = \mathbf{Z}$ the discriminant is well defined, since the only units are ± 1.

We say that A is *separable over* R if for every extension R' of R, the ring $A \otimes R'$ contains no nilpotents.

Proposition 1. *Suppose R is a field. Then A has nonzero discriminant if and only if A is separable over R.*

Proof. For the convenience of the reader, we summarize the proof in [Mat86, §26]. If A contains a nilpotent then that nilpotent is in the kernel of the trace pairing, so the discriminant is 0. Conversely, if A is separable then we may assume that R is algebraically closed. Then A is an Artinian reduced ring, hence isomorphic as a ring to a finite product of copies of R, since R is algebraically closed. Thus the trace form on A is nondegenerate.

1.2 The Discriminant Valuation

We next introduce Hecke algebras attached to certain spaces of cusp forms of prime level p, define the discriminant valuation as the exponent of the largest power of p that divides the discriminant, and observe that there are eigenform congruences modulo p exactly when the discriminant valuation is positive. We then present an example to illustrate the definitions.

Let Γ be a congruence subgroup of $\mathrm{SL}_2(\mathbf{Z})$. In this paper, we will only consider $\Gamma = \Gamma_0(p)$ for p prime. For any positive integer k, let $S_k(\Gamma)$ denote the space of holomorphic weight k cusp forms for Γ. Let

$$\mathbf{T} = \mathbf{Z}[\ldots, T_n, \ldots] \subset \mathrm{End}(S_k(\Gamma))$$

be the associated Hecke algebra, which is generated by Hecke operators T_n for all integers n, including $n = p$ (we will sometimes write U_p for T_p). Then $\mathbf{T}$ is a commutative ring that is free as a module over $\mathbf{Z}$ of rank equal to $\dim S_k(\Gamma)$. We will also sometimes consider the image $\mathbf{T}^{\mathrm{new}}$ of $\mathbf{T}$ in $\mathrm{End}(S_k(\Gamma)^{\mathrm{new}})$.

Definition 2 (Discriminant Valuation). *Let p be a prime, k a positive integer, and suppose that $\Gamma = \Gamma_0(p)$. Let $\mathbf{T}$ be the corresponding Hecke algebra. Then the* discriminant valuation *of Γ in weight k is*

$$d_k(\Gamma) = \mathrm{ord}_p(\mathrm{disc}(\mathbf{T})).$$

We expect that $d_k(\Gamma)$ is finite for the following reason. The Hecke operators T_n, with n not divisible by p, are diagonalizable since they are self adjoint with respect to the Petersson inner product. When $k = 2$ one knows that U_p is diagonalizable since the level is square free, and when $k > 2$ one expects this (see [CE98]). If $\mathbf{T}$ contains no nilpotents, Proposition 1 implies that the discriminant of $\mathbf{T}$ is nonzero. Thus $d_k(\Gamma)$ is finite when $k = 2$ and conjectured to be finite when $k > 2$.

Let p be a prime and suppose that $\Gamma = \Gamma_0(p)$. A *normalised eigenform* is an element $f = \sum a_n q^n \in S_k(\Gamma)$ that is an eigenvector for *all* Hecke operators T_ℓ, including those that divide p, normalised so that $a_1 = 1$. The quantity $d_k(\Gamma)$ is of interest because it measures mod p congruences between normalised eigenforms in $S_k(\Gamma)$.

Proposition 2. *Assume that $d_k(\Gamma)$ is finite. The discriminant valuation $d_k(\Gamma)$ is positive (i.e., the discriminant is divisible by p) if and only if there is a congruence in characteristic p between two normalized eigenforms in $S_k(\Gamma)$. (The two congruent eigenforms might be Galois conjugate.)*

Proof. It follows from Proposition 1 that $d_k(\Gamma) > 0$ if and only if $\mathbf{T} \otimes \overline{\mathbf{F}}_p$ is not separable. The Artinian ring $\mathbf{T} \otimes \overline{\mathbf{F}}_p$ is not separable if and only if the number of ring homomorphisms $\mathbf{T} \otimes \overline{\mathbf{F}}_p \to \overline{\mathbf{F}}_p$ is less than

$$\dim_{\overline{\mathbf{F}}_p} \mathbf{T} \otimes \overline{\mathbf{F}}_p = \dim_{\mathbf{C}} S_k(\Gamma).$$

Since $d_k(\Gamma)$ is finite, the number of ring homomorphisms $\mathbf{T} \otimes \overline{\mathbf{Q}}_p \to \overline{\mathbf{Q}}_p$ equals $\dim_{\mathbf{C}} S_k(\Gamma)$. The proposition follows from the fact that for any ring R, there is a bijection between ring homomorphisms $\mathbf{T} \to R$ and normalised eigenforms with q-expansion in R.

The same proof also shows that a prime ℓ divides the discriminant of $\mathbf{T}$ if and only if there is a congruence mod ℓ between two normalized eigenforms in $S_k(\Gamma)$

Example 1. If $\Gamma = \Gamma_0(389)$ and $k = 2$, then $\dim_{\mathbf{C}} S_2(\Gamma) = 32$. Let f be the characteristic polynomial of T_2. One can check that f is square free and 389 exactly divides the discriminant of f. This implies that $d_2(\Gamma) = 1$ and that T_2 generates $\mathbf{T} \otimes \mathbf{Z}_{389}$ as an algebra over $\mathbf{Z}_{389}$. (If T_2 only generated a subring of $\mathbf{T} \otimes \mathbf{Z}_{389}$ of finite index > 1, then the discriminant of f would be divisible by 389^2.)

Modulo 389 the characteristic polynomial f is congruent to

$$(x+2)(x+56)(x+135)(x+158)(x+175)^2(x+315)(x+342)(x^2+387)\\(x^2+97x+164)(x^2+231x+64)(x^2+286x+63)(x^5+88x^4+196x^3+\\113x^2+168x+349)(x^{11}+276x^{10}+182x^9+13x^8+298x^7+316x^6+\\213x^5+248x^4+108x^3+283x^2+x+101)$$

The factor $(x+175)^2$ indicates that $\mathbf{T}\otimes\mathbf{F}_{389}$ is not separable over $\mathbf{F}_{389}$ since the image of $(\overline{f}/(x+175))(T_2)$ in $\mathbf{T}\otimes\mathbf{F}_{389}$ is nilpotent (it is nonzero but its square is 0). There are 32 eigenforms over $\mathbf{Q}_2$ but only 31 mod 389 eigenforms, so there must be a congruence. There is a newform F in $S_2(\Gamma_0(389),\overline{\mathbf{Z}}_{389})$ whose a_2 term is a root of

$$x^2+(-39+190\cdot 389+96\cdot 389^2+\cdots)x+(-106+43\cdot 389+19\cdot 389^2+\cdots).$$

There is a congruence between F and its $\mathrm{Gal}(\overline{\mathbf{Q}}_{389}/\mathbf{Q}_{389})$-conjugate.

2 Computing Discriminants

In this section we sketch the algorithm that we use for computing the discriminants mentioned in this paper.

This algorithm was inspired by a discussion of the second author with Hendrik Lenstra. We leave the details of converting the description below into standard matrix operations to the reader. Also, the modular symbols algorithms needed to compute Hecke operators are quite involved.

Let $\Gamma=\Gamma_0(p)$, and let $k\geq 2$ be an integer. The following sketches an algorithm for computing the discriminant of the Hecke algebra $\mathbf{T}$ acting on $S_k(\Gamma)$.

1. For any given n, we can explicitly compute a matrix that represents the action of Hecke operators T_n on $S_k(\Gamma)$ using modular symbols. We use the second author's MAGMA [BCP97] packages for computing with modular symbols, which builds on work of many people (including [Cre97] and [Mer94]).
2. Using the Sturm bound, as described in the appendix to [LS02], find an integer b such that $T_1,\ldots,T_b$ generate $\mathbf{T}$ as a $\mathbf{Z}$-module. (The integer b is $\lceil (k/12)\cdot[\mathrm{SL}_2(\mathbf{Z}):\Gamma]\rceil$.)
3. Find a subset B of the T_i that form a $\mathbf{Q}$-basis for $\mathbf{T}\otimes_{\mathbf{Z}}\mathbf{Q}$. (This uses Gauss elimination.)
4. View $\mathbf{T}$ as a ring of matrices acting on $\mathbf{Q}^d$, where $d=\dim(S_k(\Gamma))$ and try random sparse vectors $v\in\mathbf{Q}^d$ until we find one such that the set of vectors $C=\{T(v):T\in B\}$ are linearly independent.

5. Write each of $T_1(v), \dots, T_b(v)$ as $\mathbf{Q}$-linear combinations of the elements of C.
6. Find a $\mathbf{Z}$-basis D for the $\mathbf{Z}$-span of these $\mathbf{Q}$-linear combinations of elements of C. (This basis D corresponds to a $\mathbf{Z}$-basis for $\mathbf{T}$, but is much easier to find that directly looking for a $\mathbf{Z}$-basis in the space of $d \times d$ matrices that $\mathbf{T}$ is naturally computed in.)
7. Unwinding what we have done in the previous steps, find the trace pairing on the elements of D, and deduce the discriminant of $\mathbf{T}$ by computing the determinant of the trace pairing matrix.

A very time-consuming step, at least in our implementation, is computing D from $T_1(v), \dots, T_b(v)$ expressed in terms of C, and this explains why we embed $\mathbf{T}$ in $\mathbf{Q}^d$ instead of viewing the elements of $\mathbf{T}$ as vectors in $\mathbf{Q}^{d \times d}$.

An implementation by the second author of the above algorithm is included with the MAGMA computer algebra system. The relevant source code is in the file `Geometry/ModSym/linalg.m` in the `package` directory (or ask the second author of the apper to send you a copy `linalg.m`). We illustrate the use of MAGMA to compute discriminants below, which were run under MAGMA V2.10-21 for Linux on a computer with an Athlon 2800MP processor (2.1Ghz).

```
> M := ModularSymbols(389,2, +1);
> S := CuspidalSubspace(M);
> time D  := DiscriminantOfHeckeAlgebra(S);
Time: 0.750
> D;
629670054720061882880174736321392595498204931550235108311\
04000000
> Factorisation(D);
[ <2, 53>, <3, 4>, <5, 6>, <31, 2>, <37, 1>, <389, 1>, ...]
> M := ModularSymbols(997,2, +1); S := CuspidalSubspace(M);
> time D  := DiscriminantOfHeckeAlgebra(S);
Time: 55.600
```

The reason for the $+1$ in the construction of modular symbols is so that we compute on a space that is isomorphic as a $\mathbf{T}$-module to one copy of $S_2(\Gamma_0(p))$, instead of two copies.

3 Data About Discriminant Valuations

In this section we report on our extensive computations of $d_k(\Gamma_0(p))$. We first note that there is only one $p < 50000$ such that $d_2(\Gamma_0(p)) > 0$.

Next we give a table of values of $d_4(\Gamma_0(p))$, which seems to exhibit a nice pattern.

3.1 Weight Two

Theorem 1. *The only prime* $p < 60000$ *such that* $d_2(\Gamma_0(p)) > 0$ *is* $p = 389$*, with the possible exception of* 50923 *and* 51437*.*

Computations in this direction by the second author have been cited in [Rib99], [MS01], [OW02], and [MO02]. For example, Theorem 1 is used for $p < 1000$ in [MS01] as a crucial step in proving that if E is an elliptic curve over $\mathbf{Q}(\mu_p)$, with $17 \leq p < 1000$, then not all elements of $E(\overline{\mathbf{Q}})[p]$ are rational over $\mathbf{Q}(\mu_p)$.

Proof. This is the result of a large computer computation. The rest of this proof describes how we did the computation, so the reader has some idea how to replicate or extend the computation. The computation described below took about one week using a cluster equipped with 10 Athlon 2000MP processors. The computations are nontrivial; we compute spaces of modular symbols, supersingular points, and Hecke operators on spaces of dimensions up to 5000.

The aim is to determine whether or not p divides the discriminant of the Hecke algebra of level p for each $p < 60000$. If T is an operator with integral characteristic polynomial, we write $\mathrm{disc}(T)$ for $\mathrm{disc}(\mathrm{charpoly}(T))$, which also equals $\mathrm{disc}(\mathbf{Z}[T])$. We will often use that

$$\mathrm{disc}(T) \bmod p = \mathrm{disc}(\mathrm{charpoly}(T) \bmod p).$$

We ruled out the possibility that $d_k(\Gamma_0(p)) > 0$ for most levels $p < 60000$ by computing characteristic polynomials of Hecke operators using an algorithm that the second author and D. Kohel implemented in MAGMA ([BCP97]), which is based on the Mestre-Oesterle method of graphs [Mes86] (or contact the second author for an English translation). Our implementation is available as the “Module of Supersingular Points” package that comes with MAGMA. We computed $\mathrm{disc}(T_q)$ modulo p for several small primes q, and in most cases found a prime q such that this discriminant is nonzero. The following table summarises how often we used each prime q (note that there are 6057 primes up to 60000):

q	number of $p < 60000$ where q smallest s.t. $\mathrm{disc}(T_q) \neq 0 \bmod p$
2	5809 times
3	161 (largest: 59471)
5	43 (largest: 57793)
7	15 (largest: 58699)
11	15 (the smallest is 307; the largest 50971)
13	2 (they are 577 and 5417)
17	3 (they are 17209, 24533, and 47387)
19	1 (it is 15661)

The numbers in the right column sum to 6049, so 8 levels are missing. These are

$$389, 487, 2341, 7057, 15641, 28279, 50923, \text{ and } 51437.$$

(The last two are still being processed. 51437 has the property that $\mathrm{disc}(T_q) = 0$ for $q = 2, 3, \ldots, 17$.) We determined the situation with the remaining 6 levels using Hecke operators T_n with n composite.

p	How we rule level p out, if possible
389	p does divide discriminant
487	using charpoly(T_{12})
2341	using charpoly(T_6)
7057	using charpoly(T_{18})
15641	using charpoly(T_6)
28279	using charpoly(T_{34})

Computing T_n with n composite is very time consuming when p is large, so it is important to choose the right T_n quickly. For $p = 28279$, here is a trick we used to quickly find an n such that $\mathrm{disc}(T_n)$ is not divisible by p. This trick might be used to speed up the computation for some other levels. The key idea is to efficiently discover which T_n to compute. Computing T_n on the full space of modular symbols is difficult, but using projections we can compute T_n on subspaces of modular symbols with small dimension more quickly (see, e.g., [Ste00, §3.5.2]). Let M be the space of mod p modular symbols of level $p = 28279$, and let $f = \gcd(\mathrm{charpoly}(T_2), \mathrm{deriv}(\mathrm{charpoly}(T_2)))$. Let V be the kernel of $f(T_2)$ (this takes 7 minutes to compute). If $V = 0$, we would be done, since then $\mathrm{disc}(T_2) \neq 0 \in \mathbf{F}_p$. In fact, V has dimension 7. We find the first few integers n so that the charpoly of T_n on V has distinct roots, and they are $n = 34$, 47, 53, and 89. We then computed charpoly(T_{34}) directly on the whole space and found that it has distinct roots modulo p.

3.2 Some Data About Weight 4

The following are the valuations $d = d_4(\Gamma_0(p))$ at p of the discriminant of the Hecke algebras associated to $S_4(\Gamma_0(p))$ for $p < 500$. This data suggests a pattern, which motivates Conjecture 1 below.

p	2	3	5	7	11	13	17	19	23	29	31	37	41	43	47	53	59
d	0	0	0	0	0	2	2	2	2	4	4	6	6	6	6	8	8
p	61	67	71	73	79	83	89	97	101	103	107	109	113	127	131	137	139

4 Speculations

Motivated by the promise of a pattern suggested by the table in Section 3.2, we computed $d_k(\Gamma_0(p))$ for many values of k and p. Our observations led us to the following results and conjectures.

Theorem 2. *Suppose p is a prime and $k \geq 4$ is an even integer. Then $d_k(\Gamma_0(p)) > 0$ unless*

$$\begin{aligned}(p,k) \in \{&(2,4),(2,6),(2,8),(2,10),\\ &(3,4),(3,6),(3,8),\\ &(5,4),(5,6),(7,4),(11,4)\},\end{aligned}$$

in which case $d_k(\Gamma_0(p)) = 0$.

Proof. From [Rib91], mod p eigenforms on $\Gamma_0(p)$ of weight k arise exactly from mod p eigenforms on $\Gamma_0(1)$ of weight $(k/2)(p+1)$. Moreover, there is an equality of dimensions of vector spaces:

$$\dim S_{(k/2)(p+1)}(\Gamma_0(1)) + \dim S_{(k/2)(p+1)-(p-1)}(\Gamma_0(1)) = \dim S_k(\Gamma_0(p)).$$

Thus the dimension of $S_k(\Gamma_0(p))$ is bigger than the number of mod p eigenforms whenever $\dim S_{(k/2)(p+1)-(p-1)}(\Gamma_0(1))$ is non-zero. The cases of dimension zero correspond exactly to the finite list of exceptions above, for which one can explicitly calculate that $d_k(\Gamma_0(p)) = 0$.

Note that for $k = 2$, however, there is a canonical identification of spaces

$$S_{(p+1)}(\mathit{\Gamma}_0(1), \overline{\mathbf{F}}_p) \simeq S_2(\mathit{\Gamma}_0(p), \overline{\mathbf{F}}_p),$$

described geometrically in [Gro90]. For $k = 4$, the data suggests that the discriminants $d_4(\mathit{\Gamma}_0(p))$ are significantly larger than zero for large p, and the table above suggests a formula of the form $2 \cdot \lfloor p/12 \rfloor$ (Not entirely coincidentally, this is the difference in dimension of the spaces $S_4(\mathit{\Gamma}_0(p))$ and $S_{2(p+1)}(\mathit{\Gamma}_0(1))$). This exact formula is not correct, however, as evidenced by the case when $p = 139$. If we consider the Hecke algebra $\mathbf{T}_4$ for $p = 139$ in more detail, however, we observe that $\mathbf{T}_4 \otimes \mathbf{Q}_{139}$ is *ramified* at 139, and in particular contains two copies of the field $\mathbf{Q}_{139}(\sqrt{139})$. Just as in the case when $k = 2$ and $p = 389$, there is a "self congruence" between the associated ramified eigenforms and their Galois conjugates. For all other p in the range of the table, there is no ramification, and all congruences take place between distinct eigenforms. Such congruences are measured by the *index* of the Hecke algebra, which is defined to be the index of $\mathbf{T}$ in its normalisation $\widetilde{\mathbf{T}}$. If we are only interested in mod p congruences (rather than mod ℓ congruences for $\ell \neq p$), one can restrict to the index of $\mathbf{T} \otimes \mathbf{Z}_p$ inside its normalisation. There is a direct relation between the discriminant and the index. Suppose that $\mathbf{T} \otimes \mathbf{Q}_p = \prod K_i$ for certain fields $K_i/\mathbf{Q}_p$ (We may assume here that $\mathbf{T}$ is not nilpotent, for otherwise both the discriminant and index are infinite). Then if $i_p(\mathit{\Gamma}) = \mathrm{ord}_p([\mathbf{T}, \widetilde{\mathbf{T}}])$, then

$$d_p(\mathit{\Gamma}) = 2 i_p(\mathit{\Gamma}) + \sum \mathrm{ord}_p(\mathit{\Delta}(K_i/\mathbf{Q}_p)).$$

If we now return to the example $k = 4$ and $p = 139$, we see that the discrepancy from the discriminant $d_p(\mathit{\Gamma}_0(139)) = 24$ to the estimate $2\lfloor 139/12 \rfloor = 22$ is exactly accounted for by the two eigenforms with coefficients in $\mathbf{Q}_{139}(\sqrt{139})$, which contribute 2 to the above formula. This leads us to predict that the index is exactly given by the formula $\lfloor p/12 \rfloor$. Note that for primes p this is exactly the dimension of $S_{p+3}(\mathit{\Gamma}_0(1))$. Similar computations lead to the following more general conjecture.

Let $k = 2m$ be an even integer and p a prime. Let $\mathbf{T}$ be the Hecke algebra associated to $S_k(\mathit{\Gamma}_0(p))$ and let $\widetilde{\mathbf{T}}$ be the integral closure of $\mathbf{T}$ in $\mathbf{T} \otimes \mathbf{Q}$ (which is a product of number fields).

Conjecture 1. Suppose $p \geq k - 1$. Then

$$\mathrm{ord}_p([\widetilde{\mathbf{T}} : \mathbf{T}]) = \left\lfloor \frac{p}{12} \right\rfloor \cdot \binom{m}{2} + a(p, m),$$

where

$$a(p,m) = \begin{cases} 0 & \text{if } p \equiv 1 \pmod{12}, \\ 3 \cdot \binom{\lceil \frac{m}{3} \rceil}{2} & \text{if } p \equiv 5 \pmod{12}, \\ 2 \cdot \binom{\lceil \frac{m}{2} \rceil}{2} & \text{if } p \equiv 7 \pmod{12}, \\ a(5,m) + a(7,m) & \text{if } p \equiv 11 \pmod{12}. \end{cases}$$

Here $\binom{x}{y}$ is the binomial coefficient "x choose y", and floor and ceiling are as usual. The conjecture is very false if $k \gg p$.

When $k = 2$, the conjecture specializes to the assertion that $[\widetilde{\mathbf{T}} : \mathbf{T}]$ is not divisible by p. A possibly more familiar concrete consequence of the conjecture is the following conjecture about elliptic curves. The modular degree of an elliptic curve E is the smallest degree of a surjective morphism $X_0(N) \to E$, where N is the conductor of E.

Conjecture 2. Suppose E is an elliptic curve of prime conductor p. Then p does not divide the modular degree m_E of E.

Using the algorithm in [Wat02], M. Watkins has computed modular degrees of a huge number of elliptic curves of prime conductor $p < 10^7$, and not found a counterexample. Looking at smaller data, there is only one elliptic curve E of prime conductor $p < 20000$ such that the modular degree of E is even as big as the conductor of E, and that is a curve of conductor 13723. This curve has equation $[1, 1, 1, -10481, 408636]$, modular degree $m_E = 16176 = 2^4 \cdot 3 \cdot 337$. The modular degree can be divisible by large primes. For example, there is a Neumann-Setzer elliptic curve of prime conductor 90687593 whose modular degree is 1280092043, which is over 14 times as big as 90687593. In general, for an elliptic curve of conductor N, one has the estimate $m_E \gg N^{7/6-\epsilon}$ (see [Wat04]).

5 Conjectures Inspired by Conjecture 1

First, some notation. Let p be an odd prime. Let $\mathit{\Gamma} = \mathit{\Gamma}_0(p)$, and let

$$S_k(R) := S_k(\mathit{\Gamma})^{\text{new}} \otimes R.$$

The spaces S_k carry an action of the Hecke algebra $\mathbf{T}_k^{\text{new}}$, and a Fricke involution w_p. If $\frac{1}{2} \in R$, the space S_k can be decomposed into $+$ and $-$ eigenspaces for w_p. We call the resulting spaces S_k^+ and S_k^- respectively.

Similarly, let M_k^+ and M_k^- be the $+1$ and -1 eigenspaces for w_p on the full spaces of new modular forms of weight k for $\mathit{\Gamma}_0(p)$.

It follows from [AL70, Lem. 7] (which is an explicit formula for the trace to lower level) and the fact that U_p and w_p both preserve the new subspace, that the action of the Hecke operator U_p on S_k is given by the formula

$$U_p = -p^{(k-2)/2} w_p.$$

This gives rise to two quotients of the Hecke algebra:

$$\mathbf{T}^+ = \mathbf{T}^{\mathrm{new}}/(U_p + p^{(k-2)/2}) \quad \text{and} \quad \mathbf{T}^- = \mathbf{T}^{\mathrm{new}}/(U_p - p^{(k-2)/2}).$$

where $\mathbf{T}^+$ and $\mathbf{T}^-$ act on S^+ and S^-, respectively. Recall that $\widetilde{\mathbf{T}}$ is the normalization (integral closure) of $\mathbf{T}$ in $\mathbf{T} \otimes \mathbf{Q}$. Let $\widetilde{\mathbf{T}}^{\mathrm{new}}$ denote the integral closure of $\mathbf{T}^{\mathrm{new}}$ in $\mathbf{T}^{\mathrm{new}} \otimes \mathbf{Q}$.

Lemma 1. *There are injections*

$$\mathbf{T}^{\mathrm{new}} \hookrightarrow \mathbf{T}^+ \oplus \mathbf{T}^- \hookrightarrow \widetilde{\mathbf{T}}^{\mathrm{new}}.$$

We now begin stating some conjectures regarding the rings $\mathbf{T}^{\pm}$.

Conjecture 3. Let $k < p - 1$. Then $\mathbf{T}^+$ and $\mathbf{T}^-$ are integrally closed. Equivalently, all congruences between distinct eigenforms in $S_k(\overline{\mathbf{Z}}_p)$ take place between $+$ and $-$ eigenforms.

Note that for $k = 2$, there cannot be any congruences between $+$ and $-$ forms because this would force $1 \equiv -1 \mod p$, which is false, because p is odd. Thus we recover the conjecture that $p \nmid [\widetilde{\mathbf{T}} : \mathbf{T}]$ when $k = 2$. Our further conjectures go on to describe explicitly the congruences between forms in S_k^+ and S_k^-.

Let E_2 be the non-holomorphic Eisenstein series of weight 2. The q-expansion of E_2 is given explicitly by

$$E_2 = 1 - 24 \sum_{n=1}^{\infty} q^n \left(\sum_{d|n} d \right).$$

Moreover, the function $E_2^* = E_2(\tau) - pE_2(p\tau)$ is holomorphic of weight 2 and level $\mathit{\Gamma}_0(p)$, and moreover on q-expansions, $E_2^* \equiv E_2 \mod p$.

Lemma 2. *Let $p > 3$. Let $f \in M_k(\mathit{\Gamma}_0(p), \overline{\mathbf{F}}_p)$ be a Hecke eigenform. Then θf is an eigenform inside $S_{k+2}(\mathit{\Gamma}_0(p), \overline{\mathbf{F}}_p)$.*

Proof. One knows that $\partial f = \theta f - kE_2 f/12$ is of weight $k+2$. On q-expansions, $E_2 \equiv E_2^* \mod p$, and thus for $p > 3$,

$$\theta f \equiv \partial f + kE_2^* f/12 \pmod{p}$$

is the reduction of a weight $k+2$ form of level p. It is easy to see that θf is a cuspidal Hecke eigenform.

Let us now assume Conjecture 3 and consider the implications for $k = 4$ in more detail. The space of modular forms $M_2(\Gamma_0(p), \overline{\mathbf{F}}_p)$ consists precisely of S_2 and the Eisenstein series E_2^*. The map θ defined above induces maps:

$$\theta : S_2^+(\overline{\mathbf{F}}_p) \to S_4(\overline{\mathbf{F}}_p), \qquad \theta : M_2^-(\overline{\mathbf{F}}_p) \to S_4(\overline{\mathbf{F}}_p).$$

The images are distinct, since $\theta f = \theta g$ implies (with some care about a_p) that $f = g$.

Conjecture 4. Let $f \in S_2(\overline{\mathbf{Z}}_p)$ and $g \in S_4(\overline{\mathbf{Z}}_p)$ be two eigenforms such that $\theta f \equiv g \mod p$. Then the eigenvalue of w_p on f and g have opposite signs.

Assuming this, we get inclusions:

$$\theta S_2^+(\overline{\mathbf{F}}_p) \hookrightarrow S_4^-(\overline{\mathbf{F}}_p), \qquad \theta M_2^-(\overline{\mathbf{F}}_p) \hookrightarrow S_4^+(\overline{\mathbf{F}}_p).$$

Now we are ready to state our main conjecture:

Conjecture 5. There is an Hecke equivariant exact sequence:

$$\begin{tikzcd} 0 \arrow[r] & \theta S_2^+(\overline{\mathbf{F}}_p) \arrow[r] & S_4^-(\overline{\mathbf{F}}_p) \arrow[r] & S_4^+(\overline{\mathbf{F}}_p) \arrow[r] & \theta M_2^-(\overline{\mathbf{F}}_p) \arrow[r] & 0. \end{tikzcd}$$

Moreover, the map $S_4^-(\overline{\mathbf{F}}_p) \to S_4^+(\overline{\mathbf{F}}_p)$ here is the largest such equivariant map between these spaces. Equivalently, a residual eigenform of weight 4 and level p occurs in both the $+$ and $-$ spaces if and only if it is not in the image of θ.

Let us give some consequences of our conjectures for the index of $\mathbf{T}^{\mathrm{new}}$ inside its normalisation. Fix a residual representation $\overline{\rho} : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_2(\mathbf{F}_q)$ and consider the associated maximal ideal $\mathfrak{m}$ inside $\mathbf{T}_4$. If $\overline{\rho}$ lies in the image of θ then our conjecture implies that it is not congruent to any other eigenform. If $\overline{\rho}$ is not in the image of θ, then it should arise exactly from a pair of eigenforms, one inside $S_4^+(\overline{\mathbf{Q}}_p)$ and one inside $S_4^-(\overline{\mathbf{Q}}_p)$. Suppose that $q = p^r$. If there is no ramification in $\mathbf{T} \otimes \mathbf{Q}$ over

p (this is often true), then the $+$ and $-$ eigenforms will both be defined over the ring $W(\mathbf{F}_q)$ of Witt vectors of $\mathbf{F}_q$. Since $U_p = p$ on S_4^- and $-p$ on S_4^+, these forms can be at most congruent modulo p. Thus the completed Hecke algebra $(\mathbf{T}_4)_{\mathfrak{m}}$ is exactly

$$\{(a,b) \in W(\mathbf{F}_q) \oplus W(\mathbf{F}_q), |a \equiv b \mod p\}.$$

One sees that this has index $q = p^r$ inside its normalisation. Thus the (log of the) total index is equal to $\sum r_i$ over all eigenforms that occur inside S_4^+ and S_4^-, which from our exact sequence we see is equal to

$$\dim S_4^- - \dim S_2^+.$$

Conjecture 1 when $k = 4$, would then follow from the equality of dimensions:

$$\dim S_4^-(\overline{\mathbf{F}}_p) - \dim S_2^+(\overline{\mathbf{F}}_p) = \left\lfloor \frac{p}{12} \right\rfloor.$$

We expect that something similar, but a little more complicated, should happen in general. In weight $2k$, there are mod p^{k-r} congruences exactly between forms in the image of θ^{r-1} but not of θ^r.

5.1 Examples

We write small s's and m's for dimensions below.

Let $p = 101$. Then $s_2^+ = 1$, $m_2^- = 7 + 1 = 8$, $s_4^- = 9$, $s_4^+ = 16$. We predict the index should be $9 - 1 = 8 = \lfloor 101/12 \rfloor$. In the table below, we show the characteristic polynomials of T_2 on S_4^- and S_4^+, and for weight 2, we take the characteristic polynomial of θT_2 (or the same, taking $F(x/2)$ where $F(x)$ is the characteristic polynomial of T_2). Note that we have to add the Eisenstein series, which has characteristic polynomial $x - 1 - 2$, which becomes $x - 6 \equiv x + 95 \mod 101$ under θ.

Factors of the Characteristic Polynomial of T_2 for $p = 101$.

$\theta S_2^+(\overline{\mathbf{F}}_{101})$	$S_4^-(\overline{\mathbf{F}}_{101})$	$S_4^+(\overline{\mathbf{F}}_{101})$	$\theta M_2^-(\overline{\mathbf{F}}_{101})$
(x)	(x) $(x+46)$ $(x^2+58x+100)$ $(x^5+2x^4+27x^3$ $+49x^2+7x+65)$	$(x+46)$ $(x+95)$ $(x^2+58x+100)$ $(x^2+90x+78)$ $(x^2+96x+36)$ $(x^3+16x^2+35x+72)$ $(x^5+2x^4+27x^3$ $+49x^2+7x+65)$	$(x+95)$ $(x^2+90x+78)$ $(x^2+96x+36)$ $(x^3+16x^2$ $+35x+72)$

Here are some further conjectures when $k > 4$.

Conjecture 6. Let p and k be such that $4 < k < p-1$. There is an Hecke equivariant exact sequence:

$$0 \longrightarrow \theta S^+_{k-2}(\overline{\mathbf{F}}_p) \longrightarrow S^-_k(\overline{\mathbf{F}}_p) \longrightarrow S^+_k(\overline{\mathbf{F}}_p) \longrightarrow \theta S^-_{k-2}(\overline{\mathbf{F}}_p) \longrightarrow 0.$$

Moreover, all forms not in the image of θ contribute maximally to the index (a factor of $p^{(k-2)/2}$). Thus the total index should be equal to

$$\frac{(k-2)}{2}(\dim S^+_k - \dim S^-_{k-2}) \quad + \quad \text{the index at level } p \text{ and weight } k-2.$$

This is the sum

$$\sum_{n=2}^{k} \frac{(2n-2)}{2}(s^+_{2n} - s^-_{2n-2}).$$

When $k = 4$, we need to add the Eisenstein series to S^-_2 in our previous conjecture. Note that $s^+_k - s^-_{k-2} = s^-_k - s^+_{k-2}$ for $k > 4$ (and with s^-_2 replaced by m^-_2 when $k = 2$). This follows from our conjectures, but can easily be proved directly. As an example, when $p = 101$, we have $s^+_2 = 1$, $s^-_4 = 9$, $s^+_6 = 17$, $s^-_8 = 26$, $s^+_{10} = 34$, $s^-_{12} = 42$, $s^+_{14} = 51$, and so we would predict the indexes I_k to be as given in the following table:

k	I_k?
2	0
4	$8 = 8 + 0$
6	$24 = 24 + 0$
8	$51 = 48 + 3$
10	$83 = 80 + 3$
12	$123 = 120 + 3$
14	$177 = 168 + 9$

This agrees with our conjectural formula, which says that the index should be equal in this case to

$$8\binom{k/2}{2} + 3\binom{\lceil k/6 \rceil}{2}.$$

it also agrees with computation.

22 Book – A Brief Introduction to Classical and Adelic Algebraic Number Theory

A Brief Introduction to Classical and Adelic Algebraic Number Theory

William Stein
(based heavily on works of Swinnerton-Dyer and Cassels)

May 2004

Contents

Chapter 1

Preface

This book is based on notes I created for a one-semester undergraduate course on Algebraic Number Theory, which I taught at Harvard during Spring 2004. The primary sources for the course were chapter 1 of Swinnerton-Dyer's book *A Brief Guide to Algebraic Number Theory* [SD01] and chapter 2 of Cassels's article *Global Fields* [Cas67]. I wrote these notes by following closely the above two chapters; in some cases I added substantial text and examples. For example, chapter 1 of [SD01] is 30 pages, whereas my rewrite of it occupies over 100 pages. In contrast, I follow [Cas67] more closely. *I have no intent whatever to plagiarize. I acknowledge as such those chapters in this book which are simply a close rewrite of [Cas67].* My goal is to take the useful classical article ([Cas67]) and make it more accessible to students by modernizing the notation, and adding additional explanations and examples.

I have no intent to publish this book with a traditional publisher, so it will remain freely available indefinitely. If you have comments, corrections, suggestions for additions, etc., please send them to me!

Copyright: William Stein, 2004.

License: FREE! More precisely, this book my be freely redistributed, copied, or even sold without requiring you to obtain written permission from me. You may even extend or change this book, but this preface page must remain in any derived work, and any derived work must also remain free, including the LaTeX source files. In particular, I have no interest in making any money from this book.

Please send me any typos or corrections: `was@math.harvard.edu`.

Acknowledgement: This book closely builds on Swinnerton-Dyer's book [SD01] and Cassels's article [Cas67]. Many of the students of Math 129 at Harvard during Spring 2004 made helpful comments: Jennifer Balakrishnan, Peter Behrooz, Jonathan Bloom, David Escott Jayce Getz, Michael Hamburg, Deniz Kural, Danielle li, Andrew Ostergaard Gregory Price, Grant Schoenebeck, Jennifer Sinnott, Stephen Walker, Daniel Weissman, and Inna Zakharevich. Also the course assistant Matt Bainbridge made many helpful comments.

Chapter 2

Introduction

2.1 Mathematical background I assume you have

In addition to general mathematical maturity, this book assumes you have the following background:

- Basics of finite group theory
- Commutative rings, ideals, quotient rings
- Some elementary number theory
- Basic Galois theory of fields
- Point set topology
- Basic of topological rings, groups, and measure theory

For example, if you have never worked with finite groups before, you should read another book first. If you haven't seen much elementary ring theory, there is still hope, but you will have to do some additional reading and exercises. I will briefly review the basics of the Galois theory of number fields.

Some of the homework problems involve using a computer, but I'll give you examples which you can build on. I will not assume that you have a programming background or know much about algorithms. If you don't have PARI [ABC$^+$] or Magma [BCP97], and don't want to install either one on your computer, you might want to try the following online interface to PARI and Magma:

`http://modular.fas.harvard.edu/calc/`

2.2 What is algebraic number theory?

A *number field* K is a finite algebraic extension of the rational numbers $\mathbf{Q}$. Every such extension can be represented as all polynomials in an algebraic number α:

$$K = \mathbf{Q}(\alpha) = \left\{ \sum_{n=0}^{m} a_n \alpha^n : a_n \in \mathbf{Q} \right\}.$$

Here α is a root of a polynomial with coefficients in $\mathbf{Q}$.

Algebraic number theory involves using techniques from (mostly commutative) algebra and finite group theory to gain a deeper understanding of number fields. The main objects that we study in algebraic number theory are number fields, rings of integers of number fields, unit groups, ideal class groups,norms, traces, discriminants, prime ideals, Hilbert and other class fields and associated reciprocity laws, zeta and L-functions, and algorithms for computing each of the above.

2.2.1 Topics in this book

These are some of the main topics that are discussed in this book:

- Rings of integers of number fields
- Unique factorization of ideals in Dedekind domains
- Structure of the group of units of the ring of integers
- Finiteness of the group of equivalence classes of ideals of the ring of integers (the "class group")
- Decomposition and inertia groups, Frobenius elements
- Ramification
- Discriminant and different
- Quadratic and biquadratic fields
- Cyclotomic fields (and applications)
- How to use a computer to compute with many of the above objects (both algorithms and actual use of PARI and MAGMA).
- Valuations on fields
- Completions (p-adic fields)
- Adeles and Ideles

Note that we will not do anything nontrivial with zeta functions or L-functions. This is to keep the prerequisites to algebra, and so we will have more time to discuss algorithmic questions. Depending on time and your inclination, I may also talk about integer factorization, primality testing, or complex multiplication elliptic curves (which are closely related to quadratic imaginary fields).

2.3 Some applications of algebraic number theory

The following examples are meant to convince you that learning algebraic number theory now will be an excellent investment of your time. If an example below seems vague to you, it is safe to ignore it.

1. **Integer factorization** using the number field sieve. The number field sieve is the asymptotically fastest known algorithm for factoring general large integers (that don't have too special of a form). Recently, in December 2003, the number field sieve was used to factor the RSA-576 \$10000 challenge:

$$\begin{array}{l}
188198812920607963838697239461650439807163563379417382700\ldots \\
\ldots 633564229888597152346654853190606065047430453173880113033\ldots \\
\ldots 67161996923212057340318795506569962213051687593076502570\\
= 398075086424064937397125500550386491199064362342526708\ldots \\
\quad \ldots 638518957594638895726176858331 \\
\qquad \times 4727721461074353025362230719730482246329146953020971\ldots \\
\qquad\quad \ldots 6459852171130520711256363590397527
\end{array}$$

   (The ... indicates that the newline should be removed, not that there are missing digits.) For more information on the NFS, see the paper by Lenstra et al. on the Math 129 web page.

2. **Primality test:** Agrawal and his students Saxena and Kayal from India recently (2002) found the first ever deterministic polynomial-time (in the number of digits) primality test. There methods involve arithmetic in quotients of $(\mathbf{Z}/n\mathbf{Z})[x]$, which are best understood in the context of algebraic number theory. For example, Lenstra, Bernstein, and others have done that and improved the algorithm significantly.

3. **Deeper point of view** on questions in number theory:

   (a) Pell's Equation ($x^2 - dy^2 = 1$) $\Longrightarrow$ Units in real quadratic fields $\Longrightarrow$ Unit groups in number fields

   (b) Diophantine Equations $\Longrightarrow$ For which n does $x^n + y^n = z^n$ have a nontrivial solution in $\mathbf{Q}(\sqrt{2})$?

   (c) Integer Factorization $\Longrightarrow$ Factorization of ideals

   (d) Riemann Hypothesis $\Longrightarrow$ Generalized Riemann Hypothesis

(e) Deeper proof of Gauss's quadratic reciprocity law in terms of arithmetic of cyclotomic fields $\mathbf{Q}(e^{2\pi i/n})$, which leads to class field theory.

4. Wiles's proof of **Fermat's Last Theorem**, i.e., $x^n+y^n = z^n$ has no nontrivial integer solutions, uses methods from algebraic number theory extensively (in addition to many other deep techniques). Attempts to prove Fermat's Last Theorem long ago were hugely influential in the development of algebraic number theory (by Dedekind, Kummer, Kronecker, et al.).

5. **Arithmetic geometry:** This is a huge field that studies solutions to polynomial equations that lie in arithmetically interesting rings, such as the integers or number fields. A famous major triumph of arithmetic geometry is Faltings's proof of Mordell's Conjecture.

   Theorem 2.3.1 (Faltings). *Let X be a plane algebraic curve over a number field K. Assume that the manifold $X(\mathbf{C})$ of complex solutions to X has genus at least 2 (i.e., $X(\mathbf{C})$ is topologically a donut with two holes). Then the set $X(K)$ of points on X with coordinates in K is finite.*

   For example, Theorem 2.3.1 implies that for any $n \geq 4$ and any number field K, there are only finitely many solutions in K to $x^n + y^n = 1$. A famous open problem in arithmetic geometry is the **Birch and Swinnerton-Dyer conjecture**, which gives a deep conjectural criterion for exactly when $X(K)$ should be infinite when $X(\mathbf{C})$ is a torus.

Chapter 3

Finitely generated abelian groups

We will now prove the structure theorem for finitely generated abelian groups, since it will be crucial for much of what we will do later.

Let $\mathbf{Z} = \{0, \pm 1, \pm 2, \ldots\}$ denote the ring of integers, and for each positive integer n let $\mathbf{Z}/n\mathbf{Z}$ denote the ring of integers modulo n, which is a cyclic abelian group of order n under addition.

Definition 3.0.2 (Finitely Generated). A group G is *finitely generated* if there exists $g_1, \ldots, g_n \in G$ such that every element of G can be obtained from the g_i.

Theorem 3.0.3 (Structure Theorem for Abelian Groups). *Let G be a finitely generated abelian group. Then there is an isomorphism*

$$G \cong (\mathbf{Z}/n_1\mathbf{Z}) \oplus (\mathbf{Z}/n_2\mathbf{Z}) \oplus \cdots \oplus (\mathbf{Z}/n_s\mathbf{Z}) \oplus \mathbf{Z}^r,$$

where $n_1 > 1$ and $n_1 \mid n_2 \mid \cdots \mid n_s$. Furthermore, the n_i and r are uniquely determined by G.

We will prove the theorem as follows. We first remark that any subgroup of a finitely generated free abelian group is finitely generated. Then we see that finitely generated abelian groups can be presented as quotients of finite rank free abelian groups, and such a presentation can be reinterpreted in terms of matrices over the integers. Next we describe how to use row and column operations over the integers to show that every matrix over the integers is equivalent to one in a canonical diagonal form, called the Smith normal form. We obtain a proof of the theorem by reinterpreting Smith normal form in terms of groups.

Proposition 3.0.4. *Suppose G is a free abelian group of finite rank n, and H is a subgroup of G. Then H is a free abelian group generated by at most n elements.*

The key reason that this is true is that G is a finitely generated module over the principal ideal domain $\mathbf{Z}$. We will give a complete proof of a beautiful generalization of this result in the context of Noetherian rings next time, but will not prove this proposition here.

Corollary 3.0.5. *Suppose G is a finitely generated abelian group. Then there are finitely generated free abelian groups F_1 and F_2 such that $G \cong F_1/F_2$.*

Proof. Let $x_1, \ldots, x_m$ be generators for G. Let $F_1 = \mathbf{Z}^m$ and let $\varphi : F_1 \to G$ be the map that sends the ith generator $(0, 0, \ldots, 1, \ldots, 0)$ of $\mathbf{Z}^m$ to x_i. Then φ is a surjective homomorphism, and by Proposition 3.0.4 the kernel F_2 of φ is a finitely generated free abelian group. This proves the corollary. □

Suppose G is a nonzero finitely generated abelian group. By the corollary, there are free abelian groups F_1 and F_2 such that $G \cong F_1/F_2$. Choosing a basis for F_1, we obtain an isomorphism $F_1 \cong \mathbf{Z}^n$, for some positive integer n. By Proposition 3.0.4, $F_2 \cong \mathbf{Z}^m$, for some integer m with $0 \leq m \leq n$, and the inclusion map $F_2 \hookrightarrow F_1$ induces a map $\mathbf{Z}^m \to \mathbf{Z}^n$. This homomorphism is left multiplication by the $n \times m$ matrix A whose columns are the images of the generators of F_2 in $\mathbf{Z}^n$. The *cokernel* of this homomorphism is the quotient of $\mathbf{Z}^n$ by the image of A, and the cokernel is isomorphic to G. By augmenting A with zero columns on the right we obtain a square $n \times n$ matrix A with the same cokernel. The following proposition implies that we may choose bases such that the matrix A is diagonal, and then the structure of the cokernel of A will be easy to understand.

Proposition 3.0.6 (Smith normal form). *Suppose A is an $n \times n$ integer matrix. Then there exist invertible integer matrices P and Q such that $A' = PAQ$ is a diagonal matrix with entries $n_1, n_2, \ldots, n_s, 0, \ldots, 0$, where $n_1 > 1$ and $n_1 \mid n_2 \mid \ldots \mid n_s$. This is called the Smith normal form of A.*

We will see in the proof of Theorem 3.0.3 that A' is uniquely determined by A.

Proof. The matrix P will be a product of matrices that define elementary row operations and Q will be a product corresponding to elementary column operations. The elementary operations are:

1. Add an integer multiple of one row to another (or a multiple of one column to another).

2. Interchange two rows or two columns.

3. Multiply a row by -1.

Each of these operations is given by left or right multiplying by an invertible matrix E with integer entries, where E is the result of applying the given operation to the identity matrix, and E is invertible because each operation can be reversed using another row or column operation over the integers.

To see that the proposition must be true, assume $A \neq 0$ and perform the following steps (compare [Art91, pg. 459]):

1. By permuting rows and columns, move a nonzero entry of A with smallest absolute value to the upper left corner of A. Now attempt to make all other entries in the first row and column 0 by adding multiples of row or column 1 to other rows (see step 2 below). If an operation produces a nonzero entry in the matrix with absolute value smaller than $|a_{11}|$, start the process over by permuting rows and columns to move that entry to the upper left corner of A. Since the integers $|a_{11}|$ are a decreasing sequence of positive integers, we will not have to move an entry to the upper left corner infinitely often.

2. Suppose a_{i1} is a nonzero entry in the first column, with $i > 1$. Using the division algorithm, write $a_{i1} = a_{11}q + r$, with $0 \leq r < a_{11}$. Now add $-q$ times the first row to the ith row. If $r > 0$, then go to step 1 (so that an entry with absolute value at most r is the upper left corner). Since we will only perform step 1 finitely many times, we may assume $r = 0$. Repeating this procedure we set all entries in the first column (except a_{11}) to 0. A similar process using column operations sets each entry in the first row (except a_{11}) to 0.

3. We may now assume that a_{11} is the only nonzero entry in the first row and column. If some entry a_{ij} of A is not divisible by a_{11}, add the column of A containing a_{ij} to the first column, thus producing an entry in the first column that is nonzero. When we perform step 2, the remainder r will be greater than 0. Permuting rows and columns results in a smaller $|a_{11}|$. Since $|a_{11}|$ can only shrink finitely many times, eventually we will get to a point where every a_{ij} is divisible by a_{11}. If a_{11} is negative, multiple the first row by -1.

After performing the above operations, the first row and column of A are zero except for a_{11} which is positive and divides all other entries of A. We repeat the above steps for the matrix B obtained from A by deleting the first row and column. The upper left entry of the resulting matrix will be divisible by a_{11}, since every entry of B is. Repeating the argument inductively proves the proposition. □

Example 3.0.7. The matrix $\begin{pmatrix}1 & 2\\3 & 4\end{pmatrix}$ is equivalent to $\begin{pmatrix}1 & 0\\0 & 2\end{pmatrix}$ and the matrix $\begin{pmatrix}1 & 2 & 3\\4 & 5 & 6\\7 & 8 & 9\end{pmatrix}$ is equivalent to $\begin{pmatrix}1 & 0 & 0\\0 & 3 & 0\\0 & 0 & 0\end{pmatrix}$. Note that the determinants match, up to sign.

Theorem 3.0.3. Suppose G is a finitely generated abelian group, which we may assume is nonzero. As in the paragraph before Proposition 3.0.6, we use Corollary 3.0.5 to write G as a the cokernel of an $n \times n$ integer matrix A. By Proposition 3.0.6 there are isomorphisms $Q : \mathbf{Z}^n \to \mathbf{Z}^n$ and $P : \mathbf{Z}^n \to \mathbf{Z}^n$ such that $A' = PAQ$ is a diagonal matrix with entries $n_1, n_2, \ldots, n_s, 0, \ldots, 0$, where $n_1 > 1$ and $n_1 \mid n_2 \mid \ldots \mid n_s$. Then G is isomorphic to the cokernel of the diagonal matrix A', so

$$G \cong (\mathbf{Z}/n_1\mathbf{Z}) \oplus (\mathbf{Z}/n_2\mathbf{Z}) \oplus \cdots \oplus (\mathbf{Z}/n_s\mathbf{Z}) \oplus \mathbf{Z}^r, \qquad (3.0.1)$$

as claimed. The n_i are determined by G, because n_i is the smallest positive integer n such that nG requires at most $s + r - i$ generators (we see from the representation (3.0.1) of G as a product that n_i has this property and that no smaller positive integer does).

□

Chapter 4

Commutative Algebra

We will do some serious commutative algebra in this chapter, which will provide a powerful algebraic foundation for understanding the more refined number-theoretic structures associated to number fields.

In the first section we establish the standard properties of Noetherian rings and modules, including the Hilbert basis theorem. We also observe that finitely generated abelian groups are Noetherian **Z**-modules, which fills the gap in our proof of the structure theorem for finitely generated abelian groups. After establishing properties of Noetherian rings, we consider the rings of algebraic integers and discuss some of their properties.

4.1 Noetherian Rings and Modules

Let R be a commutative ring with unit element. We will frequently work with R-modules, which are like vector spaces but over a ring. More precisely, recall that an *R-module* is an additive abelian group M equipped with a map $R \times M \to M$ such that for all $r, r' \in R$ and all $m, m' \in M$ we have $(rr')m = r(r'm)$, $(r + r')m = rm + r'm$, $r(m + m') = rm + rm'$, and $1m = m$. A *submodule* is a subgroup of M that is preserved by the action of R.

Example 4.1.1. The set of abelian groups are in natural bijection with **Z**-modules.

A *homomorphism* of R-modules $\varphi : M \to N$ is a abelian group homomorphism such that for any $r \in R$ and $m \in M$ we have $\varphi(rm) = r\varphi(m)$. A *short exact sequence* of R-modules

$$0 \to L \xrightarrow{f} M \xrightarrow{g} N \to 0$$

is a specific choice of injective homomorphism $f : L \to M$ and a surjective homomorphism $g : M \to N$ such that $\mathrm{im}(f) = \ker(g)$.

Definition 4.1.2 (Noetherian). An R-module M is *Noetherian* if every submodule of M is finitely generated. A ring R is *Noetherian* if R is Noetherian as a module over itself, i.e., if every ideal of R is finitely generated.

Notice that any submodule M' of M is Noetherian, because if every submodule of M is finitely generated then so is every submodule of M', since submodules of M' are also submodules of M.

Definition 4.1.3 (Ascending chain condition). An R-module M satisfies the *ascending chain condition* if every sequences $M_1 \subset M_2 \subset M_3 \subset \cdots$ of submodules of M eventually stabilizes, i.e., there is some n such that $M_n = M_{n+1} = M_{n+2} = \cdots$.

Proposition 4.1.4. *If M is an R-module, then the following are equivalent:*

1. *M is Noetherian,*
2. *M satisfies the ascending chain condition, and*
3. *Every nonempty set of submodules of M contains at least one maximal element.*

Proof. $1 \implies 2$**:** Suppose $M_1 \subset M_2 \subset \cdots$ is a sequence of submodules of M. Then $M_\infty = \cup_{n=1}^\infty M_n$ is a submodule of M. Since M is Noetherian, there is a finite set $a_1, \ldots, a_m$ of generators for M. Each a_i must be contained in some M_j, so there is an n such that $a_1, \ldots, a_m \in M_n$. But then $M_k = M_n$ for all $k \geq n$, which proves that the ascending chain condition holds for M.
$2 \implies 3$**:** Suppose 3 were false, so there exists a nonempty set S of submodules of M that does not contain a maximal element. We will use S to construct an infinite ascending chain of submodules of M that does not stabilize. Note that S is infinite, otherwise it would contain a maximal element. Let M_1 be any element of S. Then there is an M_2 in S that contains M_1, otherwise S would contain the maximal element M_1. Continuing inductively in this way we find an M_3 in S that properly contains M_2, etc., and we produce an infinite ascending chain of submodules of M, which contradicts the ascending chain condition.
$3 \implies 1$**:** Suppose 1 is false, so there is a submodule M' of M that is not finitely generated. We will show that the set S of all finitely generated submodules of M' does not have a maximal element, which will be a contradiction. Suppose S does have a maximal element L. Since L is finitely generated and $L \subset M'$, and M' is not finitely generated, there is an $a \in M'$ such that $a \notin L$. Then $L' = L + Ra$ is an element of S that strictly contains the presumed maximal element L, a contradiction. $\square$

Lemma 4.1.5. *If*

$$0 \to L \xrightarrow{f} M \xrightarrow{g} N \to 0$$

is a short exact sequence of R-modules, then M is Noetherian if and only if both L and N are Noetherian.

Proof. First suppose that M is Noetherian. Then L is a submodule of M, so L is Noetherian. If N' is a submodule of N, then the inverse image of N' in M is a submodule of M, so it is finitely generated, hence its image N' is finitely generated. Thus N is Noetherian as well.

Next assume nothing about M, but suppose that both L and N are Noetherian. If M' is a submodule of M, then $M_0 = \varphi(L) \cap M'$ is isomorphic to a submodule of the Noetherian module L, so M_0 is generated by finitely many elements $a_1, \ldots, a_n$. The quotient M'/M_0 is isomorphic (via g) to a submodule of the Noetherian module N, so M'/M_0 is generated by finitely many elements $b_1, \ldots, b_m$. For each $i \leq m$, let c_i be a lift of b_i to M', modulo M_0. Then the elements $a_1, \ldots, a_n, c_1, \ldots, c_m$ generate M', for if $x \in M'$, then there is some element $y \in M_0$ such that $x - y$ is an R-linear combination of the c_i, and y is an R-linear combination of the a_i. □

Proposition 4.1.6. *Suppose R is a Noetherian ring. Then an R-module M is Noetherian if and only if it is finitely generated.*

Proof. If M is Noetherian then every submodule of M is finitely generated so M is finitely generated. Conversely, suppose M is finitely generated, say by elements $a_1, \ldots, a_n$. Then there is a surjective homomorphism from $R^n = R \oplus \cdots \oplus R$ to M that sends $(0, \ldots, 0, 1, 0, \ldots, 0)$ (1 in ith factor) to a_i. Using Lemma 4.1.5 and exact sequences of R-modules such as $0 \to R \to R \oplus R \to R \to 0$, we see inductively that R^n is Noetherian. Again by Lemma 4.1.5, homomorphic images of Noetherian modules are Noetherian, so M is Noetherian. □

Lemma 4.1.7. *Suppose $\varphi : R \to S$ is a surjective homomorphism of rings and R is Noetherian. Then S is Noetherian.*

Proof. The kernel of φ is an ideal I in R, and we have an exact sequence

$$0 \to I \to R \to S \to 0$$

with R Noetherian. By Lemma 4.1.5, it follows that S is a Noetherian R-modules. Suppose J is an ideal of S. Since J is an R-submodule of S, if we view J as an R-module, then J is finitely generated. Since R acts on J through S, the R-generators of J are also S-generators of J, so J is finitely generated as an ideal. Thus S is Noetherian. □

Theorem 4.1.8 (Hilbert Basis Theorem). *If R is a Noetherian ring and S is finitely generated as a ring over R, then S is Noetherian. In particular, for any n the polynomial ring $R[x_1, \ldots, x_n]$ and any of its quotients are Noetherian.*

Proof. Assume first that we have already shown that for any n the polynomial ring $R[x_1, \ldots, x_n]$ is Noetherian. Suppose S is finitely generated as a ring over R, so there are generators $s_1, \ldots, s_n$ for S. Then the map $x_i \mapsto s_i$ extends uniquely to a surjective homomorphism $\pi : R[x_1, \ldots, x_n] \to S$, and Lemma 4.1.7 implies that S is Noetherian.

The rings $R[x_1, \ldots, x_n]$ and $(R[x_1, \ldots, x_{n-1}])[x_n]$ are isomorphic, so it suffices to prove that if R is Noetherian then $R[x]$ is also Noetherian. (Our proof follows

[Art91, §12.5].) Thus suppose I is an ideal of $R[x]$ and that R is Noetherian. We will show that I is finitely generated.

Let A be the set of leading coefficients of polynomials in I along with 0. If $a, b \in A$ are nonzero with $a + b \neq 0$, then there are polynomials f and g in I with leading coefficients a and b. If $\deg(f) \leq \deg(g)$, then $a + b$ is the leading coefficient of $x^{\deg(g)-\deg(f)}f + g$, so $a + b \in A$. If $r \in R$ and $a \in A$ with $ra \neq 0$, then ra is the leading coefficient of rf, so $ra \in A$. Thus A is an ideal in R, so since R is Noetherian there exists $a_1, \ldots, a_n$ that generate A as an ideal. Since A is the set of leading coefficients of elements of I, and the a_j are in I, we can choose for each $j \leq n$ an element $f_j \in I$ with leading coefficient a_j. By multipying the f_j by some power of x, we may assume that the f_j all have the same degree d.

Let $S_{<d}$ be the set of elements of I that have degree strictly less than d. This set is closed under addition and under multiplication by elements of R, so $S_{<d}$ is a module over R. The module $S_{<d}$ is submodule of the R-module of polynomials of degree less than n, which is Noetherian because it is generated by $1, x, \ldots, x^{n-1}$. Thus $S_{<d}$ is finitely generated, and we may choose generators $h_1, \ldots, h_m$ for $S_{<d}$.

Suppose $g \in I$ is an arbitrary element. We will show by induction on the degree of g that g is an $R[x]$-linear combination of $f_1, \ldots, f_n, h_1, \ldots h_m$. Thus suppose this statement is true for all elements of I of degree less than the degree of g. If the degree of g is less than d, then $g \in S_{<d}$, so g is in the $R[x]$-ideal generated by $h_1, \ldots, h_m$. Next suppose that g has degree $e \geq d$. Then the leading coefficient b of g lies in the ideal A of leading coefficients of g, so there exist $r_i \in R$ such that $b = r_1 a_1 + \cdots + r_n a_n$. Since f_i has leading coefficient a_i, the difference $g - x^{e-d} r_i f_i$ has degree less than the degree e of g. By induction $g - x^{e-d} r_i f_i$ is an $R[x]$ linear combination of $f_1, \ldots, f_n, h_1, \ldots h_m$, so g is also an $R[x]$ linear combination of $f_1, \ldots, f_n, h_1, \ldots h_m$. Since each f_i and h_j lies in I, it follows that I is generated by $f_1, \ldots, f_n, h_1, \ldots h_m$, so I is finitely generated, as required. □

Properties of Noetherian rings and modules will be crucial in the rest of this course. We have proved above that Noetherian rings have many desirable properties.

4.1.1 Z is Noetherian

The ring $\mathbf{Z}$ of integers is Noetherian because every ideal of $\mathbf{Z}$ is generated by one element.

Proposition 4.1.9. *Every ideal of the ring* $\mathbf{Z}$ *of integers is principal.*

Proof. Suppose I is a nonzero ideal in $\mathbf{Z}$. Let d the least positive element of I. Suppose that $a \in I$ is any nonzero element of I. Using the division algorithm, write $a = dq + r$, where q is an integer and $0 \leq r < d$. We have $r = a - dq \in I$ and $r < d$, so our assumption that d is minimal implies that $r = 0$, so $a = dq$ is in the ideal generated by d. Thus I is the principal ideal generated by d. □

Proposition 4.1.6 and 4.1.9 together imply that any finitely generated abelian group is Noetherian. This means that subgroups of finitely generated abelian groups are finitely generated, which provides the missing step in our proof of the structure theorem for finitely generated abelian groups.

Chapter 5

Rings of Algebraic Integers

In this chapter we will learn about rings of algebraic integers and discuss some of their properties. We will prove that the ring of integers $\mathcal{O}_K$ of a number field is Noetherian. We will also develop some basic properties of norms, traces, and discriminants, and give more properties of rings of integers in the general context of Dedekind domains.

5.1 Rings of Algebraic Integers

Fix an algebraic closure $\overline{\mathbf{Q}}$ of $\mathbf{Q}$. For example, $\overline{\mathbf{Q}}$ could be the subfield of the complex numbers $\mathbf{C}$ generated by all roots in $\mathbf{C}$ of all polynomials with coefficients in $\mathbf{Q}$.

Much of this course is about algebraic integers.

Definition 5.1.1 (Algebraic Integer). An element $\alpha \in \overline{\mathbf{Q}}$ is an *algebraic integer* if it is a root of some monic polynomial with coefficients in $\mathbf{Z}$.

Definition 5.1.2 (Minimal Polynomial). The *minimal polynomial* of $\alpha \in \mathbf{Q}$ is the monic polynomial $f \in \mathbf{Q}[x]$ of least positive degree such that $f(\alpha) = 0$.

The minimal polynomial of α divides any polynomial h such that $h(\alpha) = 0$, for the following reason. If $h(\alpha) = 0$, use the division algorithm to write $h = qf + r$, where $0 \leq \deg(r) < \deg(f)$. We have $r(\alpha) = h(\alpha) - q(\alpha)f(\alpha) = 0$, so α is a root of r. However, f is the polynomial of least positive degree with root α, so $r = 0$.

Lemma 5.1.3. *If α is an algebraic integer, then the minimal polynomial of α has coefficients in $\mathbf{Z}$.*

Proof. Suppose $f \in \mathbf{Q}[x]$ is the minimal polynomial of α and $g \in \mathbf{Z}[x]$ is a monic integral polynomial such that $g(\alpha) = 0$. As mentioned after the definition of minimal polynomial, we have $g = fh$, for some $h \in \mathbf{Q}[x]$. If $f \not\in \mathbf{Z}[x]$, then some prime p divides the denominator of some coefficient of f. Let p^i be the largest power of p that divides some denominator of some coefficient f, and likewise let p^j be the largest power of p that divides some denominator of a coefficient of g. Then $p^{i+j}g = (p^i f)(p^j g)$, and if we reduce both sides modulo p, then the left hand side is 0 but the right hand side is a product of two nonzero polynomials in $\mathbf{F}_p[x]$, hence nonzero, a contradiction. □

Proposition 5.1.4. *An element $\alpha \in \overline{\mathbf{Q}}$ is integral if and only if $\mathbf{Z}[\alpha]$ is finitely generated as a $\mathbf{Z}$-module.*

Proof. Suppose α is integral and let $f \in \mathbf{Z}[x]$ be the monic minimal polynomial of α (that $f \in \mathbf{Z}[x]$ is Lemma 5.1.3). Then $\mathbf{Z}[\alpha]$ is generated by $1, \alpha, \alpha^2, \ldots, \alpha^{d-1}$, where d is the degree of f. Conversely, suppose $\alpha \in \overline{\mathbf{Q}}$ is such that $\mathbf{Z}[\alpha]$ is finitely generated, say by elements $f_1(\alpha), \ldots, f_n(\alpha)$. Let d be any integer bigger than the degree of any f_i. Then there exist integers a_i such that $\alpha^d = \sum a_i f_i(\alpha)$, hence α satisfies the monic polynomial $x^d - \sum a_i f_i(x) \in \mathbf{Z}[x]$, so α is integral. □

The rational number $\alpha = 1/2$ is not integral. Note that $G = \mathbf{Z}[1/2]$ is not a finitely generated $\mathbf{Z}$-module, since G is infinite and $G/2G = 0$.

Proposition 5.1.5. *The set $\overline{\mathbf{Z}}$ of all algebraic integers is a ring, i.e., the sum and product of two algebraic integers is again an algebraic integer.*

Proof. Suppose $\alpha, \beta \in \mathbf{Z}$, and let m, n be the degrees of the minimal polynomials of α, β, respectively. Then $1, \alpha, \ldots, \alpha^{m-1}$ span $\mathbf{Z}[\alpha]$ and $1, \beta, \ldots, \beta^{n-1}$ span $\mathbf{Z}[\beta]$ as $\mathbf{Z}$-module. Thus the elements $\alpha^i \beta^j$ for $i \leq m, j \leq n$ span $\mathbf{Z}[\alpha, \beta]$. Since $\mathbf{Z}[\alpha + \beta]$ is a submodule of the finitely-generated module $\mathbf{Z}[\alpha, \beta]$, it is finitely generated, so $\alpha + \beta$ is integral. Likewise, $\mathbf{Z}[\alpha\beta]$ is a submodule of $\mathbf{Z}[\alpha, \beta]$, so it is also finitely generated and $\alpha\beta$ is integral. □

Recall that a *number field* is a subfield K of $\overline{\mathbf{Q}}$ such that the degree $[K : \mathbf{Q}] := \dim_{\mathbf{Q}}(K)$ is finite.

Definition 5.1.6 (Ring of Integers). The *ring of integers* of a number field K is the ring

$$\mathcal{O}_K = K \cap \overline{\mathbf{Z}} = \{x \in K : \ x \text{ is an algebraic integer}\}.$$

The field $\mathbf{Q}$ of rational numbers is a number field of degree 1, and the ring of integers of $\mathbf{Q}$ is $\mathbf{Z}$. The field $K = \mathbf{Q}(i)$ of Gaussian integers has degree 2 and $\mathcal{O}_K = \mathbf{Z}[i]$. The field $K = \mathbf{Q}(\sqrt{5})$ has ring of integers $\mathcal{O}_K = \mathbf{Z}[(1+\sqrt{5})/2]$. Note that the Golden ratio $(1+\sqrt{5})/2$ satisfies $x^2 - x - 1$. According to Magma, the ring of integers of $K = \mathbf{Q}(\sqrt[3]{9})$ is $\mathbf{Z}[\sqrt[3]{3}]$, where $\sqrt[3]{3} = \frac{1}{3}(\sqrt[3]{9})^2$.

Definition 5.1.7 (Order). An *order* in $\mathcal{O}_K$ is any subring R of $\mathcal{O}_K$ such that the quotient $\mathcal{O}_K/R$ of abelian groups is finite. (Note that R must contain 1 because it is a ring, and for us every ring has a 1.)

As noted above, $\mathbf{Z}[i]$ is the ring of integers of $\mathbf{Q}(i)$. For every nonzero integer n, the subring $\mathbf{Z} + ni\mathbf{Z}$ of $\mathbf{Z}[i]$ is an order. The subring $\mathbf{Z}$ of $\mathbf{Z}[i]$ is not an order, because $\mathbf{Z}$ does not have finite index in $\mathbf{Z}[i]$. Also the subgroup $2\mathbf{Z}+i\mathbf{Z}$ of $\mathbf{Z}[i]$ is not an order because it is not a ring.

We will frequently consider orders in practice because they are often much easier to write down explicitly than $\mathcal{O}_K$. For example, if $K=\mathbf{Q}(\alpha)$ and α is an algebraic integer, then $\mathbf{Z}[\alpha]$ is an order in $\mathcal{O}_K$, but frequently $\mathbf{Z}[\alpha]\neq\mathcal{O}_K$.

Lemma 5.1.8. *Let $\mathcal{O}_K$ be the ring of integers of a number field. Then $\mathcal{O}_K\cap\mathbf{Q}=\mathbf{Z}$ and $\mathbf{Q}\mathcal{O}_K=K$.*

Proof. Suppose $\alpha\in\mathcal{O}_K\cap\mathbf{Q}$ with $\alpha=a/b$ in lowest terms and $b>0$. The monic minimal polynomial of α is $bx-a\in\mathbf{Z}[x]$, so if $b\neq 1$ then Lemma 5.1.3 implies that α is not an algebraic integer, a contradiction.

To prove that $\mathbf{Q}\mathcal{O}_K=K$, suppose $\alpha\in K$, and let $f(x)\in\mathbf{Q}[x]$ be the minimal monic polynomial of α. For any positive integer d, the minimal monic polynomial of $d\alpha$ is $d^{\deg(f)}f(x/d)$, i.e., the polynomial obtained from $f(x)$ by multiplying the coefficient of $x^{\deg(f)}$ by 1, multiplying the coefficient of $x^{\deg(f)-1}$ by d, multiplying the coefficient of $x^{\deg(f)-2}$ by d^2, etc. If d is the least common multiple of the denominators of the coefficients of f, then the minimal monic polynomial of $d\alpha$ has integer coefficients, so $d\alpha$ is integral and $d\alpha\in\mathcal{O}_K$. This proves that $\mathbf{Q}\mathcal{O}_K=K$. □

In the next two sections we will develop some basic properties of norms and traces, and deduce further properties of rings of integers.

5.2 Norms and Traces

Before discussing norms and traces we introduce some notation for field extensions. If $K\subset L$ are number fields, we let $[L:K]$ denote the dimension of L viewed as a K-vector space. If K is a number field and $a\in\overline{\mathbf{Q}}$, let $K(a)$ be the number field generated by a, which is the smallest number field that contains a. If $a\in\overline{\mathbf{Q}}$ then a has a minimal polynomial $f(x)\in\mathbf{Q}[x]$, and the *Galois conjugates* of a are the roots of f. For example the element $\sqrt{2}$ has minimal polynomial x^2-2 and the Galois conjugates of $\sqrt{2}$ are $\pm\sqrt{2}$.

Suppose $K\subset L$ is an inclusion of number fields and let $a\in L$. Then left multiplication by a defines a K-linear transformation $\ell_a:L\to L$. (The transformation ℓ_a is K-linear because L is commutative.)

Definition 5.2.1 (Norm and Trace). The *norm* and *trace* of a from L to K are

$$\mathrm{Norm}_{L/K}(a)=\mathrm{Det}(\ell_a)\quad\text{ and }\quad\mathrm{tr}_{L/K}(a)=\mathrm{tr}(\ell_a).$$

It is standard from linear algebra that determinants are multiplicative and traces are additive, so for $a,b\in L$ we have

$$\mathrm{Norm}_{L/K}(ab)=\mathrm{Norm}_{L/K}(a)\cdot\mathrm{Norm}_{L/K}(b)$$

and

$$\mathrm{tr}_{L/K}(a+b)=\mathrm{tr}_{L/K}(a)+\mathrm{tr}_{L/K}(b).$$

Note that if $f \in \mathbf{Q}[x]$ is the characteristic polynomial of ℓ_a, then the constant term of f is $(-1)^{\deg(f)}\operatorname{Det}(\ell_a)$, and the coefficient of $x^{\deg(f)-1}$ is $-\operatorname{tr}(\ell_a)$.

Proposition 5.2.2. *Let $a \in L$ and let $\sigma_1, \ldots, \sigma_d$, where $d = [L : K]$, be the distinct field embeddings $L \hookrightarrow \overline{\mathbf{Q}}$ that fix every element of K. Then*

$$\operatorname{Norm}_{L/K}(a) = \prod_{i=1}^{d} \sigma_i(a) \qquad \textit{and} \qquad \operatorname{tr}_{L/K}(a) = \sum_{i=1}^{d} \sigma_i(a).$$

Proof. We prove the proposition by computing the characteristic polynomial F of a. Let $f \in K[x]$ be the minimal polynomial of a over K, and note that f has distinct roots (since it is the polynomial in $K[x]$ of least degree that is satisfied by a). Since f is irreducible, $[K(a) : K] = \deg(f)$, and a satisfies a polynomial if and only if ℓ_a does, the characteristic polynomial of ℓ_a acting on $K(a)$ is f. Let $b_1, \ldots, b_n$ be a basis for L over $K(a)$ and note that $1, \ldots, a^m$ is a basis for $K(a)/K$, where $m = \deg(f) - 1$. Then $a^i b_j$ is a basis for L over K, and left multiplication by a acts the same way on the span of $b_j, ab_j, \ldots, a^m b_j$ as on the span of $b_k, ab_k, \ldots, a^m b_k$, for any pair $j, k \leq n$. Thus the matrix of ℓ_a on L is a block direct sum of copies of the matrix of ℓ_a acting on $K(a)$, so the characteristic polynomial of ℓ_a on L is $f^{[L:K(a)]}$. The proposition follows because the roots of $f^{[L:K(a)]}$ are exactly the images $\sigma_i(a)$, with multiplicity $[L : K(a)]$ (since each embedding of $K(a)$ into $\overline{\mathbf{Q}}$ extends in exactly $[L : K(a)]$ ways to L by Exercise 9). □

The following corollary asserts that the norm and trace behave well in towers.

Corollary 5.2.3. *Suppose $K \subset L \subset M$ is a tower of number fields, and let $a \in M$. Then*

$$\operatorname{Norm}_{M/K}(a) = \operatorname{Norm}_{L/K}(\operatorname{Norm}_{M/L}(a)) \qquad \textit{and} \qquad \operatorname{tr}_{M/K}(a) = \operatorname{tr}_{L/K}(\operatorname{tr}_{M/L}(a)).$$

Proof. For the first equation, both sides are the product of $\sigma_i(a)$, where σ_i runs through the embeddings of M into K. To see this, suppose $\sigma : L \to \overline{\mathbf{Q}}$ fixes K. If σ' is an extension of σ to M, and $\tau_1, \ldots, \tau_d$ are the embeddings of M into $\overline{\mathbf{Q}}$ that fix L, then $\tau_1\sigma', \ldots, \tau_d\sigma'$ are exactly the extensions of σ to M. For the second statement, both sides are the sum of the $\sigma_i(a)$. □

The norm and trace down to $\mathbf{Q}$ of an algebraic integer a is an element of $\mathbf{Z}$, because the minimal polynomial of a has integer coefficients, and the characteristic polynomial of a is a power of the minimal polynomial, as we saw in the proof of Proposition 5.2.2.

Proposition 5.2.4. *Let K be a number field. The ring of integers $\mathcal{O}_K$ is a lattice in K, i.e., $\mathbf{Q}\mathcal{O}_K = K$ and $\mathcal{O}_K$ is an abelian group of rank $[K : \mathbf{Q}]$.*

Proof. We saw in Lemma 5.1.8 that $\mathbf{Q}\mathcal{O}_K = K$. Thus there exists a basis $a_1, \ldots, a_n$ for K, where each a_i is in $\mathcal{O}_K$. Suppose that as $x = \sum c_i a_i \in \mathcal{O}_K$ varies over all elements of $\mathcal{O}_K$ the denominators of the coefficients c_i are arbitrarily large. Then subtracting off integer multiples of the a_i, we see that as $x = \sum c_i a_i \in \mathcal{O}_K$ varies over elements of $\mathcal{O}_K$ with c_i between 0 and 1, the denominators of the c_i are also arbitrarily large. This implies that there are infinitely many elements of $\mathcal{O}_K$ in the bounded subset

$$S = \{c_1a_1 + \cdots + c_na_n : c_i \in \mathbf{Q},\ 0 \leq c_i \leq 1\} \subset K.$$

Thus for any $\varepsilon > 0$, there are elements $a, b \in \mathcal{O}_K$ such that the coefficients of $a - b$ are all less than ε (otherwise the elements of $\mathcal{O}_K$ would all be a "distance" of least ε from each other, so only finitely many of them would fit in S).

As mentioned above, the norms of elements of $\mathcal{O}_K$ are integers. Since the norm of an element is the determinant of left multiplication by that element, the norm is a homogenous polynomial of degree n in the indeterminate coefficients c_i. If the c_i get arbitrarily small for elements of $\mathcal{O}_K$, then the values of the norm polynomial get arbitrarily small, which would imply that there are elements of $\mathcal{O}_K$ with positive norm too small to be in $\mathbf{Z}$, a contradiction. So the set S contains only finitely many elements of $\mathcal{O}_K$. Thus the denominators of the c_i are bounded, so for some d, we have that $\mathcal{O}_K$ has finite index in $A = \frac{1}{d}\mathbf{Z}a_1 + \cdots + \frac{1}{d}\mathbf{Z}a_n$. Since A is isomorphic to $\mathbf{Z}^n$, it follows from the structure theorem for finitely generated abelian groups that $\mathcal{O}_K$ is isomorphic as a $\mathbf{Z}$-module to $\mathbf{Z}^n$, as claimed. □

Corollary 5.2.5. *The ring of integers $\mathcal{O}_K$ of a number field is Noetherian.*

Proof. By Proposition 5.2.4, the ring $\mathcal{O}_K$ is finitely generated as a module over $\mathbf{Z}$, so it is certainly finitely generated as a ring over $\mathbf{Z}$. By the Hilbert Basis Theorem, $\mathcal{O}_K$ is Noetherian. □

Chapter 6

Unique Factorization of Ideals

In this chapter we will deduce, with complete proofs, the most important basic property of the ring of integers $\mathcal{O}_K$ of an algebraic number, namely that every nonzero ideals can be written uniquely as products of prime ideals. After proving this fundamental theorem, we will compute some examples using Magma. The next chapter will consist mostly of examples illustrating the substantial theory we will have already developed, so hang in there!

6.1 Dedekind Domains

Recall (Corollary 5.2.5) that we proved that the ring of integers $\mathcal{O}_K$ of a number field is Noetherian. As we saw before using norms, the ring $\mathcal{O}_K$ is finitely generated as a module over $\mathbf{Z}$, so it is certainly finitely generated as a ring over $\mathbf{Z}$. By the Hilbert Basis Theorem, $\mathcal{O}_K$ is Noetherian.

If R is an integral domain, the *field of fractions* of R is the field of all elements a/b, where $a, b \in R$. The field of fractions of R is the smallest field that contains R. For example, the field of fractions of $\mathbf{Z}$ is $\mathbf{Q}$ and of $\mathbf{Z}[(1+\sqrt{5})/2]$ is $\mathbf{Q}(\sqrt{5})$.

Definition 6.1.1 (Integrally Closed). An integral domain R is *integrally closed in its field of fractions* if whenever α is in the field of fractions of R and α satisfies a monic polynomial $f \in R[x]$, then $\alpha \in R$.

Proposition 6.1.2. *If K is any number field, then $\mathcal{O}_K$ is integrally closed. Also, the ring $\overline{\mathbf{Z}}$ of all algebraic integers is integrally closed.*

Proof. We first prove that $\overline{\mathbf{Z}}$ is integrally closed. Suppose $c \in \overline{\mathbf{Q}}$ is integral over $\overline{\mathbf{Z}}$, so there is a monic polynomial $f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ with $a_i \in \overline{\mathbf{Z}}$ and $f(c) = 0$. The a_i all lie in the ring of integers $\mathcal{O}_K$ of the number field $K = \mathbf{Q}(a_0, a_1, \ldots a_{n-1})$, and $\mathcal{O}_K$ is finitely generated as a $\mathbf{Z}$-module, so $\mathbf{Z}[a_0, \ldots, a_{n-1}]$ is finitely generated as a $\mathbf{Z}$-module. Since $f(c) = 0$, we can write c^n as a $\mathbf{Z}[a_0, \ldots, a_{n-1}]$-linear combination of c^i for $i < n$, so the ring $\mathbf{Z}[a_0, \ldots, a_{n-1}, c]$ is also finitely generated as a $\mathbf{Z}$-module. Thus $\mathbf{Z}[c]$ is finitely generated as $\mathbf{Z}$-module because it is a submodule of a finitely generated $\mathbf{Z}$-module, which implies that c is integral over $\mathbf{Z}$.

Suppose $c \in K$ is integral over $\mathcal{O}_K$. Then since $\overline{\mathbf{Z}}$ is integrally closed, c is an element of $\overline{\mathbf{Z}}$, so $c \in K \cap \overline{\mathbf{Z}} = \mathcal{O}_K$, as required. □

Definition 6.1.3 (Dedekind Domain). An integral domain R is a *Dedekind domain* if it is Noetherian, integrally closed in its field of fractions, and every nonzero prime ideal of R is maximal.

The ring $\mathbf{Q} \oplus \mathbf{Q}$ is Noetherian, integrally closed in its field of fractions, and the two prime ideals are maximal. However, it is not a Dedekind domain because it is not an integral domain. The ring $\mathbf{Z}[\sqrt{5}]$ is not a Dedekind domain because it is not integrally closed in its field of fractions, as $(1+\sqrt{5})/2$ is integrally over $\mathbf{Z}$ and lies in $\mathbf{Q}(\sqrt{5})$, but not in $\mathbf{Z}[\sqrt{5}]$. The ring $\mathbf{Z}$ is a Dedekind domain, as is any ring of integers $\mathcal{O}_K$ of a number field, as we will see below. Also, any field K is a Dedekind domain, since it is a domain, it is trivially integrally closed in itself, and there are no nonzero prime ideals so that condition that they be maximal is empty.

Proposition 6.1.4. *The ring of integers $\mathcal{O}_K$ of a number field is a Dedekind domain.*

Proof. By Proposition 6.1.2, the ring $\mathcal{O}_K$ is integrally closed, and by Proposition 5.2.5 it is Noetherian. Suppose that $\mathfrak{p}$ is a nonzero prime ideal of $\mathcal{O}_K$. Let $\alpha \in \mathfrak{p}$ be a nonzero element, and let $f(x) \in \mathbf{Z}[x]$ be the minimal polynomial of α. Then

$$f(\alpha) = \alpha^n + a_{n-1}\alpha^{n-1} + \cdots + a_1\alpha + a_0 = 0,$$

so $a_0 = -(\alpha^n + a_{n-1}\alpha^{n-1} + \cdots + a_1\alpha) \in \mathfrak{p}$. Since f is irreducible, a_0 is a nonzero element of $\mathbf{Z}$ that lies in $\mathfrak{p}$. Every element of the finitely generated abelian group $\mathcal{O}_K/\mathfrak{p}$ is killed by a_0, so $\mathcal{O}_K/\mathfrak{p}$ is a finite set. Since $\mathfrak{p}$ is prime, $\mathcal{O}_K/\mathfrak{p}$ is an integral domain. Every finite integral domain is a field, so $\mathfrak{p}$ is maximal, which completes the proof. □

If I and J are ideals in a ring R, the product IJ is the ideal generated by all products of elements in I with elements in J:

$$IJ = (ab : a \in I, b \in J) \subset R.$$

Note that the set of all products ab, with $a \in I$ and $b \in J$, need not be an ideal, so it is important to take the ideal generated by that set. (See the homework problems for examples.)

Definition 6.1.5 (Fractional Ideal). A *fractional ideal* is an $\mathcal{O}_K$-submodule of $I \subset K$ that is finitely generated as an $\mathcal{O}_K$-module.

To avoid confusion, we will sometimes call a genuine ideal $I \subset \mathcal{O}_K$ an *integral ideal*. Also, since fractional ideals are finitely generated, we can clear denominators of a generating set to see that every fractional ideal is of the form $aI = \{ab : b \in I\}$ for some $a \in K$ and ideal $I \subset \mathcal{O}_K$.

For example, the collection $\frac{1}{2}\mathbf{Z}$ of rational numbers with denominator 1 or 2 is a fractional ideal of $\mathbf{Z}$.

Theorem 6.1.6. *The set of nonzero fractional ideals of a Dedekind domain R is an abelian group under ideal multiplication.*

Before proving Theorem 6.1.6 we prove a lemma. For the rest of this section $\mathcal{O}_K$ is the ring of integers of a number field K.

Definition 6.1.7 (Divides for Ideals). Suppose that I, J are ideals of $\mathcal{O}_K$. Then I *divides* J if $I \supset J$.

To see that this notion of divides is sensible, suppose $K = \mathbf{Q}$, so $\mathcal{O}_K = \mathbf{Z}$. Then $I = (n)$ and $J = (m)$ for some integer n and m, and I divides J means that $(n) \supset (m)$, i.e., that there exists an integer c such that $m = cn$, which exactly means that n divides m, as expected.

Lemma 6.1.8. *Suppose I is an ideal of $\mathcal{O}_K$. Then there exist prime ideals $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$ such that $\mathfrak{p}_1 \cdot \mathfrak{p}_2 \cdots \mathfrak{p}_n \subset I$. In other words, I divides a product of prime ideals. (By convention the empty product is the unit ideal. Also, if $I = 0$, then we take $\mathfrak{p}_1 = (0)$, which is a prime ideal.)*

Proof. The key idea is to use that $\mathcal{O}_K$ is Noetherian to deduce that the set S of ideals that do not satisfy the lemma is empty. If S is nonempty, then because $\mathcal{O}_K$ is Noetherian, there is an ideal $I \in S$ that is maximal as an element of S. If I were prime, then I would trivially contain a product of primes, so I is not prime. By definition of prime ideal, there exists $a, b \in \mathcal{O}_K$ such that $ab \in I$ but $a \notin I$ and $b \notin I$. Let $J_1 = I + (a)$ and $J_2 = I + (b)$. Then neither J_1 nor J_2 is in S, since I is maximal, so both J_1 and J_2 contain a product of prime ideals. Thus so does I, since

$$J_1 J_2 = I^2 + I(b) + (a)I + (ab) \subset I,$$

which is a contradiction. Thus S is empty, which completes the proof. □

We are now ready to prove the theorem.

Proof of Theorem 6.1.6. The product of two fractional ideals is again finitely generated, so it is a fractional ideal, and $I\mathcal{O}_K = \mathcal{O}_K$ for any nonzero ideal I, so to prove that the set of fractional ideals under multiplication is a group it suffices to show the existence of inverses. We will first prove that if $\mathfrak{p}$ is a prime ideal, then $\mathfrak{p}$ has an inverse, then we will prove that nonzero integral ideals have inverses, and finally observe that every fractional ideal has an inverse.

Suppose $\mathfrak{p}$ is a nonzero prime ideal of $\mathcal{O}_K$. We will show that the $\mathcal{O}_K$-module

$$I = \{a \in K : a\mathfrak{p} \subset \mathcal{O}_K\}$$

is a fractional ideal of $\mathcal{O}_K$ such that $I\mathfrak{p} = \mathcal{O}_K$, so that I is an inverse of $\mathfrak{p}$.

For the rest of the proof, fix a nonzero element $b \in \mathfrak{p}$. Since I is an $\mathcal{O}_K$-module, $bI \subset \mathcal{O}_K$ is an $\mathcal{O}_K$ ideal, hence I is a fractional ideal. Since $\mathcal{O}_K \subset I$ we have $\mathfrak{p} \subset I\mathfrak{p} \subset \mathcal{O}_K$, hence either $\mathfrak{p} = I\mathfrak{p}$ or $I\mathfrak{p} = \mathcal{O}_K$. If $I\mathfrak{p} = \mathcal{O}_K$, we are done since then I is an inverse of $\mathfrak{p}$. Thus suppose that $I\mathfrak{p} = \mathfrak{p}$. Our strategy is to show that there is some $d \in I$ not in $\mathcal{O}_K$; such a d would leave $\mathfrak{p}$ invariant (i.e., $d\mathfrak{p} \subset \mathfrak{p}$), so since $\mathfrak{p}$ is an $\mathcal{O}_K$-module it will follow that $d \in \mathcal{O}_K$, a contradiction.

By Lemma 6.1.8, we can choose a product $\mathfrak{p}_1, \ldots, \mathfrak{p}_m$, with m minimal, such that

$$\mathfrak{p}_1\mathfrak{p}_2 \cdots \mathfrak{p}_m \subset (b) \subset \mathfrak{p}.$$

If no $\mathfrak{p}_i$ is contained in $\mathfrak{p}$, then we can choose for each i an $a_i \in \mathfrak{p}_i$ with $a_i \notin \mathfrak{p}$; but then $\prod a_i \in \mathfrak{p}$, which contradicts that $\mathfrak{p}$ is a prime ideal. Thus some $\mathfrak{p}_i$, say $\mathfrak{p}_1$, is contained in $\mathfrak{p}$, which implies that $\mathfrak{p}_1 = \mathfrak{p}$ since every nonzero prime ideal is maximal. Because m is minimal, $\mathfrak{p}_2 \cdots \mathfrak{p}_m$ is not a subset of (b), so there exists $c \in \mathfrak{p}_2 \cdots \mathfrak{p}_m$ that does not lie in (b). Then $\mathfrak{p}(c) \subset (b)$, so by definition of I we have $d = c/b \in I$. However, $d \notin \mathcal{O}_K$, since if it were then c would be in (b). We have thus found our element $d \in I$ that does not lie in $\mathcal{O}_K$. To finish the proof that $\mathfrak{p}$ has an inverse, we observe that d preserves the $\mathcal{O}_K$-module $\mathfrak{p}$, and is hence in $\mathcal{O}_K$, a contradiction. More precisely, if $b_1, \ldots, b_n$ is a basis for $\mathfrak{p}$ as a $\mathbf{Z}$-module, then the action of d on $\mathfrak{p}$ is given by a matrix with entries in $\mathbf{Z}$, so the minimal polynomial of d has coefficients in $\mathbf{Z}$. This implies that d is integral over $\mathbf{Z}$, so $d \in \mathcal{O}_K$, since $\mathcal{O}_K$ is integrally closed by Proposition 6.1.2. (Note how this argument depends strongly on the fact that $\mathcal{O}_K$ is integrally closed!)

So far we have proved that if $\mathfrak{p}$ is a prime ideal of $\mathcal{O}_K$, then $\mathfrak{p}^{-1} = \{a \in \mathbf{K} : a\mathfrak{p} \subset \mathcal{O}_K\}$ is the inverse of $\mathfrak{p}$ in the monoid of nonzero fractional ideals of $\mathcal{O}_K$. As mentioned after Definition 6.1.5 [on Tuesday], every nonzero fractional ideal is of the form aI for $a \in K$ and I an integral ideal, so since (a) has inverse $(1/a)$, it suffices to show that every integral ideal I has an inverse. If not, then there is a nonzero integral ideal I that is maximal among all nonzero integral ideals that do not have an inverse. Every ideal is contained in a maximal ideal, so there is a nonzero prime ideal $\mathfrak{p}$ such that $I \subset \mathfrak{p}$. Multiplying both sides of this inclusion by $\mathfrak{p}^{-1}$ and using that $\mathcal{O}_K \subset \mathfrak{p}^{-1}$, we see that $I \subset \mathfrak{p}^{-1}I \subset \mathcal{O}_K$. If $I = \mathfrak{p}^{-1}I$, then arguing as in the proof that $\mathfrak{p}^{-1}$ is the inverse of $\mathfrak{p}$, we see that each element of $\mathfrak{p}^{-1}$ preserves the finitely generated $\mathbf{Z}$-module I and is hence integral. But then $\mathfrak{p}^{-1} \subset \mathcal{O}_K$, which implies that $\mathcal{O}_K = \mathfrak{p}\mathfrak{p}^{-1} \subset \mathfrak{p}$, a contradiction. Thus $I \neq \mathfrak{p}^{-1}I$. Because I is maximal among ideals that do not have an inverse, the ideal $\mathfrak{p}^{-1}I$ does have an inverse, call it J. Then $\mathfrak{p}J$ is the inverse of I, since $\mathcal{O}_K = (\mathfrak{p}J)(\mathfrak{p}^{-1}I) = JI$. □

We can finally deduce the crucial Theorem 6.1.10, which will allow us to show that any nonzero ideal of a Dedekind domain can be expressed uniquely as a product of primes (up to order). Thus unique factorization holds for ideals in a Dedekind domain, and it is this unique factorization that initially motivated the introduction of rings of integers of number fields over a century ago.

Theorem 6.1.9. *Suppose I is an integral ideal of $\mathcal{O}_K$. Then I can be written as a product*

$$I = \mathfrak{p}_1 \cdots \mathfrak{p}_n$$

of prime ideals of $\mathcal{O}_K$, and this representation is unique up to order. (Exception: If $I = 0$, then the representation is not unique.)

Proof. Suppose I is an ideal that is maximal among the set of all ideals in $\mathcal{O}_K$ that can not be written as a product of primes. Every ideal is contained in a maximal ideal, so I is contained in a nonzero prime ideal $\mathfrak{p}$. If $I\mathfrak{p}^{-1} = I$, then by Theorem 6.1.6 we can cancel I from both sides of this equation to see that $\mathfrak{p}^{-1} = \mathcal{O}_K$, a contradiction. Thus I is strictly contained in $I\mathfrak{p}^{-1}$, so by our maximality assumption on I there are maximal ideals $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$ such that $I\mathfrak{p}^{-1} = \mathfrak{p}_1 \cdots \mathfrak{p}_n$. Then $I = \mathfrak{p} \cdot \mathfrak{p}_1 \cdots \mathfrak{p}_n$, a contradiction. Thus every ideal can be written as a product of primes.

Suppose $\mathfrak{p}_1 \cdots \mathfrak{p}_n = \mathfrak{q}_1 \cdots \mathfrak{q}_m$. If no $\mathfrak{q}_i$ is contained in $\mathfrak{p}_1$, then for each i there is an $a_i \in \mathfrak{q}_i$ such that $a_i \notin \mathfrak{p}_1$. But the product of the a_i is in the $\mathfrak{p}_1 \cdots \mathfrak{p}_n$, which is a subset of $\mathfrak{p}_1$, which contradicts the fact that $\mathfrak{p}_1$ is a prime ideal. Thus $\mathfrak{q}_i = \mathfrak{p}_1$ for some i. We can thus cancel $\mathfrak{q}_i$ and $\mathfrak{p}_1$ from both sides of the equation. Repeating this argument finishes the proof of uniqueness. □

Corollary 6.1.10. *If I is a fractional ideal of $\mathcal{O}_K$ then there exists prime ideals $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$ and $\mathfrak{q}_1, \ldots, \mathfrak{q}_m$, unique up to order, such that*

$$I = (\mathfrak{p}_1 \cdots \mathfrak{p}_n)(\mathfrak{q}_1 \cdots \mathfrak{q}_m)^{-1}.$$

Proof. We have $I = (a/b)J$ for some $a, b \in \mathcal{O}_K$ and integral ideal J. Applying Theorem 6.1.10 to (a), (b), and J gives an expression as claimed. For uniqueness, if one has two such product expressions, multiply through by the denominators and use the uniqueness part of Theorem 6.1.10 □

Example 6.1.11. The ring of integers of $K = \mathbf{Q}(\sqrt{-6})$ is $\mathcal{O}_K = \mathbf{Z}[\sqrt{-6}]$. In $\mathcal{O}_K$, we have

$$6 = -\sqrt{-6}\sqrt{-6} = 2 \cdot 3.$$

If $ab = \sqrt{-6}$, with $a, b \in \mathcal{O}_K$ and neither a unit, then $\mathrm{Norm}(a)\,\mathrm{Norm}(b) = 6$, so without loss $\mathrm{Norm}(a) = 2$ and $\mathrm{Norm}(b) = 3$. If $a = c + d\sqrt{-6}$, then $\mathrm{Norm}(a) = c^2 + 6d^2$; since the equation $c^2 + 6d^2 = 2$ has no solution with $c, d \in \mathbf{Z}$, there is no element in $\mathcal{O}_K$ with norm 2, so $\sqrt{-6}$ is irreducible. Also, $\sqrt{-6}$ is not a unit times 2 or times 3, since again the norms would not match up. Thus 6 can not be written uniquely as a product of irreducibles in $\mathcal{O}_K$. Theorem 6.1.9, however, implies that the principal ideal (6) can, however, be written uniquely as a product of prime ideals. Using MAGMA we find such a decomposition:

```
> R<x> := PolynomialRing(RationalField());
> K := NumberField(x^2+6);
> OK := MaximalOrder(K);
         > [K!b : b in Basis(OK)];
         [
             1,
             K.1    // this is sqrt(-6)
         ]
         > Factorization(6*OK);
         [
             <Prime Ideal of OK
             Two element generators:
                 [2, 0]
                 [2, 1], 2>,
             <Prime Ideal of OK
             Two element generators:
                 [3, 0]
                 [3, 1], 2>
         ]
```

The output means that

$$(6) = (2, 2 + \sqrt{-6})^2 \cdot (3, 3 + \sqrt{-6})^2,$$

where each of the ideals $(2, 2 + \sqrt{-6})$ and $(3, 3 + \sqrt{-6})$ is prime. I will discuss algorithms for computing such a decomposition in detail, probably next week. The first idea is to write $(6) = (2)(3)$, and hence reduce to the case of writing the (p), for $p \in \mathbf{Z}$ prime, as a product of primes. Next one decomposes the Artinian ring $\mathcal{O}_K \otimes \mathbf{F}_p$ as a product of local Artinian rings.

Chapter 7

Computing

7.1 Algorithms for Algebraic Number Theory

I think the best overall reference for algorithms for doing basic algebraic number theory computations is [Coh93].

Our main long-term algorithmic goals for this book (which we won't succeed at reaching) are to understand good algorithms for solving the following problems in particular cases:

- **Ring of integers:** Given a number field K (by giving a polynomial), compute the full ring $\mathcal{O}_K$ of integers.

- **Decomposition of primes:** Given a prime number $p \in \mathbf{Z}$, find the decomposition of the ideal $p\mathcal{O}_K$ as a product of prime ideals of $\mathcal{O}_K$.

- **Class group:** Compute the group of equivalence classes of nonzero ideals of $\mathcal{O}_K$, where I and J are equivalent if there exists $\alpha \in \mathcal{O}_K$ such that $IJ^{-1} = (\alpha)$.

- **Units:** Compute generators for the group of units of $\mathcal{O}_K$.

As we will see, somewhat surprisingly it turns out that algorithmically by far the most time-consuming step in computing the ring of integers $\mathcal{O}_K$ seems to be to factor the discriminant of a polynomial whose root generates the field K. The algorithm(s) for computing $\mathcal{O}_K$ are quite complicated to describe, but the first step is to factor this discriminant, and it takes much longer in practice than all the other complicated steps.

7.2 Using MAGMA

This section is a first introduction to MAGMA for algebraic number theory. MAGMA is a good general purpose package for doing algebraic number theory computations. You can use it via the web page `http://modular.fas.harvard.edu/calc`. MAGMA is not free, but student discounts are available.

The following examples illustrate what we've done so far in the course using Magma, and a little of where we are going. Feel free to ask questions as we go.

7.2.1 Smith Normal Form

On the first day of class we learned about Smith normal forms of matrices.

```
> A := Matrix(2,2,[1,2,3,4]);
> A;
[1 2]
[3 4]
> SmithForm(A);
[1 0]
[0 2]

[ 1  0]
[-1  1]

[-1  2]
[ 1 -1]
```

As you can see, Magma computed the Smith form, which is $\begin{pmatrix}1 & 0\\ 0 & 2\end{pmatrix}$. What are the other two matrices it output? To see what any Magma command does, type the command by itself with no arguments followed by a semicolon.

```
> SmithForm;
Intrinsic 'SmithForm'

Signatures:

    (<Mtrx> X) -> Mtrx, AlgMatElt, AlgMatElt
    [
        k: RngIntElt,
        NormType: MonStgElt,
        Partial: BoolElt,
        RightInverse: BoolElt
    ]

        The smith form S of X, together with unimodular matrices
        P and Q such that P * X * Q = S.
```

As you can see, `SmithForm` returns three arguments, a matrix and matrices P and Q that transform the input matrix to Smith normal form. The syntax to "receive" three return arguments is natural, but uncommon in other programming languages:

```
> S, P, Q := SmithForm(A);
> S;
[1 0]
[0 2]
> P;
[ 1  0]
[-1  1]
> Q;
[-1  2]
[ 1 -1]
> P*A*Q;
[1 0]
[0 2]
```

Next, let's test the limits. We make a 10 × 10 integer matrix with entries between 0 and 99, and compute its Smith normal form.

```
> A := Matrix(10,10,[Random(100) : i in [1..100]]);
> time B := SmithForm(A);
Time: 0.000
```

Let's print the first row of A, the first and last row of B, and the diagonal of B:

```
> A[1];
( 4 48 84  3 58 61 53 26  9  5)
> B[1];
(1 0 0 0 0 0 0 0 0 0)
> B[10];
(0 0 0 0 0 0 0 0 0 51805501538039733)
> [B[i,i] : i in [1..10]];
[ 1, 1, 1, 1, 1, 1, 1, 1, 1, 51805501538039733 ]
```

Let's see how big we have to make A in order to slow down MAGMA. These timings below are on a 1.6Ghz Pentium 4-M laptop running Magma V2.11 under VMware Linux. I tried exactly the same computation running Magma V2.17 natively under Windows XP on the same machine, and it takes *twice* as long to do each computation, which is strange.

```
> n := 50; A := Matrix(n,n,[Random(100) : i in [1..n^2]]);
> time B := SmithForm(A);
Time: 0.050
> n := 100; A := Matrix(n,n,[Random(100) : i in [1..n^2]]);
> time B := SmithForm(A);
Time: 0.800
> n := 150; A := Matrix(n,n,[Random(100) : i in [1..n^2]]);
> time B := SmithForm(A);
```

```
Time: 4.900
> n := 200; A := Matrix(n,n,[Random(100) : i in [1..n^2]]);
> time B := SmithForm(A);
Time: 19.160
```

Magma can also work with finitely generated abelian groups.

```
> G := AbelianGroup([3,5,18]);
> G;
Abelian Group isomorphic to Z/3 + Z/90
Defined on 3 generators
Relations:
    3*G.1 = 0
    5*G.2 = 0
    18*G.3 = 0
> #G;
270
> H := sub<G | [G.1+G.2]>;
> #H;
15
> G/H;
Abelian Group isomorphic to Z/18
```

7.2.2 $\overline{\mathbf{Q}}$ and Number Fields

Magma has many commands for doing basic arithmetic with $\overline{\mathbf{Q}}$.

```
> Qbar := AlgebraicClosure(RationalField());
> Qbar;
> S<x> := PolynomialRing(Qbar);
> r := Roots(x^3-2);
> r;
[
    <r1, 1>,
    <r2, 1>,
    <r3, 1>
]
> a := r[1][1];
> MinimalPolynomial(a);
x^3 - 2
> s := Roots(x^2-7);
> b := s[1][1];
> MinimalPolynomial(b);
x^2 - 7
> a+b;
```

```
r4 + r1
> MinimalPolynomial(a+b);
x^6 - 21*x^4 - 4*x^3 + 147*x^2 - 84*x - 339
> Trace(a+b);
0
> Norm(a+b);
-339
```

There are few commands for general algebraic number fields, so usually we work in specific finitely generated subfields:

```
> MinimalPolynomial(a+b);
x^6 - 21*x^4 - 4*x^3 + 147*x^2 - 84*x - 339
> K := NumberField($1) ;  // $1 = result of previous computation.
> K;
Number Field with defining polynomial x^6 - 21*x^4 - 4*x^3 +
    147*x^2 - 84*x - 339 over the Rational Field
```

We can also define relative extensions of number fields and pass to the corresponding absolute extension.

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^3-2);   // a is the image of x in Q[x]/(x^3-2)
> a;
a
> a^3;
2
> S<y> := PolynomialRing(K);
> L<b> := NumberField(y^2-a);
> L;
Number Field with defining polynomial y^2 - a over K
> b^2;
a
> b^6;
2
> AbsoluteField(L);
Number Field with defining polynomial x^6 - 2 over the Rational
Field
```

7.2.3 Rings of integers

Magma computes rings of integers of number fields.

```
> RingOfIntegers(K);
Maximal Equation Order with defining polynomial x^3 - 2 over ZZ
> RingOfIntegers(L);
```

```
Maximal Equation Order with defining polynomial x^2 + [0, -1, 0]
over its ground order
```

Sometimes the ring of integers of $\mathbf{Q}(a)$ isn't just $\mathbf{Z}[a]$. First a simple example, then a more complicated one:

```
> K<a> := NumberField(2*x^2-3);   // doesn't have to be monic
> 2*a^2 - 3;
0
> K;
Number Field with defining polynomial x^2 - 3/2 over the Rational
Field
> O := RingOfIntegers(K);
> O;
Maximal Order of Equation Order with defining polynomial 2*x^2 -
    3 over ZZ
> Basis(O);
[
    O.1,
    O.2
]
> [K!x : x in Basis(O)];
[
    1,
    2*a       // this is Sqrt(3)
]
```

Here's are some more examples:

```
> procedure ints(f)   // (procedures don't return anything; functions do)
      K<a> := NumberField(f);
      O := MaximalOrder(K);
      print [K!z : z in Basis(O)];
  end procedure;
> ints(x^2-5);
[
    1,
    1/2*(a + 1)
]
> ints(x^2+5);
[
    1,
    a
]
> ints(x^3-17);
```

```
[
    1,
    a,
    1/3*(a^2 + 2*a + 1)
]
> ints(CyclotomicPolynomial(7));
[
    1,
    a,
    a^2,
    a^3,
    a^4,
    a^5
]
> ints(x^5+&+[Random(10)*x^i : i in [0..4]]);  // RANDOM
[
    1,
    a,
    a^2,
    a^3,
    a^4
]
> ints(x^5+&+[Random(10)*x^i : i in [0..4]]);  // RANDOM
[
    1,
    a,
    a^2,
    1/2*(a^3 + a),
    1/16*(a^4 + 7*a^3 + 11*a^2 + 7*a + 14)
]
```

Lets find out how high of a degree Magma can easily deal with.

```
> d := 10; time ints(x^10+&+[Random(10)*x^i : i in [0..d-1]]);
[
    1, a, a^2, a^3, a^4, a^5, a^6, a^7, a^8, a^9
]
Time: 0.030
> d := 15; time ints(x^10+&+[Random(10)*x^i : i in [0..d-1]]);
[
    1,
    7*a,
    7*a^2 + 4*a,
    7*a^3 + 4*a^2 + 4*a,
    7*a^4 + 4*a^3 + 4*a^2 + a,
    7*a^5 + 4*a^4 + 4*a^3 + a^2 + a,
    7*a^6 + 4*a^5 + 4*a^4 + a^3 + a^2 + 4*a,
    7*a^7 + 4*a^6 + 4*a^5 + a^4 + a^3 + 4*a^2,
    7*a^8 + 4*a^7 + 4*a^6 + a^5 + a^4 + 4*a^3 + 4*a,
    7*a^9 + 4*a^8 + 4*a^7 + a^6 + a^5 + 4*a^4 + 4*a^2 + 5*a,
    7*a^10 + 4*a^9 + 4*a^8 + a^7 + a^6 + 4*a^5 + 4*a^3 + 5*a^2 +  4*a,
  ...
]
Time: 0.480
> d := 20; time ints(x^10+&+[Random(10)*x^i : i in [0..d-1]]);
[
    1,
    2*a,
    4*a^2,
    8*a^3,
    8*a^4 + 2*a^2 + a,
    8*a^5 + 2*a^3 + 3*a^2,
 ...]
Time: 3.940
> d := 25; time ints(x^10+&+[Random(10)*x^i : i in [0..d-1]]);
... I stopped it after a few minutes...
```

We can also define orders in rings of integers.

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^3-2);
> O := Order([2*a]);
> O;
Transformation of Order over
Equation Order with defining polynomial x^3 - 2 over ZZ
Transformation Matrix:
[1 0 0]
[0 2 0]
[0 0 4]
> OK := MaximalOrder(K);
> Index(OK,O);
8
> Discriminant(O);
-6912
> Discriminant(OK);
-108
> 6912/108;
64    // perfect square...
```

7.2.4 Ideals

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^3-2);
> O := Order([2*a]);
> O;
Transformation of Order over
Equation Order with defining polynomial x^3 - 2 over ZZ
Transformation Matrix:
[1 0 0]
[0 2 0]
[0 0 4]
> OK := MaximalOrder(K);
> Index(OK,O);
8
> Discriminant(O);
-6912
> Discriminant(OK);
-108
> 6912/108;
64    // perfect square...
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^2-7);
> K<a> := NumberField(x^2-5);
> Discriminant(K);
20   // ????????? Yuck!
> OK := MaximalOrder(K);
> Discriminant(OK);
5    // better
> Discriminant(NumberField(x^2-20));
80
> I := 7*OK;
> I;
Principal Ideal of OK
Generator:
    [7, 0]
> J := (OK!a)*OK;    // the ! computes the natural image of a in OK
> J;
Principal Ideal of OK
Generator:
    [-1, 2]
> I*J;
Principal Ideal of OK
Generator:
    [-7, 14]
> J*I;
Principal Ideal of OK
Generator:
    [-7, 14]
> I+J;
Principal Ideal of OK
Generator:
    [1, 0]
>
> Factorization(I);
[
    <Principal Prime Ideal of OK
    Generator:
        [7, 0], 1>
]
> Factorization(3*OK);
[
    <Principal Prime Ideal of OK
    Generator:
        [3, 0], 1>
]
> Factorization(5*OK);
[
    <Prime Ideal of OK
    Two element generators:
        [5, 0]
        [4, 2], 2>
]
> Factorization(11*OK);
[
    <Prime Ideal of OK
    Two element generators:
        [11, 0]
        [14, 2], 1>,
    <Prime Ideal of OK
    Two element generators:
        [11, 0]
        [17, 2], 1>
]
```

We can even work with fractional ideals in MAGMA.

```
> K<a> := NumberField(x^2-5);
> OK := MaximalOrder(K);
> I := 7*OK;
> J := (OK!a)*OK;
> M := I/J;
> M;
Fractional Principal Ideal of OK
Generator:
    -7/5*OK.1 + 14/5*OK.2
> Factorization(M);
[
    <Prime Ideal of OK
    Two element generators:
        [5, 0]
        [4, 2], -1>,
    <Principal Prime Ideal of OK
    Generator:
        [7, 0], 1>
]
```

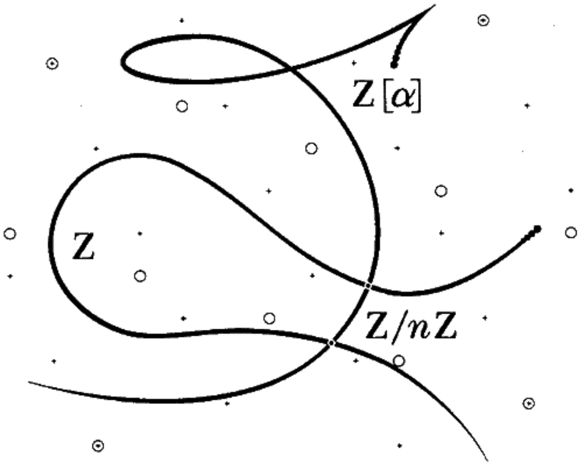
In the next chapter, we will learn about discriminants and an algorithm for "factoring primes", that is writing an ideal $p\mathcal{O}_K$ as a product of prime ideals of $\mathcal{O}_K$.

Chapter 8

Factoring Primes

First we will learn how, if $p \in \mathbf{Z}$ is a prime and $\mathcal{O}_K$ is the ring of integers of a number field, to write $p\mathcal{O}_K$ as a product of primes of $\mathcal{O}_K$. Then I will sketch the main results and definitions that we will study in detail during the next few chapters. We will cover discriminants and norms of ideals, define the class group of $\mathcal{O}_K$ and prove that it is finite and computable, and define the group of units of $\mathcal{O}_K$, determine its structure, and prove that it is also computable.

8.1 Factoring Primes



A diagram from [LL93].

"The obvious mathematical breakthrough would be development of an easy way to factor large prime numbers." –Bill Gates, *The Road Ahead*, pg. 265

Let $K = \mathbf{Q}(\alpha)$ be a number field, and let $\mathcal{O}_K$ be the ring of integers of K. To employ our geometric intuition, as the Lenstras did on the cover of [LL93], it is helpful to view $\mathcal{O}_K$ as a one-dimensional scheme

$$X = \operatorname{Spec}(\mathcal{O}_K) = \{ \text{ all prime ideals of } \mathcal{O}_K \ \}$$

over

$$Y = \operatorname{Spec}(\mathbf{Z}) = \{(0)\} \cup \{p\mathbf{Z} : p \in \mathbf{Z} \text{ is prime } \}.$$

There is a natural map $\pi : X \to Y$ that sends a prime ideal $\mathfrak{p} \in X$ to $\mathfrak{p} \cap \mathbf{Z} \in Y$. For much more on this point of view, see [EH00, Ch. 2].

Ideals were originally introduced by Kummer because, as we proved last Tuesday, in rings of integers of number fields ideals factor uniquely as products of primes ideals, which is something that is not true for general algebraic integers. (The failure of unique factorization for algebraic integers was used by Liouville to destroy Lamé's purported 1847 "proof" of Fermat's Last Theorem.)

If $p \in \mathbf{Z}$ is a prime number, then the ideal $p\mathcal{O}_K$ of $\mathcal{O}_K$ factors uniquely as a product $\prod \mathfrak{p}_i^{e_i}$, where the $\mathfrak{p}_i$ are maximal ideals of $\mathcal{O}_K$. We may imagine the decomposition of $p\mathcal{O}_K$ into prime ideals geometrically as the fiber $\pi^{-1}(p\mathbf{Z})$ (with multiplicities).

How can we compute $\pi^{-1}(p\mathbf{Z})$ in practice?

Example 8.1.1. The following MAGMA session shows the commands needed to compute the factorization of $p\mathcal{O}_K$ in MAGMA for K the number field defined by a root of $x^5 + 7x^4 + 3x^2 - x + 1$.

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^5 + 7*x^4 + 3*x^2 - x + 1);
> OK := MaximalOrder(K);
> I := 2*OK;
> Factorization(I);
[
<Principal Prime Ideal of OK
Generator:
[2, 0, 0, 0, 0], 1>
]
> J := 5*OK;
> Factorization(J);
[
<Prime Ideal of OK
Two element generators:
[5, 0, 0, 0, 0]
[2, 1, 0, 0, 0], 1>,
<Prime Ideal of OK
Two element generators:
[5, 0, 0, 0, 0]
[3, 1, 0, 0, 0], 2>,
<Prime Ideal of OK
Two element generators:
[5, 0, 0, 0, 0]
[2, 4, 1, 0, 0], 1>
]
> [K!OK.i : i in [1..5]];
[ 1, a, a^2, a^3, a^4 ]
```

Thus $2\mathcal{O}_K$ is already a prime ideal, and

$$5\mathcal{O}_K = (5, 2+a) \cdot (5, 3+a)^2 \cdot (5, 2+4a+a^2).$$

Notice that in this example $\mathcal{O}_K = \mathbf{Z}[a]$. (Warning: There are examples of $\mathcal{O}_K$ such that $\mathcal{O}_K \neq \mathbf{Z}[a]$ for any $a \in \mathcal{O}_K$, as Example 8.1.6 below illustrates.) When $\mathcal{O}_K = \mathbf{Z}[a]$ it is very easy to factor $p\mathcal{O}_K$, as we will see below. The following factorization gives a hint as to why:

$$x^5 + 7x^4 + 3x^2 - x + 1 \equiv (x+2) \cdot (x+3)^2 \cdot (x^2 + 4x + 2) \pmod 5.$$

The exponent 2 of $(5, 3+a)^2$ in the factorization of $5\mathcal{O}_K$ above suggests "ramification", in the sense that the cover $X \to Y$ has less points (counting their "size", i.e., their residue class degree) in its fiber over 5 than it has generically. Here's a suggestive picture:

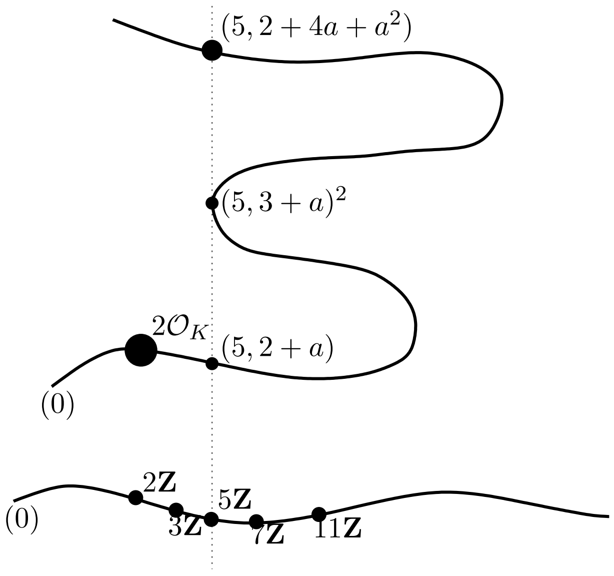


Diagram of $\mathrm{Spec}(\mathcal{O}_K) \to \mathrm{Spec}(\mathbf{Z})$

8.1.1 A Method for Factoring that Often Works

Suppose $a \in \mathcal{O}_K$ is such that $K = \mathbf{Q}(a)$, and let $g(x)$ be the minimal polynomial of a. Then $\mathbf{Z}[a] \subset \mathcal{O}_K$, and we have a diagram of schemes

$$\begin{tikzcd}
(??) \arrow[r, hook] \arrow[d] & \mathrm{Spec}(\mathcal{O}_K) \arrow[d] \\
\bigcup \mathrm{Spec}(\mathbf{F}_p[x]/(\overline{g}_i^{e_i})) \arrow[r, hook] \arrow[d] & \mathrm{Spec}(\mathbf{Z}[a]) \arrow[d] \\
\mathrm{Spec}(\mathbf{F}_p) \arrow[r, hook] & \mathrm{Spec}(\mathbf{Z})
\end{tikzcd}$$

where $\overline{g} = \prod_i \overline{g}_i^{e_i}$ is the factorization of the image of g in $\mathbf{F}_p[x]$.

The cover $\pi : \mathrm{Spec}(\mathbf{Z}[a]) \to \mathrm{Spec}(\mathbf{Z})$ is easy to understand because it is defined by the single equation $g(x)$. To give a maximal ideal $\mathfrak{p}$ of $\mathbf{Z}[a]$ such that $\pi(\mathfrak{p}) = p\mathbf{Z}$ is the same as giving a homomorphism $\varphi : \mathbf{Z}[x]/(g) \to \overline{\mathbf{F}}_p$ (up to automorphisms of the image), which is in turn the same as giving a root of g in $\overline{\mathbf{F}}_p$ (up to automorphism), which is the same as giving an irreducible factor of the reduction of g modulo p.

Lemma 8.1.2. *Suppose the index of $\mathbf{Z}[a]$ in $\mathcal{O}_K$ is coprime to p. Then the primes $\mathfrak{p}_i$ in the factorization of $p\mathbf{Z}[a]$ do not decompose further going from $\mathbf{Z}[a]$ to $\mathcal{O}_K$, so finding the prime ideals of $\mathbf{Z}[a]$ that contain p yields the factorization of $p\mathcal{O}_K$.*

Proof. Hi-brow argument: By hypothesis we have an exact sequence of abelian groups

$$0 \to \mathbf{Z}[a] \to \mathcal{O}_K \to H \to 0,$$

where H is a finite abelian group of order coprime to p. Tensor product is right exact, and there is an exact sequence

$$\mathrm{Tor}_1(H, \mathbf{F}_p) \to \mathbf{Z}[a] \otimes \mathbf{F}_p \to \mathcal{O}_K \otimes \mathbf{F}_p \to H \otimes \mathbf{F}_p \to 0,$$

and $\mathrm{Tor}_1(H, \mathbf{F}_p) = H \otimes \mathbf{F}_p = 0$, so $\mathbf{Z}[a] \otimes \mathbf{F}_p \cong \mathcal{O}_K \otimes \mathbf{F}_p$.

Low-brow argument: The inclusion map $\mathbf{Z}[a] \hookrightarrow \mathcal{O}_K$ is defined by a matrix over $\mathbf{Z}$ that has determinant $\pm[\mathcal{O}_K : \mathbf{Z}[a]]$, which is coprime to p. The reduction of this matrix modulo p is invertible, so it defines an isomorphism $\mathbf{Z}[a] \otimes \mathbf{F}_p \to \mathcal{O}_K \otimes \mathbf{F}_p$. Any homomorphism $\mathcal{O}_K \to \overline{\mathbf{F}}_p$ is the composition of a homomorphism $\mathcal{O}_K \to \mathcal{O}_K \otimes \mathbf{F}_p$ with a homomorphism $\mathcal{O}_K \otimes \mathbf{F}_p \to \overline{\mathbf{F}}_p$. Since $\mathcal{O}_K \otimes \mathbf{F}_p \cong \mathbf{Z}[a] \otimes \mathbf{F}_p$, the homomorphisms $\mathcal{O}_K \to \overline{\mathbf{F}}_p$ are in bijection with the homomorphisms $\mathbf{Z}[a] \to \overline{\mathbf{F}}_p$, which proves the lemma. □

As suggested in the proof of the lemma, we find all homomorphisms $\mathcal{O}_K \to \overline{\mathbf{F}}_p$ by finding all homomorphism $\mathbf{Z}[a] \to \overline{\mathbf{F}}_p$. In terms of ideals, if $\mathfrak{p} = (g(a), p)\mathbf{Z}[a]$ is a maximal ideal of $\mathbf{Z}[a]$, then the ideal $\mathfrak{p}' = (g(a), p)\mathcal{O}_K$ of $\mathcal{O}_K$ is also maximal, since

$$\mathcal{O}_K/\mathfrak{p}' \cong (\mathcal{O}_K \otimes \mathbf{F}_p)/(g(\tilde{a})) \cong (\mathbf{Z}[a] \otimes \mathbf{F}_p)/(g(\tilde{a})) \subset \overline{\mathbf{F}}_p.$$

We formalize the above discussion in the following theorem:

Theorem 8.1.3. *Let $f(x)$ denote the minimal polynomial of a over $\mathbf{Q}$. Suppose that $p \nmid [\mathcal{O}_K : \mathbf{Z}[a]]$ is a prime. Let*

$$\overline{f} = \prod_{i=1}^{t} \overline{f}_i^{e_i} \in \mathbf{F}_p[x]$$

where the $\overline{f}_i$ are distinct monic irreducible polynomials. Let $\mathfrak{p}_i = (p, f_i(a))$ where $f_i \in \mathbf{Z}[x]$ is a lift of $\overline{f}_i$ in $\mathbf{F}_p[X]$. Then

$$p\mathcal{O}_K = \prod_{i=1}^{t} \mathfrak{p}_i^{e_i}.$$

We return to the example from above, in which $K = \mathbf{Q}(a)$, where a is a root of $x^5+7x^4+3x^2-x+1$. According to Magma, the maximal order $\mathcal{O}_K$ has discriminant 2945785:

```
> Discriminant(MaximalOrder(K));
2945785
```

The order $\mathbf{Z}[a]$ has the same discriminant as $\mathcal{O}_K$, so $\mathbf{Z}[a] = \mathcal{O}_K$ and we can apply the above theorem.

```
> Discriminant(x^5 + 7*x^4 + 3*x^2 - x + 1);
2945785
```

We have

$$x^5 + 7x^4 + 3x^2 - x + 1 \equiv (x+2) \cdot (x+3)^2 \cdot (x^2 + 4x + 2) \pmod{5},$$

which yields the factorization of $5\mathcal{O}_K$ given before the theorem.

If we replace a by $b = 7a$, then the index of $\mathbf{Z}[b]$ in $\mathcal{O}_K$ will be a power of 7, which is coprime to 5, so the above method will still work.

```
> f:=MinimalPolynomial(7*a);
> f;
x^5 + 49*x^4 + 1029*x^2 - 2401*x + 16807
> Discriminant(f);
235050861175510968365785
> Discriminant(f)/Discriminant(MaximalOrder(K));
79792266297612001    // coprime to 5
> S<t> := PolynomialRing(GF(5));
> Factorization(S!f);
[
    <t + 1, 2>,
    <t + 4, 1>,
    <t^2 + 3*t + 3, 1>
]
```

Thus 5 factors in $\mathcal{O}_K$ as

$$5\mathcal{O}_K = (5, 7a+1)^2 \cdot (5, 7a+4) \cdot (5, (7a)^2 + 3(7a) + 3).$$

If we replace a by $b = 5a$ and try the above algorithm with $\mathbf{Z}[b]$, then the method fails because the index of $\mathbf{Z}[b]$ in $\mathcal{O}_K$ is divisible by 5.

```
> f:=MinimalPolynomial(5*a);
> f;
x^5 + 35*x^4 + 375*x^2 - 625*x + 3125
> Discriminant(f) / Discriminant(MaximalOrder(K));
95367431640625    // divisible by 5
> Factorization(S!f);
[
    <t, 5>
]
```

8.1.2 A Method for Factoring that Always Works

There are numbers fields K such that $\mathcal{O}_K$ is not of the form $\mathbf{Z}[a]$ for any $a \in K$. Even worse, Dedekind found a field K such that $2 \mid [\mathcal{O}_K : \mathbf{Z}[a]]$ for *all* $a \in \mathcal{O}_K$, so there is no choice of a such that Theorem 8.1.3 can be used to factor 2 for K (see Example 8.1.6 below).

Most algebraic number theory books do not describe an algorithm for decomposing primes in the general case. Fortunately, Cohen's book [Coh93, §6.2]) describes how to solve the general problem. The solutions are somewhat surprising, since the algorithms are much more sophisticated than the one suggested by Theorem 8.1.3. However, these complicated algorithms all run very quickly in practice, even without assuming the maximal order is already known.

For simplicity we consider the following slightly easier problem whose solution contains the key ideas: *Let $\mathcal{O}$ be any order in $\mathcal{O}_K$ and let p be a prime of $\mathbf{Z}$. Find the prime ideals of $\mathcal{O}$ that contain p.*

To go from this special case to the general case, given a prime p that we wish to factor in $\mathcal{O}_K$, we find a p-maximal order $\mathcal{O}$, i.e., an order $\mathcal{O}$ such that $[\mathcal{O}_K : \mathcal{O}]$ is coprime to p. A p-maximal order can be found very quickly in practice using the "round 2" or "round 4" algorithms. (Remark: Later we will see that to compute $\mathcal{O}_K$, we take the sum of p-maximal orders, one for every p such that p^2 divides $\mathrm{Disc}(\mathcal{O}_K)$. The time-consuming part of this computation of $\mathcal{O}_K$ is finding the primes p such that $p^2 \mid \mathrm{Disc}(\mathcal{O}_K)$, not finding the p-maximal orders. Thus a fast algorithm for factoring integers would not only break many cryptosystems, but would massively speed up computation of the ring of integers of a number field.)

Algorithm 8.1.4. Suppose $\mathcal{O}$ is an order in the ring $\mathcal{O}_K$ of integers of a number field K. For any prime $p \in \mathbf{Z}$, the following (sketch of an) algorithm computes the set of maximal ideals of $\mathcal{O}$ that contain p.

Sketch of algorithm. Let $K = \mathbf{Q}(a)$ be a number field given by an algebraic integer a as a root of its minimal monic polynomial f of degree n. We assume that an order $\mathcal{O}$ has been given by a basis $w_1, \ldots, w_n$ and that $\mathcal{O}$ that contains $\mathbf{Z}[a]$. Each of the following steps can be carried out efficiently using little more than linear algebra over $\mathbf{F}_p$. The details are in [Coh93, §6.2.5].

1. [Check if easy] If $p \nmid \mathrm{disc}(\mathbf{Z}[a])/\mathrm{disc}(\mathcal{O})$ (so $p \nmid [\mathcal{O} : \mathbf{Z}[a]]$), then by a slight modification of Theorem 8.1.3, we easily factor $p\mathcal{O}$.

2. [Compute radical] Let I be the *radical* of $p\mathcal{O}$, which is the ideal of elements $x \in \mathcal{O}$ such that $x^m \in p\mathcal{O}$ for some positive integer m. Using linear algebra over the finite field $\mathbf{F}_p$, we can quickly compute a basis for $I/p\mathcal{O}$. (We never compute $I \subset \mathcal{O}$.)

3. [Compute quotient by radical] Compute an $\mathbf{F}_p$ basis for
$$A = \mathcal{O}/I = (\mathcal{O}/p\mathcal{O})/(I/p\mathcal{O}).$$
The second equality comes from the fact that $p\mathcal{O} \subset I$, which is clear by definition. Note that $\mathcal{O}/p\mathcal{O} \cong \mathcal{O} \otimes \mathbf{F}_p$ is obtained by simply reducing the basis $w_1, \ldots, w_n$ modulo p.

4. [Decompose quotient] The ring A is a finite Artin ring with no nilpotents, so it decomposes as a product $A \cong \prod \mathbf{F}_p[x]/g_i(x)$ of fields. We can quickly find such a decomposition explicitly, as described in [Coh93, §6.2.5].

5. [Compute the maximal ideals over p] Each maximal ideal $\mathfrak{p}_i$ lying over p is the kernel of $\mathcal{O} \to A \to \mathbf{F}_p[x]/g_i(x)$.

The algorithm finds all primes of $\mathcal{O}$ that contain the radical I of $p\mathcal{O}$. Every such prime clearly contains p, so to see that the algorithm is correct, we must prove that the primes $\mathfrak{p}$ of $\mathcal{O}$ that contain p also contain I. If $\mathfrak{p}$ is a prime of $\mathcal{O}$ that contains p, then $p\mathcal{O} \subset \mathfrak{p}$. If $x \in I$ then $x^m \in p\mathcal{O}$ for some m, so $x^m \in \mathfrak{p}$ which implies that $x \in \mathfrak{p}$ by primality of $\mathfrak{p}$. Thus $\mathfrak{p}$ contains I, as required.

8.1.3 Essential Discriminant Divisors

Definition 8.1.5. A prime p is an *essential discriminant divisor* if $p \mid [\mathcal{O}_K : \mathbf{Z}[a]]$ for *every* $a \in \mathcal{O}_K$.

Since $[\mathcal{O}_K : \mathbf{Z}[a]]$ is the absolute value of $\mathrm{Disc}(f(x))/\mathrm{Disc}(\mathcal{O}_K)$, where $f(x)$ is the characteristic polynomial of $f(x)$, an essential discriminant divisor divides the discriminant of the characteristic polynomial of any element of $\mathcal{O}_K$.

Example 8.1.6 *(Dedekind).* Let $K = \mathbf{Q}(a)$ be the cubic field defined by a root a of the polynomial $f = x^3 + x^2 - 2x + 8$. We will use MAGMA, which implements the algorithm described in the previous section, to show that 2 is an essential discriminant divisor for K.

```
> K<a> := NumberField(x^3 + x^2 - 2*x + 8);
> OK := MaximalOrder(K);
> Factorization(2*OK);
[
<Prime Ideal of OK
Basis:
[2 0 0]
[0 1 0]
[0 0 1], 1>,
<Prime Ideal of OK
Basis:
[1 0 1]
[0 1 0]
[0 0 2], 1>,
<Prime Ideal of OK
Basis:
[1 0 1]
[0 1 1]
[0 0 2], 1>
]
```

Thus $2\mathcal{O}_K = \mathfrak{p}_1\mathfrak{p}_2\mathfrak{p}_3$, with the $\mathfrak{p}_i$ distinct. Moreover, one can check that $\mathcal{O}_K/\mathfrak{p}_i \cong \mathbf{F}_2$. If $\mathcal{O}_K = \mathbf{Z}[a]$ for some $a \in \mathcal{O}_K$ with minimal polynomial g, then $\overline{g}(x) \in \mathbf{F}_2[x]$ must be a product of three *distinct* linear factors, which is impossible.

Chapter 9

Chinese Remainder Theorem

In this section we will prove the Chinese Remainder Theorem for rings of integers, deduce several surprising and useful consequences, then learn about discriminants, and finally norms of ideals. We will also define the class group of $\mathcal{O}_K$ and state the main theorem about it. The tools we develop here illustrate the power of what we have already proved about rings of integers, and will be used over and over again to prove other deeper results in algebraic number theory. It is essentially to understand everything we discuss in this chapter very well.

9.1 The Chinese Remainder Theorem

Recall that the Chinese Remainder Theorem from elementary number theory asserts that if $n_1, \ldots, n_r$ are integers that are coprime in pairs, and $a_1, \ldots, a_r$ are integers, then there exists an integer a such that $a \equiv a_i \pmod{n_i}$ for each $i = 1, \ldots, r$. In terms of rings, the Chinese Remainder Theorem asserts that the natural map

$$\mathbf{Z}/(n_1 \cdots n_r)\mathbf{Z} \to (\mathbf{Z}/n_1\mathbf{Z}) \oplus \cdots \oplus (\mathbf{Z}/n_r\mathbf{Z})$$

is an isomorphism. This result generalizes to rings of integers of number fields.

Lemma 9.1.1. *If I and J are coprime ideals in $\mathcal{O}_K$, then $I \cap J = IJ$.*

Proof. The ideal $I \cap J$ is the largest ideal of $\mathcal{O}_K$ that is divisible by (contained in) both I and J. Since I and J are coprime, $I \cap J$ is divisible by IJ, i.e., $I \cap J \subset IJ$. By definition of ideal $IJ \subset I \cap J$, which completes the proof. □

Remark 9.1.2. This lemma is true for any ring R and ideals $I, J \subset R$ such that $I + J = R$. For the general proof, choose $x \in I$ and $y \in J$ such that $x + y = 1$. If $c \in I \cap J$ then

$$c = c \cdot 1 = c \cdot (x + y) = cx + cy \in IJ + IJ = IJ,$$

so $I \cap J \subset IJ$, and the other inclusion is obvious by definition.

Theorem 9.1.3 (Chinese Remainder Theorem). *Suppose $I_1, \ldots, I_r$ are ideals of $\mathcal{O}_K$ such that $I_m + I_n = \mathcal{O}_K$ for any $m \neq n$. Then the natural homomorphism $\mathcal{O}_K \to \bigoplus_{n=1}^r (\mathcal{O}_K/I_n)$ induces an isomorphism*

$$\mathcal{O}_K/\left(\prod_{n=1}^r I_n\right) \to \bigoplus_{n=1}^r (\mathcal{O}_K/I_n).$$

Thus given any $a_n \in I_n$ then there exists $a \in \mathcal{O}_K$ such that $a \equiv a_n \pmod{I_n}$ for $n = 1, \ldots, r$.

Proof. First assume that we know the theorem in the case when the I_n are powers of prime ideals. Then we can deduce the general case by noting that each $\mathcal{O}_K/I_n$ is isomorphic to a product $\prod \mathcal{O}_K/\mathfrak{p}_m^{e_m}$, where $I_n = \prod \mathfrak{p}_m^{e_m}$, and $\mathcal{O}_K/(\prod_n I_n)$ is isomorphic to the product of the $\mathcal{O}_K/\mathfrak{p}^e$, where the $\mathfrak{p}$ and e run through the same prime powers as appear on the right hand side.

It thus suffices to prove that if $\mathfrak{p}_1, \ldots, \mathfrak{p}_r$ are distinct prime ideals of $\mathcal{O}_K$ and $e_1, \ldots, e_r$ are positive integers, then

$$\psi : \mathcal{O}_K/\left(\prod_{n=1}^r \mathfrak{p}_n^{e_n}\right) \to \bigoplus_{n=1}^r (\mathcal{O}_K/\mathfrak{p}_n^{e_n})$$

is an isomorphism. Let $\varphi : \mathcal{O}_K \to \oplus_{n=1}^r (\mathcal{O}_K/\mathfrak{p}_n^{e_n})$ be the natural map induced by reduction mod $\mathfrak{p}_n^{e_n}$. Then kernel of φ is $\cap_{n=1}^r \mathfrak{p}_n^{e_n}$, which by Lemma 9.1.1 is equal to $\prod_{n=1}^r \mathfrak{p}_n^{e_n}$, so ψ is injective. Note that the projection $\mathcal{O}_K \to \mathcal{O}_K/\mathfrak{p}_n^{e_n}$ of φ onto each factor is obviously surjective, so it suffices to show that the element $(1, 0, \ldots, 0)$ is in the image of φ (and the similar elements for the other factors). Since $J = \prod_{n=2}^r \mathfrak{p}_n^{e_n}$ is not divisible by $\mathfrak{p}_1$, hence not contained in $\mathfrak{p}_1$, there is an element $a \in J$ with $a \notin \mathfrak{p}_1$. Since $\mathfrak{p}_1$ is maximal, $\mathcal{O}_K/\mathfrak{p}_1$ is a field, so there exists $b \in \mathcal{O}_K$ such that $ab = 1 - c$, for some $c \in \mathfrak{p}_1$. Then

$$1 - c^{n_1} = (1 - c)(1 + c + c^2 + \cdots + c^{n_1 - 1}) = ab(1 + c + c^2 + \cdots + c^{n_1 - 1})$$

is congruent to 0 mod $\mathfrak{p}_n^{e_n}$ for each $n \geq 2$ since it is in $\prod_{n=2}^r \mathfrak{p}_n^{e_n}$, and it is congruent to 1 modulo $\mathfrak{p}_1^{n_1}$. □

Remark 9.1.4. In fact, the surjectivity part of the above proof is easy to prove for any commutative ring; indeed, the above proof illustrates how trying to prove something in a special case can result in a more complicated proof!! Suppose R is a ring and I, J are ideals in R such that $I + J = R$. Choose $x \in I$ and $y \in J$ such that $x + y = 1$. Then $x = 1 - y$ maps to $(0, 1)$ in $R/I \oplus R/J$ and $y = 1 - x$ maps to $(1, 0)$ in $R/I \oplus R/J$. Thus the map $R/(I \cap J) \to R/I \oplus R/J$ is surjective. Also, as mentioned above, $R/(I \cap J) = R/(IJ)$.

Example 9.1.5. The MAGMA command `ChineseRemainderTheorem` implements the algorithm suggested by the above theorem. In the following example, we compute a prime over (3) and a prime over (5) of the ring of integers of $\mathbf{Q}(\sqrt[3]{2})$, and find an element of $\mathcal{O}_K$ that is congruent to $\sqrt[3]{2}$ modulo one prime and 1 modulo the other.

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^3-2);
> OK := MaximalOrder(K);
> I := Factorization(3*OK)[1][1];
> J := Factorization(5*OK)[1][1];
> I;
Prime Ideal of OK
Two element generators:
    [3, 0, 0]
    [4, 1, 0]
> J;
Prime Ideal of OK
Two element generators:
    [5, 0, 0]
    [7, 1, 0]
> b := ChineseRemainderTheorem(I, J, OK!a, OK!1);
> b - a in I;
true
> b - 1 in J;
true
> K!b;
-4
```

The element found by the Chinese Remainder Theorem algorithm in this case is -4.

The following lemma is a nice application of the Chinese Remainder Theorem. We will use it to prove that every ideal of $\mathcal{O}_K$ can be generated by two elements. Suppose I is a nonzero integral ideals of $\mathcal{O}_K$. If $a \in I$, then $(a) \subset I$, so I divides (a) and the quotient $(a)/I$ is an integral ideal. The following lemma asserts that (a) can be chosen so the quotient $(a)/I$ is coprime to any given ideal.

Lemma 9.1.6. *If I, J are nonzero integral ideals in $\mathcal{O}_K$, then there exists an $a \in I$ such that $(a)/I$ is coprime to J.*

Proof. Let $\mathfrak{p}_1, \ldots, \mathfrak{p}_r$ be the prime divisors of J. For each n, let v_n be the largest power of $\mathfrak{p}_n$ that divides I. Choose an element $a_n \in \mathfrak{p}_n^{v_n}$ that is not in $\mathfrak{p}_n^{v_n+1}$ (there is such an element since $\mathfrak{p}_n^{v_n} \neq \mathfrak{p}_n^{v_n+1}$, by unique factorization). By Theorem 9.1.3, there exists $a \in \mathcal{O}_K$ such that

$$a \equiv a_n \pmod{\mathfrak{p}_n^{v_n+1}}$$

for all $n = 1, \ldots, r$ and also

$$a \equiv 0 \pmod{I/\prod \mathfrak{p}_n^{v_n}}.$$

(We are applying the theorem with the coprime integral ideals $\mathfrak{p}_n^{v_n+1}$, for $n = 1, \ldots, r$ and the integral ideal $I/\prod \mathfrak{p}_n^{v_n}$.)

To complete the proof we must show that $(a)/I$ is not divisible by any $\mathfrak{p}_n$, or equivalently, that the $\mathfrak{p}_n^{v_n}$ exactly divides (a). Because $a \equiv a_n \pmod{\mathfrak{p}_n^{v_n+1}}$, there is $b \in \mathfrak{p}_n^{v_n+1}$ such that $a = a_n + b$. Since $a_n \in \mathfrak{p}_n^{v_n}$, it follows that $a \in \mathfrak{p}_n^{v_n}$, so $\mathfrak{p}_n^{v_n}$ divides (a). If $a \in \mathfrak{p}_n^{v_n+1}$, then $a_n = a - b \in \mathfrak{p}_n^{v_n+1}$, a contradiction, so $\mathfrak{p}_n^{v_n+1}$ does not divide (a), which completes the proof. □

Suppose I is a nonzero ideal of $\mathcal{O}_K$. As an abelian group $\mathcal{O}_K$ is free of rank equal to the degree $[K : \mathbf{Q}]$ of K, and I is of finite index in $\mathcal{O}_K$, so I can be generated as an abelian group, hence as an ideal, by $[K : \mathbf{Q}]$ generators. The following proposition asserts something much better, namely that I can be generated *as an ideal* in $\mathcal{O}_K$ by at most two elements.

Proposition 9.1.7. *Suppose I is a fractional ideal in the ring $\mathcal{O}_K$ of integers of a number field. Then there exist $a, b \in K$ such that $I = (a, b)$.*

Proof. If $I = (0)$, then I is generated by 1 element and we are done. If I is not an integral ideal, then there is $x \in K$ such that xI is an integral ideal, and the number of generators of xI is the same as the number of generators of I, so we may assume that I is an integral ideal.

Let a be any nonzero element of the integral ideal I. We will show that there is some $b \in I$ such that $I = (a, b)$. Let $J = (b)$. By Lemma 9.1.6, there exists $a \in I$ such that $(a)/I$ is coprime to (b). The ideal $(a, b) = (a) + (b)$ is the greatest common divisor of (a) and (b), so I divides (a, b), since I divides both (a) and (b). Suppose $\mathfrak{p}^n$ is a prime power that divides (a, b), so $\mathfrak{p}^n$ divides both (a) and (b). Because $(a)/I$ and (b) are coprime and $\mathfrak{p}^n$ divides (b), we see that $\mathfrak{p}^n$ does not divide $(a)/I$, so $\mathfrak{p}^n$ must divide I. Thus (a, b) divides I, so $(a, b) = I$ as claimed. □

We can also use Theorem 9.1.3 to determine the $\mathcal{O}_K$-module structure of the successive quotients $\mathfrak{p}^n/\mathfrak{p}^{n+1}$.

Proposition 9.1.8. *Let $\mathfrak{p}$ be a nonzero prime ideal of $\mathcal{O}_K$, and let $n \geq 0$ be an integer. Then $\mathfrak{p}^n/\mathfrak{p}^{n+1} \cong \mathcal{O}_K/\mathfrak{p}$ as $\mathcal{O}_K$-modules.*

Proof. (Compare page 13 of Swinnerton-Dyer.) Since $\mathfrak{p}^n \neq \mathfrak{p}^{n+1}$ (by unique factorization), we can fix an element $b \in \mathfrak{p}^n$ such that $b \notin \mathfrak{p}^{n+1}$. Let $\varphi : \mathcal{O}_K \to \mathfrak{p}^n/\mathfrak{p}^{n+1}$ be the $\mathcal{O}_K$-module morphism defined by $\varphi(a) = ab$. The kernel of φ is $\mathfrak{p}$ since clearly $\varphi(\mathfrak{p}) = 0$ and if $\varphi(a) = 0$ then $ab \in \mathfrak{p}^{n+1}$, so $\mathfrak{p}^{n+1} \mid (a)(b)$, so $\mathfrak{p} \mid (a)$, since $\mathfrak{p}^{n+1}$ does not divide (b). Thus φ induces an injective $\mathcal{O}_K$-module homomorphism $\mathcal{O}_K/\mathfrak{p} \hookrightarrow \mathfrak{p}^n/\mathfrak{p}^{n+1}$.

It remains to show that φ is surjective, and this is where we will use Theorem 9.1.3. Suppose $c \in \mathfrak{p}^n$. By Theorem 9.1.3 there exists $d \in \mathcal{O}_K$ such that

$$d \equiv c \pmod{\mathfrak{p}^{n+1}} \qquad \text{and} \qquad d \equiv 0 \pmod{(b)/\mathfrak{p}^n}.$$

We have $\mathfrak{p}^n \mid (c)$ since $c \in \mathfrak{p}^n$ and $(b)/\mathfrak{p}^n \mid (d)$ by the second displayed condition, so $(b) = \mathfrak{p}^n \cdot (b)/\mathfrak{p}^n \mid (d)$, hence $d/b \in \mathcal{O}_K$. Finally

$$\varphi\left(\frac{d}{b}\right) \quad = \quad \frac{d}{b} \cdot b \pmod{\mathfrak{p}^{n+1}} \quad = \quad b \pmod{p^{n+1}} \quad = \quad c \pmod{p^{n+1}},$$

so φ is surjective. □

Chapter 10

Discrimannts, Norms, and Finiteness of the Class Group

10.1 Preliminary Remarks

Let K be a number field of degree n. Then there are n embeddings

$$\sigma_1, \ldots, \sigma_n : K \hookrightarrow \mathbf{C}.$$

Let $\sigma : K \to \mathbf{C}^n$ be the product map $a \mapsto (\sigma_1(a), \ldots, \sigma_n(a))$. Let $V = \mathbf{R}\sigma(K)$ be the $\mathbf{R}$-span of $\sigma(K)$ inside $\mathbf{C}^n$.

Proposition 10.1.1. *The $\mathbf{R}$-vector space $V = \mathbf{R}\sigma(K)$ spanned by the image $\sigma(K)$ has dimension n.*

Proof. We prove this by showing that the image $\sigma(\mathcal{O}_K)$ is discrete. If $\sigma(\mathcal{O}_K)$ were not discrete it would contain elements all of whose coordinates are simultaneously arbitrarily small. The norm of an element $a \in \mathcal{O}_K$ is the product of the entries of $\sigma(a)$, so the norms of nonzero elements of $\mathcal{O}_K$ would go to 0. This is a contradiction, since the norms of elements of $\mathcal{O}_K$ are integers.

The fact that $\sigma(\mathcal{O}_K)$ is discrete in $\mathbf{C}^n$ implies that $\mathbf{R}\sigma(\mathcal{O}_K)$ has dimension equal to the rank n of $\sigma(\mathcal{O}_K)$, as claimed. This last assertion is not obvious, and requires observing that if L if a free abelian group that is discrete in a real vector space W and $\mathbf{R}L = W$, then the rank of L equals the dimension of W. Here's why this is true. If $x_1, \ldots, x_m \in L$ are a basis for $\mathbf{R}L$, then $\mathbf{Z}x_1 + \cdots + \mathbf{Z}x_m$ has finite index in L, since otherwise there would be infinitely many elements of L in a fundamental domain for $\mathbf{Z}x_1 + \cdots + \mathbf{Z}x_m$, which would contradict discreteness of L. Thus the rank of L is $m = \dim(\mathbf{R}L)$, as claimed. □

Since $\sigma(\mathcal{O}_K)$ is a lattice in V, the volume of $V/\sigma(\mathcal{O}_K)$ is finite. Suppose $w_1, \ldots, w_n$ is a basis for $\mathcal{O}_K$. Then if A is the matrix whose ith row is $\sigma(w_i)$, then $|\operatorname{Det}(A)|$ is the volume of $V/\sigma(\mathcal{O}_K)$. (Take this determinant as the definition of the volume—we won't be using "volume" here except in a formal motivating way.)

Example 10.1.2. Let $\mathcal{O}_K = \mathbf{Z}[i]$ be the ring of integers of $K = \mathbf{Q}(i)$. Then $w_1 = 1$, $w_2 = i$ is a basis for $\mathcal{O}_K$. The map $\sigma : K \to \mathbf{C}^2$ is given by

$$\sigma(a + bi) = (a + bi, a - bi) \in \mathbf{C}^2.$$

The image $\sigma(\mathcal{O}_K)$ is spanned by $(1, 1)$ and $(i, -i)$. The volume determinant is

$$\left| \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix} \right| = |-2i| = 2.$$

Let $\mathcal{O}_K = \mathbf{Z}[\sqrt{2}]$ be the ring of integers of $K = \mathbf{Q}(\sqrt{2})$. The map σ is

$$\sigma(a + b\sqrt{2}) = (a + b\sqrt{2}, a - b\sqrt{2}) \in \mathbf{R}^2,$$

and

$$A = \begin{pmatrix} 1 & 1 \\ \sqrt{2} & -\sqrt{2} \end{pmatrix},$$

which has determinant $-2\sqrt{2}$, so the volume of the ring of integers is $2\sqrt{2}$.

As the above example illustrates, the volume of the ring of integers is not a great invariant of $\mathcal{O}_K$. For example, it need not be an integer. If we consider $\mathrm{Det}(A)^2$ instead, we obtain a number that is a well-defined integer which can be either positive or negative. In the next section we will do just this.

10.2 Discriminants

Suppose $w_1, \ldots, w_n$ are a basis for a number field K, which we view as a $\mathbf{Q}$-vector space. Let $\sigma : K \hookrightarrow \mathbf{C}^n$ be the embedding $\sigma(a) = (\sigma_1(a), \ldots, \sigma_n(a))$, where $\sigma_1, \ldots, \sigma_n$ are the distinct embeddings of K into $\mathbf{C}$. Let A be the matrix whose rows are $\sigma(w_1), \ldots, \sigma(w_n)$. The quantity $\mathrm{Det}(A)$ depends on the ordering of the w_i, and need not be an integer.

If we consider $\mathrm{Det}(A)^2$ instead, we obtain a number that is a well-defined integer which can be either positive or negative. Note that

$$\begin{aligned} \mathrm{Det}(A)^2 &= \mathrm{Det}(AA) = \mathrm{Det}(AA^t) \\ &= \mathrm{Det}\left(\sum_{k=1,\ldots,n} \sigma_k(w_i)\sigma_k(w_j) \right) \\ &= \mathrm{Det}(\mathrm{Tr}(w_i w_j)_{1 \le i,j \le n}), \end{aligned}$$

so $\mathrm{Det}(A)^2$ can be defined purely in terms of the trace without mentioning the embeddings σ_i. Also, changing the basis for $\mathcal{O}_K$ is the same as left multiplying A by an integer matrix U of determinant ± 1, which does not change the squared determinant, since $\mathrm{Det}(UA)^2 = \mathrm{Det}(U)^2 \, \mathrm{Det}(A)^2 = \mathrm{Det}(A)^2$. Thus $\mathrm{Det}(A)^2$ is well defined, and does not depend on the choice of basis.

If we view K as a $\mathbf{Q}$-vector space, then $(x, y) \mapsto \mathrm{Tr}(xy)$ defines a bilinear pairing $K \times K \to \mathbf{Q}$ on K, which we call the *trace pairing.* The following lemma asserts that this pairing is nondegenerate, so $\mathrm{Det}(\mathrm{Tr}(w_i w_j)) \neq 0$ hence $\mathrm{Det}(A) \neq 0$.

Lemma 10.2.1. *The trace pairing is nondegenerate.*

Proof. If the trace pairing is degenerate, then there exists $a \in K$ such that for every $b \in K$ we have $\mathrm{Tr}(ab) = 0$. In particularly, taking $b = a^{-1}$ we see that $0 = \mathrm{Tr}(aa^{-1}) = \mathrm{Tr}(1) = [K : \mathbf{Q}] > 0$, which is absurd. □

Definition 10.2.2 (Discriminant). Suppose $a_1, \ldots, a_n$ is any $\mathbf{Q}$-basis of K. The *discriminant* of $a_1, \ldots, a_n$ is

$$\mathrm{Disc}(a_1, \ldots, a_n) = \mathrm{Det}(\mathrm{Tr}(a_i a_j)_{1 \leq i,j \leq n}) \in \mathbf{Q}.$$

The *discriminant* $\mathrm{Disc}(\mathcal{O})$ of an order $\mathcal{O}$ in $\mathcal{O}_K$ is the discriminant of any basis for $\mathcal{O}$. The *discriminant* $d_K = \mathrm{Disc}(K)$ of the number field K is the discrimimant of $\mathcal{O}_K$.

Note that the discriminants defined above are all nonzero by Lemma 10.2.1.

Warning: In Magma $\mathrm{Disc}(K)$ is defined to be the discriminant of the polynomial you happened to use to define K, which is (in my opinion) a poor choice and goes against most of the literature.

The following proposition asserts that the discriminant of an order $\mathcal{O}$ in $\mathcal{O}_K$ is bigger than $\mathrm{disc}(\mathcal{O}_K)$ by a factor of the square of the index.

Proposition 10.2.3. *Suppose $\mathcal{O}$ is an order in $\mathcal{O}_K$. Then*

$$\mathrm{Disc}(\mathcal{O}) = \mathrm{Disc}(\mathcal{O}_K) \cdot [\mathcal{O}_K : \mathcal{O}]^2.$$

Proof. Let A be a matrix whose rows are the images via σ of a basis for $\mathcal{O}_K$, and let B be a matrix whose rows are the images via σ of a basis for $\mathcal{O}$. Since $\mathcal{O} \subset \mathcal{O}_K$ has finite index, there is an integer matrix C such that $CA = B$, and $|\mathrm{Det}(C)| = [\mathcal{O}_K : \mathcal{O}]$. Then

$$\mathrm{Disc}(\mathcal{O}) = \mathrm{Det}(B)^2 = \mathrm{Det}(CA)^2 = \mathrm{Det}(C)^2 \,\mathrm{Det}(A)^2 = [\mathcal{O}_K : \mathcal{O}]^2 \cdot \mathrm{Disc}(\mathcal{O}_K).$$

□

This result is enough to give an algorithm for computing $\mathcal{O}_K$, albeit a potentially slow one. Given K, find some order $\mathcal{O} \subset K$, and compute $d = \mathrm{Disc}(\mathcal{O})$. Factor d, and use the factorization to write $d = s \cdot f^2$, where f^2 is the largest square that divides d. Then the index of $\mathcal{O}$ in $\mathcal{O}_K$ is a divisor of f, and we (tediously) can enumerate all rings R with $\mathcal{O} \subset R \subset K$ and $[R : \mathcal{O}] \mid f$, until we find the largest one all of whose elements are integral.

Example 10.2.4. Consider the ring $\mathcal{O}_K = \mathbf{Z}[(1+\sqrt{5})/2]$ of integers of $K = \mathbf{Q}(\sqrt{5})$. The discriminant of the basis $1, a = (1+\sqrt{5})/2$ is

$$\mathrm{Disc}(\mathcal{O}_K) = \left|\begin{pmatrix} 2 & 1 \\ 1 & 3 \end{pmatrix}\right| = 5.$$

Let $\mathcal{O} = \mathbf{Z}[\sqrt{5}]$ be the order generated by $\sqrt{5}$. Then $\mathcal{O}$ has basis $1, \sqrt{5}$, so

$$\mathrm{Disc}(\mathcal{O}) = \left|\begin{pmatrix} 2 & 0 \\ 0 & 10 \end{pmatrix}\right| = 20 = [\mathcal{O}_K : \mathcal{O}]^2 \cdot 5.$$

10.3 Norms of Ideals

In this section we extend the notion of norm to ideals. This will be helpful in proving of class groups in the next section. For example, we will prove that the group of fractional ideals modulo principal fractional ideals of a number field is finite by showing that every ideal is equivalent to an ideal with norm at most some a priori bound.

Definition 10.3.1 (Lattice Index). If L and M are two lattices in vector space V, then the *lattice index* $[L : M]$ is by definition the absolute value of the determinant of any linear automorphism A of V such that $A(L) = M$.

The lattice index has the following properties:

- If $M \subset L$, then $[L : M] = \#(L/M)$.
- If M, L, N are lattices then $[L : N] = [L : M] \cdot [M : N]$.

Definition 10.3.2 (Norm of Fractional Ideal). Suppose I is a fractional ideal of $\mathcal{O}_K$. The *norm* of I is the lattice index

$$\mathrm{Norm}(I) = [\mathcal{O}_K : I] \in \mathbf{Q}_{\geq 0},$$

or 0 if $I = 0$.

Note that if I is an integral ideal, then $\mathrm{Norm}(I) = \#(\mathcal{O}_K/I)$.

Lemma 10.3.3. *Suppose $a \in K$ and I is an integral ideal. Then*

$$\mathrm{Norm}(aI) = |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)|\,\mathrm{Norm}(I).$$

Proof. By properties of the lattice index mentioned above we have

$$[\mathcal{O}_K : aI] = [\mathcal{O}_K : I] \cdot [I : aI] = \mathrm{Norm}(I) \cdot |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)|.$$

Here we have used that $[I : aI] = |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)|$, which is because left multiplication ℓ_a is an automorphism of K that sends I onto aI, so $[I : aI] = |\,\mathrm{Det}(\ell_a)| = |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)|$. □

Proposition 10.3.4. *If I and J are fractional ideals, then*

$$\mathrm{Norm}(IJ) = \mathrm{Norm}(I) \cdot \mathrm{Norm}(J).$$

Proof. By Lemma 10.3.3, it suffices to prove this when I and J are integral ideals. If I and J are coprime, then Theorem 9.1.3 (Chinese Remainder Theorem) implies that $\mathrm{Norm}(IJ) = \mathrm{Norm}(I)\cdot\mathrm{Norm}(J)$. Thus we reduce to the case when $I = \mathfrak{p}^m$ and $J = \mathfrak{p}^k$ for some prime ideal $\mathfrak{p}$ and integers m, k. By Proposition 9.1.8 (consequence of CRT that $\mathcal{O}_K/\mathfrak{p} \cong \mathfrak{p}^n/\mathfrak{p}^{n+1}$), the filtration of $\mathcal{O}_K/\mathfrak{p}^n$ given by powers of $\mathfrak{p}$ has successive quotients isomorphic to $\mathcal{O}_K/\mathfrak{p}$, so we see that $\#(\mathcal{O}_K/\mathfrak{p}^n) = \#(\mathcal{O}_K/\mathfrak{p})^n$, which proves that $\mathrm{Norm}(\mathfrak{p}^n) = \mathrm{Norm}(\mathfrak{p})^n$. □

Lemma 10.3.5. *Fix a number field K. Let B be a positive integer. There are only finitely many integral ideals I of $\mathcal{O}_K$ with norm at most B.*

Proof. An integral ideal I is a subgroup of $\mathcal{O}_K$ of index equal to the norm of I. If G is any finitely generated abelian group, then there are only finitely many subgroups of G of index at most B, since the subgroups of index dividing an integer n are all subgroups of G that contain nG, and the group G/nG is finite. This proves the lemma. □

10.4 Finiteness of the Class Group via Geometry of Numbers

We have seen examples in which $\mathcal{O}_K$ is not a unique factorization domain. If $\mathcal{O}_K$ is a principal ideal domain, then it is a unique factorization domain, so it is of interest to understand how badly $\mathcal{O}_K$ fails to be a principal ideal domain. The class group of $\mathcal{O}_K$ measures this failure. As one sees in a course on Class Field Theory, the class group and its generalizations also yield deep insight into the possible abelian Galois extensions of K.

Definition 10.4.1 (Class Group). Let $\mathcal{O}_K$ be the ring of integers of a number field K. The *class group* C_K of K is the group of nonzero fractional ideals modulo the sugroup of principal fractional ideals (a), for $a \in K$.

Note that if we let $\mathrm{Div}(K)$ denote the group of nonzero fractional ideals, then there is an exact sequence

$$0 \to \mathcal{O}_K^* \to K^* \to \mathrm{Div}(K) \to C_K \to 0.$$

A basic theorem in algebraic number theory is that the class group C_K is finite, which follows from the first part of the following theorem and the fact that there are only finitely many ideals of norm less than a given integer.

Theorem 10.4.2 (Finiteness of the Class Group). *Let K be a number field. There is a constant $C_{r,s}$ that depends only on the number r, s of real and pairs of complex conjugate embeddings of K such that every ideal class of $\mathcal{O}_K$ contains an integral ideal of norm at most $C_{r,s}\sqrt{|d_K|}$, where $d_K = \mathrm{Disc}(\mathcal{O}_K)$. Thus by Lemma 10.3.5 the class group C_K of K is finite. One can choose $C_{r,s}$ such that every ideal class in C_K contains an integral ideal of norm at most*

$$\sqrt{|d_K|} \cdot \left(\frac{4}{\pi}\right)^s \frac{n!}{n^n}.$$

The explicit bound in the theorem is called the Minkowski bound, and I think it is the best known unconditional general bound (though there are better bounds in certain special cases).

Before proving Theorem 10.4.2, we prove a few lemmas. The strategy of the proof will be to start with any nonzero ideal I, and prove that there is some nonzero $a \in K$, with very small norm, such that aI is an integral ideal. Then $\mathrm{Norm}(aI) = \mathrm{Norm}_{K/\mathbf{Q}}(a)\,\mathrm{Norm}(I)$ will be small, since $\mathrm{Norm}_{K/\mathbf{Q}}(a)$ is small. The trick is to determine precisely how small an a we can choose subject to the condition that aI be an integral ideal, i.e., that $a \in I^{-1}$.

Let S be a subset of $V = \mathbf{R}^n$. Then S is *convex* if whenever $x, y \in S$ then the line connecting x and y lies entirely in S. We say that S is *symmetric about the origin* if whenever $x \in S$ then $-x \in S$ also. If L is a lattice in V, then the *volume* of V/L is the volume of the compact real manifold V/L, which is the same thing as the absolute value of the determinant of any matrix whose rows form a basis for L.

Lemma 10.4.3 (Blichfeld). *Let L be a lattice in $V = \mathbf{R}^n$, and let S be a bounded closed convex subset of V that is symmetric about the origin. Assume that* $\mathrm{Vol}(S) \geq 2^n\,\mathrm{Vol}(V/L)$*. Then S contains a nonzero element of L.*

Proof. First assume that $\mathrm{Vol}(S) > 2^n \cdot \mathrm{Vol}(V/L)$. If the map $\pi : \frac{1}{2}S \to V/L$ is injective, then

$$\frac{1}{2^n}\,\mathrm{Vol}(S) = \mathrm{Vol}\left(\frac{1}{2}S\right) \leq \mathrm{Vol}(V/L),$$

a contradiction. Thus π is not injective, so there exist $P_1 \neq P_2 \in \frac{1}{2}S$ such that $P_1 - P_2 \in L$. By symmetry $-P_2 \in \frac{1}{2}S$. By convexity, the average $\frac{1}{2}(P_1 - P_2)$ of P_1 and $-P_2$ is also in $\frac{1}{2}S$. Thus $0 \neq P_1 - P_2 \in S \cap L$, as claimed.

Next assume that $\mathrm{Vol}(S) = 2^n \cdot \mathrm{Vol}(V/L)$. Then for all $\varepsilon > 0$ there is $0 \neq Q_\varepsilon \in L \cap (1+\varepsilon)S$, since $\mathrm{Vol}((1+\varepsilon)S) > \mathrm{Vol}(S) = 2^n \cdot \mathrm{Vol}(V/L)$. If $\varepsilon < 1$ then the Q_ε are all in $L \cap 2S$, which is finite since $2S$ is bounded and L is discrete. Hence there exists $Q = Q_\varepsilon \in L \cap (1+\varepsilon)S$ for arbitrarily small ε. Since S is closed, $Q \in L \cap S$. □

Lemma 10.4.4. *If L_1 and L_2 are lattices in V, then*

$$\mathrm{Vol}(V/L_2) = \mathrm{Vol}(V/L_1) \cdot [L_1 : L_2].$$

Proof. Let A be an automorphism of V such that $A(L_1) = L_2$. Then A defines an isomorphism of real manifolds $V/L_1 \to V/L_2$ that changes volume by a factor of $|\mathrm{Det}(A)| = [L_1 : L_2]$. The claimed formula then follows. □

Fix a number field K with ring of integers $\mathcal{O}_K$. Let $\sigma : K \to V = \mathbf{R}^n$ be the embedding

$$\begin{aligned}\sigma(x) = \big(&\sigma_1(x), \sigma_2(x), \ldots, \sigma_r(x),\\ &\mathrm{Re}(\sigma_{r+1}(x)), \ldots, \mathrm{Re}(\sigma_{r+s}(x)), \mathrm{Im}(\sigma_{r+1}(x)), \ldots, \mathrm{Im}(\sigma_{r+s}(x))\big),\end{aligned}$$

where $\sigma_1, \ldots, \sigma_r$ are the real embeddings of K and $\sigma_{r+1}, \ldots, \sigma_{r+s}$ are half the complex embeddings of K, with one representative of each pair of complex conjugate embeddings. Note that this σ is *not* exactly the same as the one at the beginning of Section 10.2.

Lemma 10.4.5.
$$\mathrm{Vol}(V/\sigma(\mathcal{O}_K)) = 2^{-s}\sqrt{|d_K|}.$$

Proof. Let $L = \sigma(\mathcal{O}_K)$. From a basis $w_1, \ldots, w_n$ for $\mathcal{O}_K$ we obtain a matrix A whose ith row is

$$(\sigma_1(w_i), \cdots, \sigma_r(w_i), \mathrm{Re}(\sigma_{r+1}(w_i)), \ldots, \mathrm{Re}(\sigma_{r+s}(w_1)), \mathrm{Im}(\sigma_{r+1}(w_i)), \ldots, \mathrm{Im}(\sigma_{r+s}(w_1)))$$

and whose determinant has absolute value equal to the volume of V/L. By doing the following three column operations, we obtain a matrix whose rows are exactly the images of the w_i under *all* embeddings of K into $\mathbf{C}$, which is the matrix that came up when we defined d_K.

1. Add $i = \sqrt{-1}$ times each column with entries $\mathrm{Im}(\sigma_{r+j}(w_i))$ to the column with entries $\mathrm{Re}(\sigma_{r+j}(w_i))$.

2. Multiply all columns $\mathrm{Im}(\sigma_{r+j}(w_i))$ by $-2i$, thus changing the determinant by $(-2i)^s$.

3. Add each columns with entries $\mathrm{Re}(\sigma_{r+j}(w_i))$ to the the column with entries $-2i\mathrm{Im}(\sigma_{r+j}(w_i))$.

Recalling the definition of discriminant, we see that if B is the matrix constructed by the above three operations, then $\mathrm{Det}(B)^2 = d_K$. Thus

$$\mathrm{Vol}(V/L) = |\,\mathrm{Det}(A)| = |(-2i)^{-s} \cdot \mathrm{Det}(B)| = 2^{-s}\sqrt{|d_K|}.$$

□

Lemma 10.4.6. *If I is a nonzero fractional ideal for $\mathcal{O}_K$, then $\sigma(I)$ is a lattice in V, and*
$$\mathrm{Vol}(V/\sigma(I)) = 2^{-s}\sqrt{|d_K|} \cdot \mathrm{Norm}(I).$$

Proof. We know that $[\mathcal{O}_K : I] = \mathrm{Norm}(I)$ is a nonzero rational number. Lemma 10.4.5 implies that $\sigma(\mathcal{O}_K)$ is a lattice in V, since $\sigma(\mathcal{O}_K)$ has rank n as abelian group and spans V, so $\sigma(I)$ is also a lattice in V. For the volume formula, combine Lemmas 10.4.4–10.4.5 to get

$$\mathrm{Vol}(V/\sigma(I)) = \mathrm{Vol}(V/\sigma(\mathcal{O}_K)) \cdot [\mathcal{O}_K : I] = 2^{-s}\sqrt{|d_K|}\,\mathrm{Norm}(I).$$

□

Proof of Theorem 10.4.2. Let K be a number field with ring of integers $\mathcal{O}_K$, let $\sigma : K \hookrightarrow V \cong \mathbf{R}^n$ be as above, and let $f : V \to \mathbf{R}$ be the function defined by

$$f(x_1, \ldots, x_n) = |x_1 \cdots x_r \cdot (x_{r+1}^2 + x_{(r+1)+s}^2) \cdots (x_{r+s}^2 + x_n^2).$$

Notice that if $x \in K$ then $f(\sigma(x)) = |\,\mathrm{Norm}_{K/\mathbf{Q}}(x)|$.

Let $S \subset V$ be any closed, bounded, convex, subset that is symmetric with respect to the origin and has positive volume. Since S is closed and bounded,

$$M = \max\{f(x) : x \in S\}$$

exists.

Suppose I is any nonzero fractional ideal of $\mathcal{O}_K$. Our goal is to prove there is an integral ideal aI with small norm. We will do this by finding an appropriate $a \in I^{-1}$. By Lemma 10.4.6,

$$c = \mathrm{Vol}(V/I^{-1}) = \frac{2^{-s}\sqrt{|d_K|}}{\mathrm{Norm}(I)}.$$

Let $\lambda = 2 \cdot \left(\frac{c}{v}\right)^{1/n}$, where $v = \mathrm{Vol}(S)$. Then

$$\mathrm{Vol}(\lambda S) = \lambda^n \,\mathrm{Vol}(S) = 2^n \frac{c}{v} \cdot v = 2^n \cdot c = 2^n \,\mathrm{Vol}(V/I^{-1}),$$

so by Lemma 10.4.3 there exists $0 \neq a \in I^{-1} \cap \lambda S$. Since M is the largest norm of an element of S, the largest norm of an element of $I^{-1} \cap \lambda S$ is at most $\lambda^n M$, so

$$|\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| \leq \lambda^n M.$$

Since $a \in I^{-1}$, we have $aI \subset \mathcal{O}_K$, so aI is an integral ideal of $\mathcal{O}_K$ that is equivalent to I, and

$$\begin{aligned}
\mathrm{Norm}(aI) &= |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| \cdot \mathrm{Norm}(I)\\
&\leq \lambda^n M \cdot \mathrm{Norm}(I)\\
&\leq 2^n \frac{c}{v} M \cdot \mathrm{Norm}(I)\\
&\leq 2^n \cdot 2^{-s}\sqrt{|d_K|} \cdot M \cdot v^{-1}\\
&= 2^{r+s}\sqrt{|d_K|} \cdot M \cdot v^{-1}.
\end{aligned}$$

Notice that the right hand side is independent of I. It depends only on r, s, $|d_K|$, and our choice of S. This completes the proof of the theorem, except for the assertion that S can be chosen to give the claim at the end of the theorem, which we leave as an exercise. □

Corollary 10.4.7. *Suppose that $K \neq \mathbf{Q}$ is a number field. Then $|d_K| > 1$.*

Proof. Applying Theorem 10.4.2 to the unit ideal, we get the bound

$$1 \leq \sqrt{|d_K|} \cdot \left(\frac{4}{\pi}\right)^s \frac{n!}{n^n}.$$

Thus

$$\sqrt{|d_K|} \geq \left(\frac{\pi}{4}\right)^s \frac{n^n}{n!},$$

and the right hand quantity is strictly bigger than 1 for any $s \leq n/2$ and any $n > 1$ (exercise). □

10.4.1 An Open Problem

Conjecture 10.4.8. *There are infinitely many number fields K such that the class group of K has order* 1.

For example, if we consider real quadratic fields $K = \mathbf{Q}(\sqrt{d})$, with d positive and square free, many class numbers are probably 1, as suggested by the MAGMA output below. It looks like 1's will keep appearing infinitely often, and indeed Cohen and Lenstra conjecture that they do. Nobody has found a way to prove this yet.

```
> for d in [2..1000] do
     if d eq SquareFree(d) then
        h := ClassNumber(NumberField(x^2-d));
        if h eq 1 then
           printf "%o, ", d;
        end if;
     end if;
   end for;

823, 827, 829, 838, 849, 853, 857, 859, 862, 863, 869, 877, 878,
881, 883, 886, 887, 889, 893, 907, 911, 913, 917, 919, 921, 926,
929, 933, 937, 941, 947, 953, 958, 967, 971, 973, 974, 977, 983,
989, 991, 997, 998,
```

In contrast, if we look at class numbers of quadratic imaginary fields, only a few at the beginning have class number 1.

```
> for d in [1..1000] do
     if d eq SquareFree(d) then
        h := ClassNumber(NumberField(x^2+d));
```

```
           if h eq 1 then
              printf "%o, ", d;
           end if;
        end if;
     end for;
  1, 2, 3, 7, 11, 19, 43, 67, 163
```

It is a theorem that the above list of 9 fields is the complete list with class number 1. More generally, it is possible (in theory), using deep work of Gross, Zagier, and Goldfeld involving zeta functions and elliptic curves, to enumerate all quadratic number fields with a given class number.

Chapter 11

Computing Class Groups

In this chapter we discuss how to compute class groups in some examples, then introduce the group of units. We will prove the main structure theorem for the group of units in the next chapter.

11.1 Remarks on Computing the Class Group

If $\mathfrak{p}$ is a prime of $\mathcal{O}_K$, then the intersection $\mathfrak{p} \cap \mathbf{Z} = p\mathbf{Z}$ is a prime ideal of $\mathbf{Z}$. We say that $\mathfrak{p}$ *lies over* $p \in \mathbf{Z}$. Note $\mathfrak{p}$ lies over $p \in \mathbf{Z}$ if and only if $\mathfrak{p}$ is one of the prime factors in the factorization of the ideal $p\mathcal{O}_K$. Geometrically, $\mathfrak{p}$ is a point of $\mathrm{Spec}(\mathcal{O}_K)$ that lies over the point $p\mathbf{Z}$ of $\mathrm{Spec}(\mathbf{Z})$ under the map induced by the inclusion $\mathbf{Z} \hookrightarrow \mathcal{O}_K$.

Lemma 11.1.1. *Let K be a number field with ring of integers $\mathcal{O}_K$. Then the class group $\mathrm{Cl}(K)$ is generated by the prime ideals $\mathfrak{p}$ of $\mathcal{O}_K$ lying over primes $p \in \mathbf{Z}$ with $p \leq B_K = \sqrt{|d_K|} \cdot \left(\frac{4}{\pi}\right)^s \cdot \frac{n!}{n^n}$, where s is the number of complex conjugate pairs of embeddings $K \hookrightarrow \mathbf{C}$.*

Proof. We proved before that every ideal class in $\mathrm{Cl}(K)$ is represented by an ideal I with $\mathrm{Norm}(I) \leq B_K$. Write $I = \prod_{i=1}^{m} \mathfrak{p}_i^{e_i}$, with each $e_i \geq 1$. Then by multiplicativity of the norm, each $\mathfrak{p}_i$ also satisfies $\mathrm{Norm}(\mathfrak{p}_i) \leq B_K$. If $\mathfrak{p}_i \cap \mathbf{Z} = p\mathbf{Z}$, then $p \mid \mathrm{Norm}(\mathfrak{p}_i)$, since p is the residue characteristic of $\mathcal{O}_K/\mathfrak{p}$, so $p \leq B_K$. Thus I is a product of primes $\mathfrak{p}$ that satisfies the norm bound of the lemma, whcih proves the lemma. □

This is a sketch of how to compute $\mathrm{Cl}(K)$:

1. Use the "factoring primes" algorithm to list all prime ideals $\mathfrak{p}$ of $\mathcal{O}_K$ that appear in the factorization of a prime $p \in \mathbf{Z}$ with $p \leq B_K$.

2. Find the group generated by the ideal classes $[\mathfrak{p}]$, where the $\mathfrak{p}$ are the prime ideals found in step 1. (In general, one must think more carefully about how to do this step.)

The following three examples illustrate computation of $\mathrm{Cl}(K)$ for $K = \mathbf{Q}(i), \mathbf{Q}(\sqrt{5})$ and $\mathbf{Q}(\sqrt{-6})$.

Example 11.1.2. We compute the class group of $K = \mathbf{Q}(i)$. We have

$$n = 2, \quad r = 0, \quad s = 1, \quad d_K = -4,$$

so

$$B_K = \sqrt{4} \cdot \left(\frac{4}{\pi}\right)^1 \cdot \left(\frac{2!}{2^2}\right) = \frac{8}{\pi} < 3.$$

Thus $\mathrm{Cl}(K)$ is generated by the prime divisors of 2. We have

$$2\mathcal{O}_K = (1+i)^2,$$

so $\mathrm{Cl}(K)$ is generated by the principal prime ideal $\mathfrak{p} = (1+i)$. Thus $\mathrm{Cl}(K) = 0$ is trivial.

Example 11.1.3. We compute the class group of $K = \mathbf{Q}(\sqrt{5})$. We have

$$n = 2, \quad r = 2, \quad s = 0, \quad d_K = 5,$$

so

$$B = \sqrt{5} \cdot \left(\frac{4}{\pi}\right)^0 \cdot \left(\frac{2!}{2^2}\right) < 3.$$

Thus $\mathrm{Cl}(K)$ is generated by the primes that divide 2. We have $\mathcal{O}_K = \mathbf{Z}[\gamma]$, where $\gamma = \frac{1+\sqrt{5}}{2}$ satisfies $x^2 - x - 1$. The polynomial $x^2 - x - 1$ is irreducible mod 2, so $2\mathcal{O}_K$ is prime. Since it is principal, we see that $\mathrm{Cl}(K) = 1$ is trivial.

Example 11.1.4. In this example, we compute the class group of $K = \mathbf{Q}(\sqrt{-6})$. We have

$$n = 2, \quad r = 0, \quad s = 1, \quad d_K = -24,$$

so

$$B = \sqrt{24} \cdot \frac{4}{\pi} \cdot \left(\frac{2!}{2^2}\right) \sim 3.1.$$

Thus $\mathrm{Cl}(K)$ is generated by the prime ideals lying over 2 and 3. We have $\mathcal{O}_K = \mathbf{Z}[\sqrt{-6}]$, and $\sqrt{-6}$ satisfies $x^2 + 6 = 0$. Factoring $x^2 + 6$ modulo 2 and 3 we see that the class group is generated by the prime ideals

$$\mathfrak{p}_2 = (2, \sqrt{-6}) \qquad \text{and} \qquad \mathfrak{p}_3 = (3, \sqrt{-6}).$$

Also, $\mathfrak{p}_2^2 = 2\mathcal{O}_K$ and $\mathfrak{p}_3^2 = 3\mathcal{O}_K$, so $\mathfrak{p}_2$ and $\mathfrak{p}_3$ define elements of order dividing 2 in $\mathrm{Cl}(K)$.

Is either $\mathfrak{p}_2$ or $\mathfrak{p}_3$ principal? Fortunately, there is an easier norm trick that allows us to decide. Suppose $\mathfrak{p}_2 = (\alpha)$, where $\alpha = a + b\sqrt{-6}$. Then

$$2 = \mathrm{Norm}(\mathfrak{p}_2) = |\,\mathrm{Norm}(\alpha)| = (a + b\sqrt{-6})(a - b\sqrt{-6}) = a^2 + 6b^2.$$

Trying the first few values of $a, b \in \mathbf{Z}$, we see that this equation has no solutions, so $\mathfrak{p}_2$ can not be principal. By a similar argument, we see that $\mathfrak{p}_3$ is not principal either. Thus $\mathfrak{p}_2$ and $\mathfrak{p}_3$ define elements of order 2 in $\mathrm{Cl}(K)$.

Does the class of $\mathfrak{p}_2$ equal the class of $\mathfrak{p}_3$? Since $\mathfrak{p}_2$ and $\mathfrak{p}_3$ define classes of order 2, we can decide this by finding the class of $\mathfrak{p}_2 \cdot \mathfrak{p}_3$. We have

$$\mathfrak{p}_2 \cdot \mathfrak{p}_3 = (2, \sqrt{-6}) \cdot (3, \sqrt{-6}) = (6, 2\sqrt{-6}, 3\sqrt{-6}) \subset (\sqrt{-6}).$$

The ideals on both sides of the inclusion have norm 6, so by multiplicativity of the norm, they must be the same ideal. Thus $\mathfrak{p}_2 \cdot \mathfrak{p}_3 = (\sqrt{-6})$ is principal, so $\mathfrak{p}_2$ and $\mathfrak{p}_3$ represent the same element of $\mathrm{Cl}(K)$. We conclude that

$$\mathrm{Cl}(K) = \langle \mathfrak{p}_2 \rangle = \mathbf{Z}/2\mathbf{Z}.$$

Chapter 12

Dirichlet's Unit Theorem

In this chapter we will prove the main structure theorem for the group of units of the ring of integers of a number field. The answer is remarkably simple: if K has r real and s complex embeddings, then

$$\mathcal{O}_K^* \approx \mathbf{Z}^{r+s-1} \oplus W,$$

where W is the finite cyclic group of roots of unity in K. Examples will follow on Thursday (application: the solutions to Pell's equation $x^2 - dy^2 = 1$, for $d > 1$ squarefree, form a free abelian group of rank 1).

12.1 The Group of Units

Definition 12.1.1 (Unit Group). The *group of units* U_K associated to a number field K is the group of elements of $\mathcal{O}_K$ that have an inverse in $\mathcal{O}_K$.

Theorem 12.1.2 (Dirichlet). *The group U_K is the product of a finite cyclic group of roots of unity with a free abelian group of rank $r + s - 1$, where r is the number of real embeddings of K and s is the number of complex conjugate pairs of embeddings.*

We prove the theorem by defining a map $\varphi : U_K \to \mathbf{R}^{r+s}$, and showing that the kernel of φ is finite and the image of φ is a lattice in a hyperplane in $\mathbf{R}^{r+s}$. The trickiest part of the proof is showing that the image of φ spans a hyperplane, and we do this by a clever application of Blichfeldt's lemma (that if S is closed, bounded, symmetric, etc., and has volume at least $2^n \cdot \mathrm{Vol}(V/L)$, then $S \cap L$ contains a nonzero element).

Remark 12.1.3. Theorem 12.1.2 is due to Dirichlet who lived 1805–1859. Thomas Hirst described Dirichlet as follows:

> He is a rather tall, lanky-looking man, with moustache and beard about to turn grey with a somewhat harsh voice and rather deaf. He was unwashed, with his cup of coffee and cigar. One of his failings is forgetting time, he pulls his watch out, finds it past three, and runs out without even finishing the sentence.

Koch wrote that:

> ... important parts of mathematics were influenced by Dirichlet. His proofs characteristically started with surprisingly simple observations, followed by extremely sharp analysis of the remaining problem.

I think Koch's observation nicely describes the proof we will give of Theorem 12.1.2.

The following proposition explains how to think about units in terms of the norm.

Proposition 12.1.4. *An element $a \in \mathcal{O}_K$ is a unit if and only if* $\mathrm{Norm}_{K/\mathbf{Q}}(a) = \pm 1$.

Proof. Write $\mathrm{Norm} = \mathrm{Norm}_{K/\mathbf{Q}}$. If a is a unit, then a^{-1} is also a unit, and $1 = \mathrm{Norm}(a)\,\mathrm{Norm}(a^{-1})$. Since both $\mathrm{Norm}(a)$ and $\mathrm{Norm}(a^{-1})$ are integers, it follows that $\mathrm{Norm}(a) = \pm 1$. Conversely, if $a \in \mathcal{O}_K$ and $\mathrm{Norm}(a) = \pm 1$, then the equation $aa^{-1} = 1 = \pm\,\mathrm{Norm}(a)$ implies that $a^{-1} = \pm\,\mathrm{Norm}(a)/a$. But $\mathrm{Norm}(a)$ is the product of the images of a in $\mathbf{C}$ by all embeddings of K into $\mathbf{C}$, so $\mathrm{Norm}(a)/a$ is also a product of images of a in $\mathbf{C}$, hence a product of algebraic integers, hence an algebraic integer. Thus $a^{-1} \in \mathcal{O}_K$, which proves that a is a unit. □

Let r be the number of real and s the number of complex conjugate embeddings of K into $\mathbf{C}$, so $n = [K : \mathbf{Q}] = r + 2s$. Define a map

$$\varphi : U_K \to \mathbf{R}^{r+s}$$

by

$$\varphi(a) = (\log|\sigma_1(a)|, \ldots, \log|\sigma_{r+s}(a)|).$$

Lemma 12.1.5. *The image of φ lies in the hyperplane*

$$H = \{(x_1, \ldots, x_{r+s}) \in \mathbf{R}^{r+s} : x_1 + \cdots + x_r + 2x_{r+1} + \cdots + 2x_{r+s} = 0\}. \quad (12.1.1)$$

Proof. If $a \in U_K$, then by Proposition 12.1.4,

$$\left(\prod_{i=1}^{r} |\sigma_i(a)|\right) \cdot \left(\prod_{i=r+1}^{s} |\sigma_i(a)|^2\right) = 1.$$

Taking logs of both sides proves the lemma. □

Lemma 12.1.6. *The kernel of φ is finite.*

Proof. We have

$$\begin{aligned} \mathrm{Ker}(\varphi) &\subset \{a \in \mathcal{O}_K : |\sigma_i(a)| = 1 \text{ for all } i = 1, \ldots, r+2s\} \\ &\subset \sigma(\mathcal{O}_K) \cap X, \end{aligned}$$

where X is the bounded subset of $\mathbf{R}^{r+2s}$ of elements all of whose coordinates have absolute value at most 1. Since $\sigma(\mathcal{O}_K)$ is a lattice (see Proposition 5.2.4), the intersection $\sigma(\mathcal{O}_K) \cap X$ is finite, so $\mathrm{Ker}(\varphi)$ is finite. □

Lemma 12.1.7. *The kernel of φ is a finite cyclic group.*

Proof. It is a general fact that any finite subgroup of the multiplicative group of a field is cyclic. [Homework.] □

To prove Theorem 12.1.2, it suffices to proove that $\mathrm{Im}(\varphi)$ is a lattice in the hyperplane H from (12.1.1), which we view as a vector space of dimension $r+s-1$.

Define an embedding

$$\sigma : K \hookrightarrow \mathbf{R}^n \tag{12.1.2}$$

given by $\sigma(x) = (\sigma_1(x), \ldots, \sigma_{r+s}(x))$, where we view $\mathbf{C} \cong \mathbf{R} \times \mathbf{R}$ via $a + bi \mapsto (a, b)$. Note that this is exactly the same as the embedding

$$x \mapsto \big(\sigma_1(x), \sigma_2(x), \ldots, \sigma_r(x),\\ \mathrm{Re}(\sigma_{r+1}(x)), \ldots, \mathrm{Re}(\sigma_{r+s}(x)), \mathrm{Im}(\sigma_{r+1}(x)), \ldots, \mathrm{Im}(\sigma_{r+s}(x))\big),$$

from before, except that we have re-ordered the last s imaginary components to be next to their corresponding real parts.

Lemma 12.1.8. *The image of φ is discrete in $\mathbf{R}^{r+s}$.*

Proof. Suppose X is any bounded subset of $\mathbf{R}^{r+s}$. Then for any $u \in Y = \varphi^{-1}(X)$ the coordinates of $\sigma(u)$ are bounded in terms of X (since log is an increasing function). Thus $\sigma(Y)$ is a bounded subset of $\mathbf{R}^n$. Since $\sigma(Y) \subset \sigma(\mathcal{O}_K)$, and $\sigma(\mathcal{O}_K)$ is a lattice in $\mathbf{R}^n$, it follows that $\sigma(Y)$ is finite. Since σ is injective, Y is finite, and φ has finite kernel, so $\varphi(U_K) \cap X$ is finite, which implies that $\varphi(U_K)$ is discrete. □

To finish the proof of Theorem 12.1.2, we will show that the image of φ spans H. Let W be the $\mathbf{R}$-span of the image $\varphi(U_K)$, and note that W is a subspace of H. We will show that $W = H$ indirectly by showing that if $v \notin H^\perp$, where $\perp$ is with respect to the dot product on $\mathbf{R}^{r+s}$, then $v \notin W^\perp$. This will show that $W^\perp \subset H^\perp$, hence that $H \subset W$, as required.

Thus suppose $z = (z_1, \ldots, z_{r+s}) \notin H^\perp$. Define a function $f : K^* \to \mathbf{R}$ by

$$f(x) = z_1 \log|\sigma_1(x)| + \cdots z_{r+s} \log|\sigma_{r+s}(x)|. \tag{12.1.3}$$

To show that $z \notin W^\perp$ we show that there exists some $u \in U_K$ with $f(u) \neq 0$.

Let

$$A = \sqrt{|d_K|} \cdot \left(\frac{2}{\pi}\right)^s \in \mathbf{R}_{>0}.$$

Choose any positive real numbers $c_1, \ldots, c_{r+s} \in \mathbf{R}_{>0}$ such that

$$c_1 \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = A.$$

Let

$$S = \{(x_1, \ldots, x_n) \in \mathbf{R}^n :\\ |x_i| \leq c_i \text{ for } 1 \leq i \leq r,\\ |x_i^2 + x_{i+s}^2| \leq c_i^2 \text{ for } r < i \leq r+s\} \subset \mathbf{R}^n.$$

Then S is closed, bounded, convex, symmetric with respect to the origin, and of dimension $r+2s$, since S is a product of r intervals and s discs, each of which has these properties. Viewing S as a product of intervals and discs, we see that the volume of S is

$$\mathrm{Vol}(S) = \prod_{i=1}^{r}(2c_i) \cdot \prod_{i=1}^{s}(\pi c_i^2) = 2^r \cdot \pi^s \cdot A.$$

Recall *Blichfeldt's lemma* that if L is a lattice and S is closed, bounded, etc., and has volume at least $2^n \cdot \mathrm{Vol}(V/L)$, then $S \cap L$ contains a nonzero element. To apply this lemma, we take $L = \sigma(\mathcal{O}_K) \subset \mathbf{R}^n$, where σ is as in (12.1.2). We showed, when proving finiteness of the class group, that $\mathrm{Vol}(\mathbf{R}^n/L) = 2^{-s}\sqrt{|d_K|}$. To check the hypothesis to Blichfeld's lemma, note that

$$\mathrm{Vol}(S) = 2^{r+s}\sqrt{|d_K|} = 2^n 2^{-s}\sqrt{|d_K|} = 2^n \,\mathrm{Vol}(\mathbf{R}^n/L).$$

Thus there exists a nonzero element $a \in S \cap \sigma(\mathcal{O}_K)$, i.e., a nonzero $a \in \mathcal{O}_K$ such that $|\sigma_i(a)| \leq c_i$ for $1 \leq i \leq r+s$. We then have

$$\begin{aligned} |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| &= \left|\prod_{i=1}^{r+2s} \sigma_i(a)\right| \\ &= \prod_{i=1}^{r} |\sigma_i(a)| \cdot \prod_{i=r+1}^{s} |\sigma_i(a)|^2 \\ &\leq c_1 \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = A. \end{aligned}$$

Since $a \in \mathcal{O}_K$ is nonzero, we also have

$$|\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| \geq 1.$$

Moreover, if for any $i \leq r$, we have $|\sigma_i(a)| < \frac{c_i}{A}$, then

$$1 \leq |\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| < c_1 \cdots \frac{c_i}{A} \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = \frac{A}{A} = 1,$$

a contradiction, so $|\sigma_i(a)| \geq \frac{c_i}{A}$ for $i = 1, \ldots, r$. Likewise, $|\sigma_i(a)|^2 \geq \frac{c_i^2}{A}$, for $i = r+1, \ldots, r+s$. Rewriting this we have

$$\frac{c_i}{|\sigma_i(a)|} \leq A \quad \text{for } i \leq r \quad \text{and} \quad \left(\frac{c_i}{|\sigma_i(a)|}\right)^2 \leq A \quad \text{for } i = r+1, \ldots, r+s.$$

Our strategy is to use an appropriately chosen a to construct a unit $u \in U_K$ such $f(u) \neq 0$. First, let $b_1, \ldots, b_m$ be representative generators for the finitely many nonzero principal ideals of $\mathcal{O}_K$ of norm at most A. Since $|\,\mathrm{Norm}_{K/\mathbf{Q}}(a)| \leq A$, we have $(a) = (b_j)$, for some j, so there is a unit $u \in \mathcal{O}_K$ such that $a = ub_j$.

Let

$$s = s(c_1, \ldots, c_{r+s}) = z_1 \log(c_1) + \cdots + z_{r+s} \log(c_{r+s}),$$

and recall $f : K^* \to \mathbf{R}$ defined in (12.1.3) above. We first show that

$$|f(u) - s| \leq B = |f(b_j)| + \log(A) \cdot \left(\sum_{i=1}^{r} |z_i| + \frac{1}{2} \cdot \sum_{i=r+1}^{s} |z_i| \right). \qquad (12.1.4)$$

We have

$$\begin{aligned}
|f(u) - s| &= |f(a) - f(b_j) - s| \\
&\leq |f(b_j)| + |s - f(a)| \\
&= |f(b_j)| + |z_1(\log(c_1) - \log(|\sigma_1(a)|)) + \cdots + z_{r+s}(\log(c_{r+s}) - \log(|\sigma_{r+s}(a)|))| \\
&= |f(b_j)| + |z_1 \cdot \log(c_1/|\sigma_1(a)|) + \cdots + \frac{z_{r+s}}{2} \cdot \log((c_{r+s}/|\sigma_{r+s}(a)|)^2)| \\
&\leq |f(b_j)| + \log(A) \cdot \left(\sum_{i=1}^{r} |z_i| + \frac{1}{2} \cdot \sum_{i=r+1}^{s} |z_i| \right).
\end{aligned}$$

The amazing thing about (12.1.4) is that the bound B on the right hand side does not depend on the c_i. Suppose we can choose positive real numbers c_i such that

$$c_1 \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = A$$

and $s = s(c_1, \ldots, c_{r+s})$ is such that $|s| > B$. Then $|f(u) - s| \leq B$ would imply that $|f(u)| > 0$, which is exactly what we aimed to prove. It is possible to choose such c_i, by proceeding as follows. If $r + s = 1$, then we are trying to prove that $\varphi(U_K)$ is a lattice in $\mathbf{R}^0 = \mathbf{R}^{r+s-1}$, which is automatically true, so assume $r + s > 1$. Then there are at least two distinct c_i. Let j be such that $z_j \neq 0$ (which exists since $z \neq 0$). Then $|z_j \log(c_j)| \to \infty$ as $c_j \to \infty$, so we choose c_j very large and the other c_i, for $i \neq j$, in any way we want subject to the condition

$$\prod_{i=1, i\neq j}^{r} c_i \cdot \prod_{i=r+1}^{s} c_i^2 = \frac{A}{c_j}.$$

Since it is possible to choose the c_i as needed, it is possible to find a unit u such that $f(u) > 0$. We conclude that $z \notin W^\perp$, so $W^\perp \subset Z^\perp$, whence $Z \subset W$, which finishes the proof Theorem 12.1.2.

12.2 Finishing the proof of Dirichlet's Unit Theorem

We begin by finishing Dirichlet's proof that the group of units U_K of $\mathcal{O}_K$ is isomorphic to $\mathbf{Z}^{r+s-1} \oplus \mathbf{Z}/m\mathbf{Z}$, where r is the number of real embeddings, s is half the number of complex embeddings, and m is the number of roots of unity in K. Recall that we defined a map $\varphi : U_K \to \mathbf{R}^{r+s}$ by

$$\varphi(x) = (\log |\sigma_1(x)|, \ldots, \log |\sigma_{r+s}(x)|).$$

Without much trouble, we proved that the kernel of φ if finite and the image φ is discrete, and in the last section we were finishing the proof that the image of φ spans the subspace H of elements of $\mathbf{R}^{r+s}$ that are orthogonal to $v = (1, \ldots, 1, 2, \ldots, 2)$, where r of the entries are 1's and s of them are 2's. The somewhat indirect route we followed was to suppose

$$z \notin H^{\perp} = \mathrm{Span}(v),$$

i.e., that z is not a multiple of v, and prove that z is not orthogonal to some element of $\varphi(U_K)$. Writing $W = \mathrm{Span}(\varphi(U_K))$, this would show that $W^{\perp} \subset H^{\perp}$, so $H \subset W$. We ran into two problems: (1) we ran out of time, and (2) the notes contained an incomplete argument that a quantity $s = s(c_1, \ldots, c_{r+s})$ can be chosen to be arbitrarily large. We will finish going through a complete proof, then compute many examples of unit groups using Magma.

Recall that $f : K^* \to \mathbf{R}$ was defined by

$$f(x) = z_1 \log |\sigma_1(x)| + \cdots + z_{r+s} \log |\sigma_{r+s}(x)| = z \bullet \varphi(x) \qquad \text{(dot product)},$$

and our goal is to show that there is a $u \in U_K$ such that $f(u) \neq 0$.

Our strategy is to use an appropriately chosen a to construct a unit $u \in U_K$ such $f(u) \neq 0$. Recall that we used Blichfeld's lemma to find an $a \in \mathcal{O}_K$ such that $1 \leq |\operatorname{Norm}_{K/\mathbf{Q}}(a)| \leq A$, and

$$\frac{c_i}{|\sigma_i(a)|} \leq A \quad \text{for } i \leq r \quad \text{and} \quad \left(\frac{c_i}{|\sigma_i(a)|}\right)^2 \leq A \quad \text{for } i = r+1, \ldots, r+s. \tag{12.2.1}$$

Let $b_1, \ldots, b_m$ be representative generators for the finitely many nonzero principal ideals of $\mathcal{O}_K$ of norm at most $A = A_K = \sqrt{|d_K|} \cdot \left(\frac{2}{\pi}\right)^s$. Modify the b_i to have the property that $|f(b_i)|$ is minimal among generators of (b_i) (this is possible because ideals are discrete). Note that the set $\{|f(b_i)| : i = 1, \ldots, m\}$ depends only on A. Since $|\operatorname{Norm}_{K/\mathbf{Q}}(a)| \leq A$, we have $(a) = (b_j)$, for some j, so there is a unit $u \in \mathcal{O}_K$ such that $a = ub_j$.

Let

$$s = s(c_1, \ldots, c_{r+s}) = z_1 \log(c_1) + \cdots + z_{r+s} \log(c_{r+s}) \in \mathbf{R}.$$

Lemma 12.2.1. *We have*

$$|f(u) - s| \leq B = \max_i(|f(b_i)|) + \log(A) \cdot \left(\sum_{i=1}^{r} |z_i| + \frac{1}{2} \cdot \sum_{i=r+1}^{s} |z_i|\right),$$

and B depends only on K and our fixed choice of $z \in H^{\perp}$.

Proof. By properties of logarithms, $f(u) = f(a/b_j) = f(a) - f(b_j)$. We next use the triangle inequality $|a + b| \leq |a| + |b|$ in various ways, properties of logarithms, and the bounds (12.2.1) in the following computation:

$$\begin{aligned}|f(u)-s| &= |f(a)-f(b_j)-s|\\ &\le |f(b_j)|+|s-f(a)|\\ &= |f(b_j)|+|z_1(\log(c_1)-\log(|\sigma_1(a)|))+\cdots+z_{r+s}(\log(c_{r+s})-\log(|\sigma_{r+s}(a)|))|\\ &= |f(b_j)|+|z_1\cdot\log(c_1/|\sigma_1(a)|)+\cdots+\frac{1}{2}\cdot z_{r+s}\log((c_{r+s}/|\sigma_{r+s}(a)|)^2)|\\ &\le |f(b_j)|+\log(A)\cdot\left(\sum_{i=1}^{r}|z_i|+\frac{1}{2}\cdot\sum_{i=r+1}^{s}|z_i|\right).\end{aligned}$$

The inequality of the lemma now follows. That B only depends on K and our choice of z follows from the formula for A and how we chose the b_i. □

The amazing thing about Lemma 12.2.1 is that the bound B on the right hand side does not depend on the c_i. Suppose we could somehow cleverly choose the positive real numbers c_i in such a way that

$$c_1\cdots c_r\cdot(c_{r+1}\cdots c_{r+s})^2=A \qquad\text{and}\qquad |s(c_1,\ldots,c_{r+s})|>B.$$

Then the facts that $|f(u)-s|\le B$ and $|s|>B$ would together imply that $|f(u)|>0$ (since $f(u)$ is closer to s than s is to 0), which is exactly what we aimed to prove. We finish the proof by showing that it is possible to choose such c_i. Note that if we change the c_i, then a could change, hence the j such that a/b_j is a unit could change, but the b_j don't change, just the subscript j. Also note that if $r+s=1$, then we are trying to prove that $\varphi(U_K)$ is a lattice in $\mathbf{R}^0=\mathbf{R}^{r+s-1}$, which is automatically true, so we may assume that $r+s>1$.

Lemma 12.2.2. *Assume $r+s>1$. Then there is a choice of $c_1,\ldots,c_{r+s}\in\mathbf{R}_{>0}$ such that*

$$|z_1\log(c_1)+\cdots+z_{r+s}\log(c_{r+s})|>B.$$

Proof. It is easier if we write

$$\begin{aligned}&z_1\log(c_1)+\cdots+z_{r+s}\log(c_{r+s})=\\ &\qquad z_1\log(c_1)+\cdots+z_r\log(c_r)+\frac{1}{2}\cdot z_{r+1}\log(c_{r+1}^2)+\cdots+\frac{1}{2}\cdot z_{r+s}\log(c_{r+s}^2)\\ &\qquad = w_1\log(d_1)+\cdots+w_r\log(d_r)+w_{r+1}\log(d_{r+1})+\cdots+\cdot w_{r+s}\log(d_{r+s}),\end{aligned}$$

where $w_i=z_i$ and $d_i=c_i$ for $i\le r$, and $w_i=\frac{1}{2}z_i$ and $d_i=c_i^2$ for $r<i\le s$,

The condition that $z\notin H^\perp$ is that the w_i are not all the same, and in our new coordinates the lemma is equivalent to showing that $|\sum_{i=1}^{r+s}w_i\log(d_i)|>B$, subject to the condition that $\prod_{i=1}^{r+s}d_i=A$. Order the w_i so that $w_1\ne0$. By hypothesis there exists a w_j such that $w_j\ne w_1$, and again re-ordering we may assume that

$j = 2$. Set $d_3 = \cdots = d_{r+s} = 1$. Then $d_1 d_2 = A$ and $\log(1) = 0$, so

$$\begin{aligned}\left|\sum_{i=1}^{r+s} w_i \log(d_i)\right| &= |w_1 \log(d_1) + w_2 \log(d_2)| \\ &= |w_1 \log(d_1) + w_2 \log(A/d_1)| \\ &= |(w_1 - w_2)\log(d_1) + w_2 \log(A)|\end{aligned}$$

Since $w_1 \neq w_2$, we have $|(w_1 - w_2)\log(d_1) + w_2 \log(A)| \to \infty$ as $d_1 \to \infty$. □

12.3 Some Examples of Units in Number Fields

The classical Pell's equation is, given square-free $d > 0$, to find all positive integer solutions (x, y) to the equation $x^2 - dy^2 = 1$. Note that if $x + y\sqrt{d} \in \mathbf{Q}(\sqrt{d})$, then

$$\mathrm{Norm}(x + y\sqrt{d}) = (x + y\sqrt{d})(x - y\sqrt{d}) = x^2 - dy^2.$$

The solutions to Pell's equation thus form a finite-index subgroup of the group of units in the ring of integers of $\mathbf{Q}(\sqrt{d})$. Dirichlet's unit theorem implies that for any d the solutions to Pell's equation form an infinite cyclic group, a fact that takes substantial work to prove using only elementary number theory (for example, using continued fractions).

We first solve the Pell equation $x^2 - 5y^2 = 1$ by finding the units of a field using Magma (we will likely discuss algorithms for computing unit groups later in the course...).

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^2-5);
> G, phi := UnitGroup(K);
> G;
Abelian Group isomorphic to Z/2 + Z
Defined on 2 generators
Relations:
    2*G.1 = 0
> K!phi(G.1);
-1
> u := K!phi(G.2); u;
1/2*(a + 1)
> u^2;
1/2*(a + 3)
> u^3;
a + 2
> Norm(u);
-1
> Norm(u^3);
```

```
-1
> Norm(u^6);
1
> fund := u^6;
> fund;
4*a + 9
> 9^2 - 5*4^2;
1
> fund^2;
72*a + 161
> fund^3;
1292*a + 2889
> fund^4;
23184*a + 51841
> fund^5;
416020*a + 930249
```

I think in practice for solving Pell's equation it's best to use the ideas in the paper [Len02]. A review of this paper says: "This wonderful article begins with history and some elementary facts and proceeds to greater and greater depth about the existence of solutions to Pell equations and then later the algorithmic issues of finding those solutions. The cattle problem is discussed, as are modern smooth number methods for solving Pell equations and the algorithmic issues of representing very large solutions in a reasonable way." You can get the paper freely online from the Notices web page.

The simplest solutions to Pell's equation can be huge, even when d is quite small. Read Lenstra's paper for some awesome examples from antiquity.

```

The Magma `Signature` command returns the number of real and complex conjugate embeddings of K into $\mathbf{C}$. The command `UnitGroup`, which we used above, returns the unit group U_K as an abstract abelian group and a homomorphism $U_K \to \mathcal{O}_K$. Note that we have to bang (!) into K to get the units as elements of K.

First we consider $K = \mathbf{Q}(i)$.

```
> R<x> := PolynomialRing(RationalField());
> K<a> := NumberField(x^2+1);
> Signature(K);
0 1    // r=0, s=1
> G,phi := UnitGroup(K);
> G;
Abelian Group isomorphic to Z/4
Defined on 1 generator
Relations:
    4*G.1 = 0
> K!phi(G.1);
-a
```

Next we consider $K = \mathbf{Q}(\sqrt[3]{2})$.

```
> K<a> := NumberField(x^3-2);
> Signature(K);
1 1
> G,phi := UnitGroup(K);
> G;
Abelian Group isomorphic to Z/2 + Z
Defined on 2 generators
Relations:
    2*G.1 = 0
> K!phi(G.2);
-a + 1
```

The Conjugates command returns the sequence $(\sigma_1(x), \ldots, \sigma_{r+2s}(x))$ of all embeddings of $x \in K$ into $\mathbf{C}$. The Logs command returns the sequence

$$(\log(|\sigma_1(x)|), \ldots, \log(|\sigma_{r+s}(x)|)).$$

Continuing the above example, we have

```
> Conjugates(K!phi(G.2));
[ -0.2599210498948731647672106072782283505702514647009999999999995,

```

Let's try a field such that $r + s - 1 = 2$. First, one with $r = 0$ and $s = 3$:

```
> K<a> := NumberField(x^6+x+1);
> Signature(K);
0 3
> G, phi := UnitGroup(K);
> G;
Abelian Group isomorphic to Z/2 + Z + Z
Defined on 3 generators
Relations:
    2*G.1 = 0
> u1 := K!phi(G.2); u1;
a
> u2 := K!phi(G.3); u2;
-2*a^5 - a^3 + a^2 + a
> Logs(u1);
[ 0.11877157353322375762475480482285510811783185904379239999998,
0.04864390975267339963515094053332998614834212839311989999997,
-0.16741548328589715725990574535618509426617398743691229999999 ]
> Logs(u2);
[ 1.6502294567845884711894772749682228152154948421589999999997,

0.44615593456068932413543932586548670421832624686433469999994 ]
```

Notice that the log image of u_1 is clearly not a real multiple of the log image of u_2 (e.g., the scalar would have to be positive because of the first coefficient, but negative because of the second). This illustrates the fact that the log images of u_1 and u_2 span a two-dimensional space.

Next we compute a field with $r = 3$ and $s = 0$. (A field with $s = 0$ is called "totally real".)

```
> K<a> := NumberField(x^3 + x^2 - 5*x - 1);
> Signature(K);
3 0
> G, phi := UnitGroup(K);
> G;
Abelian Group isomorphic to Z/2 + Z + Z
Defined on 3 generators
Relations:
    2*G.1 = 0
> u1 := K!phi(G.2); u1;
1/2*(a^2 + 2*a - 1)
> u2 := K!phi(G.3); u2;
a
> Logs(u1);
```

```

A family of fields with $r = 0$ (totally complex) is the *cyclotomic fields* $\mathbf{Q}(\zeta_n)$. The degree of $\mathbf{Q}(\zeta_n)$ over $\mathbf{Q}$ is $\varphi(n)$ and $r = 0$, so $s = \varphi(n)/2$ (assuming $n > 2$).

```

In the next chapter we will study extra structure in the case when K is Galois over $\mathbf{Q}$; the results are nicely algebraic, beautiful, and have interesting ramifications. We'll learn about Frobenius elements, the Artin symbol, decomposition groups, and how the Galois group of K is related to Galois groups of residue class fields. These are the basic structures needed to make any sense of representations of Galois groups, which is at the heart of much of number theory.

Chapter 13

Decomposition and Inertia Groups

13.1 Galois Extensions

Suppose $K \subset \mathbf{C}$ is a number field. Then K is *Galois* if every field homomorphism $K \to \mathbf{C}$ has image K, or equivalently, $\#\operatorname{Aut}(K) = [K : \mathbf{Q}]$. More generally, we have the following definition.

Definition 13.1.1 (Galois). An extension K/L of number fields is *Galois* if $\#\operatorname{Aut}(K/L) = [K : L]$, where $\operatorname{Aut}(K/L)$ is the group of automorphisms of K that fix L. We write $\operatorname{Gal}(K/L) = \operatorname{Aut}(K/L)$.

For example, $\mathbf{Q}$ is Galois (over itself), any quadratic extension K/L is Galois, since it is of the form $L(\sqrt{a})$, for some $a \in L$, and the nontrivial embedding is induced by $\sqrt{a} \mapsto -\sqrt{a}$, so there is always one nontrivial automorphism. If $f \in L[x]$ is an irreducible cubic polynomial, and a is a root of f, then one proves in a course in Galois theory that $L(a)$ is Galois over L if and only if the discriminant of f is a perfect square in L. Random number fields of degree bigger than 2 are rarely Galois (I will not justify this claim further in this course).

If $K/\mathbf{Q}$ is a number field, then the Galois closure K^{gc} of K is the field generated by all images of K under all embeddings in $\mathbf{C}$ (more generally, if K/L is an extension, the Galois closure of K over L is the field generated by images of embeddings $K \to \mathbf{C}$ that are the identity map on L). If $K = \mathbf{Q}(a)$, then K^{gc} is generated by each of the conjugates of a, and is hence Galois over $\mathbf{Q}$, since the image under an embedding of any polynomial in the conjugates of a is again a polynomial in conjugates of a.

How much bigger can the degree of K^{gc} be as compared to the degree of $K = \mathbf{Q}(a)$? There is a natural embedding of $\operatorname{Gal}(K^{\mathrm{gc}}/\mathbf{Q})$ into the group of permutations of the conjugates of a. If there are n conjugates of a, then this is an embedding $\operatorname{Gal}(K^{\mathrm{gc}}/\mathbf{Q}) \hookrightarrow S_n$, where S_n is the symmetric group on n symbols, which has order $n!$. Thus the degree of the K^{gc} over $\mathbf{Q}$ is a divisor of $n!$. Also the Galois group is a transitive subgroup of S_n, which constrains the possibilities further. When

$n = 2$, we recover the fact that quadratic extensions are Galois. When $n = 3$, we see that the Galois closure of a cubic extension is either the cubic extension or a quadratic extension of the cubic extension. It turns out that that Galois closure of a cubic extension is obtained by adjoining the square root of the discriminant. For an extension K of degree 5, it is "frequently" the case that the Galois closure has degree 120, and in fact it is a difficult and interesting problem to find examples of degree 5 extension in which the Galois closure has degree smaller than 120 (according to Magma: the only possibilities for the order of a transitive proper subgroup of S_5 are 5, 10, 20, and 60; there are five transitive subgroups of S_5 out of the total of 19 subgroups of S_5).

Let n be a positive integer. Consider the field $K = \mathbf{Q}(\zeta_n)$, where $\zeta_n = e^{2\pi i/n}$ is a primitive nth root of unity. If $\sigma : K \to \mathbf{C}$ is an embedding, then $\sigma(\zeta_n)$ is also an nth root of unity, and the group of nth roots of unity is cyclic, so $\sigma(\zeta_n) = \zeta_n^m$ for some m which is invertible modulo n. Thus K is Galois and $\text{Gal}(K/\mathbf{Q}) \hookrightarrow (\mathbf{Z}/n\mathbf{Z})^*$. However, $[K : \mathbf{Q}] = n$, so this map is an isomorphism. (Side note: Taking a p-adic limit and using the maps $\text{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \text{Gal}(\mathbf{Q}(\zeta_{p^r})/\mathbf{Q})$, we obtain a homomorphism $\text{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathbf{Z}_p^*$, which is called the p-adic cyclotomic character.)

Compositums of Galois extensions are Galois. For example, the biquadratic field $K = \mathbf{Q}(\sqrt{5}, \sqrt{-1})$ is a Galois extension of $\mathbf{Q}$ of degree 4.

Fix a number field K that is Galois over a subfield L. Then the Galois group $G = \text{Gal}(K/L)$ acts on many of the object that we have associated to K, including:

- the integers $\mathcal{O}_K$,
- the units U_K,
- the group of nonzero fractional ideals of $\mathcal{O}_K$,
- the class group $\text{Cl}(K)$, and
- the set $S_\mathfrak{p}$ of prime ideals $\mathfrak{P}$ lying over a given prime $\mathfrak{p}$ of $\mathcal{O}_L$.

In the next section we will be concerned with the action of $\text{Gal}(K/L)$ on $S_\mathfrak{p}$, though actions on each of the other objects, especially $\text{Cl}(K)$, will be of further interest.

13.2 Decomposition of Primes

Fix a prime $\mathfrak{p} \subset \mathcal{O}_K$ and write $\mathfrak{p}\mathcal{O}_K = \mathfrak{P}_1^{e_1} \cdots \mathfrak{P}_g^{e_g}$, so $S_\mathfrak{p} = \{\mathfrak{P}_1, \dots, \mathfrak{P}_g\}$.

Definition 13.2.1 (Residue class degree). Suppose $\mathfrak{P}$ is a prime of $\mathcal{O}_K$ lying over $\mathfrak{p}$. Then the *residue class degree* of $\mathfrak{P}$ is

$$f_{\mathfrak{P}/\mathfrak{p}} = [\mathcal{O}_K/\mathfrak{P} : \mathcal{O}_L/\mathfrak{p}],$$

i.e., the degree of the extension of residue class fields.

If $M/K/L$ is a tower of field extensions and $\mathfrak{q}$ is a prime of M over $\mathfrak{P}$, then

$$f_{\mathfrak{q}/\mathfrak{p}} = [\mathcal{O}_M/\mathfrak{q} : \mathcal{O}_L/\mathfrak{p}] = [\mathcal{O}_M/\mathfrak{q} : \mathcal{O}_K/\mathfrak{P}] \cdot [\mathcal{O}_K/\mathfrak{P} : \mathcal{O}_L/\mathfrak{p}] = f_{\mathfrak{q}/\mathfrak{P}} \cdot f_{\mathfrak{P}/\mathfrak{p}},$$

so the residue class degree is multiplicative in towers.

Note that if $\sigma \in \mathrm{Gal}(K/L)$ and $\mathfrak{P} \in S_p$, then σ induces an isomorphism of finite fields $\mathcal{O}_K/\mathfrak{P} \to \mathcal{O}_K/\sigma(\mathfrak{P})$ that fixes the common subfield $\mathcal{O}_L/\mathfrak{p}$. Thus the residue class degrees of $\mathfrak{P}$ and $\sigma(\mathfrak{P})$ are the same. In fact, much more is true.

Theorem 13.2.2. *Suppose K/L is a Galois extension of number fields, and let $\mathfrak{p}$ be a prime of $\mathcal{O}_L$. Write $\mathfrak{p}\mathcal{O}_K = \prod_{i=1}^{g} \mathfrak{P}_i^{e_i}$, and let $f_i = f_{\mathfrak{P}_i/\mathfrak{p}}$. Then $G = \mathrm{Gal}(K/L)$ acts transitively on the set $S_{\mathfrak{p}}$ of primes $\mathfrak{P}_i$,*

$$e_1 = \cdots = e_g, \qquad f_1 = \cdots = f_g,$$

and $efg = [K : L]$, where e is the common value of the e_i and f is the common value of the f_i.

Proof. For simplicity, we will give the proof only in the case $L = \mathbf{Q}$, but the proof works in general. Suppose $p \in \mathbf{Z}$ and $p\mathcal{O}_K = \mathfrak{p}_1^{e_1} \cdots \mathfrak{p}_g^{e_g}$, and $S = \{\mathfrak{p}_1, \ldots, \mathfrak{p}_g\}$. We will first prove that G acts transitively on S. Let $\mathfrak{p} = \mathfrak{p}_i$ for some i. Recall that we proved long ago, using the Chinese Remainder Theorem (Theorem 9.1.3) that there exists $a \in \mathfrak{p}$ such that $(a)/\mathfrak{p}$ is an integral ideal that is coprime to $p\mathcal{O}_K$. The product

$$I = \prod_{\sigma \in G} \sigma((a)/\mathfrak{p}) = \prod_{\sigma \in G} \frac{(\sigma(a))\mathcal{O}_K}{\sigma(\mathfrak{p})} = \frac{(\mathrm{Norm}_{K/\mathbf{Q}}(a))\mathcal{O}_K}{\displaystyle\prod_{\sigma \in G} \sigma(\mathfrak{p})} \qquad (13.2.1)$$

is a nonzero integral $\mathcal{O}_K$ ideal since it is a product of nonzero integral $\mathcal{O}_K$ ideals. Since $a \in \mathfrak{p}$ we have that $\mathrm{Norm}_{K/\mathbf{Q}}(a) \in \mathfrak{p} \cap \mathbf{Z} = p\mathbf{Z}$. Thus the numerator of the rightmost expression in (13.2.1) is divisible by $p\mathcal{O}_K$. Also, because $(a)/\mathfrak{p}$ is coprime to $p\mathcal{O}_K$, each $\sigma((a)/\mathfrak{p})$ is coprime to $p\mathcal{O}_K$ as well. Thus I is coprime to $p\mathcal{O}_K$. Thus the denominator of the rightmost expression in (13.2.1) must also be divisibly by $p\mathcal{O}_K$ in order to cancel the $p\mathcal{O}_K$ in the numerator. Thus for any i we have

$$\prod_{j=1}^{g} \mathfrak{p}_j^{e_j} = p\mathcal{O}_K \;\Big|\; \prod_{\sigma \in G} \sigma(\mathfrak{p}_i),$$

which in particular implies that G acts transitively on the $\mathfrak{p}_i$.

Choose some j and suppose that $k \neq j$ is another index. Because G acts transitively, there exists $\sigma \in G$ such that $\sigma(\mathfrak{p}_k) = \mathfrak{p}_j$. Applying σ to the factorization $p\mathcal{O}_K = \prod_{i=1}^{g} \mathfrak{p}_i^{e_i}$, we see that

$$\prod_{i=1}^{g} \mathfrak{p}_i^{e_i} = \prod_{i=1}^{g} \sigma(\mathfrak{p}_i)^{e_i}.$$

Taking $\mathrm{ord}_{\mathfrak{p}_j}$ on both sides we get $e_j = e_k$. Thus $e_1 = e_2 = \cdots = e_g$.

As was mentioned right before the statement of the theorem, for any $\sigma \in G$ we have $\mathcal{O}_K/\mathfrak{p}_i \cong \mathcal{O}_K/\sigma(\mathfrak{p}_i)$, so by transitivity $f_1 = f_2 = \cdots = f_g$. Since $\mathcal{O}_K$ is a lattice in K, we have

$$\begin{aligned}[K:\mathbf{Q}] &= \dim_{\mathbf{Z}} \mathcal{O}_K = \dim_{\mathbf{F}_p} \mathcal{O}_K/p\mathcal{O}_K \\ &= \dim_{\mathbf{F}_p}\left(\bigoplus_{i=1}^{g} \mathcal{O}_K/\mathfrak{p}_i^{e_i}\right) = \sum_{i=1}^{g} e_i f_i = efg,\end{aligned}$$

which completes the proof. □

The rest of this section illustrates the theorem for quadratic fields and a cubic field and its Galois closure.

13.2.1 Quadratic Extensions

Suppose $K/\mathbf{Q}$ is a quadratic field. Then K is Galois, so for each prime $p \in \mathbf{Z}$ we have $2 = efg$. There are exactly three possibilties:

- **Ramified:** $e = 2$, $f = g = 1$: The prime p ramifies in $\mathcal{O}_K$, so $p\mathcal{O}_K = \mathfrak{p}^2$. There are only finitely many such primes, since if $f(x)$ is the minimal polynomial of a generator for $\mathcal{O}_K$, then p ramifies if and only if $f(x)$ has a multiple root modulo p. However, $f(x)$ has a multiple root modulo p if and only if p divides the discriminant of $f(x)$, which is nonzero because $f(x)$ is irreducible over $\mathbf{Z}$. (This argument shows there are only finitely many ramified primes in any number field. In fact, we will later show that the ramified primes are exactly the ones that divide the discriminant.)

- **Inert:** $e = 1$, $f = 2$, $g = 1$: The prime p is inert in $\mathcal{O}_K$, so $p\mathcal{O}_K = \mathfrak{p}$ is prime. This happens 50% of the time, which is suggested by quadratic reciprocity (but not proved this way), as we will see illustrated below for a particular example.

- **Split:** $e = f = 1$, $g = 2$: The prime p splits in $\mathcal{O}_K$, in the sense that $p\mathcal{O}_K = \mathfrak{p}_1\mathfrak{p}_2$ with $\mathfrak{p}_1 \neq \mathfrak{p}_2$. This happens the other 50% of the time.

Suppose, in particular, that $K = \mathbf{Q}(\sqrt{5})$, so $\mathcal{O}_K = \mathbf{Z}[\gamma]$, where $\gamma = (1+\sqrt{5})/2$. Then $p = 5$ is ramified, since $p\mathcal{O}_K = (\sqrt{5})^2$. More generally, the order $\mathbf{Z}[\sqrt{5}]$ has index 2 in $\mathcal{O}_K$, so for any prime $p \neq 2$ we can determine the factorization of p in $\mathcal{O}_K$ by finding the factorization of the polynomial $x^2 - 5 \in \mathbf{F}_p[x]$. The polynomial $x^2 - 5$ splits as a product of two distinct factors in $\mathbf{F}_p[x]$ if and only if $e = f = 1$ and $g = 2$. For $p \neq 2, 5$ this is the case if and only if 5 is a square in $\mathbf{F}_p$, i.e., if $\left(\frac{5}{p}\right) = 1$, where $\left(\frac{5}{p}\right)$ is $+1$ if 5 is a square mod p and -1 if 5 is not. By quadratic reciprocity,

$$\left(\frac{5}{p}\right) = (-1)^{\frac{5-1}{2}\cdot\frac{p-1}{2}} \cdot \left(\frac{p}{5}\right) = \left(\frac{p}{5}\right) = \begin{cases} +1 & \text{if } p \equiv \pm 1 \pmod{5} \\ -1 & \text{if } p \equiv \pm 2 \pmod{5}. \end{cases}$$

Thus whether p splits or is inert in $\mathcal{O}_K$ is determined by the residue class of p modulo 5.

13.2.2 The Cube Roots of Two

Suppose $K/\mathbf{Q}$ is not Galois. Then e_i, f_i, and g are defined for each prime $p \in \mathbf{Z}$, but we need not have $e_1 = \cdots = e_g$ or $f_1 = \cdots = f_g$. We do still have that $\sum_{i=1}^{g} e_i f_i = n$, by the Chinese Remainder Theorem.

For example, let $K = \mathbf{Q}(\sqrt[3]{2})$. We know that $\mathcal{O}_K = \mathbf{Z}[\sqrt[3]{2}]$. Thus $2\mathcal{O}_K = (\sqrt[3]{2})^3$, so for 2 we have $e = 3$ and $f = g = 1$. To factor $3\mathcal{O}_K$, we note that working modulo 3 we have

$$x^3 - 2 = (x-2)(x^2+2x+1) = (x-2)(x+1)^2 \in \mathbf{F}_3[x],$$

so

$$3\mathcal{O}_K = (3, \sqrt[3]{2} - 2) \cdot (3, \sqrt[3]{2} + 1)^2.$$

Thus $e_1 = 1$, $e_2 = 2$, $f_1 = f_2 = 1$, and $g = 2$. Next, working modulo 5 we have

$$x^3 - 2 = (x+2)(x^2+3x+4) \in \mathbf{F}_5[x],$$

and the quadratic factor is irreducible. Thus

$$5\mathcal{O}_K = (5, \sqrt[3]{2} + 2) \cdot (5, \sqrt[3]{2}^2 + 3\sqrt[3]{2} + 4).$$

Thus here $e_1 = e_2 = 1$, $f_1 = 1$, $f_2 = 2$, and $g = 2$.

Next we consider what happens in the Galois closure of K. Since the three embeddings of $\sqrt[3]{2}$ in $\mathbf{C}$ are $\sqrt[3]{2}$, $\zeta_3\sqrt[3]{2}$, and $\zeta_3^2\sqrt[3]{2}$, we have

$$M = K^{\mathrm{gc}} = \mathbf{Q}(\sqrt[3]{2}, \zeta_3) = K.L,$$

where $L = \mathbf{Q}(\zeta_3) = \mathbf{Q}(\sqrt{-3})$, since $\zeta_3 = (-1+\sqrt{-3})/2$ is a primitive cube root of unity. The notation $K.L$ means the "compositum of K and L", which is the smallest field generated by K and L.

Let's figure out e, f, and g for the prime $p = 3$ relative to the degree six Galois field $M/\mathbf{Q}$ by using Theorem 13.2.2 and what we can easily determine about K and L. First, we know that $efg = 6$. We have $3\mathcal{O}_K = \mathfrak{p}_1\mathfrak{p}_2^2$, so $3\mathcal{O}_M = \mathfrak{p}_1\mathcal{O}_M \cdot (\mathfrak{p}_2\mathcal{O}_M)^2$, and the prime factors of $\mathfrak{p}_1\mathcal{O}_M$ are disjoint from the prime factors of $\mathfrak{p}_2\mathcal{O}_M$. Thus $e > 1$ is even and also $g > 1$. The only possibility for e, f, g satisfying these two conditions is $e = 2$, $f = 1$, $g = 3$, so we conclude that $3\mathcal{O}_M = \mathfrak{q}_1^2\mathfrak{q}_2^2\mathfrak{q}_3^2$ without doing any further work, and without actually knowing the $\mathfrak{q}_i$ explicitly.

Here's another interesting deduction that we can make "by hand". Suppose for the moment that $\mathcal{O}_M = \mathbf{Z}[\sqrt[3]{2}, \zeta_3]$ (this will turn out to be false). Then the factorization of $(\sqrt{-3}) \subset \mathcal{O}_L$ in $\mathcal{O}_M$ would be exactly reflected by the factorization of $x^3 - 2$ in $\mathbf{F}_3 = \mathcal{O}_L/(\sqrt{-3})$. Modulo 3 we have $x^3 - 2 = x^3 + 1 = (x+1)^3$, which would imply that $(\sqrt{-3}) = \mathfrak{q}^3$ for some prime $\mathfrak{q}$ of $\mathcal{O}_M$, i.e., that $e = 6$ and $f = g = 1$, which is incorrect. Thus $\mathcal{O}_M \neq \mathbf{Z}[\sqrt[3]{2}, \zeta_3]$. Indeed, this conclusion agrees with the following Magma computation, which asserts that $[\mathcal{O}_M : \mathbf{Z}[\sqrt[3]{2}, \zeta_3]] = 24$:

```
> R<x> := PolynomialRing(RationalField());
> K := NumberField(x^3-2);
> L := NumberField(x^2+3);
> M := CompositeFields(K,L)[1];
> O_M := MaximalOrder(M);
> a := M!K.1;
> b := M!L.1;
> O := Order([a,b]);
> Index(O_M,O);
24
```

Chapter 14

Decomposition Groups and Galois Representations

14.1 The Decomposition Group

Suppose K is a number field that is Galois over $\mathbf{Q}$ with group $G = \mathrm{Gal}(K/\mathbf{Q})$. Fix a prime $\mathfrak{p} \subset \mathcal{O}_K$ lying over $p \in \mathbf{Z}$.

Definition 14.1.1 (Decomposition group). The *decomposition group* of $\mathfrak{p}$ is the subgroup

$$D_\mathfrak{p} = \{\sigma \in G : \sigma(\mathfrak{p}) = \mathfrak{p}\} \leq G.$$

(Note: The decomposition group is called the "splitting group" in Swinnerton-Dyer. Everybody I know calls it the decomposition group, so we will too.)

Let $\mathbf{F}_\mathfrak{p} = \mathcal{O}_K/\mathfrak{p}$ denote the residue class field of $\mathfrak{p}$. In this section we will prove that there is a natural exact sequence

$$1 \to I_\mathfrak{p} \to D_\mathfrak{p} \to \mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p) \to 1,$$

where $I_\mathfrak{p}$ is the *inertia subgroup* of $D_\mathfrak{p}$, and $\#I_\mathfrak{p} = e$. The most interesting part of the proof is showing that the natural map $D_\mathfrak{p} \to \mathrm{Gal}(\mathbf{F}_\mathfrak{p}/\mathbf{F}_p)$ is surjective.

We will also discuss the structure of $D_\mathfrak{p}$ and introduce Frobenius elements, which play a crucial roll in understanding Galois representations.

Recall that G acts on the set of primes $\mathfrak{p}$ lying over p. Thus the decomposition group is the stabilizer in G of $\mathfrak{p}$. The orbit-stabilizer theorem implies that $[G : D_\mathfrak{p}]$ equals the orbit of $\mathfrak{p}$, which by Theorem 13.2.2 equals the number g of primes lying over p, so $[G : D_\mathfrak{p}] = g$.

Lemma 14.1.2. *The decomposition subgroups $D_\mathfrak{p}$ corresponding to primes $\mathfrak{p}$ lying over a given p are all conjugate in G.*

Proof. We have $\tau(\sigma(\tau^{-1}(\mathfrak{p}))) = \mathfrak{p}$ if and only if $\sigma(\tau^{-1}(\mathfrak{p})) = \tau^{-1}\mathfrak{p}$. Thus $\tau\sigma\tau^{-1} \in D_p$ if and only if $\sigma \in D_{\tau^{-1}\mathfrak{p}}$, so $\tau^{-1}D_p\tau = D_{\tau^{-1}\mathfrak{p}}$. The lemma now follows because, by Theorem 13.2.2, G acts transitively on the set of $\mathfrak{p}$ lying over p. □

The decomposition group is extremely useful because it allows us to see the extension $K/\mathbf{Q}$ as a tower of extensions, such that at each step in the tower we understand well the splitting behavior of the primes lying over p. Now might be a good time to glance ahead at Figure 14.1.2 on page 101.

We characterize the fixed field of $D = D_{\mathfrak{p}}$ as follows.

Proposition 14.1.3. *The fixed field K^D of D*

$$K^D = \{a \in K : \sigma(a) = a \textit{ for all } \sigma \in D\}$$

is the smallest subfield $L \subset K$ such that $\mathfrak{p} \cap L$ does not split in K (i.e., $g(K/L) = 1$).

Proof. First suppose $L = K^D$, and note that by Galois theory $\mathrm{Gal}(K/L) \cong D$, and by Theorem 13.2.2, the group D acts transitively on the primes of K lying over $\mathfrak{p} \cap L$. One of these primes is $\mathfrak{p}$, and D fixes $\mathfrak{p}$ by definition, so there is only one prime of K lying over $\mathfrak{p} \cap L$, i.e., $\mathfrak{p} \cap L$ does not split in K. Conversely, if $L \subset K$ is such that $\mathfrak{p} \cap L$ does not split in K, then $\mathrm{Gal}(K/L)$ fixes $\mathfrak{p}$ (since it is the only prime over $\mathfrak{p} \cap L$), so $\mathrm{Gal}(K/L) \subset D$, hence $K^D \subset L$. □

Thus p does not split in going from K^D to K—it does some combination of ramifying and staying inert. To fill in more of the picture, the following proposition asserts that p splits completely and does not ramify in $K^D/\mathbf{Q}$.

Proposition 14.1.4. *Let $L = K^D$ for our fixed prime p and Galois extension $K/\mathbf{Q}$. Let $e = e(L/\mathbf{Q}), f = f(L/\mathbf{Q}), g = g(L/\mathbf{Q})$ be for $L/\mathbf{Q}$ and p. Then $e = f = 1$ and $g = [L : \mathbf{Q}]$, i.e., p does not ramify and splits completely in L. Also $f(K/\mathbf{Q}) = f(K/L)$ and $e(K/\mathbf{Q}) = e(K/L)$.*

Proof. As mentioned right after Definition 14.1.1, the orbit-stabilizer theorem implies that $g(K/\mathbf{Q}) = [G : D]$, and by Galois theory $[G : D] = [L : \mathbf{Q}]$. Thus

$$\begin{aligned} e(K/L) \cdot f(K/L) &= [K : L] = [K : \mathbf{Q}]/[L : \mathbf{Q}] \\ &= \frac{e(K/\mathbf{Q}) \cdot f(K/\mathbf{Q}) \cdot g(K/\mathbf{Q})}{[L : \mathbf{Q}]} = e(K/\mathbf{Q}) \cdot f(K/\mathbf{Q}). \end{aligned}$$

Now $e(K/L) \leq e(K/\mathbf{Q})$ and $f(K/L) \leq f(K/\mathbf{Q})$, so we must have $e(K/L) = e(K/\mathbf{Q})$ and $f(K/L) = f(K/\mathbf{Q})$. Since $e(K/\mathbf{Q}) = e(K/L) \cdot e(L/\mathbf{Q})$ and $f(K/\mathbf{Q}) = f(K/L) \cdot f(L/\mathbf{Q})$, the proposition follows. □

14.1.1 Galois groups of finite fields

Each $\sigma \in D = D_{\mathfrak{p}}$ acts in a well-defined way on the finite field $\mathbf{F}_{\mathfrak{p}} = \mathcal{O}_K/\mathfrak{p}$, so we obtain a homomorphism

$$\varphi : D_{\mathfrak{p}} \to \mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p).$$

We pause for a moment and derive a few basic properties of $\mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$, which are in fact general properties of Galois groups for finite fields. Let $f = [\mathbf{F}_{\mathfrak{p}} : \mathbf{F}_p]$.

The group $\mathrm{Aut}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ contains the element Frob_p defined by

$$\mathrm{Frob}_p(x) = x^p,$$

because $(xy)^p = x^p y^p$ and

$$(x+y)^p = x^p + px^{p-1}y + \cdots + y^p \equiv x^p + y^p \pmod{p}.$$

By Exercise 29 (see Chapter 22), the group $\mathbf{F}_{\mathfrak{p}}^*$ is cyclic, so there is an element $a \in \mathbf{F}_{\mathfrak{p}}^*$ of order $p^f - 1$, and $\mathbf{F}_{\mathfrak{p}} = \mathbf{F}_p(a)$. Then $\mathrm{Frob}_p^n(a) = a^{p^n} = a$ if and only if $(p^f - 1) \mid p^n - 1$ which is the case preciselywhen $f \mid n$, so the order of Frob_p is f. Since the order of the automorphism group of a field extension is at most the degree of the extension, we conclude that $\mathrm{Aut}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ is generated by Frob_p. Also, since $\mathrm{Aut}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ has order equal to the degree, we conclude that $\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p$ is Galois, with group $\mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ cyclic of order f generated by Frob_p. (Anther general fact: Up to isomorphism there is exactly one finite field of each degree. Indeed, if there were two of degree f, then both could be characterized as the set of roots in the compositum of $x^{p^f} - 1$, hence they would be equal.)

14.1.2 The Exact Sequence

There is a natural reduction homomorphism

$$\varphi : D_{\mathfrak{p}} \to \mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p).$$

Theorem 14.1.5. *The homomorphism φ is surjective.*

Proof. Let $\tilde{a} \in \mathbf{F}_{\mathfrak{p}}$ be an element such that $\mathbf{F}_{\mathfrak{p}} = \mathbf{F}_p(a)$. Lift $\tilde{a}$ to an algebraic integer $a \in \mathcal{O}_K$, and let $f = \prod_{\sigma \in D_p}(x - \sigma(a)) \in K^D[x]$ be the characteristic polynomial of a over K^D. Using Proposition 14.1.4 we see that f reduces to the minimal polynomial $\tilde{f} = \prod(x - \widetilde{\sigma(a)}) \in \mathbf{F}_p[x]$ of $\tilde{a}$ (by the Proposition the coefficients of $\tilde{f}$ are in $\mathbf{F}_p$, and $\tilde{a}$ satisfies $\tilde{f}$, and the degree of $\tilde{f}$ equals the degree of the minimal polynomial of $\tilde{a}$). The roots of $\tilde{f}$ are of the form $\tilde{\sigma}(a)$, and the element $\mathrm{Frob}_p(a)$ is also a root of $\tilde{f}$, so it is of the form $\widetilde{\sigma(a)}$. We conclude that the generator Frob_p of $\mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ is in the image of φ, which proves the theorem. □

Definition 14.1.6 (Inertia Group). The *inertia group* is the kernel $I_{\mathfrak{p}}$ of $D_{\mathfrak{p}} \to \mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$.

Combining everything so far, we find an exact sequence of groups

$$1 \to I_{\mathfrak{p}} \to D_{\mathfrak{p}} \to \mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p) \to 1. \tag{14.1.1}$$

The inertia group is a measure of how p ramifies in K.

Corollary 14.1.7. *We have $\#I_{\mathfrak{p}} = e(\mathfrak{p}/p)$, where $\mathfrak{p}$ is a prime of K over p.*

Proof. The sequence (14.1.1) implies that $\#I_{\mathfrak{p}} = \#D_{\mathfrak{p}}/f(K/\mathbf{Q})$. Applying Propositions 14.1.3–14.1.4, we have

$$\#D_{\mathfrak{p}} = [K : L] = \frac{[K : \mathbf{Q}]}{g} = \frac{efg}{g} = ef.$$

Dividing both sides by $f = f(K/\mathbf{Q})$ proves the corollary. □

We have the following characterization of $I_{\mathfrak{p}}$.

Proposition 14.1.8. *Let $K/\mathbf{Q}$ be a Galois extension with group G, let $\mathfrak{p}$ be a prime lying over a prime p. Then*

$$I_{\mathfrak{p}} = \{\sigma \in G : \sigma(a) = a \pmod{\mathfrak{p}} \textit{ for all } a \in \mathcal{O}_K\}.$$

Proof. By definition $I_{\mathfrak{p}} = \{\sigma \in D_{\mathfrak{p}} : \sigma(a) = a \pmod{\mathfrak{p}}$ for all $a \in \mathcal{O}_K\}$, so it suffices to show that if $\sigma \notin D_{\mathfrak{p}}$, then there exists $a \in \mathcal{O}_K$ such that $\sigma(a) = a \pmod{\mathfrak{p}}$. If $\sigma \notin D_{\mathfrak{p}}$, we have $\sigma^{-1}(\mathfrak{p}) \neq \mathfrak{p}$, so since both are maximal ideals, there exists $a \in \mathfrak{p}$ with $a \notin \sigma^{-1}(\mathfrak{p})$, i.e., $\sigma(a) \notin \mathfrak{p}$. Thus $\sigma(a) \not\equiv a \pmod{\mathfrak{p}}$. □

Figure 14.1.2 is a picture of the splitting behavior of a prime $p \in \mathbf{Z}$.

14.2 Frobenius Elements

Suppose that $K/\mathbf{Q}$ is a finite Galois extension with group G and p is a prime such that $e = 1$ (i.e., an unramified prime). Then $I = I_{\mathfrak{p}} = 1$ for any $\mathfrak{p} \mid p$, so the map φ of Theorem 14.1.5 is a canonical isomorphism $D_{\mathfrak{p}} \cong \mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$. By Section 14.1.1, the group $\mathrm{Gal}(\mathbf{F}_{\mathfrak{p}}/\mathbf{F}_p)$ is cyclic with canonical generator Frob_p. The *Frobenius element* corresponding to $\mathfrak{p}$ is $\mathrm{Frob}_{\mathfrak{p}} \in D_{\mathfrak{p}}$. It is the unique element of G such that for all $a \in \mathcal{O}_K$ we have

$$\mathrm{Frob}_{\mathfrak{p}}(a) \equiv a^p \pmod{\mathfrak{p}}.$$

(To see this argue as in the proof of Proposition 14.1.8.) Just as the primes $\mathfrak{p}$ and decomposition groups D are all conjugate, the Frobenius elements over a given prime are conjugate.

Proposition 14.2.1. *For each $\sigma \in G$, we have*

$$\mathrm{Frob}_{\sigma\mathfrak{p}} = \sigma \, \mathrm{Frob}_{\mathfrak{p}} \, \sigma^{-1}.$$

In particular, the Frobenius elements lying over a given prime are all conjugate.

Proof. Fix $\sigma \in G$. For any $a \in \mathcal{O}_K$ we have $\mathrm{Frob}_{\mathfrak{p}}(\sigma^{-1}(a)) - \sigma^{-1}(a) \in \mathfrak{p}$. Multiply by σ we see that $\sigma \, \mathrm{Frob}_{\mathfrak{p}}(\sigma^{-1}(a)) - a \in \sigma\mathfrak{p}$, which proves the proposition. □

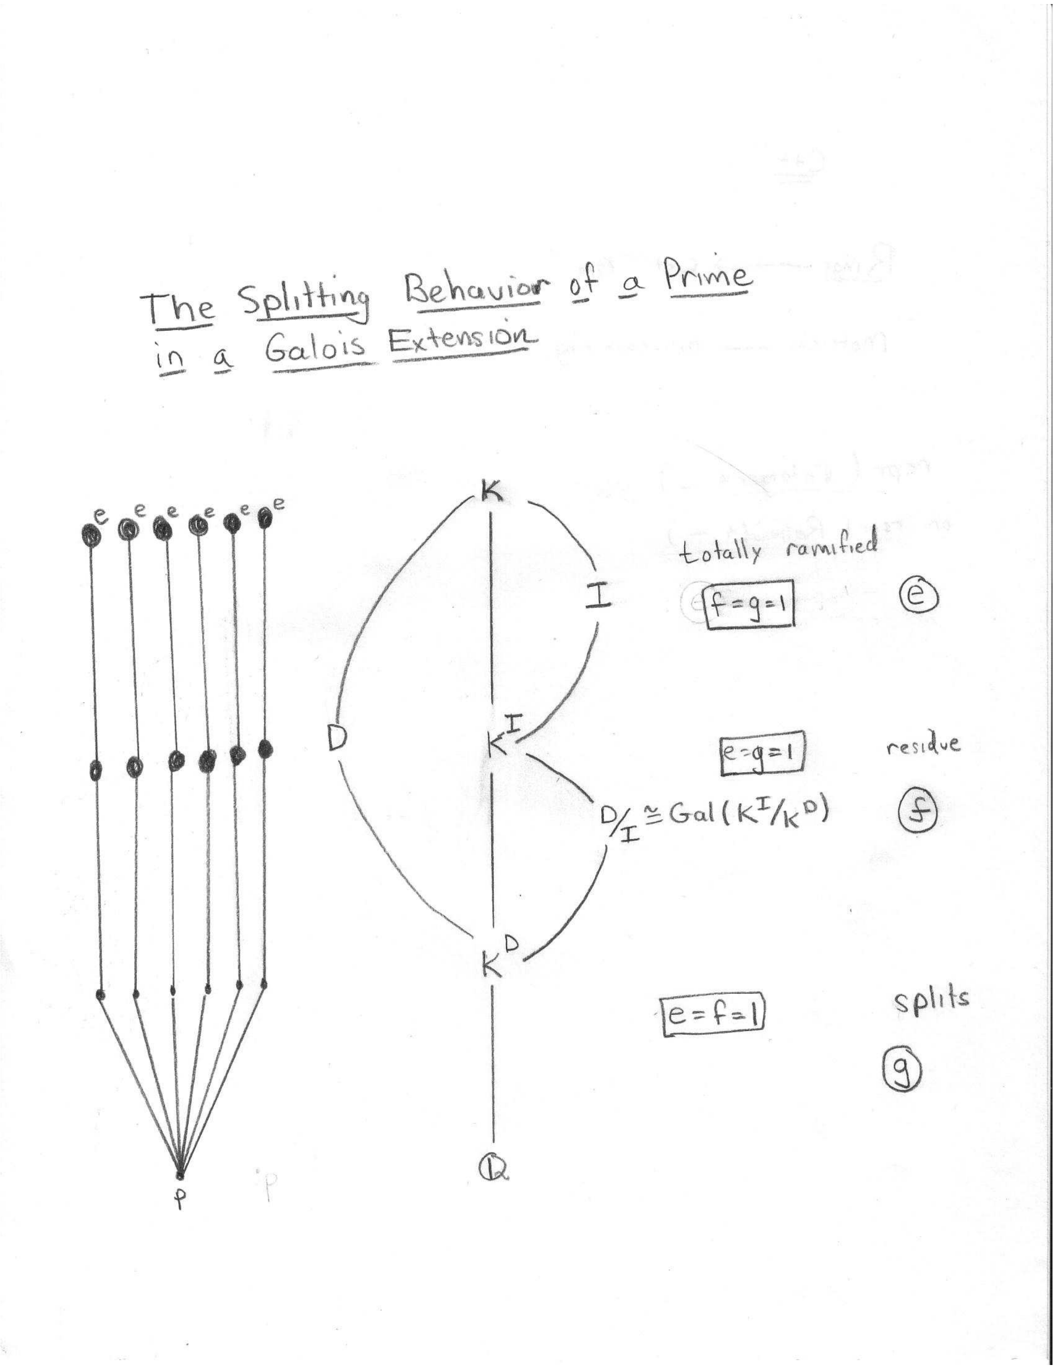

Figure 14.1.1: The Splitting of Behavior of a Prime in a Galois Extension

Thus the conjugacy class of $\mathrm{Frob}_{\mathfrak{p}}$ in G is a well defined function of p. For example, if G is abelian, then $\mathrm{Frob}_{\mathfrak{p}}$ does not depend on the choice of $\mathfrak{p}$ lying over p and we obtain a well defined symbol $\left(\frac{K/\mathbf{Q}}{p}\right) = \mathrm{Frob}_{\mathfrak{p}} \in G$ called the *Artin symbol.* It extends to a map from the free abelian group on unramified primes to the group G (the fractional ideals of $\mathbf{Z}$). Class field theory (for $\mathbf{Q}$) sets up a natural bijection between abelian Galois extensions of $\mathbf{Q}$ and certain maps from certain subgroups of the group of fractional ideals for $\mathbf{Z}$. We have just described one direction of this bijection, which associates to an abelian extension the Artin symbol (which induces a homomorphism). The Kronecker-Weber theorem asserts that the abelian extensions of $\mathbf{Q}$ are exactly the subfields of the fields $\mathbf{Q}(\zeta_n)$, as n varies over all positive integers. By Galois theory there is a correspondence between the subfields of $\mathbf{Q}(\zeta_n)$ (which has Galois group $(\mathbf{Z}/n\mathbf{Z})^*$) and the subgroups of $(\mathbf{Z}/n\mathbf{Z})^*$. Giving an abelian extension of $\mathbf{Q}$ is *exactly the same* as giving an integer n and a subgroup of $(\mathbf{Z}/n\mathbf{Z})^*$. Even more importantly, the reciprocity map $p \mapsto \left(\frac{Q(\zeta_n)/\mathbf{Q}}{p}\right)$ is simply $p \mapsto p \in (\mathbf{Z}/n\mathbf{Z})^*$. This is a nice generalization of quadratic reciprocity: for $\mathbf{Q}(\zeta_n)$, the efg for a prime p depends in a simple way on nothing but $p \mod n$.

14.3 Galois Representations and a Conjecture of Artin

The Galois group $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ is an object of central importance in number theory, and I've often heard that in some sense number theory is the study of this group. A good way to study a group is to study how it acts on various objects, that is, to study its representations.

Endow $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ with the topology which has as a basis of open neighborhoods of the origin the subgroups $\mathrm{Gal}(\overline{\mathbf{Q}}/K)$, where K varies over finite Galois extensions of $\mathbf{Q}$. (Note: This is **not** the topology got by taking as a basis of open neighborhoods the collection of finite-index normal subgroups of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$.) Fix a positive integer n and let $\mathrm{GL}_n(\mathbf{C})$ be the group of $n \times n$ invertible matrices over $\mathbf{C}$ with the discrete topology.

Definition 14.3.1. A *complex n-dimensional representation* of $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q})$ is a continuous homomorphism

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_n(\mathbf{C}).$$

For ρ to be continuous means that there is a finite Galois extension $K/\mathbf{Q}$ such that ρ factors through $\mathrm{Gal}(K/\mathbf{Q})$:

$$\begin{tikzcd}
\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \arrow[rr, "\rho"] \arrow[dr] & & \mathrm{GL}_n(\mathbf{C}) \\
& \mathrm{Gal}(K/\mathbf{Q}) \arrow[ur, "\rho'"'] &
\end{tikzcd}$$

For example, one could take K to be the fixed field of $\ker(\rho)$. (Note that continous implies that the image of ρ is finite, but using Zorn's lemma one can show that there are homomorphisms $\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \{\pm 1\}$ with finite image that are not continuous, since they do not factor through the Galois group of any finite Galois extension.)

Fix a Galois representation ρ and a finite Galois extension K such that ρ factors through $\mathrm{Gal}(K/\mathbf{Q})$. For each prime $p \in \mathbf{Z}$ that is not ramified in K, there is an element $\mathrm{Frob}_{\mathfrak{p}} \in \mathrm{Gal}(K/\mathbf{Q})$ that is well-defined up to conjugation by elements of $\mathrm{Gal}(K/\mathbf{Q})$. This means that $\rho'(\mathrm{Frob}_p) \in \mathrm{GL}_n(\mathbf{C})$ is well-defined up to conjugation. Thus the characteristic polynomial $F_p \in \mathbf{C}[x]$ is a well-defined invariant of p and ρ. Let

$$R_p(x) = x^{\deg(F_p)} \cdot F_p(1/x) = 1 + \cdots + \mathrm{Det}(\mathrm{Frob}_p) \cdot x^{\deg(F_p)}$$

be the polynomial obtain by reversing the order of the coefficients of F_p. Following E. Artin, set

$$L(\rho, s) = \prod_{p \text{ unramified}} \frac{1}{R_p(p^{-s})}. \tag{14.3.1}$$

We view. $L(\rho, s)$ as a function of a single complex variable s. One can prove that $L(\rho, s)$ is holomorphic on some right half plane, and extends to a meromorphic function on all $\mathbf{C}$.

Conjecture 14.3.2 (Artin). *The L-series of any continuous representation*

$$\mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{GL}_n(\mathbf{C})$$

is an entire function on all $\mathbf{C}$, except possibly at 1.

This conjecture asserts that there is some way to analytically continue $L(\rho, s)$ to the whole complex plane, except possibly at 1. (A standard fact from complex analysis is that this analytic continuation must be unique.) The simple pole at $s = 1$ corresponds to the trivial representation (the Riemann zeta function), and if $n \geq 2$ and ρ is irreducible, then the conjecture is that ρ extends to a holomorphic function on all $\mathbf{C}$.

The conjecture follows from class field theory for $\mathbf{Q}$ when $n = 1$. When $n = 2$ and the image of ρ in $\mathrm{PGL}_2(\mathbf{C})$ is a solvable group, the conjecture is known, and is a deep theorem of Langlands and others (see [Lan80]), which played a crucial roll in Wiles's proof of Fermat's Last Theorem. When $n = 2$ and the projective image is not solvable, the only possibility is that the projective image is isomorphic to the alternating group A_5. Because A_5 is the symmetric group of the icosahedron, these representations are called *icosahedral*. In this case, Joe Buhler's Harvard Ph.D. thesis gave the first example, there is a whole book [Fre94], which proves Artin's conjecture for 7 icosahedral representation (none of which are twists of each other). Kevin Buzzard and I (Stein) proved the conjecture for 8 more examples. Subsequently, Richard Taylor, Kevin Buzzard, and Mark Dickinson proved the conjecture for an infinite class of icosahedral Galois representations (disjoint from the examples). The general problem for $n = 2$ is still open, but perhaps Taylor and others are still making progress toward it.

Chapter 15

Valuations

The rest of this book is a partial rewrite of [Cas67] meant to make it more accessible. I have attempted to add examples and details of the implicit exercises and remarks that are left to the reader.

15.1 Valuations

Definition 15.1.1 (Valuation). A *valuation* $|\cdot|$ on a field K is a function defined on K with values in $\mathbf{R}_{\geq 0}$ satisfying the following axioms:

(1) $|a| = 0$ if and only if $a = 0$,

(2) $|ab| = |a|\,|b|$, and

(3) there is a constant $C \geq 1$ such that $|1 + a| \leq C$ whenever $|a| \leq 1$.

The *trivial valuation* is the valuation for which $|a| = 1$ for all $a \neq 0$. We will often tacitly exclude the trivial valuation from consideration.

From (2) we have

$$|1| = |1| \cdot |1|,$$

so $|1| = 1$ by (1). If $w \in K$ and $w^n = 1$, then $|w| = 1$ by (2). In particular, the only valuation of a finite field is the trivial one. The same argument shows that $|-1| = |1|$, so

$$|-a| = |a| \qquad \text{all } a \in K.$$

Definition 15.1.2 (Equivalent). Two valuations $|\cdot|_1$ and $|\cdot|_2$ on the same field are *equivalent* if there exists $c > 0$ such that

$$|a|_2 = |a|_1^c$$

for all $a \in K$.

Note that if $|\cdot|_1$ is a valuation, then $|\cdot|_2 = |\cdot|_1^c$ is also a valuation. Also, equivalence of valuations is an equivalence relation.

If $|\cdot|$ is a valuation and C is the constant from Axiom (3), then there is a $c > 0$ such that $C^c = 2$ (i.e., $c = \log(C)/\log(2)$). Then we can take 2 as constant for the equivalent valuation $|\cdot|^c$. Thus every valuation is equivalent to a valuation with $C = 2$. Note that if $C = 1$, e.g., if $|\cdot|$ is the trivial valuation, then we could simply take $C = 2$ in Axiom (3).

Proposition 15.1.3. *Suppose $|\cdot|$ is a valuation with $C = 2$. Then for all $a, b \in K$ we have*

$$|a + b| \leq |a| + |b| \qquad \textit{(triangle inequality).} \tag{15.1.1}$$

Proof. Suppose $a_1, a_2 \in K$ with $|a_1| \geq |a_2|$. Then $a = a_2/a_1$ satisfies $|a| \leq 1$. By Axiom (3) we have $|1 + a| \leq 2$, so multiplying by a_1 we see that

$$|a_1 + a_2| \leq 2|a_1| = 2 \cdot \max\{|a_1|, |a_2|\}.$$

Also we have

$$|a_1 + a_2 + a_3 + a_4| \leq 2 \cdot \max\{|a_1 + a_2|, |a_3 + a_4|\} \leq 4 \cdot \max\{|a_1|, |a_2|, |a_3|, |a_4|\},$$

and inductively we have for any $r > 0$ that

$$|a_1 + a_2 + \cdots + a_{2^r}| \leq 2^r \cdot \max |a_j|.$$

If n is any positive integer, let r be such that $2^{r-1} \leq n \leq 2^r$. Thenn

$$|a_1 + a_2 + \cdots + a_n| \leq 2^r \cdot \max\{|a_j|\} \leq 2n \cdot \max\{|a_j|\},$$

since $2^r \leq 2n$. In particular,

$$|n| \leq 2n \cdot |1| = 2n \qquad \text{(for } n > 0). \tag{15.1.2}$$

Applying (15.1.2) to $\left|\binom{n}{j}\right|$ and using the binomial expansion, we have for any $a, b \in K$ that

$$\begin{aligned}
|a + b|^n &= \left|\sum_{j=0}^{n} \binom{n}{j} a^j b^{n-j}\right| \\
&\leq 2(n+1) \max_j \left\{ \left|\binom{n}{j}\right| |a|^j\, |b|^{n-j} \right\} \\
&\leq 2(n+1) \max_j \left\{ 2\binom{n}{j} |a|^j\, |b|^{n-j} \right\} \\
&\leq 4(n+1) \max_j \left\{ \binom{n}{j} |a|^j\, |b|^{n-j} \right\} \\
&\leq 4(n+1)(|a| + |b|)^n.
\end{aligned}$$

Now take nth roots of both sides to obtain

$$|a+b| \leq \sqrt[n]{4(n+1)} \cdot (|a|+|b|).$$

We have by elementary calculus that

$$\lim_{n\to\infty} \sqrt[n]{4(n+1)} = 1,$$

so $|a+b| \leq |a|+|b|$. (The "elementary calculus": We instead prove that $\sqrt[n]{n} \to 1$, since the argument is the same and the notation is simpler. First, for any $n \geq 1$ we have $\sqrt[n]{n} \geq 1$, since upon taking nth powers this is equivalent to $n \geq 1^n$, which is true by hypothesis. Second, suppose there is an $\varepsilon > 0$ such that $\sqrt[n]{n} \geq 1+\varepsilon$ for all $n \geq 1$. Then taking logs of boths sides we see that $\frac{1}{n}\log(n) \geq \log(1+\varepsilon) > 0$. But $\log(n)/n \to 0$, so there is no such ε. Thus $\sqrt[n]{n} \to 1$ as $n \to \infty$.) □

Note that Axioms (1), (2) and Equation (15.1.1) imply Axiom (3) with $C = 2$. We take Axiom (3) instead of Equation (15.1.1) for the technical reason that we will want to call the square of the absolute value of the complex numbers a valuation.

Lemma 15.1.4. *Suppose $a, b \in K$, and $|\cdot|$ is a valuation on K with $C \leq 2$. Then*

$$\Big| |a| - |b| \Big| \leq |a-b|\,.$$

(Here the big absolute value on the outside of the left-hand side of the inequality is the usual absolute value on real numbers, but the other absolute values are a valuation on an arbitrary field K.)

Proof. We have

$$|a| = |b + (a-b)| \leq |b| + |a-b|,$$

so $|a| - |b| \leq |a-b|$. The same argument with a and b swapped implies that $|b| - |a| \leq |a-b|$, which proves the lemma. □

15.2 Types of Valuations

We define two important properties of valuations, both of which apply to equivalence classes of valuations (i.e., the property holds for $|\cdot|$ if and only if it holds for a valuation equivalent to $|\cdot|$).

Definition 15.2.1 (Discrete). A valuation $|\cdot|$ is *discrete* if there is a $\delta > 0$ such that for any $a \in K$

$$1 - \delta < |a| < 1 + \delta \implies |a| = 1.$$

Thus the absolute values are bounded away from 1.

To say that $|\cdot|$ is discrete is the same as saying that the set

$$G = \bigl\{\log|a| : a \in K, a \neq 0\bigr\} \subset \mathbf{R}$$

forms a discrete subgroup of the reals under addition (because the elements of the group G are bounded away from 0).

Proposition 15.2.2. *A nonzero discrete subgroup G of $\mathbf{R}$ is free on one generator.*

Proof. Since G is discrete there is a positive $m \in G$ such that for any positive $x \in G$ we have $m \leq x$. Suppose $x \in G$ is an arbitrary positive element. By subtracting off integer multiples of m, we find that there is a unique n such that

$$0 \leq x - nm < m.$$

Since $x - nm \in G$ and $0 < x - nm < m$, it follows that $x - nm = 0$, so x is a multiple of m. □

By Proposition 15.2.2, the set of $\log|a|$ for nonzero $a \in K$ is free on one generator, so there is a $c < 1$ such that $|a|$, for $a \neq 0$, runs precisely through the set

$$c^{\mathbf{Z}} = \{c^m : m \in \mathbf{Z}\}$$

(Note: we can replace c by c^{-1} to see that we can assume that $c < 1$).

Definition 15.2.3 (Order). If $|a| = c^m$, we call $m = \mathrm{ord}(a)$ the *order* of a.

Axiom (2) of valuations translates into

$$\mathrm{ord}(ab) = \mathrm{ord}(a) + \mathrm{ord}(b).$$

Definition 15.2.4 (Non-archimedean). A valuation $|\cdot|$ is *non-archimedean* if we can take $C = 1$ in Axiom (3), i.e., if

$$|a + b| \leq \max\bigl\{|a|, |b|\bigr\}. \tag{15.2.1}$$

If $|\cdot|$ is not non-archimedean then it is *archimedean*.

Note that if we can take $C = 1$ for $|\cdot|$ then we can take $C = 1$ for any valuation equivalent to $|\cdot|$. To see that (15.2.1) is equivalent to Axiom (3) with $C = 1$, suppose $|b| \leq |a|$. Then $|b/a| \leq 1$, so Axiom (3) asserts that $|1 + b/a| \leq 1$, which implies that $|a + b| \leq |a| = \max\{|a|, |b|\}$, and conversely.

We note at once the following consequence:

Lemma 15.2.5. *Suppose $|\cdot|$ is a non-archimedean valuation. If $a, b \in K$ with $|b| < |a|$, then $|a + b| = |a|$.*

Proof. Note that $|a+b| \leq \max\{|a|,|b|\} = |a|$, which is true even if $|b| = |a|$. Also,

$$|a| = |(a+b) - b| \leq \max\{|a+b|, |b|\} = |a+b|,$$

where for the last equality we have used that $|b| < |a|$ (if $\max\{|a+b|,|b|\} = |b|$, then $|a| \leq |b|$, a contradiction).

□

Definition 15.2.6 (Ring of Integers). Suppose $|\cdot|$ is a non-archimedean absolute value on a field K. Then

$$\mathcal{O} = \{a \in K : |a| \leq 1\}$$

is a ring called the *ring of integers* of K with respect to $|\cdot|$.

Lemma 15.2.7. *Two non-archimedean valuations $|\cdot|_1$ and $|\cdot|_2$ are equivalent if and only if they give the same $\mathcal{O}$.*

We will prove this modulo the claim (to be proved later in Section 16.1) that valuations are equivalent if (and only if) they induce the same topology.

Proof. Suppose suppose $|\cdot|_1$ is equivalent to $|\cdot|_2$, so $|\cdot|_1 = |\cdot|_2^c$, for some $c > 0$. Then $|c|_1 \leq 1$ if and only if $|c|_2^c \leq 1$, i.e., if $|c|_2 \leq 1^{1/c} = 1$. Thus $\mathcal{O}_1 = \mathcal{O}_2$.

Conversely, suppose $\mathcal{O}_1 = \mathcal{O}_2$. Then $|a|_1 < |b|_1$ if and only if $a/b \in \mathcal{O}_1$ and $b/a \notin \mathcal{O}_1$, so

$$|a|_1 < |b|_1 \iff |a|_2 < |b|_2. \tag{15.2.2}$$

The topology induced by $|\;|_1$ has as basis of open neighborhoods the set of open balls

$$B_1(z,r) = \{x \in K : |x - z|_1 < r\},$$

for $r > 0$, and likewise for $|\;|_2$. Since the absolute values $|b|_1$ get arbitrarily close to 0, the set $\mathcal{U}$ of open balls $B_1(z, |b|_1)$ also forms a basis of the topology induced by $|\;|_1$ (and similarly for $|\;|_2$). By (15.2.2) we have

$$B_1(z, |b|_1) = B_2(z, |b|_2),$$

so the two topologies both have $\mathcal{U}$ as a basis, hence are equal. That equal topologies imply equivalence of the corresponding valuations will be proved in Section 16.1. □

The set of $a \in \mathcal{O}$ with $|a| < 1$ forms an ideal $\mathfrak{p}$ in $\mathcal{O}$. The ideal $\mathfrak{p}$ is maximal, since if $a \in \mathcal{O}$ and $a \notin \mathfrak{p}$ then $|a| = 1$, so $|1/a| = 1/|a| = 1$, hence $1/a \in \mathcal{O}$, so a is a unit.

Lemma 15.2.8. *A non-archimedean valuation $|\cdot|$ is discrete if and only if $\mathfrak{p}$ is a principal ideal.*

Proof. First suppose that $|\cdot|$ is discrete. Choose $\pi \in \mathfrak{p}$ with $|\pi|$ maximal, which we can do since

$$S = \{\log|a| : a \in \mathfrak{p}\} \subset (-\infty, 1],$$

so the discrete set S is bounded above. Suppose $a \in \mathfrak{p}$. Then

$$\left|\frac{a}{\pi}\right| = \frac{|a|}{|\pi|} \leq 1,$$

so $a/\pi \in \mathcal{O}$. Thus

$$a = \pi \cdot \frac{a}{\pi} \in \pi\mathcal{O}.$$

Conversely, suppose $\mathfrak{p} = (\pi)$ is principal. For any $a \in \mathfrak{p}$ we have $a = \pi b$ with $b \in \mathcal{O}$. Thus

$$|a| = |\pi| \cdot |b| \leq |\pi| < 1.$$

Thus $\{|a| : |a| < 1\}$ is bounded away from 1, which is exactly the definition of discrete. □

Example 15.2.9. For any prime p, define the p-adic valuation $|\cdot|_p : \mathbf{Q} \to \mathbf{R}$ as follows. Write a nonzero $\alpha \in K$ as $p^n \cdot \frac{a}{b}$, where $\gcd(a,p) = \gcd(b,p) = 1$. Then

$$\left|p^n \cdot \frac{a}{b}\right|_p := p^{-n} = \left(\frac{1}{p}\right)^n.$$

This valuation is both discrete and non-archimedean. The ring $\mathcal{O}$ is the local ring

$$\mathbf{Z}_{(p)} = \left\{\frac{a}{b} \in \mathbf{Q} : p \nmid b\right\},$$

which has maximal ideal generated by p. Note that $\mathrm{ord}(p^n \cdot \frac{a}{b}) = p^n$.

We will using the following lemma later (e.g., in the proof of Corollary 16.2.4 and Theorem 15.3.2).

Lemma 15.2.10. *A valuation $|\cdot|$ is non-archimedean if and only if $|n| \leq 1$ for all n in the ring generated by 1 in K.*

Note that we cannot identify the ring generated by 1 with $\mathbf{Z}$ in general, because K might have characteristic $p > 0$.

Proof. If $|\cdot|$ is non-archimedean, then $|1| \leq 1$, so by Axiom (3) with $a = 1$, we have $|1 + 1| \leq 1$. By induction it follows that $|n| \leq 1$.

Conversely, suppose $|n| \leq 1$ for all integer multiples n of 1. This condition is also true if we replace $|\cdot|$ by any equivalent valuation, so replace $|\cdot|$ by one with $C \leq 2$, so that the triangle inequality holds. Suppose $a \in K$ with $|a| \leq 1$. Then by the triangle inequality,

$$\begin{aligned}|1+a|^n &= |(1+a)^n|\\ &\leq \sum_{j=0}^{n} \left|\binom{n}{j}\right| |a|\\ &\leq 1 + 1 + \cdots + 1 = n.\end{aligned}$$

Now take nth roots of both sides to get

$$|1+a| \leq \sqrt[n]{n},$$

and take the limit as $n \to \infty$ to see that $|1+a| \leq 1$. This proves that one can take $C = 1$ in Axiom (3), hence that $|\cdot|$ is non-archimedean. □

15.3 Examples of Valuations

The archetypal example of an archimedean valuation is the absolute value on the complex numbers. It is essentially the only one:

Theorem 15.3.1 (Gelfand-Tornheim). *Any field K with an archimedean valuation is isomorphic to a subfield of $\mathbf{C}$, the valuation being equivalent to that induced by the usual absolute value on $\mathbf{C}$.*

We do not prove this here as we do not need it. For a proof, see [Art59, pg. 45, 67].

There are many non-archimedean valuations. On the rationals $\mathbf{Q}$ there is one for every prime $p > 0$, the p-adic valuation, as in Example 15.2.9.

Theorem 15.3.2 (Ostrowski). *The nontrivial valuations on $\mathbf{Q}$ are those equivalent to $|\cdot|_p$, for some prime p, and the usual absolute value $|\cdot|_\infty$.*

Remark 15.3.3. Before giving the proof, we pause with a brief remark about Ostrowski. According to

`http://www-gap.dcs.st-and.ac.uk/~history/Mathematicians/Ostrowski.html`

Ostrowski was a Ukrainian mathematician who lived 1893–1986. Gautschi writes about Ostrowski as follows: "... you are able, on the one hand, to emphasise the abstract and axiomatic side of mathematics, as for example in your theory of general norms, or, on the other hand, to concentrate on the concrete and constructive aspects of mathematics, as in your study of numerical methods, and to do both with equal ease. *You delight in finding short and succinct proofs, of which you have given many examples* ..." [italics mine]

We will now give an example of one of these short and succinct proofs.

Proof. Suppose $|\cdot|$ is a nontrivial valuation on $\mathbf{Q}$.

Nonarchimedean case: Suppose $|c| \leq 1$ for all $c \in \mathbf{Z}$, so by Lemma 15.2.10, $|\cdot|$ is nonarchimedean. Since $|\cdot|$ is nontrivial, the set

$$\mathfrak{p} = \{a \in \mathbf{Z} : |a| < 1\}$$

is nonzero. Also $\mathfrak{p}$ is an ideal and if $|ab| < 1$, then $|a|\,|b| = |ab| < 1$, so $|a| < 1$ or $|b| < 1$, so $\mathfrak{p}$ is a prime ideal of $\mathbf{Z}$. Thus $\mathfrak{p} = p\mathbf{Z}$, for some prime number p. Since every element of $\mathbf{Z}$ has valuation at most 1, if $u \in \mathbf{Z}$ with $\gcd(u,p) = 1$, then $u \notin \mathfrak{p}$, so $|u| = 1$. Let $\alpha = \log_{|p|} \frac{1}{p}$, so $|p|^{\alpha} = \frac{1}{p}$. Then for any r and any $u \in \mathbf{Z}$ with $\gcd(u, p) = 1$, we have

$$|up^r|^{\alpha} = |u|^{\alpha} |p|^{\alpha r} = |p|^{\alpha r} = p^{-r} = |up^r|_p .$$

Thus $|\cdot|^{\alpha} = |\cdot|_p$ on $\mathbf{Z}$, hence on $\mathbf{Q}$ by multiplicativity, so $|\cdot|$ is equivalent to $|\cdot|_p$, as claimed.

Archimedean case: By replacing $|\cdot|$ by a power of $|\cdot|$, we may assume without loss that $|\cdot|$ satisfies the triangle inequality. We first make some general remarks about any valuation that satisfies the triangle inequality. Suppose $a \in \mathbf{Z}$ is greater than 1. Consider, for any $b \in \mathbf{Z}$ the base-a expansion of b:

$$b = b_m a^m + b_{m-1} a^{m-1} + \cdots + b_0,$$

where

$$0 \le b_j < a \qquad (0 \le j \le m),$$

and $b_m \neq 0$. Since $a^m \le b$, taking logs we see that $m \log(a) \le \log(b)$, so

$$m \le \frac{\log(b)}{\log(a)}.$$

Let $M = \max_{1 \le d < a} |d|$. Then by the triangle inequality for $|\cdot|$, we have

$$\begin{aligned}
|b| &\le |b_m|\, a^m + \cdots + |b_1|\, |a| + |b_0| \\
&\le M \cdot (|a|^m + \cdots + |a| + 1) \\
&\le M \cdot (m+1) \cdot \max(1, |a|^m) \\
&\le M \cdot \left(\frac{\log(b)}{\log(a)} + 1\right) \cdot \max\left(1, |a|^{\log(b)/\log(a)}\right),
\end{aligned}$$

where in the last step we use that $m \le \frac{\log(b)}{\log(a)}$. Setting $b = c^n$, for $c \in \mathbf{Z}$, in the above inequality and taking nth roots, we have

$$\begin{aligned}
|c| &\le \left(M \cdot \left(\frac{\log(c^n)}{\log(a)} + 1\right) \cdot \max(1, |a|^{log(c^n)/\log(a)})\right)^{1/n} \\
&= M^{1/n} \cdot \left(\frac{\log(c^n)}{\log(a)} + 1\right)^{1/n} \cdot \max\left(1, |a|^{\log(c^n)/\log(a)}\right)^{1/n}.
\end{aligned}$$

The first factor $M^{1/n}$ converges to 1 as $n \to \infty$, since $M \ge 1$ (because $|1| = 1$). The second factor is

$$\left(\frac{\log(c^n)}{\log(a)} + 1\right)^{1/n} = \left(n \cdot \frac{\log(c)}{\log(a)} + 1\right)^{1/n}$$

which also converges to 1, for the same reason that $n^{1/n} \to 1$ (because $\log(n^{1/n}) = \frac{1}{n}\log(n) \to 0$ as $n \to \infty$). The third factor is

$$\max\left(1, |a|^{\log(c^n)/\log(a)}\right)^{1/n} = \begin{cases} 1 & \text{if } |a| < 1, \\ |a|^{\log(c)/\log(a)} & \text{if } |a| \ge 1. \end{cases}$$

Putting this all together, we see that

$$|c| \leq \max\left(1, |a|^{\frac{\log(c)}{\log(a)}}\right).$$

Our assumption that $|\cdot|$ is nonarchimedean implies that there is $c \in \mathbf{Z}$ with $c > 1$ and $|c| > 1$. Then for all $a \in \mathbf{Z}$ with $a > 1$ we have

$$1 < |c| \leq \max\left(1, |a|^{\frac{\log(c)}{\log(a)}}\right), \tag{15.3.1}$$

so $1 < |a|^{\log(c)/\log(a)}$, so $1 < |a|$ as well (i.e., any $a \in \mathbf{Z}$ with $a > 1$ automatically satisfies $|a| > 1$). Also, taking the $1/\log(c)$ power on both sides of (15.3.1) we see that

$$|c|^{\frac{1}{\log(c)}} \leq |a|^{\frac{1}{\log(a)}}. \tag{15.3.2}$$

Because, as mentioned above, $|a| > 1$, we can interchange the roll of a and c to obtain the reverse inequality of (15.3.2). We thus have

$$|c| = |a|^{\frac{\log(c)}{\log(a)}}.$$

Letting $\alpha = \log(2) \cdot \log_{|2|}(e)$ and setting $a = 2$, we have

$$|c|^{\alpha} = |2|^{\frac{\alpha}{\log(2)} \cdot \log(c)} = \left(|2|^{\log_{|2|}(e)}\right)^{\log(c)} = e^{\log(c)} = c = |c|_{\infty}.$$

Thus for all integers $c \in \mathbf{Z}$ with $c > 1$ we have $|c|^{\alpha} = |c|_{\infty}$, which implies that $|\cdot|$ is equivalent to $|\cdot|_{\infty}$. □

Let k be any field and let $K = k(t)$, where t is transcendental. Fix a real number $c > 1$. If $p = p(t)$ is an irreducible polynomial in the ring $k[t]$, we define a valuation by

$$\left|p^a \cdot \frac{u}{v}\right|_p = c^{-\deg(p)\cdot a}, \tag{15.3.3}$$

where $a \in \mathbf{Z}$ and $u, v \in k[t]$ with $p \nmid u$ and $p \nmid v$.

Remark 15.3.4. This definition differs from the one page 46 of [Cassels-Frohlich, Ch. 2] in two ways. First, we assume that $c > 1$ instead of $c < 1$, since otherwise $|\cdot|_p$ does not satisfy Axiom 3 of a valuation. Also, we write $c^{-\deg(p)\cdot a}$ instead of c^{-a}, so that the product formula will hold. (For more about the product formula, see Section 20.1.)

In addition there is a a non-archimedean valuation $|\cdot|_{\infty}$ defined by

$$\left|\frac{u}{v}\right|_{\infty} = c^{\deg(u)-\deg(v)}. \tag{15.3.4}$$

This definition differs from the one in [Cas67, pg. 46] in two ways. First, we assume that $c > 1$ instead of $c < 1$, since otherwise $|\cdot|_p$ does not satisfy Axiom 3 of a valuation. Here's why: Recall that Axiom 3 for a non-archimedean valuation on K asserts that whenever $a \in K$ and $|a| \leq 1$, then $|a+1| \leq 1$. Set $a = p - 1$, where $p = p(t) \in K[t]$ is an irreducible polynomial. Then $|a| = c^0 = 1$, since $\mathrm{ord}_p(p-1) = 0$. However, $|a+1| = |p-1+1| = |p| = c^1 < 1$, since $\mathrm{ord}_p(p) = 1$. If we take $c > 1$ instead of $c < 1$, as I propose, then $|p| = c^1 > 1$, as required.

Note the (albeit imperfect) analogy between $K = k(t)$ and $\mathbf{Q}$. If $s = t^{-1}$, so $k(t) = k(s)$, the valuation $|\cdot|_\infty$ is of the type (15.3.3) belonging to the irreducible polynomial $p(s) = s$.

The reader is urged to prove the following lemma as a homework problem.

Lemma 15.3.5. *The only nontrivial valuations on $k(t)$ which are trivial on k are equivalent to the valuation (15.3.3) or (15.3.4).*

For example, if k is a finite field, there are no nontrivial valuations on k, so the only nontrivial valuations on $k(t)$ are equivalent to (15.3.3) or (15.3.4).

Chapter 16

Topology and Completeness

16.1 Topology

A valuation $|\cdot|$ on a field K induces a topology in which a basis for the neighborhoods of a are the *open balls*

$$B(a,d) = \{x \in K : |x-a| < d\}$$

for $d > 0$.

Lemma 16.1.1. *Equivalent valuations induce the same topology.*

Proof. If $|\cdot|_1 = |\cdot|_2^r$, then $|x-a|_1 < d$ if and only if $|x-a|_2^r < d$ if and only if $|x-a|_2 < d^{1/r}$ so $B_1(a,d) = B_2(a,d^{1/r})$. Thus the basis of open neighborhoods of a for $|\cdot|_1$ and $|\cdot|_2$ are identical. □

A valuation satisfying the triangle inequality gives a metric for the topology on defining the distance from a to b to be $|a-b|$. Assume for the rest of this section that we only consider valuations that satisfy the triangle inequality.

Lemma 16.1.2. *A field with the topology induced by a valuation is a* topological field, *i.e., the operations sum, product, and reciprocal are continuous.*

Proof. For example (product) the triangle inequality implies that

$$|(a+\varepsilon)(b+\delta) - ab| \leq |\varepsilon|\,|\delta| + |a|\,|\delta| + |b|\,|\varepsilon|$$

is small when $|\varepsilon|$ and $|\delta|$ are small (for fixed a,b). □

Lemma 16.1.3. *Suppose two valuations $|\cdot|_1$ and $|\cdot|_2$ on the same field K induce the same topology. Then for any sequence $\{x_n\}$ in K we have*

$$|x_n|_1 \to 0 \iff |x_n|_2 \to 0.$$

Proof. It suffices to prove that if $|x_n|_1 \to 0$ then $|x_n|_2 \to 0$, since the proof of the other implication is the same. Let $\varepsilon > 0$. The topologies induced by the two absolute values are the same, so $B_2(0, \varepsilon)$ can be covered by open balls $B_1(a_i, r_i)$. One of these open balls $B_1(a, r)$ contains 0. There is $\varepsilon' > 0$ such that

$$B_1(0, \varepsilon') \subset B_1(a, r) \subset B_2(0, \varepsilon).$$

Since $|x_n|_1 \to 0$, there exists N such that for $n \geq N$ we have $|x_n|_1 < \varepsilon'$. For such n, we have $x_n \in B_1(0, \varepsilon')$, so $x_n \in B_2(0, \varepsilon)$, so $|x_n|_2 < \varepsilon$. Thus $|x_n|_2 \to 0$. □

Proposition 16.1.4. *If two valuations $|\cdot|_1$ and $|\cdot|_2$ on the same field induce the same topology, then they are equivalent in the sense that there is a positive real α such that $|\cdot|_1 = |\cdot|_2^\alpha$.*

Proof. If $x \in K$ and $i = 1, 2$, then $|x^n|_i \to 0$ if and only if $|x|_i^n \to 0$, which is the case if and only if $|x|_i < 1$. Thus Lemma 16.1.3 implies that $|x|_1 < 1$ if and only if $|x|_2 < 1$. On taking reciprocals we see that $|x|_1 > 1$ if and only if $|x|_2 > 1$, so finally $|x|_1 = 1$ if and only if $|x|_2 = 1$.

Let now $w, z \in K$ be nonzero elements with $|w|_i \neq 1$ and $|z|_i \neq 1$. On applying the foregoing to

$$x = w^m z^n \qquad (m, n \in \mathbf{Z})$$

we see that

$$m \log |w|_1 + n \log |z|_1 \geq 0$$

if and only if

$$m \log |w|_2 + n \log |z|_2 \geq 0.$$

Dividing through by $\log |z|_i$, and rearranging, we see that for every rational number $\alpha = -n/m$,

$$\frac{\log |w|_1}{\log |z|_1} \geq \alpha \iff \frac{\log |w|_2}{\log |z|_2} \geq \alpha.$$

Thus

$$\frac{\log |w|_1}{\log |z|_1} = \frac{\log |w|_2}{\log |z|_2},$$

so

$$\frac{\log |w|_1}{\log |w|_2} = \frac{\log |z|_1}{\log |z|_2}.$$

Since this equality does not depend on the choice of z, we see that there is a constant c ($= \log |z|_1 / \log |z|_2$) such that $\log |w|_1 / \log |w|_2 = c$ for all w. Thus $\log |w|_1 = c \cdot \log |w|_2$, so $|w|_1 = |w|_2^c$, which implies that $|\cdot|_1$ is equivalent to $|\cdot|_2$. □

16.2 Completeness

We recall the definition of metric on a set X.

Definition 16.2.1 (Metric). A *metric* on a set X is a map

$$d : X \times X \to \mathbf{R}$$

such that for all $x, y, z \in X$,

1. $d(x, y) \geq 0$ and $d(x, y) = 0$ if and only if $x = y$,

2. $d(x, y) = d(y, x)$, and

3. $d(x, z) \leq d(x, y) + d(y, z)$.

A *Cauchy sequence* is a sequence (x_n) in X such that for all $\varepsilon > 0$ there exists M such that for all $n, m > M$ we have $d(x_n, x_m) < \varepsilon$. The *completion* of X is the set of Cauchy sequences (x_n) in X modulo the equivalence relation in which two Cauchy sequences (x_n) and (y_n) are equivalent if $\lim_{n\to\infty} d(x_n, y_n) = 0$. A metric space is *complete* if every Cauchy sequence converges, and one can show that the completion of X with respect to a metric is complete.

For example, $d(x, y) = |x - y|$ (usual archimedean absolute value) defines a metric on $\mathbf{Q}$. The completion of $\mathbf{Q}$ with respect to this metric is the field $\mathbf{R}$ of real numbers. More generally, whenever $|\cdot|$ is a valuation on a field K that satisfies the triangle inequality, then $d(x, y) = |x - y|$ defines a metric on K. Consider for the rest of this section only valuations that satisfy the triangle inequality.

Definition 16.2.2 (Complete). A field K is *complete* with respect to a valuation $|\cdot|$ if given any Cauchy sequence a_n, $(n = 1, 2, \ldots)$, i.e., one for which

$$|a_m - a_n| \to 0 \qquad (m, n \to \infty, \infty),$$

there is an $a^* \in K$ such that

$$a_n \to a^* \qquad \text{w.r.t. } |\cdot|$$

(i.e., $|a_n - a^*| \to 0$).

Theorem 16.2.3. *Every field K with valuation $v = |\cdot|$ can be embedded in a complete field K_v with a valuation $|\cdot|$ extending the original one in such a way that K_v is the closure of K with respect to $|\cdot|$. Further K_v is unique up to a unique isomorphism fixing K.*

Proof. Define K_v to be the completion of K with respect to the metric defined by $|\cdot|$. Thus K_v is the set of equivalence classes of Cauchy sequences, and there is a natural injective map from K to K_v sending an element $a \in K$ to the constant Cauchy sequence (a). Because the field operations on K are continuous, they induce well-defined field operations on equivalence classes of Cauchy sequences componentwise. Also, define a valuation on K_v by

$$|(a_n)_{n=1}^{\infty}| = \lim_{n\to\infty} |a_n|,$$

and note that this is well defined and extends the valuation on K.

To see that K_v is unique up to a unique isomorphism fixing K, we observe that there are no nontrivial continuous automorphisms $K_v \to K_v$ that fix K. This is because, by denseness, a continuous automorphism $\sigma : K_v \to K_v$ is determined by what it does to K, and by assumption σ is the identity map on K. More precisely, suppose $a \in K_v$ and n is a positive integer. Then by continuity there is $\delta > 0$ (with $\delta < 1/n$) such that if $a_n \in K_v$ and $|a - a_n| < \delta$ then $|\sigma(a) - \sigma(a_n)| < 1/n$. Since K is dense in K_v, we can choose the a_n above to be an element of K. Then by hypothesis $\sigma(a_n) = a_n$, so $|\sigma(a) - a_n| < 1/n$. Thus $\sigma(a) = \lim_{n\to\infty} a_n = a$. □

Corollary 16.2.4. *The valuation $|\cdot|$ is non-archimedean on K_v if and only if it is so on K. If $|\cdot|$ is non-archimedean, then the set of values taken by $|\cdot|$ on K and K_v are the same.*

Proof. The first part follows from Lemma 15.2.10 which asserts that a valuation is non-archimedean if and only if $|n| < 1$ for all integers n. Since the valuation on K_v extends the valuation on K, and all n are in K, the first statement follows.

For the second, suppose that $|\cdot|$ is non-archimedean (but not necessarily discrete). Suppose $b \in K_v$ with $b \neq 0$. First I claim that there is $c \in K$ such that $|b - c| < |b|$. To see this, let $c' = b - \frac{b}{a}$, where a is some element of K_v with $|a| > 1$, note that $|b - c'| = \left|\frac{b}{a}\right| < |b|$, and choose $c \in K$ such that $|c - c'| < |b - c'|$, so

$$|b - c| = \left|b - c' - (c - c')\right| \leq \max\left(\left|b - c'\right|, \left|c - c'\right|\right) = \left|b - c'\right| < |b|.$$

Since $|\cdot|$ is non-archimedean, we have

$$|b| = |(b - c) + c| \leq \max\left(|b - c|, |c|\right) = |c|,$$

where in the last equality we use that $|b - c| < |b|$. Also,

$$|c| = |b + (c - b)| \leq \max\left(|b|, |c - b|\right) = |b|,$$

so $|b| = |c|$, which is in the set of values of $|\cdot|$ on K. □

16.2.1 p-adic Numbers

This section is about the p-adic numbers $\mathbf{Q}_p$, which are the completion of $\mathbf{Q}$ with respect to the p-adic valuation. Alternatively, to give a p-adic *integer* in $\mathbf{Z}_p$ is the same as giving for every prime power p^r an element $a_r \in \mathbf{Z}/p^r\mathbf{Z}$ such that if $s \leq r$ then a_s is the reduction of a_r modulo p^s. The field $\mathbf{Q}_p$ is then the field of fractions of $\mathbf{Z}_p$.

We begin with the definition of the N-adic numbers for any positive integer N. Section 16.2.1 is about the N-adics in the special case $N = 10$; these are fun because they can be represented as decimal expansions that go off infinitely far to the left. Section 16.2.3 is about how the topology of $\mathbf{Q}_N$ is nothing like the topology of $\mathbf{R}$. Finally, in Section 16.2.4 we state the Hasse-Minkowski theorem, which shows how to use p-adic numbers to decide whether or not a quadratic equation in n variables has a rational zero.

The N-adic Numbers

Lemma 16.2.5. *Let N be a positive integer. Then for any nonzero rational number α there exists a unique $e \in \mathbf{Z}$ and integers a, b, with b positive, such that $\alpha = N^e \cdot \frac{a}{b}$ with $N \nmid a$, $\gcd(a, b) = 1$, and $\gcd(N, b) = 1$.*

Proof. Write $\alpha = c/d$ with $c, d \in \mathbf{Z}$ and $d > 0$. First suppose d is exactly divisible by a power of N, so for some r we have $N^r \mid d$ but $\gcd(N, d/N^r) = 1$. Then

$$\frac{c}{d} = N^{-r}\frac{c}{d/N^r}.$$

If N^s is the largest power of N that divides c, then $e = s - r$, $a = c/N^s$, $b = d/N^r$ satisfy the conclusion of the lemma.

By unique factorization of integers, there is a smallest multiple f of d such that fd is exactly divisible by N. Now apply the above argument with c and d replaced by cf and df. □

Definition 16.2.6 (N-adic valuation). Let N be a positive integer. For any positive $\alpha \in \mathbf{Q}$, the *N-adic valuation* of α is e, where e is as in Lemma 16.2.5. The N-adic valuation of 0 is ∞.

We denote the N-adic valuation of α by $\mathrm{ord}_N(\alpha)$. (Note: Here we are using "valuation" in a different way than in the rest of the text. This valuation is not an absolute value, but the logarithm of one.)

Definition 16.2.7 (N-adic metric). For $x, y \in \mathbf{Q}$ the *N-adic distance* between x and y is

$$d_N(x, y) = N^{-\mathrm{ord}_N(x-y)}.$$

We let $d_N(x, x) = 0$, since $\mathrm{ord}_N(x - x) = \mathrm{ord}_N(0) = \infty$.

For example, $x, y \in \mathbf{Z}$ are close in the N-adic metric if their difference is divisible by a large power of N. E.g., if $N = 10$ then 93427 and 13427 are close because their difference is 80000, which is divisible by a large power of 10.

Proposition 16.2.8. *The distance d_N on $\mathbf{Q}$ defined above is a metric. Moreover, for all $x, y, z \in \mathbf{Q}$ we have*

$$d(x, z) \leq \max(d(x, y), d(y, z)).$$

(This is the "nonarchimedean" triangle inequality.)

Proof. The first two properties of Definition 16.2.1 are immediate. For the third, we first prove that if $\alpha, \beta \in \mathbf{Q}$ then

$$\mathrm{ord}_N(\alpha+\beta) \geq \min(\mathrm{ord}_N(\alpha), \mathrm{ord}_N(\beta)).$$

Assume, without loss, that $\mathrm{ord}_N(\alpha) \leq \mathrm{ord}_N(\beta)$ and that both α and β are nonzero. Using Lemma 16.2.5 write $\alpha = N^e(a/b)$ and $\beta = N^f(c/d)$ with a or c possibly negative. Then

$$\alpha+\beta = N^e\left(\frac{a}{b} + N^{f-e}\frac{c}{d}\right) = N^e\left(\frac{ad + bcN^{f-e}}{bd}\right).$$

Since $\gcd(N, bd) = 1$ it follows that $\mathrm{ord}_N(\alpha+\beta) \geq e$. Now suppose $x, y, z \in \mathbf{Q}$. Then

$$x - z = (x-y) + (y-z),$$

so

$$\mathrm{ord}_N(x-z) \geq \min(\mathrm{ord}_N(x-y), \mathrm{ord}_N(y-z)),$$

hence $d_N(x,z) \leq \max(d_N(x,y), d_N(y,z))$. □

We can finally define the N-adic numbers.

Definition 16.2.9 (The N-adic Numbers). The set of *N-adic numbers*, denoted $\mathbf{Q}_N$, is the completion of $\mathbf{Q}$ with respect to the metric d_N.

The set $\mathbf{Q}_N$ is a ring, but it need not be a field as you will show in Exercises 57 and 58. It is a field if and only if N is prime. Also, $\mathbf{Q}_N$ has a "bizarre" topology, as we will see in Section 16.2.3.

The 10-adic Numbers

It's a familiar fact that every real number can be written in the form

$$d_n \dots d_1 d_0 . d_{-1} d_{-2} \dots = d_n 10^n + \cdots + d_1 10 + d_0 + d_{-1}10^{-1} + d_{-2}10^{-2} + \cdots$$

where each digit d_i is between 0 and 9, and the sequence can continue indefinitely to the right.

The 10-adic numbers also have decimal expansions, but everything is backward! To get a feeling for why this might be the case, we consider Euler's nonsensical series

$$\sum_{n=1}^{\infty}(-1)^{n+1}n! = 1! - 2! + 3! - 4! + 5! - 6! + \cdots.$$

One can prove (see Exercise 55) that this series converges in $\mathbf{Q}_{10}$ to some element $\alpha \in \mathbf{Q}_{10}$.

What is α? How can we write it down? First note that for all $M \geq 5$, the terms of the sum are divisible by 10, so the difference between α and $1! - 2! + 3! - 4!$ is divisible by 10. Thus we can compute α modulo 10 by computing $1! - 2! + 3! - 4!$ modulo 10. Likewise, we can compute α modulo 100 by compute $1! - 2! + \cdots + 9! - 10!$, etc. We obtain the following table:

α	mod 10^r
1	mod 10
81	mod 10^2
981	mod 10^3
2981	mod 10^4
22981	mod 10^5
422981	mod 10^6

Continuing we see that

$$1! - 2! + 3! - 4! + \cdots = \ldots 637838364422981 \qquad \text{in } \mathbf{Q}_{10}\ !$$

Here's another example. Reducing 1/7 modulo larger and larger powers of 10 we see that

$$\frac{1}{7} = \ldots 857142857143 \qquad \text{in } \mathbf{Q}_{10}.$$

Here's another example, but with a decimal point.

$$\frac{1}{70} = \frac{1}{10} \cdot \frac{1}{7} = \ldots 85714285714.3$$

We have

$$\frac{1}{3} + \frac{1}{7} = \ldots 66667 + \ldots 57143 = \frac{10}{21} = \ldots 23810,$$

which illustrates that addition with carrying works as usual.

Fermat's Last Theorem in $\mathbf{Z}_{10}$

An amusing observation, which people often argued about on USENET news back in the 1990s, is that Fermat's last theorem is false in $\mathbf{Z}_{10}$. For example, $x^3 + y^3 = z^3$ has a nontrivial solution, namely $x = 1$, $y = 2$, and $z = \ldots 60569$. Here z is a cube root of 9 in $\mathbf{Z}_{10}$. Note that it takes some work to prove that there is a cube root of 9 in $\mathbf{Z}_{10}$ (see Exercise 56).

16.2.2 The Field of p-adic Numbers

The ring $\mathbf{Q}_{10}$ of 10-adic numbers is isomorphic to $\mathbf{Q}_2 \times \mathbf{Q}_5$ (see Exercise 58), so it is not a field. For example, the element $\ldots 8212890625$ corresponding to $(1, 0)$ under this isomorphism has no inverse. (To compute n digits of $(1, 0)$ use the Chinese remainder theorem to find a number that is 1 modulo 2^n and 0 modulo 5^n.)

If p is prime then $\mathbf{Q}_p$ is a field (see Exercise 57). Since $p \neq 10$ it is a little more complicated to write p-adic numbers down. People typically write p-adic numbers in the form

$$\frac{a_{-d}}{p^d} + \cdots + \frac{a_{-1}}{p} + a_0 + a_1 p + a_2 p^2 + a_3 p^3 + \cdots$$

where $0 \le a_i < p$ for each i.

16.2.3 The Topology of $\mathbf{Q}_N$ (is Weird)

Definition 16.2.10 (Connected). Let X be a topological space. A subset S of X is *disconnected* if there exist open subsets $U_1, U_2 \subset X$ with $U_1 \cap U_2 \cap S = \emptyset$ and $S = (S \cap U_1) \cup (S \cap U_2)$ with $S \cap U_1$ and $S \cap U_2$ nonempty. If S is not disconnected it is *connected*.

The topology on $\mathbf{Q}_N$ is induced by d_N, so every open set is a union of open balls

$$B(x, r) = \{y \in \mathbf{Q}_N : d_N(x, y) < r\}.$$

Recall Proposition 16.2.8, which asserts that for all x, y, z,

$$d(x, z) \leq \max(d(x, y), d(y, z)).$$

This translates into the following shocking and bizarre lemma:

Lemma 16.2.11. *Suppose $x \in \mathbf{Q}_N$ and $r > 0$. If $y \in \mathbf{Q}_N$ and $d_N(x, y) \geq r$, then $B(x, r) \cap B(y, r) = \emptyset$.*

Proof. Suppose $z \in B(x, r)$ and $z \in B(y, r)$. Then

$$r \leq d_N(x, y) \leq \max(d_N(x, z), d_N(z, y)) < r,$$

a contradiction. □

You should draw a picture to illustrates Lemma 16.2.11.

Lemma 16.2.12. *The open ball $B(x, r)$ is also closed.*

Proof. Suppose $y \notin B(x, r)$. Then $r \leq d(x, y)$ so

$$B(y, d(x, y)) \cap B(x, r) \subset B(y, d(x, y)) \cap B(x, d(x, y)) = \emptyset.$$

Thus the complement of $B(x, r)$ is a union of open balls. □

The lemmas imply that $\mathbf{Q}_N$ is *totally disconnected*, in the following sense.

Proposition 16.2.13. *The only connected subsets of $\mathbf{Q}_N$ are the singleton sets $\{x\}$ for $x \in \mathbf{Q}_N$ and the empty set.*

Proof. Suppose $S \subset \mathbf{Q}_N$ is a nonempty connected set and x, y are distinct elements of S. Let $r = d_N(x, y) > 0$. Let $U_1 = B(x, r)$ and U_2 be the complement of U_1, which is open by Lemma 16.2.12. Then U_1 and U_2 satisfies the conditions of Definition 16.2.10, so S is not connected, a contradiction. □

16.2.4 The Local-to-Global Principle of Hasse and Minkowski

Section 16.2.3 might have convinced you that $\mathbf{Q}_N$ is a bizarre pathology. In fact, $\mathbf{Q}_N$ is omnipresent in number theory, as the following two fundamental examples illustrate.

In the statement of the following theorem, a *nontrivial solution* to a homogeneous polynomial equation is a solution where not all indeterminates are 0.

Theorem 16.2.14 (Hasse-Minkowski). *The quadratic equation*

$$a_1x_1^2 + a_2x_2^2 + \cdots + a_nx_n^2 = 0, \tag{16.2.1}$$

with $a_i \in \mathbf{Q}^\times$, has a nontrivial solution with $x_1, \ldots, x_n$ in $\mathbf{Q}$ if and only if (16.2.1) has a solution in $\mathbf{R}$ and in $\mathbf{Q}_p$ for all primes p.

This theorem is very useful in practice because the p-adic condition turns out to be easy to check. For more details, including a complete proof, see [Ser73, IV.3.2].

The analogue of Theorem 16.2.14 for cubic equations is false. For example, Selmer proved that the cubic

$$3x^3 + 4y^3 + 5z^3 = 0$$

has a solution other than $(0,0,0)$ in $\mathbf{R}$ and in $\mathbf{Q}_p$ for all primes p but has no solution other than $(0,0,0)$ in $\mathbf{Q}$ (for a proof see [Cas91, §18]).

Open Problem. Give an algorithm that decides whether or not a cubic

$$ax^3 + by^3 + cz^3 = 0$$

has a nontrivial solution in $\mathbf{Q}$.

This open problem is closely related to the Birch and Swinnerton-Dyer Conjecture for elliptic curves. The truth of the conjecture would follow if we knew that "Shafarevich-Tate Groups" of elliptic curves were finite.

16.3 Weak Approximation

The following theorem asserts that inequivalent valuations are in fact almost totally indepedent. For our purposes it will be superseded by the strong approximation theorem (Theorem 20.4.4).

Theorem 16.3.1 (Weak Approximation). *Let $|\cdot|_n$, for $1 \leq n \leq N$, be inequivalent nontrivial valuations of a field K. For each n, let K_n be the topological space consisting of the set of elements of K with the topology induced by $|\cdot|_n$. Let Δ be the image of K in the topological product*

$$A = \prod_{1 \leq n \leq N} K_n$$

equipped with the product topology. Then Δ is dense in A.

The conclusion of the theorem may be expressed in a less topological manner as follows: given any $a_n \in K$, for $1 \leq n \leq N$, and real $\varepsilon > 0$, there is an $b \in K$ such that simultaneously

$$|a_n - b|_n < \varepsilon \qquad (1 \leq n \leq N).$$

If $K = \mathbf{Q}$ and the $|\cdot|$ are p-adic valuations, Theorem 16.3.1 is related to the Chinese Remainder Theorem (Theorem 9.1.3), but the strong approximation theorem (Theorem 20.4.4) is the real generalization.

Proof. We note first that it will be enough to find, for each n, an element $c_n \in K$ such that

$$|c_n|_n > 1 \quad \text{and} \quad |c_n|_m < 1 \quad \text{for } n \neq m,$$

where $1 \leq n, m \leq N$. For then as $r \to +\infty$, we have

$$\frac{c_n^r}{1 + c_n^r} = \frac{1}{1 + \left(\frac{1}{c_n}\right)^r} \to \begin{cases} 1 & \text{with respect to } |\cdot|_n \text{ and} \\ 0 & \text{with respect to } |\cdot|_m\text{, for } m \neq n. \end{cases}$$

It is then enough to take

$$b = \sum_{n=1}^{N} \frac{c_n^r}{1 + c_n^r} \cdot a_n$$

By symmetry it is enough to show the existence of $c = c_1$ with

$$|c|_1 > 1 \qquad \text{and} \qquad |c|_n < 1 \quad \text{for} \quad 2 \leq n \leq N.$$

We will do this by induction on N.

First suppose $N = 2$. Since $|\cdot|_1$ and $|\cdot|_2$ are inequivalent (and all absolute values are assumed nontrivial) there is an $a \in K$ such that

$$|a|_1 < 1 \qquad \text{and} \qquad |a|_2 \geq 1 \tag{16.3.1}$$

and similarly a b such that

$$|b|_1 \geq 1 \qquad \text{and} \qquad |b|_2 < 1.$$

Then $c = \dfrac{b}{a}$ will do.

Remark 16.3.2. It is not completely clear that one can choose an a such that (16.3.1) is satisfied. Suppose it were impossible. Then because the valuations are nontrivial, we would have that for any $a \in K$ if $|a|_1 < 1$ then $|a|_2 < 1$. This implies the converse statement: if $a \in K$ and $|a|_2 < 1$ then $|a|_1 < 1$. To see this, suppose there is an $a \in K$ such that $|a|_2 < 1$ and $|a|_1 \geq 1$. Choose $y \in K$ such that $|y|_1 < 1$. Then for any integer $n > 0$ we have $|y/a^n|_1 < 1$, so by hypothesis $|y/a^n|_2 < 1$. Thus $|y|_2 < |a|_2^n < 1$ for all n. Since $|a|_2 < 1$ we have $|a|_2^n \to 0$ as $n \to \infty$, so $|y|_2 = 0$, a contradiction since $y \neq 0$. Thus $|a|_1 < 1$ if and only if $|a|_2 < 1$, and we have proved before that this implies that $|\cdot|_1$ is equivalent to $|\cdot|_2$.

Next suppose $N \geq 3$. By the case $N-1$, there is an $a \in K$ such that

$$|a|_1 > 1 \qquad \text{and} \qquad |a|_n < 1 \quad \text{for} \quad 2 \leq n \leq N-1.$$

By the case for $N = 2$ there is a $b \in K$ such that

$$|b|_1 > 1 \qquad \text{and} \qquad |b|_N < 1.$$

Then put

$$c = \begin{cases} a & \text{if } |a|_N < 1 \\ a^r \cdot b & \text{if } |a|_N = 1 \\ \dfrac{a^r}{1+a^r} \cdot b & \text{if } |a|_N > 1 \end{cases}$$

where $r \in \mathbf{Z}$ is sufficiently large so that $|c|_1 > 1$ and $|c|_n < 1$ for $2 \leq n \leq N$. □

Example 16.3.3. Suppose $K = \mathbf{Q}$, let $|\cdot|_1$ be the archimedean absolute value and let $|\cdot|_2$ be the 2-adic absolute value. Let $a_1 = -1$, $a_2 = 8$, and $\varepsilon = 1/10$, as in the remark right after Theorem 16.3.1. Then the theorem implies that there is an element $b \in \mathbf{Q}$ such that

$$|-1-b|_1 < \frac{1}{10} \qquad \text{and} \qquad |8-b|_2 < \frac{1}{10}.$$

As in the proof of the theorem, we can find such a b by finding a $c_1, c_2 \in \mathbf{Q}$ such that $|c_1|_1 > 1$ and $|c_1|_2 < 1$, and a $|c_2|_1 < 1$ and $|c_2|_2 > 1$. For example, $c_1 = 2$ and $c_2 = 1/2$ works, since $|2|_1 = 2$ and $|2|_2 = 1/2$ and $|1/2|_1 = 1/2$ and $|1/2|_2 = 2$. Again following the proof, we see that for sufficiently large r we can take

$$\begin{aligned} b_r &= \frac{c_1^r}{1+c_1^r} \cdot a_1 + \frac{c_2^r}{1+c_2^r} \cdot a_2 \\ &= \frac{2^r}{1+2^r} \cdot (-1) + \frac{(1/2)^r}{1+(1/2)^r} \cdot 8. \end{aligned}$$

We have $b_1 = 2$, $b_2 = 4/5$, $b_3 = 0$, $b_4 = -8/17$, $b_5 = -8/11$, $b_6 = -56/55$. None of the b_i work for $i < 6$, but b_6 works.

Chapter 17

Adic Numbers: The Finite Residue Field Case

17.1 Finite Residue Field Case

Let K be a field with a non-archimedean valuation $v = |\cdot|$. Recall that the set of $a \in K$ with $|a| \leq 1$ forms a ring $\mathcal{O}$, the ring of integers for v. The set of $u \in K$ with $|u| = 1$ are a group U under multiplication, the group of units for v. Finally, the set of $a \in K$ with $|a| < 1$ is a maximal ideal $\mathfrak{p}$, so the quotient ring $\mathcal{O}/\mathfrak{p}$ is a field. In this section we consider the case when $\mathcal{O}/\mathfrak{p}$ is a finite field of order a prime power q. For example, K could be $\mathbf{Q}$ and $|\cdot|$ could be a p-adic valuation, or K could be a number field and $|\cdot|$ could be the valuation corresponding to a maximal ideal of the ring of integers. Among other things, we will discuss in more depth the topological and measure-theoretic nature of the completion of K at v.

Suppose further for the rest of this section that $|\cdot|$ is discrete. Then by Lemma 15.2.8, the ideal $\mathfrak{p}$ is a principal ideal (π), say, and every $a \in K$ is of the form $a = \pi^n \varepsilon$, where $n \in \mathbf{Z}$ and $\varepsilon \in U$ is a unit. We call

$$n = \operatorname{ord}(a) = \operatorname{ord}_\pi(a) = \operatorname{ord}_\mathfrak{p}(a) = \operatorname{ord}_v(a)$$

the ord of a at v. (Some authors, including me (!) also call this integer the *valuation* of a with respect to v.) If $\mathfrak{p} = (\pi')$, then π/π' is a unit, and conversely, so $\operatorname{ord}(a)$ is independent of the choice of π.

Let $\mathcal{O}_v$ and $\mathfrak{p}_v$ be defined with respect to the completion K_v of K at v.

Lemma 17.1.1. *There is a natural isomorphism*

$$\varphi : \mathcal{O}_v/\mathfrak{p}_v \to \mathcal{O}/\mathfrak{p},$$

and $\mathfrak{p}_v = (\pi)$ *as an* $\mathcal{O}_v$*-ideal.*

Proof. We may view $\mathcal{O}_v$ as the set of equivalence classes of Cauchy sequences (a_n) in K such that $a_n \in \mathcal{O}$ for n sufficiently large. For any ε, given such a sequence

(a_n), there is N such that for $n, m \geq N$, we have $|a_n - a_m| < \varepsilon$. In particular, we can choose N such that $n, m \geq N$ implies that $a_n \equiv a_m \pmod{\mathfrak{p}}$. Let $\varphi((a_n)) = a_N \pmod{\mathfrak{p}}$, which is well-defined. The map φ is surjective because the constant sequences are in $\mathcal{O}_v$. Its kernel is the set of Cauchy sequences whose elements are eventually all in $\mathfrak{p}$, which is exactly $\mathfrak{p}_v$. This proves the first part of the lemma. The second part is true because any element of $\mathfrak{p}_v$ is a sequence all of whose terms are eventually in $\mathfrak{p}$, hence all a multiple of π (we can set to 0 a finite number of terms of the sequence without changing the equivalence class of the sequence). □

Assume for the rest of this section that K is complete with respect to $|\cdot|$.

Lemma 17.1.2. *Then ring $\mathcal{O}$ is precisely the set of infinite sums*

$$a = \sum_{j=0}^{\infty} a_j \cdot \pi^j \tag{17.1.1}$$

where the a_j run independently through some set $\mathcal{R}$ of representatives of $\mathcal{O}$ in $\mathcal{O}/\mathfrak{p}$.

By (17.1.1) is meant the limit of the Cauchy sequence $\sum_{j=0}^{n} a_j \cdot \pi^j$ as $j \to \infty$.

Proof. There is a uniquely defined $a_0 \in \mathcal{R}$ such that $|a - a_0| < 1$. Then $a' = \pi^{-1} \cdot (a - a_0) \in \mathcal{O}$. Now define $a_1 \in \mathcal{R}$ by $|a' - a_1| < 1$. And so on. □

Example 17.1.3. Suppose $K = \mathbf{Q}$ and $|\cdot| = |\cdot|_p$ is the p-adic valuation, for some prime p. We can take $\mathcal{R} = \{0, 1, \ldots, p-1\}$. The lemma asserts that

$$\mathcal{O} = \mathbf{Z}_p = \left\{ \sum_{j=0}^{\infty} a_n p^n : 0 \leq a_n \leq p - 1 \right\}.$$

Notice that $\mathcal{O}$ is uncountable since there are p choices for each p-adic "digit". We can do arithmetic with elements of $\mathbf{Z}_p$, which can be thought of "backwards" as numbers in base p. For example, with $p = 3$ we have

$$\begin{aligned}
&(1 + 2\cdot 3 + 3^2 + \cdots) + (2 + 2\cdot 3 + 3^2 + \cdots)\\
&= 3 + 4\cdot 3 + 2\cdot 3^2 + \cdots \qquad \text{not in canonical form}\\
&= 0 + 2\cdot 3 + 3\cdot 3 + 2\cdot 3^2 + \cdots \qquad \text{still not canonical}\\
&= 0 + 2\cdot 3 + 0\cdot 3^2 + \cdots
\end{aligned}$$

Basic arithmetic with the p-adics in MAGMA is really weird (even weirder than it was a year ago... There are presumably efficiency advantages to using the MAGMA formalization, and it's supposed to be better for working with extension fields. But I can't get it to do even the calculation below in a way that is clear.) In PARI (gp) the p-adics work as expected:

```
? a = 1 + 2*3 + 3^2 + O(3^3);
? b = 2 + 2*3 + 3^2 + O(3^3);
? a+b
%3 = 2*3 + O(3^3)
? sqrt(1+2*3+O(3^20))
%5 = 1 + 3 + 3^2 + 2*3^4 + 2*3^7 + 3^8 + 3^9 + 2*3^10 + 2*3^12
       + 2*3^13 + 2*3^14 + 3^15 + 2*3^17 + 3^18 + 2*3^19 + O(3^20)
? 1/sqrt(1+2*3+O(3^20))
%6 = 1 + 2*3 + 2*3^2 + 2*3^7 + 2*3^10 + 2*3^11 + 2*3^12 + 2*3^13
       + 2*3^14 + 3^15 + 2*3^16 + 2*3^17 + 3^18 + 3^19 + O(3^20)
```

Theorem 17.1.4. *Under the conditions of the preceding lemma, $\mathcal{O}$ is compact with respect to the $|\cdot|$-topology.*

Proof. Let V_λ, for λ running through some index set Λ, be some family of open sets that cover $\mathcal{O}$. We must show that there is a finite subcover. We suppose not.

Let $\mathcal{R}$ be a set of representatives for $\mathcal{O}/\mathfrak{p}$. Then $\mathcal{O}$ is the union of the finite number of cosets $a + \pi\mathcal{O}$, for $a \in \mathcal{R}$. Hence for at lest one $a_0 \in \mathcal{R}$ the set $a_0 + \pi\mathcal{O}$ is not covered by finitely many of the V_λ. Then similarly there is an $a_1 \in \mathcal{R}$ such that $a_0 + a_1\pi + \pi^2\mathcal{O}$ is not finitely covered. And so on. Let

$$a = a_0 + a_1\pi + a_2\pi^2 + \cdots \in \mathcal{O}.$$

Then $a \in V_{\lambda_0}$ for some $\lambda_0 \in \Lambda$. Since V_{λ_0} is an open set, $a + \pi^J \cdot \mathcal{O} \subset V_{\lambda_0}$ for some J (since those are exactly the open balls that form a basis for the topology). This is a contradiction because we constructed a so that none of the sets $a + \pi^n \cdot \mathcal{O}$, for each n, are not covered by any finite subset of the V_λ. $\square$

Definition 17.1.5 (Locally compact). A topological space X is *locally compact* at a point x if there is some compact subset C of X that contains a neighborhood of x. The space X is locally compact if it is locally compact at each point in X.

Corollary 17.1.6. *The complete local field K is locally compact.*

Proof. If $x \in K$, then $x \in C = x + \mathcal{O}$, and C is a compact subset of K by Theorem 17.1.4. Also C contains the neighborhood $x + \pi\mathcal{O} = B(x, 1)$ of x. Thus K is locally compact at x. $\square$

Remark 17.1.7. The converse is also true. If K is locally compact with respect to a non-archimedean valuation $|\cdot|$, then

1. K is complete,
2. the residue field is finite, and
3. the valuation is discrete.

For there is a compact neighbourhood C of 0. Let π be any nonzero with $|\pi| < 1$. Then $\pi^n \cdot \mathcal{O} \subset C$ for sufficiently large n, so $\pi^n \cdot \mathcal{O}$ is compact, being closed. Hence $\mathcal{O}$ is compact. Since $|\cdot|$ is a metric, $\mathcal{O}$ is sequentially compact, i.e., every fundamental sequence in $\mathcal{O}$ has a limit, which implies (1). Let a_λ (for $\lambda \in \Lambda$) be a set of representatives in $\mathcal{O}$ of $\mathcal{O}/\mathfrak{p}$. Then $\mathcal{O}_\lambda = \{z : |z - a_\lambda| < 1\}$ is an open covering of $\mathcal{O}$. Thus (2) holds since $\mathcal{O}$ is compact. Finally, $\mathfrak{p}$ is compact, being a closed subset of $\mathcal{O}$. Let S_n be the set of $a \in K$ with $|a| < 1 - 1/n$. Then S_n (for $1 \leq n < \infty$) is an open covering of $\mathfrak{p}$, so $\mathfrak{p} = S_n$ for some n, i.e., (3) is true.

If we allow $|\cdot|$ to be archimedean the only further possibilities are $k = \mathbf{R}$ and $k = \mathbf{C}$ with $|\cdot|$ equivalent to the usual absolute value.

We denote by K^+ the commutative topological group whose points are the elements of K, whose group law is addition and whose topology is that induced by $|\cdot|$. General theory tells us that there is an invariant Haar measure defined on K^+ and that this measure is unique up to a multiplicative constant.

Definition 17.1.8 (Haar Measure). A *Haar measure* on a locally compact topological group G is a translation invariant measure such that every open set can be covered by open sets with finite measure.

Lemma 17.1.9. *Haar measure of any compact subset C of G is finite.*

Proof. The whole group G is open, so there is a covering U_α of G by open sets each of which has finite measure. Since C is compact, there is a finite subset of the U_α that covers C. The measure of C is at most the sum of the measures of these finitely many U_α, hence finite. □

Remark 17.1.10. Usually one defined Haar measure to be a translation invariant measure such that the measure of compact sets is finite. Because of local compactness, this definition is equivalent to Definition 17.1.8. We take this alternative viewpoint because Haar measure is constructed naturally on the topological groups we will consider by defining the measure on each member of a basis of open sets for the topology.

We now deduce what any such measure μ on $G = K^+$ must be. Since $\mathcal{O}$ is compact (Theorem 17.1.4), the measure of $\mathcal{O}$ is finite. Since μ is translation invariant,

$$\mu_n = \mu(a + \pi^n \mathcal{O})$$

is independent of a. Further,

$$a + \pi^n \mathcal{O} = \bigcup_{1 \leq j \leq q} a + \pi^n a_j + \pi^{n+1}\mathcal{O}, \qquad \text{(disjoint union)}$$

where a_j (for $1 \leq j \leq q$) is a set of representatives of $\mathcal{O}/\mathfrak{p}$. Hence

$$\mu_n = q \cdot \mu_{n+1}.$$

If we normalize μ by putting

$$\mu(\mathcal{O}) = 1$$

we have $\mu_0 = 1$, hence $\mu_1 = q$, and in general

$$\mu_n = q^{-n}.$$

Conversely, without the theory of Haar measure, we could *define* μ to be the necessarily unique measure on K^+ such that $\mu(\mathcal{O}) = 1$ that is translation invariant. This would have to be the μ we just found above.

Everything so far in this section has depended not on the valuation $|\cdot|$ but only on its equivalence class. The above considerations now single out one valuation in the equivalence class as particularly important.

Definition 17.1.11 (Normalized valuation). Let K be a field equipped with a discrete valuation $|\cdot|$ and residue class field with $q < \infty$ elements. We say that $|\cdot|$ is *normalized* if

$$|\pi| = \frac{1}{q},$$

where $\mathfrak{p} = (\pi)$ is the maximal ideal of $\mathcal{O}$.

Example 17.1.12. The normalized valuation on the p-adic numbers $\mathbf{Q}_p$ is $|u \cdot p^n| = p^{-n}$, where u is a rational number whose numerator and denominator are coprime to p.

Next suppose $K = \mathbf{Q}_p(\sqrt{p})$. Then the p-adic valuation on $\mathbf{Q}_p$ extends uniquely to one on K such that $\left|\sqrt{p}\right|^2 = |p| = 1/p$. Since $\pi = \sqrt{p}$ for K, this valuation is not normalized. (Note that the ord of $\pi = \sqrt{p}$ is $1/2$.) The normalized valuation is $v = |\cdot|' = |\cdot|^2$. Note that $|\cdot|' \, p = 1/p^2$, or $\mathrm{ord}_v(p) = 2$ instead of 1.

Finally suppose that $K = \mathbf{Q}_p(\sqrt{q})$ where $x^2 - q$ has not root mod p. Then the residue class field degree is 2, and the normalized valuation must satisfy $\left|\sqrt{q}\right| = 1/p^2$.

The following proposition makes clear why this is the best choice of normalization.

Theorem 17.1.13. *Suppose further that K is complete with respect to the normalized valuation $|\cdot|$. Then*

$$\mu(a + b\mathcal{O}) = |b|\,,$$

where μ is the Haar measure on K^+ normalized so that $\mu(\mathcal{O}) = 1$.

Proof. Since μ is translation invariant, $\mu(a + b\mathcal{O}) = \mu(b\mathcal{O})$. Write $b = u \cdot \pi^n$, where u is a unit. Then since $u \cdot \mathcal{O} = \mathcal{O}$, we have

$$\mu(b\mathcal{O}) = \mu(u \cdot \pi^n \cdot \mathcal{O}) = \mu(\pi^n \cdot u \cdot \mathcal{O}) = \mu(\pi^n \cdot \mathcal{O}) = q^{-n} = |\pi^n| = |b|\,.$$

Here we have $\mu(\pi^n \cdot \mathcal{O}) = q^{-n}$ by the discussion before Definition 17.1.11. □

We can express the result of the theorem in a more suggestive way. Let $b \in K$ with $b \neq 0$, and let μ be a Haar measure on K^+ (not necessarily normalized as in the theorem). Then we can define a new Haar measure μ_b on K^+ by putting $\mu_b(E) = \mu(bE)$ for $E \subset K^+$. But Haar measure is unique up to a multiplicative constant and so $\mu_b(E) = \mu(bE) = c \cdot \mu(E)$ for all measurable sets E, where the factor c depends only on b. Putting $E = \mathcal{O}$, shows that the theorem implies that c is just $|b|$, when $|\cdot|$ is the normalized valuation.

Remark 17.1.14. The theory of locally compact topological groups leads to the consideration of the dual (character) group of K^+. It turns out that it is isomorphic to K^+. We do not need this fact for class field theory, so do not prove it here. For a proof and applications see Tate's thesis or Lang's *Algebraic Numbers*, and for generalizations see Weil's *Adeles and Algebraic Groups* and Godement's Bourbaki seminars 171 and 176. The determination of the character group of K^* is local class field theory.

The set of nonzero elements of K is a group K^* under multiplication. Multiplication and inverses are continuous with respect to the topology induced on K^* as a subset of K, so K^* is a topological group with this topology. We have

$$U_1 \subset U \subset K^*$$

where U is the group of units of $\mathcal{O} \subset K$ and U_1 is the group of 1-units, i.e., those units $\varepsilon \in U$ with $|\varepsilon - 1| < 1$, so

$$U_1 = 1 + \pi\mathcal{O}.$$

The set U is the open ball about 0 of radius 1, so is open, and because the metric is nonarchimedean U is also closed. Likewise, U_1 is both open and closed.

The quotient $K^*/U = \{\pi^n \cdot U : n \in \mathbf{Z}\}$ is isomorphic to the additive group $\mathbf{Z}^+$ of integers with the discrete topology, where the map is

$$\pi^n \cdot U \mapsto n \qquad \text{for } n \in \mathbf{Z}.$$

The quotient U/U_1 is isomorphic to the multiplicative group $\mathbf{F}^*$ of the nonzero elements of the residue class field, where the finite gorup $\mathbf{F}^*$ has the discrete topology. Note that $\mathbf{F}^*$ is cyclic of order $q-1$, and Hensel's lemma implies that K^* contains a primitive $(q-1)$th root of unity ζ. Thus K^* has the following structure:

$$K^* = \{\pi^n\zeta^m\varepsilon : n \in \mathbf{Z}, m \in \mathbf{Z}/(q-1)\mathbf{Z}, \varepsilon \in U_1\} \cong \mathbf{Z} \ \times \ \mathbf{Z}/(q-1)\mathbf{Z} \ \times \ U_1.$$

(How to apply Hensel's lemma: Let $f(x) = x^{q-1} - 1$ and let $a \in \mathcal{O}$ be such that a mod $\mathfrak{p}$ generates K^*. Then $|f(a)| < 1$ and $|f'(a)| = 1$. By Hensel's lemma there is a $\zeta \in K$ such that $f(\zeta) = 0$ and $\zeta \equiv a \pmod{\mathfrak{p}}$.)

Since U is compact and the cosets of U cover K, we see that K^* is locally compact.

Lemma 17.1.15. *The additive Haar measure μ on K^+, when restricted to U_1 gives a measure on U_1 that is also invariant under multiplication, so gives a Haar measure on U_1.*

Proof. It suffices to show that

$$\mu(1+\pi^n\mathcal{O}) = \mu(u\cdot(1+\pi^n\mathcal{O})),$$

for any $u \in U_1$ and $n > 0$. Write $u = 1 + a_1\pi + a_2\pi^2 + \cdots$. We have

$$\begin{aligned} u\cdot(1+\pi^n\mathcal{O}) &= (1 + a_1\pi + a_2\pi^2 + \cdots)\cdot(1+\pi^n\mathcal{O}) \\ &= 1 + a_1\pi + a_2\pi^2 + \cdots + \pi^n\mathcal{O} \\ &= a_1\pi + a_2\pi^2 + \cdots + (1+\pi^n\mathcal{O}), \end{aligned}$$

which is an additive translate of $1+\pi^n\mathcal{O}$, hence has the same measure. □

Thus μ gives a Haar measure on K^* by translating U_1 around to cover K^*.

Lemma 17.1.16. *The topological spaces K^+ and K^* are totally disconnected (the only connected sets are points).*

Proof. The proof is the same as that of Proposition 16.2.13. The point is that the non-archimedean triangle inequality forces the complement an open disc to be open, hence any set with at least two distinct elements "falls apart" into a disjoint union of two disjoint open subsets. □

Remark 17.1.17. Note that K^* and K^+ are locally isomorphic if K has characteristic 0. We have the exponential map

$$a \mapsto \exp(a) = \sum_{n=0}^{\infty} \frac{a^n}{n!}$$

defined for all sufficiently small a with its inverse

$$\log(a) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}(a-1)^n}{n},$$

which is defined for all a sufficiently close to 1.

Chapter 18

Normed Spaces and Tensor Products

Much of this chapter is preparation for what we will do later when we will prove that if K is complete with respect to a valuation (and locally compact) and L is a finite extension of K, then there is a *unique* valuation on L that extends the valuation on K. Also, if K is a number field, $v = |\cdot|$ is a valuation on K, K_v is the completion of K with respect to v, and L is a finite extension of K, we'll prove that

$$K_v \otimes_K L = \bigoplus_{j=1}^{J} L_j,$$

where the L_j are the completions of L with respect to the equivalence classes of extensions of v to L. In particular, if L is a number field defined by a root of $f(x) \in \mathbf{Q}[x]$, then

$$\mathbf{Q}_p \otimes_{\mathbf{Q}} L = \bigoplus_{j=1}^{J} L_j,$$

where the L_j correspond to the irreducible factors of the polynomial $f(x) \in \mathbf{Q}_p[x]$ (hence the extensions of $|\cdot|_p$ correspond to irreducible factors of $f(x)$ over $\mathbf{Q}_p[x]$).

In preparation for this clean view of the local nature of number fields, we will prove that the norms on a finite-dimensional vector space over a complete field are all equivalent. We will also explicitly construct tensor products of fields and deduce some of their properties.

18.1 Normed Spaces

Definition 18.1.1 (Norm). Let K be a field with valuation $|\cdot|$ and let V be a vector space over K. A real-valued function $\|\cdot\|$ on V is called a *norm* if

1. $\|v\| > 0$ for all nonzero $v \in V$ (positivity).

2. $\|v + w\| \leq \|v\| + \|w\|$ for all $v, w \in V$ (triangle inequality).

3. $\|av\| = |a|\,\|v\|$ for all $a \in K$ and $v \in V$ (homogeneity).

Note that setting $\|v\| = 1$ for all $v \neq 0$ does *not* define a norm unless the absolute value on K is trivial, as $1 = \|av\| = |a|\,\|v\| = |a|$. We assume for the rest of this section that $|\cdot|$ is not trivial.

Definition 18.1.2 (Equivalent). Two norms $\|\cdot\|_1$ and $\|\cdot\|_2$ on the same vector space V are *equivalent* if there exists positive real numbers c_1 and c_2 such that for all $v \in V$

$$\|v\|_1 \leq c_1 \|v\|_2 \qquad \text{and} \qquad \|v\|_2 \leq c_2 \|v\|_1 .$$

Lemma 18.1.3. *Suppose that K is a field that is complete with respect to a valuation $|\cdot|$ and that V is a finite dimensional K vector space. Continue to assume, as mentioned above, that K is complete with respect to $|\cdot|$. Then any two norms on V are equivalent.*

Remark 18.1.4. As we shall see soon (see Theorem 19.1.8), the lemma is usually false if we do not assume that K is complete. For example, when $K = \mathbf{Q}$ and $|\cdot|_p$ is the p-adic valuation, and V is a number field, then there may be several extensions of $|\cdot|_p$ to inequivalent norms on V.

If two norms are equivalent then the corresponding topologies on V are equal, since very open ball for $\|\cdot\|_1$ is contained in an open ball for $\|\cdot\|_2$, and conversely. (The converse is also true, since, as we will show, all norms on V are equivalent.)

Proof. Let $v_1, \ldots, v_N$ be a basis for V. Define the max norm $\|\cdot\|_0$ by

$$\left\| \sum_{n=1}^{N} a_n v_n \right\|_0 = \max \{|a_n| : n = 1, \ldots, N\} .$$

It is enough to show that any norm $\|\cdot\|$ is equivalent to $\|\cdot\|_0$. We have

$$\begin{aligned} \left\| \sum_{n=1}^{N} a_n v_n \right\| &\leq \sum_{n=1}^{N} |a_n|\,\|v_n\| \\ &\leq \sum_{n=1}^{N} \max |a_n|\,\|v_n\| \\ &= c_1 \cdot \left\| \sum_{n=1}^{N} a_n v_n \right\|_0 , \end{aligned}$$

where $c_1 = \sum_{n=1}^{N} \|v_n\|$.

To finish the proof, we show that there is a $c_2 \in \mathbf{R}$ such that for all $v \in V$,

$$\|v\|_0 \leq c_2 \cdot \|v\| .$$

We will only prove this in the case when K is not just merely complete with respect to $|\cdot|$ but also locally compact. This will be the case of primary interest to us. For a proof in the general case, see the original article by Cassels (page 53).

By what we have already shown, the function $\|v\|$ is continuous in the $\|\cdot\|_0$-topology, so by local compactness it attains its lower bound δ on the unit circle $\{v \in V : \|v\|_0 = 1\}$. (Why is the unit circle compact? With respect to $\|\cdot\|_0$, the topology on V is the same as that of a product of copies of K. If the valuation is archimedean then $K \cong \mathbf{R}$ or $\mathbf{C}$ with the standard topology and the unit circle is compact. If the valuation is non-archimedean, then we saw (see Remark 17.1.7) that if K is locally compact, then the valuation is discrete, in which case we showed that the unit disc is compact, hence the unit circle is also compact since it is closed.) Note that $\delta > 0$ by part 1 of Definition 18.1.1. Also, by definition of $\|\cdot\|_0$, for any $v \in V$ there exists $a \in K$ such that $\|v\|_0 = |a|$ (just take the max coefficient in our basis). Thus we can write any $v \in V$ as $a \cdot w$ where $a \in K$ and $w \in V$ with $\|w\|_0 = 1$. We then have

$$\frac{\|v\|_0}{\|v\|} = \frac{\|aw\|_0}{\|aw\|} = \frac{|a|\,\|w\|_0}{|a|\,\|w\|} = \frac{1}{\|w\|} \leq \frac{1}{\delta}.$$

Thus for all v we have

$$\|v\|_0 \leq c_2 \cdot \|v\|,$$

where $c_2 = 1/\delta$, which proves the theorem. □

18.2 Tensor Products

We need only a special case of the tensor product construction. Let A and B be commutative rings containing a field K and suppose that B is of finite dimension N over K, say, with basis

$$1 = w_1, w_2, \ldots, w_N.$$

Then B is determined up to isomorphism as a ring over K by the multiplication table $(c_{i,j,n})$ defined by

$$w_i \cdot w_j = \sum_{n=1}^{N} c_{i,j,n} \cdot w_n.$$

We define a new ring C containing K whose elements are the set of all expressions

$$\sum_{n=1}^{N} a_n \underline{w}_n$$

where the $\underline{w}_n$ have the same multiplication rule

$$\underline{w}_i \cdot \underline{w}_j = \sum_{n=1}^{N} c_{i,j,n} \cdot \underline{w}_n$$

as the w_n.

There are injective ring homomorphisms

$$i : A \hookrightarrow C, \qquad i(a) = a\underline{w}_1 \qquad \text{(note that } \underline{w}_1 = 1\text{)}$$

and

$$j : B \hookrightarrow C, \qquad j\left(\sum_{n=1}^{N} c_n w_n\right) = \sum_{n=1}^{N} c_n \underline{w}_n.$$

Moreover C is defined, up to isomorphism, by A and B and is independent of the particular choice of basis w_n of B (i.e., a change of basis of B induces a canonical isomorphism of the C defined by the first basis to the C defined by the second basis). We write

$$C = A \otimes_K B$$

since C is, in fact, a special case of the ring tensor product.

Let us now suppose, further, that A is a topological ring, i.e., has a topology with respect to which addition and multiplication are continuous. Then the map

$$C \to A \oplus \cdots \oplus A, \qquad \sum_{m=1}^{N} a_m \underline{w}_m \mapsto (a_1, \ldots, a_N)$$

defines a bijection between C and the product of N copies of A (considered as sets). We give C the product topology. It is readily verified that this topology is independent of the choice of basis $w_1, \ldots, w_N$ and that multiplication and addition on C are continuous, so C is a topological ring. We call this topology on C the *tensor product topology.*

Now drop our assumption that A and B have a topology, but suppose that A and B are not merely rings but fields. Recall that a finite extension L/K of fields is *separable* if the number of embeddings $L \hookrightarrow \overline{K}$ that fix K equals the degree of L over K, where $\overline{K}$ is an algebraic closure of K. The primitive element theorem from Galois theory asserts that any such extension is generated by a single element, i.e., $L = K(a)$ for some $a \in L$.

Lemma 18.2.1. *Let A and B be fields containing the field K and suppose that B is a separable extension of finite degree $N = [B : K]$. Then $C = A \otimes_K B$ is the direct sum of a finite number of fields K_j, each containing an isomorphic image of A and an isomorphic image of B.*

Proof. By the primitive element theorem, we have $B = K(b)$, where b is a root of some separable irreducible polynomial $f(x) \in K[x]$ of degree N. Then $1, b, \ldots, b^{N-1}$ is a basis for B over K, so

$$A \otimes_K B = A[\underline{b}] \cong A[x]/(f(x))$$

where $1, \underline{b}, \underline{b}^2, \ldots, \underline{b}^{N-1}$ are linearly independent over A and $\underline{b}$ satisfies $f(\underline{b}) = 0$.

Although the polynomial $f(x)$ is irreducible as an element of $K[x]$, it need not be irreducible in $A[x]$. Since A is a field, we have a factorization

$$f(x) = \prod_{j=1}^{J} g_j(x)$$

where $g_j(x) \in A[x]$ is irreducible. The $g_j(x)$ are distinct because $f(x)$ is separable (i.e., has distinct roots in any algebraic closure).

For each j, let $\underline{b}_j \in \overline{A}$ be a root of $g_j(x)$, where $\overline{A}$ is a fixed algebraic closure of the field A. Let $K_j = A(\underline{b}_j)$. Then the map

$$\varphi_j : A \otimes_K B \to K_j \tag{18.2.1}$$

given by sending any polynomial $h(\underline{b})$ in $\underline{b}$ (where $h \in A[x]$) to $h(\underline{b}_j)$ is a ring homomorphism, because the image of $\underline{b}$ satisfies the polynomial $f(x)$, and $A \otimes_K B \cong A[x]/(f(x))$.

By the Chinese Remainder Theorem, the maps from (18.2.1) combine to define a ring isomorphism

$$A \otimes_K B \cong A[x]/(f(x)) \cong \bigoplus_{j=1}^{J} A[x]/(g_j(x)) \cong \bigoplus_{j=1}^{J} K_j.$$

Each K_j is of the form $A[x]/(g_j(x))$, so contains an isomorphic image of A. It thus remains to show that the ring homomorphisms

$$\lambda_j : B \xrightarrow{b \mapsto 1 \otimes b} A \otimes_K B \xrightarrow{\varphi_j} K_j$$

are injections. Since B and K_j are both fields, λ_j is either the 0 map or injective. However, λ_j is not the 0 map since $\lambda_j(1) = 1 \in K_j$. □

Example 18.2.2. If A and B are finite extensions of $\mathbf{Q}$, then $A \otimes_{\mathbf{Q}} B$ is an algebra of degree $[A : \mathbf{Q}] \cdot [B : \mathbf{Q}]$. For example, suppose A is generated by a root of $x^2 + 1$ and B is generated by a root of $x^3 - 2$. We can view $A \otimes_{\mathbf{Q}} B$ as either $A[x]/(x^3 - 2)$ or $B[x]/(x^2 + 1)$. The polynomial $x^2 + 1$ is irreducible over $\mathbf{Q}$, and if it factored over the cubic field B, then there would be a root of $x^2 + 1$ in B, i.e., the quadratic field $A = \mathbf{Q}(i)$ would be a subfield of the cubic field $B = \mathbf{Q}(\sqrt[3]{2})$, which is impossible. Thus $x^2 + 1$ is irreducible over B, so $A \otimes_{\mathbf{Q}} B = A.B = \mathbf{Q}(i, \sqrt[3]{2})$ is a degree 6 extension of $\mathbf{Q}$. Notice that $A.B$ contains a copy A and a copy of B. By the primitive element theorem the composite field $A.B$ can be generated by the root of a single polynomial. For example, the minimal polynomial of $i + \sqrt[3]{2}$ is $x^6 + 3x^4 - 4x^3 + 3x^2 + 12x + 5$, hence $\mathbf{Q}(i + \sqrt[3]{2}) = A.B$.

Example 18.2.3. The case $A \cong B$ is even more exciting. For example, suppose $A = B = \mathbf{Q}(i)$. Using the Chinese Remainder Theorem we have that

$$\mathbf{Q}(i) \otimes_{\mathbf{Q}} \mathbf{Q}(i) \cong \mathbf{Q}(i)[x]/(x^2 + 1) \cong \mathbf{Q}(i)[x]/((x - i)(x + i)) \cong \mathbf{Q}(i) \oplus \mathbf{Q}(i),$$

since $(x-i)$ and $(x+i)$ are coprime. The last isomorphism sends $a+bx$, with $a,b\in\mathbf{Q}(i)$, to $(a+bi,a-bi)$. Since $\mathbf{Q}(i)\oplus\mathbf{Q}(i)$ has zero divisors, the tensor product $\mathbf{Q}(i)\otimes_{\mathbf{Q}}\mathbf{Q}(i)$ must also have zero divisors. For example, $(1,0)$ and $(0,1)$ is a zero divisor pair on the right hand side, and we can trace back to the elements of the tensor product that they define. First, by solving the system

$$a+bi=1 \qquad \text{and} \qquad a-bi=0$$

we see that $(1,0)$ corresponds to $a=1/2$ and $b=-i/2$, i.e., to the element

$$\frac{1}{2}-\frac{i}{2}x\in\mathbf{Q}(i)[x]/(x^2+1).$$

This element in turn corresponds to

$$\frac{1}{2}\otimes 1-\frac{i}{2}\otimes i\in\mathbf{Q}(i)\otimes_{\mathbf{Q}}\mathbf{Q}(i).$$

Similarly the other element $(0,1)$ corresponds to

$$\frac{1}{2}\otimes 1+\frac{i}{2}\otimes i\in\mathbf{Q}(i)\otimes_{\mathbf{Q}}\mathbf{Q}(i).$$

As a double check, observe that

$$\begin{aligned}\left(\frac{1}{2}\otimes 1-\frac{i}{2}\otimes i\right)\cdot\left(\frac{1}{2}\otimes 1+\frac{i}{2}\otimes i\right)&=\frac{1}{4}\otimes 1+\frac{i}{4}\otimes i-\frac{i}{4}\otimes i-\frac{i^2}{4}\otimes i^2\\&=\frac{1}{4}\otimes 1-\frac{1}{4}\otimes 1=0\in\mathbf{Q}(i)\otimes_{\mathbf{Q}}\mathbf{Q}(i).\end{aligned}$$

Clearing the denominator of 2 and writing $1\otimes 1=1$, we have $(1-i\otimes i)(1+i\otimes i)=0$, so $i\otimes i$ is a root of the polynomimal x^2-1, and $i\otimes i$ is not ± 1, so x^2-1 has more than 2 roots.

In general, to understand $A\otimes_K B$ explicitly is the same as factoring either the defining polynomial of B over the field A, or factoring the defining polynomial of A over B.

Corollary 18.2.4. *Let $a\in B$ be any element and let $f(x)\in K[x]$ be the characteristic polynomials of a over K and let $g_j(x)\in A[x]$ (for $1\le j\le J$) be the characteristic polynomials of the images of a under $B\to A\otimes_K B\to K_j$ over A, respectively. Then*

$$f(x)=\prod_{j=1}^{J}g_j(X). \tag{18.2.2}$$

Proof. We show that both sides of (18.2.2) are the characteristic polynomial $T(x)$ of the image of a in $A\otimes_K B$ over A. That $f(x)=T(x)$ follows at once by computing the characteristic polynomial in terms of a basis $\underline{w}_1,\ldots,\underline{w}_N$ of $A\otimes_K B$, where $w_1,\ldots,w_N$ is a basis for B over K (this is because the matrix of left multiplication by b on $A \otimes_K B$ is exactly the same as the matrix of left multiplication on B, so the characteristic polynomial doesn't change). To see that $T(X) = \prod g_j(X)$, compute the action of the image of a in $A \otimes_K B$ with respect to a basis of

$$A \otimes_K B \cong \bigoplus_{j=1}^{J} K_j \tag{18.2.3}$$

composed of basis of the individual extensions K_j of A. The resulting matrix will be a block direct sum of submatrices, each of whose characteristic polynomials is one of the $g_j(X)$. Taking the product gives the claimed identity (18.2.2). □

Corollary 18.2.5. *For $a \in B$ we have*

$$\mathrm{Norm}_{B/K}(a) = \prod_{j=1}^{J} \mathrm{Norm}_{K_j/A}(a),$$

and

$$\mathrm{Tr}_{B/K}(a) = \sum_{j=1}^{J} \mathrm{Tr}_{K_j/A}(a),$$

Proof. This follows from Corollary 18.2.4. First, the norm is ± the constant term of the characteristic polynomial, and the constant term of the product of polynomials is the product of the constant terms (and one sees that the sign matches up correctly). Second, the trace is minus the second coefficient of the characteristic polynomial, and second coefficients add when one multiplies polynomials:

$$(x^n+a_{n-1}x^{n-1}+\cdots)\cdot(x^m+a_{m-1}x^{m-1}+\cdots) = x^{n+m}+x^{n+m-1}(a_{m-1}+a_{n-1})+\cdots .$$

One could also see both the statements by considering a matrix of left multiplication by a first with respect to the basis of $\underline{w}_n$ and second with respect to the basis coming from the left side of (18.2.3).

□

Chapter 19

Extensions and Normalizations of Valuations

19.1 Extensions of Valuations

In this section we continue to tacitly assume that all valuations are nontrivial. We do not assume all our valuations satisfy the triangle

Suppose $K \subset L$ is a finite extension of fields, and that $|\cdot|$ and $\|\cdot\|$ are valuations on K and L, respectively.

Definition 19.1.1 (Extends). We say that $\|\cdot\|$ *extends* $|\cdot|$ if $|a| = \|a\|$ for all $a \in K$.

Theorem 19.1.2. *Suppose that K is a field that is complete with respect to $|\cdot|$ and that L is a finite extension of K of degree $N = [L : K]$. Then there is precisely one extension of $|\cdot|$ to K, namely*

$$\|a\| = \left|\mathrm{Norm}_{L/K}(a)\right|^{1/N}, \tag{19.1.1}$$

where the Nth root is the non-negative real Nth root of the nonnegative real number $\left|\mathrm{Norm}_{L/K}(a)\right|$.

Proof. We may assume that $|\cdot|$ is normalized so as to satisfy the triangle inequality. Otherwise, normalize $|\cdot|$ so that it does, prove the theorem for the normalized valuation $|\cdot|^c$, then raise both sides of (19.1.1) to the power $1/c$. In the uniqueness proof, by the same argument we may assume that $\|\cdot\|$ also satisfies the triangle inequality.

Uniqueness. View L as a finite-dimensional vector space over K. Then $\|\cdot\|$ is a norm in the sense defined earlier (Definition 18.1.1). Hence any two extensions $\|\cdot\|_1$ and $\|\cdot\|_2$ of $|\cdot|$ are equivalent as norms, so induce the same topology on K. But as we have seen (Proposition 16.1.4), two valuations which induce the same topology are equivalent valuations, i.e., $\|\cdot\|_1 = \|\cdot\|_2^c$, for some positive real c. Finally $c = 1$ since $\|a\|_1 = |a| = \|a\|_2$ for all $a \in K$.

Existence. We do not give a proof of existence in the general case. Instead we give a proof, which was suggested by Dr. Geyer at the conference out of which [Cas67] arose. It is valid when K is locally compact, which is the only case we will use later.

We see at once that the function defined in (19.1.1) satisfies the condition (i) that $\|a\| \geq 0$ with equality only for $a = 0$, and (ii) $\|ab\| = \|a\| \cdot \|b\|$ for all $a, b \in L$. The difficult part of the proof is to show that there is a constant $C > 0$ such that

$$\|a\| \leq 1 \implies \|1 + a\| \leq C.$$

Note that we do not know (and will not show) that $\|\cdot\|$ as defined by (19.1.1) is a norm as in Definition 18.1.1, since showing that $\|\cdot\|$ is a norm would entail showing that it satisfies the triangle inequality, which is not obvious.

Choose a basis $b_1, \ldots, b_N$ for L over K. Let $\|\cdot\|_0$ be the max norm on L, so for $a = \sum_{i=1}^N c_i b_i$ with $c_i \in K$ we have

$$\|a\|_0 = \left\|\sum_{i=1}^N c_i b_i\right\|_0 = \max\{|c_i| : i = 1, \ldots, N\}.$$

(Note: in Cassels's original article he let $\|\cdot\|_0$ be *any* norm, but we don't because the rest of the proof does not work, since we can't use homogeneity as he claims to do. This is because it need not be possible to find, for any nonzero $a \in L$ some element $c \in K$ such that $\|ac\|_0 = 1$. This would fail, e.g., if $\|a\|_0 \neq |c|$ for any $c \in K$.) The rest of the argument is very similar to our proof from Lemma 18.1.3 of uniqueness of norms on vector spaces over complete fields.

With respect to the $\|\cdot\|_0$-topology, L has the product topology as a product of copies of K. The function $a \mapsto \|a\|$ is a composition of continuous functions on L with respect to this topology (e.g., $\mathrm{Norm}_{L/K}$ is the determinant, hence polynomial), hence $\|\cdot\|$ defines nonzero continuous function on the compact set

$$S = \{a \in L : \|a\|_0 = 1\}.$$

By compactness, there are real numbers $\delta, \Delta \in \mathbf{R}_{>0}$ such that

$$0 < \delta \leq \|a\| \leq \Delta \qquad \text{for all } a \in S.$$

For any nonzero $a \in L$ there exists $c \in K$ such that $\|a\|_0 = |c|$; to see this take c to be a c_i in the expression $a = \sum_{i=1}^N c_i b_i$ with $|c_i| \geq |c_j|$ for any j. Hence $\|a/c\|_0 = 1$, so $a/c \in S$ and

$$0 \leq \delta \leq \frac{\|a/c\|}{\|a/c\|_0} \leq \Delta.$$

Then by homogeneity

$$0 \leq \delta \leq \frac{\|a\|}{\|a\|_0} \leq \Delta.$$

Suppose now that $\|a\| \leq 1$. Then $\|a\|_0 \leq \delta^{-1}$, so

$$\begin{aligned} \|1+a\| &\leq \Delta \cdot \|1+a\|_0 \\ &\leq \Delta \cdot (\|1\|_0 + \|a\|_0) \\ &\leq \Delta \cdot \left(\|1\|_0 + \delta^{-1}\right) \\ &= C \quad \text{(say)}, \end{aligned}$$

as required. □

Example 19.1.3. Consider the extension $\mathbf{C}$ of $\mathbf{R}$ equipped with the archimedean valuation. The unique extension is the ordinary absolute value on $\mathbf{C}$:

$$\|x+iy\| = \left(x^2+y^2\right)^{1/2}.$$

Example 19.1.4. Consider the extension $\mathbf{Q}_2(\sqrt{2})$ of $\mathbf{Q}_2$ equipped with the 2-adic absolute value. Since x^2-2 is irreducible over $\mathbf{Q}_2$ we can do some computations by working in the subfield $\mathbf{Q}(\sqrt{2})$ of $\mathbf{Q}_2(\sqrt{2})$.

```
> K<a> := NumberField(x^2-2);
> K;
Number Field with defining polynomial x^2 - 2 over the Rational Field
> function norm(x) return Sqrt(2^(-Valuation(Norm(x),2))); end function;
> norm(1+a);
1.000000000000000000000000000
> norm(1+a+1);
0.7071067811865475244008443621 
> z := 3+2*a;
> norm(z);
1.000000000000000000000000000
> norm(z+1);
0.3535533905932737622004221810 
```

Remark 19.1.5. Geyer's existence proof gives (19.1.1). But it is perhaps worth noting that in any case (19.1.1) is a consequence of unique existence, as follows. Suppose L/K is as above. Suppose M is a finite Galois extension of K that contains L. Then by assumption there is a unique extension of $|\cdot|$ to M, which we shall also denote by $\|\cdot\|$. If $\sigma \in \mathrm{Gal}(M/K)$, then

$$\|a\|_\sigma := \|\sigma(a)\|$$

is also an extension of $|\cdot|$ to M, so $\|\cdot\|_\sigma = \|\cdot\|$, i.e.,

$$\|\sigma(a)\| = \|a\| \qquad \text{for all } a \in M.$$

But now

$$\mathrm{Norm}_{L/K}(a) = \sigma_1(a) \cdot \sigma_2(a) \cdots \sigma_N(a)$$

for $a \in K$, where $\sigma_1, \ldots, \sigma_N \in \mathrm{Gal}(M/K)$ extend the embeddings of L into M. Hence

$$\begin{aligned} \left|\mathrm{Norm}_{L/K}(a)\right| &= \left\|\mathrm{Norm}_{L/K}(a)\right\| \\ &= \prod_{1\leq n\leq N} \|\sigma_n(a)\| \\ &= \|a\|^N, \end{aligned}$$

as required.

Corollary 19.1.6. *Let $w_1, \ldots, w_N$ be a basis for L over K. Then there are positive constants c_1 and c_2 such that*

$$c_1 \leq \frac{\left\|\sum_{n=1}^{N} b_n w_n\right\|}{\max\{|b_n| : n = 1, \ldots, N\}} \leq c_2$$

for any $b_1, \ldots, b_N \in K$ not all 0.

Proof. For $\left|\sum_{n=1}^{N} b_n w_n\right|$ and $\max |b_n|$ are two norms on L considered as a vector space over K.

I don't believe this proof, which I copied from Cassels's article. My problem with it is that the proof of Theorem 19.1.2 does not give that $C \leq 2$, i.e., that the triangle inequality holds for $\|\cdot\|$. By changing the basis for L/K one can make any nonzero vector $a \in L$ have $\|a\|_0 = 1$, so if we choose a such that $|a|$ is very large, then the Δ in the proof will also be very large. One way to fix the corollary is to only claim that there are positive constants c_1, c_2, c_3, c_4 such that

$$c_1 \leq \frac{\left\|\sum_{n=1}^{N} b_n w_n\right\|^{c_3}}{\max\{|b_n|^{c_4} : n = 1, \ldots, N\}} \leq c_2.$$

Then choose c_3, c_4 such that $\|\cdot\|^{c_3}$ and $|\cdot|^{c_4}$ satisfies the triangle inequality, and prove the modified corollary using the proof suggested by Cassels. □

Corollary 19.1.7. *A finite extension of a completely valued field K is complete with respect to the extended valuation.*

Proof. By the proceeding corollary it has the topology of a finite-dimensional vector space over K. (The problem with the proof of the previous corollary is not an issue, because we can replace the extended valuation by an inequivalent one that satisfies the triangle inequality and induces the same topology.) □

When K is no longer complete under $|\cdot|$ the position is more complicated:

Theorem 19.1.8. *Let L be a separable extension of K of finite degree $N = [L : K]$. Then there are at most N extensions of a valuation $|\cdot|$ on K to L, say $\|\cdot\|_j$, for $1 \leq j \leq J$. Let K_v be the completion of K with respect to $|\cdot|$, and for each j let L_j be the completion of L with respect to $\|\cdot\|_j$. Then*

$$K_v \otimes_K L \cong \bigoplus_{1\leq j\leq J} L_j \tag{19.1.2}$$

algebraically and topologically, where the right hand side is given the product topology.

Proof. We already know (Lemma 18.2.1) that $K_v \otimes_K L$ is of the shape (19.1.2), where the L_j are finite extensions of K_v. Hence there is a unique extension $|\cdot|_j^*$ of $|\cdot|$ to the L_j, and by Corollary 19.1.7 the L_j are complete with respect to the extended valuation. Further, the ring homomorphisms

$$\lambda_j : L \to K_v \otimes_K L \to L_j$$

are injections. Hence we get an extension $\|\cdot\|_j$ of $|\cdot|$ to L by putting

$$\|b\|_j = |\lambda_j(b)|_j^* .$$

Further, $L \cong \lambda_j(L)$ is dense in L_j with respect to $\|\cdot\|_j$ because $L = K \otimes_K L$ is dense in $K_v \otimes_K L$ (since K is dense in K_v). Hence L_j is exactly the completion of L.

It remains to show that the $\|\cdot\|_j$ are distinct and that they are the only extensions of $|\cdot|$ to L.

Suppose $\|\cdot\|$ is any valuation of L that extends $|\cdot|$. Then $\|\cdot\|$ extends by continuity to a real-valued function on $K_v \otimes_K L$, which we also denote by $\|\cdot\|$. (We are again using that L is dense in $K_v \otimes_K L$.) By continuity we have for all $a, b \in K_v \otimes_K L$,

$$\|ab\| = \|a\| \cdot \|b\|$$

and if C is the constant in axiom (iii) for L and $\|\cdot\|$, then

$$\|a\| \leq 1 \implies \|1 + a\| \leq C.$$

(In Cassels, he inexplicable assume that $C = 1$ at this point in the proof.)

We consider the restriction of $\|\cdot\|$ to one of the L_j. If $\|a\| \neq 0$ for some $a \in L_j$, then $\|a\| = \|b\| \cdot \left\|ab^{-1}\right\|$ for every $b \neq 0$ in L_j so $\|b\| \neq 0$. Hence either $\|\cdot\|$ is identically 0 on L_j or it induces a valuation on L_j.

Further, $\|\cdot\|$ cannot induce a valuation on two of the L_j. For

$$(a_1, 0, \ldots, 0) \cdot (0, a_2, 0, \ldots, 0) = (0, 0, 0, \ldots, 0),$$

so for any $a_1 \in L_1$, $a_2 \in L_2$,

$$\|a_1\| \cdot \|a_2\| = 0.$$

Hence $\|\cdot\|$ induces a valuation in precisely one of the L_j, and it extends the given valuation $|\cdot|$ of K_v. Hence $\|\cdot\| = \|\cdot\|_j$ for precisely one j.

It remains only to show that (19.1.2) is a topological homomorphism. For

$$(b_1, \ldots, b_J) \in L_1 \oplus \cdots \oplus L_J$$

put

$$\|(b_1, \ldots, b_J)\|_0 = \max_{1 \le j \le J} \|b_j\|_j \,.$$

Then $\|\cdot\|_0$ is a norm on the right hand side of (19.1.2), considered as a vector space over K_v and it induces the product topology. On the other hand, any two norms are equivalent, since K_v is complete, so $\|\cdot\|_0$ induces the tensor product topology on the left hand side of (19.1.2). □

Corollary 19.1.9. *Suppose $L = K(a)$, and let $f(x) \in K[x]$ be the minimal polynomial of a. Suppose that*

$$f(x) = \prod_{1 \le j \le J} g_j(x)$$

in $K_v[x]$, where the g_j are irreducible. Then $L_j = K_v(b_j)$, where b_j is a root of g_j.

19.2 Extensions of Normalized Valuations

Let K be a complete field with valuation $|\cdot|$. We consider the following three cases:

(1) $|\cdot|$ is discrete non-archimedean and the residue class field is finite.

(2i) The completion of K with respect to $|\cdot|$ is **R**.

(2ii) The completion of K with respect to $|\cdot|$ is **C**.

(Alternatively, these cases can be subsumed by the hypothesis that the completion of K is locally compact.)

In case (1) we defined the normalized valuation to be the one such that if Haar measure of the ring of integers $\mathcal{O}$ is 1, then $\mu(a\mathcal{O}) = |a|$ (see Definition 17.1.11). In case (2i) we say that $|\cdot|$ is normalized if it is the ordinary absolute value, and in (2ii) if it is the *square* of the ordinary absolute value:

$$|x + iy| = x^2 + y^2 \qquad \text{(normalized)}.$$

In every case, for every $a \in K$, the map

$$a : x \mapsto ax$$

on K^+ multiplies any choice of Haar measure by $|a|$, and this characterizes the normalized valuations among equivalent ones.

We have already verified the above characterization for non-archimedean valuations, and it is clear for the ordinary absolute value on **R**, so it remains to verify it for $\mathbf{C}$. The additive group $\mathbf{C}^+$ is topologically isomorphic to $\mathbf{R}^+ \oplus \mathbf{R}^+$, so a choice of Haar measure of $\mathbf{C}^+$ is the usual area measure on the Euclidean plane. Multiplication by $x+iy \in \mathbf{C}$ is the same as rotation followed by scaling by a factor of $\sqrt{x^2+y^2}$, so if we rescale a region by a factor of $x+iy$, the area of the region changes by a factor of the square of $\sqrt{x^2+y^2}$. This explains why the normalized valuation on $\mathbf{C}$ is the square of the usual absolute value. Note that the normalized valuation on $\mathbf{C}$ does not satisfy the triangle inequality:

$$|1+(1+i)| = |2+i| = 2^2+1^2 = 5 \not\leq 3 = 1^2 + (1^2+1^2) = |1| + |1+i|\,.$$

The constant C in axiom (3) of a valuation for the ordinary absolute value on $\mathbf{C}$ is 2, so the constant for the normalized valuation $|\cdot|$ is $C \leq 4$:

$$|x+iy| \leq 1 \implies |x+iy+1| \leq 4.$$

Note that $x^2+y^2 \leq 1$ implies

$$(x+1)^2+y^2 = x^2+2x+1+y^2 \leq 1+2x+1 \leq 4$$

since $x \leq 1$.

Lemma 19.2.1. *Suppose K is a field that is complete with respect to a normalized valuation $|\cdot|$ and let L be a finite extension of K of degree $N = [L : K]$. Then the normalized valuation $\|\cdot\|$ on L which is equivalent to the unique extension of $|\cdot|$ to L is given by the formula*

$$\|a\| = \left|\mathrm{Norm}_{L/K}(a)\right| \qquad \textit{all } a \in L. \tag{19.2.1}$$

Proof. Let $\|\cdot\|$ be the normalized valuation on L that extends $|\cdot|$. Our goal is to identify $\|\cdot\|$, and in particular to show that it is given by (19.2.1).

By the preceding section there is a positive real number c such that for all $a \in L$ we have

$$\|a\| = \left|\mathrm{Norm}_{L/K}(a)\right|^c.$$

Thus all we have to do is prove that $c = 1$. In case 2 the only nontrivial situation is $L = \mathbf{C}$ and $K = \mathbf{R}$, in which case $\left|\mathrm{Norm}_{\mathbf{C}/\mathbf{R}}(x+iy)\right| = \left|x^2+y^2\right|$, which is the normalized valuation on $\mathbf{C}$ defined above.

One can argue in a unified way in all cases as follows. Let $w_1, \ldots, w_N$ be a basis for L/K. Then the map

$$\varphi : L^+ \to \bigoplus_{n=1}^{N} K^+, \qquad \sum a_n w_n \mapsto (a_1, \ldots, a_N)$$

is an isomorphism between the additive group L^+ and the direct sum $\oplus_{n=1}^N K^+$, and this is a homeomorphism if the right hand side is given the product topology. In particular, the Haar measures on L^+ and on $\oplus_{n=1}^N K^+$ are the same up to a multiplicative constant in $\mathbf{Q}^*$.

Let $b \in K$. Then the left-multiplication-by-b map

$$b : \sum a_n w_n \mapsto \sum b a_n w_n$$

on L^+ is the same as the map

$$(a_1, \ldots, a_N) \mapsto (ba_1, \ldots, ba_N)$$

on $\oplus_{n=1}^{N} K^+$, so it multiplies the Haar measure by $|b|^N$, since $|\cdot|$ on K is assumed normalized (the measure of each factor is multiplied by $|b|$, so the measure on the product is multiplied by $|b|^N$). Since $\|\cdot\|$ is assumed normalized, so multiplication by b rescales by $\|b\|$, we have

$$\|b\| = |b|^N .$$

But $b \in K$, so $\mathrm{Norm}_{L/K}(b) = b^N$. Since $|\cdot|$ is nontrivial and for $a \in K$ we have

$$\|a\| = |a|^N = \left|a^N\right| = \left|\mathrm{Norm}_{L/K}(a)\right| ,$$

so we must have $c = 1$ in (19.2.1), as claimed. □

In the case when K need not be complete with respect to the valuation $|\cdot|$ on K, we have the following theorem.

Theorem 19.2.2. *Suppose $|\cdot|$ is a (nontrivial as always) normalized valuation of a field K and let L be a finite extension of K. Then for any $a \in L$,*

$$\prod_{1 \leq j \leq J} \|a\|_j = \left|\mathrm{Norm}_{L/K}(a)\right|$$

where the $\|\cdot\|_j$ are the normalized valuations equivalent to the extensions of $|\cdot|$ to K.

Proof. Let K_v denote the completion of K with respect to $|\cdot|$. Write

$$K_v \otimes_K L = \bigoplus_{1 \leq j \leq J} L_j .$$

Then Theorem 19.2.2 asserts that

$$\mathrm{Norm}_{L/K}(a) = \prod_{1 \leq j \leq J} \mathrm{Norm}_{L_j/K_v}(a). \qquad (19.2.2)$$

By Theorem 19.1.8, the $\|\cdot\|_j$ are exactly the normalizations of the extensions of $|\cdot|$ to the L_j (i.e., the L_j are in bijection with the extensions of valuations, so there are no other valuations missed). By Lemma 19.1.1, the normalized valuation $\|\cdot\|_j$ on L_j is $|a| = \left|\mathrm{Norm}_{L_J/K_v}(a)\right|$. The theorem now follows by taking absolute values of both sides of (19.2.2). □

What next?! We'll building up to giving a new proof of finiteness of the class group that uses that the class group naturally has the discrete topology and is the continuous image of a compact group.

Chapter 20

Global Fields and Adeles

20.1 Global Fields

Definition 20.1.1 (Global Field). A *global field* is a number field or a finite separable extension of $\mathbf{F}(t)$, where $\mathbf{F}$ is a finite field, and t is transcendental over $\mathbf{F}$.

Below we will focus attention on number fields leaving the function field case to the reader.

The following lemma essentially says that the denominator of an element of a global field is only "nontrivial" at a finite number of valuations.

Lemma 20.1.2. *Let $a \in K$ be a nonzero element of a global field K. Then there are only finitely many inequivalent valuations $|\cdot|$ of K for which*

$$|a| > 1.$$

Proof. If $K = \mathbf{Q}$ or $\mathbf{F}(t)$ then the lemma follows by Ostrowski's classification of all the valuations on K (see Theorem 15.3.2). For example, when $a = \frac{n}{d} \in \mathbf{Q}$, with $n, d \in \mathbf{Z}$, then the valuations where we could have $|a| > 1$ are the archimedean one, or the p-adic valuations $|\cdot|_p$ for which $p \mid d$.

Suppose now that K is a finite extension of $\mathbf{Q}$, so a satisfies a monic polynomial

$$a^n + c_{n-1}a^{n-1} + \cdots + c_0 = 0,$$

for some n and $c_0, \ldots, c_{n-1} \in \mathbf{Q}$. If $|\cdot|$ is a non-archimedean valuation on K, we have

$$\begin{aligned} |a|^n &= \left|-(c_{n-1}a^{n-1} + \cdots + c_0)\right| \\ &\leq \max(1, |a|^{n-1}) \cdot \max(|c_0|, \ldots, |c_{n-1}|). \end{aligned}$$

Dividing each side by $|a|^{n-1}$, we have that

$$|a| \leq \max(|c_0|, \ldots, |c_{n-1}|),$$

so in all cases we have

$$|a| \le \max(1, |c_0|, \ldots, |c_{n-1}|)^{1/(n-1)}. \tag{20.1.1}$$

We know the lemma for $\mathbf{Q}$, so there are only finitely many valuations $|\cdot|$ on $\mathbf{Q}$ such that the right hand side of (20.1.1) is bigger than 1. Since each valuation of $\mathbf{Q}$ has finitely many extensions to K, and there are only finitely many archimedean valuations, it follows that there are only finitely many valuations on K such that $|a| > 1$. □

Any valuation on a global field is either archimedean, or discrete non-archimedean with finite residue class field, since this is true of $\mathbf{Q}$ and $\mathbf{F}(t)$ and is a property preserved by extending a valuation to a finite extension of the base field. Hence it makes sense to talk of normalized valuations. Recall that the normalized p-adic valuation on $\mathbf{Q}$ is $|x|_p = p^{-\operatorname{ord}_p(x)}$, and if v is a valuation on a number field K equivalent to an extension of $|\cdot|_p$, then the normalization of v is the composite of the sequence of maps

$$K \hookrightarrow K_v \xrightarrow{\text{Norm}} \mathbf{Q}_p \xrightarrow{|\cdot|_p} \mathbf{R},$$

where K_v is the completion of K at v.

Example 20.1.3. Let $K = \mathbf{Q}(\sqrt{2})$, and let $p = 2$. Because $\sqrt{2} \notin \mathbf{Q}_2$, there is exactly one extension of $|\cdot|_2$ to K, and it sends $a = 1/\sqrt{2}$ to

$$\left|\text{Norm}_{\mathbf{Q}_2(\sqrt{2})/\mathbf{Q}_2}(1/\sqrt{2})\right|_2^{1/2} = \sqrt{2}.$$

Thus the normalized valuation of a is 2.

There are two extensions of $|\cdot|_7$ to $\mathbf{Q}(\sqrt{2})$, since $\mathbf{Q}(\sqrt{2}) \otimes_{\mathbf{Q}} \mathbf{Q}_7 \cong \mathbf{Q}_7 \oplus \mathbf{Q}_7$, as $x^2 - 2 = (x-3)(x-4) \pmod 7$. The image of $\sqrt{2}$ under each embedding into $\mathbf{Q}_7$ is a unit in $\mathbf{Z}_7$, so the normalized valuation of $a = 1/\sqrt{2}$ is, in both cases, equal to 1. More generally, for any valuation of K of characteristic an odd prime p, the normalized valuation of a is 1.

Since $K = \mathbf{Q}(\sqrt{2}) \hookrightarrow \mathbf{R}$ in two ways, there are exactly two normalized archimedean valuations on K, and both of their values on a equal $1/\sqrt{2}$. Notice that the product of the absolute values of a with respect to all normalized valuations is

$$2 \cdot \frac{1}{\sqrt{2}} \cdot \frac{1}{\sqrt{2}} \cdot 1 \cdot 1 \cdot 1 \cdots = 1.$$

This "product formula" holds in much more generality, as we will now see.

Theorem 20.1.4 (Product Formula). *Let $a \in K$ be a nonzero element of a global field K. Let $|\cdot|_v$ run through the normalized valuations of K. Then $|a|_v = 1$ for almost all v, and*

$$\prod_{\text{all } v} |a|_v = 1 \qquad \text{(the product formula).}$$

We will later give a more conceptual proof of this using Haar measure (see Remark 20.3.9).

Proof. By Lemma 20.1.2, we have $|a|_v \leq 1$ for almost all v. Likewise, $1/|a|_v = |1/a|_v \leq 1$ for almost all v, so $|a|_v = 1$ for almost all v.

Let w run through all normalized valuations of $\mathbf{Q}$ (or of $\mathbf{F}(t)$), and write $v \mid w$ if the restriction of v to $\mathbf{Q}$ is equivalent to w. Then by Theorem 19.2.2,

$$\prod_v |a|_v = \prod_w \left(\prod_{v|w} |a|_v \right) = \prod_w \left|\mathrm{Norm}_{K/\mathbf{Q}}(a)\right|_w,$$

so it suffices to prove the theorem for $K = \mathbf{Q}$.

By multiplicativity of valuations, if the theorem is true for b and c then it is true for the product bc and quotient b/c (when $c \neq 0$). The theorem is clearly true for -1, which has valuation 1 at all valuations. Thus to prove the theorem for $\mathbf{Q}$ it suffices to prove it when $a = p$ is a prime number. Then we have $|p|_\infty = p$, $|p|_p = 1/p$, and for primes $q \neq p$ that $|p|_q = 1$. Thus

$$\prod_v |p|_v = p \cdot \frac{1}{p} \cdot 1 \cdot 1 \cdot 1 \cdots = 1,$$

as claimed. □

If v is a valuation on a field K, recall that we let K_v denote the completion of K with respect to v. Also when v is non-archimedean, let

$$\mathcal{O}_v = \mathcal{O}_{K,v} = \{x \in K_v : |x| \leq 1\}$$

be the ring of integers of the completion.

Definition 20.1.5 (Almost All). We say a condition holds for *almost all* elements of a set if it holds for all but finitely many elements.

We will use the following lemma later (see Lemma 20.3.3) to prove that formation of the adeles of a global field is compatible with base change.

Lemma 20.1.6. *Let $\omega_1, \ldots, \omega_n$ be a basis for L/K, where L is a finite separable extension of the global field K of degree n. Then for almost all normalized non-archimedean valuations v on K we have*

$$\omega_1 \mathcal{O}_v \oplus \cdots \oplus \omega_n \mathcal{O}_v = \mathcal{O}_{w_1} \oplus \cdots \oplus \mathcal{O}_{w_g} \subset K_v \otimes_K L, \tag{20.1.2}$$

where $w_1, \ldots, w_g$ are the extensions of v to L. Here we have identified $a \in L$ with its canonical image in $K_v \otimes_K L$, and the direct sum on the left is the sum taken inside the tensor product (so directness means that the intersections are trivial).

Proof. The proof proceeds in two steps. First we deduce easily from Lemma 20.1.2 that for almost all v the left hand side of (20.1.2) is contained in the right hand side. Then we use a trick involving discriminants to show the opposite inclusion for all but finitely many primes.

Since $\mathcal{O}_v \subset \mathcal{O}_{w_i}$ for all i, the left hand side of (20.1.2) is contained in the right hand side if $|\omega_i|_{w_j} \leq 1$ for $1 \leq i \leq n$ and $1 \leq j \leq g$. Thus by Lemma 20.1.2, for all but finitely many v the left hand side of (20.1.2) is contained in the right hand side. We have just eliminated the finitely many primes corresponding to "denominators" of some ω_i, and now only consider v such that $\omega_1, \ldots, \omega_n \in \mathcal{O}_w$ for all $w \mid v$.

For any elements $a_1, \ldots, a_n \in K_v \otimes_K L$, consider the discriminant

$$D(a_1, \ldots, a_n) = \mathrm{Det}(\mathrm{Tr}(a_i a_j)) \in K_v,$$

where the trace is induced from the L/K trace. Since each ω_i is in each $\mathcal{O}_w$, for $w \mid v$, the traces lie in $\mathcal{O}_v$, so

$$d = D(\omega_1, \ldots, \omega_n) \in \mathcal{O}_v.$$

Also note that $d \in K$ since each ω_i is in L. Now suppose that

$$\alpha = \sum_{i=1}^{n} a_i \omega_i \in \mathcal{O}_{w_1} \oplus \cdots \oplus \mathcal{O}_{w_g},$$

with $a_i \in K_v$. Then by properties of determinants for any m with $1 \leq m \leq n$, we have

$$D(\omega_1, \ldots, \omega_{m-1}, \alpha, \omega_{m+1}, \ldots, \omega_n) = a_m^2 D(\omega_1, \ldots, \omega_n). \tag{20.1.3}$$

The left hand side of (20.1.3) is in $\mathcal{O}_v$, so the right hand side is well, i.e.,

$$a_m^2 \cdot d \in \mathcal{O}_v, \qquad (\text{for } m = 1, \ldots, n),$$

where $d \in K$. Since $\omega_1, \ldots, \omega_n$ are a basis for L over K and the trace pairing is nondegenerate, we have $d \neq 0$, so by Theorem 20.1.4 we have $|d|_v = 1$ for all but finitely many v. Then for all but finitely many v we have that $a_m^2 \in \mathcal{O}_v$. For these v, that $a_m^2 \in \mathcal{O}_v$ implies $a_m \in \mathcal{O}_v$ since $a_m \in K_v$, i.e., α is in the left hand side of (20.1.2). □

Example 20.1.7. Let $K = \mathbf{Q}$ and $L = \mathbf{Q}(\sqrt{2})$. Let $\omega_1 = 1/3$ and $\omega_2 = 2\sqrt{2}$. In the first stage of the above proof we would eliminate $|\cdot|_3$ because ω_2 is not integral at 3. The discriminant is

$$d = D\left(\frac{1}{3}, 2\sqrt{2}\right) = \mathrm{Det}\begin{pmatrix} \frac{2}{9} & 0 \\ 0 & 16 \end{pmatrix} = \frac{32}{9}.$$

As explained in the second part of the proof, as long as $v \neq 2, 3$, we have equality of the left and right hand sides in (20.1.2).

20.2 Restricted Topological Products

In this section we describe a topological tool, which we need in order to define adeles (see Definition 20.3.1).

Definition 20.2.1 (Restricted Topological Products). Let X_λ, for $\lambda \in \Lambda$, be a family of topological spaces, and for almost all λ let $Y_\lambda \subset X_\lambda$ be an open subset of X_λ. Consider the space X whose elements are sequences $\mathbf{x} = \{x_\lambda\}_{\lambda\in\Lambda}$, where $x_\lambda \in X_\lambda$ for every λ, and $x_\lambda \in Y_\lambda$ for almost all λ. We give X a topology by taking as a basis of open sets the sets $\prod U_\lambda$, where $U_\lambda \subset X_\lambda$ is open for all λ, and $U_\lambda = Y_\lambda$ for almost all λ. We call X with this topology the *restricted topological product* of the X_λ with respect to the Y_λ.

Corollary 20.2.2. *Let S be a finite subset of Λ, and let X_S be the set of $\mathbf{x} \in X$ with $x_\lambda \in Y_\lambda$ for all $\lambda \notin S$, i.e.,*

$$X_S = \prod_{\lambda\in S} X_\lambda \times \prod_{\lambda\notin S} Y_\lambda \subset X.$$

Then X_S is an open subset of X, and the topology induced on X_S as a subset of X is the same as the product topology.

The restricted topological product depends on the totality of the Y_λ, but not on the individual Y_λ:

Lemma 20.2.3. *Let $Y'_\lambda \subset X_\lambda$ be open subsets, and suppose that $Y_\lambda = Y'_\lambda$ for almost all λ. Then the restricted topological product of the X_λ with respect to the Y'_λ is canonically isomorphic to the restricted topological product with respect to the Y_λ.*

Lemma 20.2.4. *Suppose that the X_λ are locally compact and that the Y_λ are compact. Then the restricted topological product X of the X_λ is locally compact.*

Proof. For any finite subset S of Λ, the open subset $X_S \subset X$ is locally compact, because by Lemma 20.2.2 it is a product of finitely many locally compact sets with an infinite product of compact sets. (Here we are using Tychonoff's theorem from topology, which asserts that an arbitrary product of compact topological spaces is compact (see Munkres's *Topology, a first course*, chapter 5).) Since $X = \cup_S X_S$, and the X_S are open in X, the result follows. □

The following measure will be extremely important in deducing topological properties of the ideles, which will be used in proving finiteness of class groups. See, e.g., the proof of Lemma 20.4.1, which is a key input to the proof of strong approximation (Theorem 20.4.4).

Definition 20.2.5 (Product Measure). For all $\lambda \in \Lambda$, suppose μ_λ is a measure on X_λ with $\mu_\lambda(Y_\lambda) = 1$ when Y_λ is defined. We define the *product measure* μ on X to be that for which a basis of measurable sets is

$$\prod_\lambda M_\lambda$$

where each $M_\lambda \subset X_\lambda$ has finite μ_λ-measure and $M_\lambda = Y_\lambda$ for almost all λ, and where

$$\mu\left(\prod_\lambda M_\lambda\right) = \prod_\lambda \mu_\lambda(M_\lambda).$$

20.3 The Adele Ring

Let K be a global field. For each normalization $|\cdot|_v$ of K, let K_v denote the completion of K. If $|\cdot|_v$ is non-archimedean, let $\mathcal{O}_v$ denote the ring of integers of K_v.

Definition 20.3.1 (Adele Ring). The *adele ring* $\mathbb{A}_K$ of K is the topological ring whose underlying topological space is the restricted topological product of the K_v with respect to the $\mathcal{O}_v$, and where addition and multiplication are defined componentwise:

$$(\mathbf{x}\mathbf{y})_v = \mathbf{x}_v\mathbf{y}_v \qquad (\mathbf{x}+\mathbf{y})_v = \mathbf{x}_v + \mathbf{y}_v \qquad \text{for } \mathbf{x}, \mathbf{y} \in \mathbb{A}_K. \tag{20.3.1}$$

It is readily verified that (i) this definition makes sense, i.e., if $\mathbf{x}, \mathbf{y} \in \mathbb{A}_K$, then $\mathbf{x}\mathbf{y}$ and $\mathbf{x}+\mathbf{y}$, whose components are given by (20.3.1), are also in $\mathbb{A}_K$, and (ii) that addition and multiplication are continuous in the $\mathbb{A}_K$-topology, so $\mathbb{A}_K$ is a topological ring, as asserted. Also, Lemma 20.2.4 implies that $\mathbb{A}_K$ is locally compact because the K_v are locally compact (Corollary 17.1.6), and the $\mathcal{O}_v$ are compact (Theorem 17.1.4).

There is a natural continuous ring inclusion

$$K \hookrightarrow \mathbb{A}_K \tag{20.3.2}$$

that sends $x \in K$ to the adele every one of whose components is x. This is an adele because $x \in \mathcal{O}_v$ for almost all v, by Lemma 20.1.2. The map is injective because each map $K \to K_v$ is an inclusion.

Definition 20.3.2 (Principal Adeles). The image of (20.3.2) is the ring of *principal adeles.*

It will cause no trouble to identify K with the principal adeles, so we shall speak of K as a subring of $\mathbb{A}_K$.

Formation of the adeles is compatibility with base change, in the following sense.

Lemma 20.3.3. *Suppose L is a finite (separable) extension of the global field K. Then*

$$\mathbb{A}_K \otimes_K L \cong \mathbb{A}_L \tag{20.3.3}$$

both algebraically and topologically. Under this isomorphism,

$$L \cong K \otimes_K L \subset \mathbb{A}_K \otimes_K L$$

maps isomorphically onto $L \subset \mathbb{A}_L$.

Proof. Let $\omega_1, \ldots, \omega_n$ be a basis for L/K and let v run through the normalized valuations on K. The left hand side of (20.3.3), with the tensor product topology, is the restricted product of the tensor products

$$K_v \otimes_K L \cong K_v \cdot \omega_1 \oplus \cdots \oplus K_v \cdot \omega_n$$

with respect to the integers

$$\mathcal{O}_v \cdot \omega_1 \oplus \cdots \oplus \mathcal{O}_v \cdot \omega_n. \tag{20.3.4}$$

(An element of the left hand side is a finite linear combination $\sum \mathbf{x}_i \otimes a_i$ of adeles $\mathbf{x}_i \in \mathbb{A}_K$ and coefficients $a_i \in L$, and there is a natural isomorphism from the ring of such formal sums to the restricted product of the $K_v \otimes_K L$.)

We proved before (Theorem 19.1.8) that

$$K_v \otimes_K L \cong L_{w_1} \oplus \cdots \oplus L_{w_g},$$

where $w_1, \ldots, w_g$ are the normalizations of the extensions of v to L. Furthermore, as we proved using discriminants (see Lemma 20.1.6), the above identification identifies (20.3.4) with

$$\mathcal{O}_{L_{w_1}} \oplus \cdots \oplus \mathcal{O}_{L_{w_g}},$$

for almost all v. Thus the left hand side of (20.3.3) is the restricted product of the $L_{w_1} \oplus \cdots \oplus L_{w_g}$ with respect to the $\mathcal{O}_{L_{w_1}} \oplus \cdots \oplus \mathcal{O}_{L_{w_g}}$. But this is canonically isomorphic to the restricted product of all completions L_w with respect to $\mathcal{O}_w$, which is the right hand side of (20.3.3). This establishes an isomorphism between the two sides of (20.3.3) as topological spaces. The map is also a ring homomorphism, so the two sides are algebraically isomorphic, as claimed. □

Corollary 20.3.4. *Let $\mathbb{A}_K^+$ denote the topological group obtained from the additive structure on $\mathbb{A}_K$. Suppose L is a finite seperable extension of K. Then*

$$\mathbb{A}_L^+ = \mathbb{A}_K^+ \oplus \cdots \oplus \mathbb{A}_K^+, \qquad (\text{[}L:K\text{] } \textit{summands}).$$

In this isomorphism the additive group $L^+ \subset \mathbb{A}_L^+$ of the principal adeles is mapped isomorphically onto $K^+ \oplus \cdots \oplus K^+$.

Proof. For any nonzero $\omega \in L$, the subgroup $\omega \cdot \mathbb{A}_K^+$ of $\mathbb{A}_L^+$ is isomorphic as a topological group to $\mathbb{A}_K^+$ (the isomorphism is multiplication by $1/\omega$). By Lemma 20.3.3, we have isomorphisms

$$\mathbb{A}_L^+ = \mathbb{A}_K^+ \otimes_K L \cong \omega_1 \cdot \mathbb{A}_K^+ \oplus \cdots \oplus \omega_n \cdot \mathbb{A}_K^+ \cong \mathbb{A}_K^+ \oplus \cdots \oplus \mathbb{A}_K^+.$$

If $a \in L$, write $a = \sum b_i \omega_i$, with $b_i \in K$. Then a maps via the above map to

$$x = (\omega_1 \cdot \{b_1\}, \ldots, \omega_n \cdot \{b_n\}),$$

where $\{b_i\}$ denotes the principal adele defined by b_i. Under the final map, x maps to the tuple

$$(b_1, \ldots, b_n) \in K \oplus \cdots \oplus K \subset \mathbb{A}_K^+ \oplus \cdots \oplus \mathbb{A}_K^+.$$

The dimensions of L and of $K \oplus \cdots \oplus K$ over K are the same, so this proves the final claim of the corollary. □

Theorem 20.3.5. *The global field K is discrete in $\mathbb{A}_K$ and the quotient $\mathbb{A}_K^+/K^+$ of additive groups is compact in the quotient topology.*

At this point Cassels remarks

> "It is impossible to conceive of any other uniquely defined topology on K. This metamathematical reason is more persuasive than the argument that follows!"

Proof. Corollary 20.3.4, with K for L and $\mathbf{Q}$ or $\mathbf{F}(t)$ for K, shows that it is enough to verify the theorem for $\mathbf{Q}$ or $\mathbf{F}(t)$, and we shall do it here for $\mathbf{Q}$.

To show that $\mathbf{Q}^+$ is discrete in $\mathbb{A}_{\mathbf{Q}}^+$ it is enough, because of the group structure, to find an open set U that contains $0 \in \mathbb{A}_{\mathbf{Q}}^+$, but which contains no other elements of $\mathbf{Q}^+$. (If $\alpha \in \mathbf{Q}^+$, then $U + \alpha$ is an open subset of $\mathbb{A}_{\mathbf{Q}}^+$ whose intersection with $\mathbf{Q}^+$ is $\{\alpha\}$.) We take for U the set of $\mathbf{x} = \{x_v\}_v \in \mathbb{A}_{\mathbf{Q}}^+$ with

$$|x_\infty|_\infty < 1 \qquad \text{and} \qquad |x_p|_p \leq 1 \quad (\text{all } p),$$

where $|\cdot|_p$ and $|\cdot|_\infty$ are respectively the p-adic and the usual archimedean absolute values on $\mathbf{Q}$. If $b \in \mathbf{Q} \cap U$, then in the first place $b \in \mathbf{Z}$ because $|b|_p \leq 1$ for all p, and then $b = 0$ because $|b|_\infty < 1$. This proves that K^+ is discrete in $\mathbb{A}_{\mathbf{Q}}^+$. (If we leave out one valuation, as we will see later (Theorem 20.4.4), this theorem is false—what goes wrong with the proof just given?)

Next we prove that the quotient $\mathbb{A}_{\mathbf{Q}}^+/\mathbf{Q}^+$ is compact. Let $W \subset \mathbb{A}_{\mathbf{Q}}^+$ consist of the $\mathbf{x} = \{x_v\}_v \in \mathbb{A}_{\mathbf{Q}}^+$ with

$$|x_\infty|_\infty \leq \frac{1}{2} \qquad \text{and} \qquad |x_p|_p \leq 1 \qquad \text{for all primes } p.$$

We show that every adele $\mathbf{y} = \{y_v\}_v$ is of the form

$$\mathbf{y} = a + \mathbf{x}, \qquad a \in \mathbf{Q}, \quad \mathbf{x} \in W,$$

which will imply that the compact set W maps surjectively onto $\mathbb{A}_{\mathbf{Q}}^{+}/\mathbf{Q}^{+}$. Fix an adele $\mathbf{y} = \{y_v\} \in \mathbb{A}_{\mathbf{Q}}^{+}$. Since $\mathbf{y}$ is an adele, for each prime p we can find a rational number

$$r_p = \frac{z_p}{p^{n_p}} \qquad \text{with} \quad z_p \in \mathbf{Z} \quad \text{and} \quad n_p \in \mathbf{Z}_{\geq 0}$$

such that

$$|y_p - r_p|_p \leq 1,$$

and

$$r_p = 0 \qquad \text{almost all } p.$$

More precisely, for the finitely many p such that

$$y_p = \sum_{n \geq -|s|} a_n p^n \notin \mathbf{Z}_p,$$

choose r_p to be a rational number that is the value of an appropriate truncation of the p-adic expansion of y_p, and when $y_p \in \mathbf{Z}_p$ just choose $r_p = 0$. Hence $r = \sum_p r_p \in \mathbf{Q}$ is well defined. The r_q for $q \neq p$ do not mess up the inequality $|y_p - r|_p \leq 1$ since the valuation $|\cdot|_p$ is non-archimedean and the r_q do not have any p in their denominator:

$$|y_p - r|_p = \left| y_p - r_p - \sum_{q \neq p} r_q \right|_p \leq \max\left(|y_p - r_p|_p, \left| \sum_{q \neq p} r_q \right|_p \right) \leq \max(1, 1) = 1.$$

Now choose $s \in \mathbf{Z}$ such that

$$|b_\infty - r - s| \leq \frac{1}{2}.$$

Then $a = r + s$ and $\mathbf{x} = \mathbf{y} - a$ do what is required, since $\mathbf{y} - a = \mathbf{y} - r - s$ has the desired property (since $s \in \mathbf{Z}$ and the p-adic valuations are non-archimedean).

Hence the continuous map $W \to \mathbb{A}_{\mathbf{Q}}^{+}/\mathbf{Q}^{+}$ induced by the quotient map $\mathbb{A}_{\mathbf{Q}}^{+} \to \mathbb{A}_{\mathbf{Q}}^{+}/\mathbf{Q}^{+}$ is surjective. But W is compact (being the topological product of the compact spaces $|x_\infty|_\infty \leq 1/2$ and the $\mathbf{Z}_p$ for all p), hence $\mathbb{A}_{\mathbf{Q}}^{+}/\mathbf{Q}^{+}$ is also compact. □

Corollary 20.3.6. *There is a subset W of $\mathbb{A}_K$ defined by inequalities of the type $|x_v|_v \leq \delta_v$, where $\delta_v = 1$ for almost all v, such that every $\mathbf{y} \in \mathbb{A}_K$ can be put in the form*

$$\mathbf{y} = a + \mathbf{x}, \qquad a \in K, \quad \mathbf{x} \in W,$$

i.e., $\mathbb{A}_K = K + W$.

Proof. We constructed such a set for $K = \mathbf{Q}$ when proving Theorem 20.3.5. For general K the W coming from the proof determines compenent-wise a subset of $\mathbb{A}_K^{+} \cong \mathbb{A}_{\mathbf{Q}}^{+} \oplus \cdots \oplus \mathbb{A}_{\mathbf{Q}}^{+}$ that is a subset of a set with the properties claimed by the corollary. □

As already remarked, $\mathbb{A}_K^+$ is a locally compact group, so it has an invariant Haar measure. In fact one choice of this Haar measure is the product of the Haar measures on the K_v, in the sense of Definition 20.2.5.

Corollary 20.3.7. *The quotient $\mathbb{A}_K^+/K^+$ has finite measure in the quotient measure induced by the Haar measure on $\mathbb{A}_K^+$.*

Remark 20.3.8. This statement is independent of the particular choice of the multiplicative constant in the Haar measure on $\mathbb{A}_K^+$. We do not here go into the question of finding the measure $\mathbb{A}_K^+/K^+$ in terms of our explicitly given Haar measure. (See Tate's thesis, [Cp86, Chapter XV].)

Proof. This can be reduced similarly to the case of $\mathbf{Q}$ or $\mathbf{F}(t)$ which is immediate, e.g., the W defined above has measure 1 for our Haar measure.

Alternatively, finite measure follows from compactness. To see this, cover $\mathbb{A}_K/K^+$ with the translates of U, where U is a nonempty open set with finite measure. The existence of a finite subcover implies finite measure. □

Remark 20.3.9. We give an alternative proof of the product formula $\prod |a|_v = 1$ for nonzero $a \in K$. We have seen that if $x_v \in K_v$, then multiplication by x_v magnifies the Haar measure in K_v^+ by a factor of $|x_v|_v$. Hence if $\mathbf{x} = \{x_v\} \in \mathbb{A}_K$, then multiplication by $\mathbf{x}$ magnifies the Haar measure in $\mathbb{A}_K^+$ by $\prod |x_v|_v$. But now multiplication by $a \in K$ takes $K^+ \subset \mathbb{A}_K^+$ into K^+, so gives a well-defined bijection of $\mathbb{A}_K^+/K^+$ onto $\mathbb{A}_K^+/K^+$ which magnifies the measure by the factor $\prod |a|_v$. Hence $\prod |a|_v = 1$ Corollary 20.3.7. (The point is that if μ is the measure of $\mathbb{A}_K^+/K^+$, then $\mu = \prod |a|_v \cdot \mu$, so because μ is finite we must have $\prod |a|_v = 1$.)

20.4 Strong Approximation

We first prove a technical lemma and corollary, then use them to deduce the strong approximation theorem, which is an extreme generalization of the Chinese Remainder Theorem; it asserts that K^+ is dense in the analogue of the adeles with one valuation removed.

The proof of Lemma 20.4.1 below will use in a crucial way the normalized Haar measure on $\mathbb{A}_K$ and the induced measure on the compact quotient $\mathbb{A}_K^+/K^+$. Since I am not formally developing Haar measure on locally compact groups, and since I didn't explain induced measures on quotients well in the last chapter, hopefully the following discussion will help clarify what is going on.

The real numbers $\mathbf{R}^+$ under addition is a locally compact topological group. Normalized Haar measure μ has the property that $\mu([a, b]) = b - a$, where $a \leq b$ are real numbers and $[a, b]$ is the closed interval from a to b. The subset $\mathbf{Z}^+$ of $\mathbf{R}^+$ is discrete, and the quotient $S^1 = \mathbf{R}^+/\mathbf{Z}^+$ is a compact topological group, which thus has a Haar measure. Let $\overline{\mu}$ be the Haar measure on S^1 normalized so that the natural quotient $\pi : \mathbf{R}^+ \to S^1$ preserves the measure, in the sense that if $X \subset \mathbf{R}^+$ is a measurable set that maps injectively into S^1, then $\mu(X) = \overline{\mu}(\pi(X))$. This determine $\overline{\mu}$ and we have $\overline{\mu}(S^1) = 1$ since $X = [0, 1)$ is a measurable set that maps bijectively onto S^1 and has measure 1. The situation for the map $\mathbb{A}_K \to \mathbb{A}_K/K^+$ is pretty much the same.

Lemma 20.4.1. *There is a constant $C > 0$ that depends only on the global field K with the following property:*

Whenever $\mathbf{x} = \{x_v\}_v \in \mathbb{A}_K$ is such that

$$\prod_v |x_v|_v > C, \tag{20.4.1}$$

then there is a nonzero principal adele $a \in K \subset \mathbb{A}_K$ such that

$$|a|_v \leq |x_v|_v \qquad \text{for all } v.$$

Proof. This proof is modelled on Blichfeldt's proof of Minkowski's Theorem in the Geometry of Numbers, and works in quite general circumstances.

First we show that (20.4.1) implies that $|x_v|_v = 1$ for almost all v. Because $\mathbf{x}$ is an adele, we have $|x_v|_v \leq 1$ for almost all v. If $|x_v|_v < 1$ for infinitely many v, then the product in (20.4.1) would have to be 0. (We prove this only when K is a finite extension of $\mathbf{Q}$.) Excluding archimedean valuations, this is because the normalized valuation $|x_v|_v = |\mathrm{Norm}(x_v)|_p$, which if less than 1 is necessarily $\leq 1/p$. Any infinite product of numbers $1/p_i$ must be 0, whenever p_i is a sequence of primes.

Let c_0 be the Haar measure of $\mathbb{A}_K^+/K^+$ induced from normalized Haar measure on $\mathbb{A}_K^+$, and let c_1 be the Haar measure of the set of $\mathbf{y} = \{y_v\}_v \in \mathbb{A}_K^+$ that satisfy

$$\begin{aligned} |y_v|_v &\leq \frac{1}{2} && \text{if } v \text{ is real archimedean,} \\ |y_v|_v &\leq \frac{1}{2} && \text{if } v \text{ is complex archimedean,} \\ |y_v|_v &\leq 1 && \text{if } v \text{ is non-archimedean.} \end{aligned}$$

(As we will see, any positive real number $\leq 1/2$ would suffice in the definition of c_1 above. For example, in Cassels's article he uses the mysterious 1/10. He also doesn't discuss the subtleties of the complex archimedean case separately.)

Then $0 < c_0 < \infty$ since $\mathbb{A}_K/K^+$ is compact, and $0 < c_1 < \infty$ because the number of archimedean valuations v is finite. We show that

$$C = \frac{c_0}{c_1}$$

will do. Thus suppose $\mathbf{x}$ is as in (20.4.1).

The set T of $\mathbf{t} = \{t_v\}_v \in \mathbb{A}_K^+$ such that

$$\begin{aligned} |t_v|_v &\leq \frac{1}{2}\,|x_v|_v && \text{if } v \text{ is real archimedean,} \\ |t_v|_v &\leq \frac{1}{2}\sqrt{|x_v|_v} && \text{if } v \text{ is complex archimedean,} \\ |t_v|_v &\leq |x_v|_v && \text{if } v \text{ is non-archimedean} \end{aligned}$$

has measure

$$c_1 \cdot \prod_v |x_v|_v > c_1 \cdot C = c_0. \tag{20.4.2}$$

(Note: If there are complex valuations, then the some of the $|x_v|_v$'s in the product must be squared.)

Because of (20.4.2), in the quotient map $\mathbb{A}_K^+ \to \mathbb{A}_K^+/K^+$ there must be a pair of distinct points of T that have the same image in $\mathbb{A}_K^+/K^+$, say

$$\mathbf{t}' = \{t'_v\}_v \in T \quad \text{and} \quad \mathbf{t}'' = \{t''_v\}_v \in T$$

and

$$a = \mathbf{t}' - \mathbf{t}'' \in K^+$$

is nonzero. Then

$$|a|_v = \left|t'_v - t''_v\right|_v \leq \begin{cases} |t'_v| + |t''_v| \leq 2 \cdot \frac{1}{2} |x_v|_v \leq |x_v|_v & \text{if } v \text{ is real archimedean, or} \\ \max(|t'_v|, |t''_v|) \leq |x_v|_v & \text{if } v \text{ is non-archimedean,} \end{cases}$$

for all v. In the case of complex archimedean v, we must be careful because the normalized valuation $|\cdot|_v$ is the *square* of the usual archimedean complex valuation $|\cdot|_\infty$ on $\mathbf{C}$, so e.g., it does not satisfy the triangle inequality. In particular, the quantity $|t'_v - t''_v|_v$ is at most the square of the maximum distance between two points in the disc in $\mathbf{C}$ of radius $\frac{1}{2}\sqrt{|x_v|_v}$, where by distance we mean the usual distance. This maximum distance in such a disc is at most $\sqrt{|x_v|_v}$, so $|t'_v - t''_v|_v$ is at most $|x_v|_v$, as required. Thus a satisfies the requirements of the lemma. □

Corollary 20.4.2. *Let v_0 be a normalized valuation and let $\delta_v > 0$ be given for all $v \neq v_0$ with $\delta_v = 1$ for almost all v. Then there is a nonzero $a \in K$ with*

$$|a|_v \leq \delta_v \qquad \textit{(all } v \neq v_0\textit{)}.$$

Proof. This is just a degenerate case of Lemma 20.4.1. Choose $x_v \in K_v$ with $0 < |x_v|_v \leq \delta_v$ and $|x_v|_v = 1$ if $\delta_v = 1$. We can then choose $x_{v_0} \in K_{v_0}$ so that

$$\prod_{\text{all } v \text{ including } v_0} |x_v|_v > C.$$

Then Lemma 20.4.1 does what is required. □

Remark 20.4.3. The character group of the locally compact group $\mathbb{A}_K^+$ is isomorphic to $\mathbb{A}_K^+$ and K^+ plays a special role. See Chapter XV of [Cp86], Lang's [Lan64], Weil's [Wei82], and Godement's Bourbaki seminars 171 and 176. This duality lies behind the functional equation of ζ and L-functions. Iwasawa has shown [Iwa53] that the rings of adeles are characterized by certain general topologico-algebraic properties.

We proved before that K is discrete in $\mathbb{A}_K$. If one valuation is removed, the situation is much different.

Theorem 20.4.4 (Strong Approximation). *Let v_0 be any normalized nontrivial valuation of the global field K. Let $\mathbb{A}_{K,v_0}$ be the restricted topological product of the K_v with respect to the $\mathcal{O}_v$, where v runs through all normalized valuations $v \neq v_0$. Then K is dense in $\mathbb{A}_{K,v_0}$.*

Proof. This proof was suggested by Prof. Kneser at the Cassels-Frohlich conference.

Recall that if $\mathbf{x} = \{x_v\}_v \in \mathbb{A}_{K,v_0}$ then a basis of open sets about $\mathbf{x}$ is the collection of products

$$\prod_{v \in S} B(x_v, \varepsilon_v) \times \prod_{v \notin S,\ v \neq v_0} \mathcal{O}_v,$$

where $B(x_v, \varepsilon_v)$ is an open ball in K_v about x_v, and S runs through finite sets of normalized valuations (not including v_0). Thus denseness of K in $\mathbb{A}_{K,v_0}$ is equivalent to the following statement about elements. Suppose we are given (i) a finite set S of valuations $v \neq v_0$, (ii) elements $x_v \in K_v$ for all $v \in S$, and (iii) an $\varepsilon > 0$. Then there is an element $b \in K$ such that $|b - x_v|_v < \varepsilon$ for all $v \in S$ and $|b|_v \leq 1$ for all $v \notin S$ with $v \neq v_0$.

By the corollary to our proof that $\mathbb{A}_K^+/K^+$ is compact (Corollary 20.3.6), there is a $W \subset \mathbb{A}_K$ that is defined by inequalities of the form $|y_v|_v \leq \delta_v$ (where $\delta_v = 1$ for almost all v) such that ever $\mathbf{z} \in \mathbb{A}_K$ is of the form

$$\mathbf{z} = \mathbf{y} + c, \qquad \mathbf{y} \in W, \quad c \in K. \tag{20.4.3}$$

By Corollary 20.4.2, there is a nonzero $a \in K$ such that

$$\begin{aligned} |a|_v &< \frac{1}{\delta_v} \cdot \varepsilon && \text{for } v \in S, \\ |a|_v &\leq \frac{1}{\delta_v} && \text{for } v \notin S,\ v \neq v_0. \end{aligned}$$

Hence on putting $\mathbf{z} = \frac{1}{a} \cdot \mathbf{x}$ in (20.4.3) and multiplying by a, we see that every $\mathbf{x} \in \mathbb{A}_K$ is of the shape

$$\mathbf{x} = \mathbf{w} + b, \qquad \mathbf{w} \in a \cdot W, \quad b \in K,$$

where $a \cdot W$ is the set of $a\mathbf{y}$ for $\mathbf{y} \in W$. If now we let $\mathbf{x}$ have components the given x_v at $v \in S$, and (say) 0 elsewhere, then $b = \mathbf{x} - \mathbf{w}$ has the properties required. □

Remark 20.4.5. The proof gives a quantitative form of the theorem (i.e., with a bound for $|b|_{v_0}$). For an alternative approach, see [Mah64].

In the next chapter we'll introduce the ideles $\mathbb{A}_K^*$. Finally, we'll relate ideles to ideals, and use everything so far to give a new interpretation of class groups and their finiteness.

Chapter 21

Ideles and Ideals

In this chapter, we introduce the ideles $\mathbb{I}_K$, and relate ideles to ideals, and use what we've done so far to give an alternative interpretation of class groups and their finiteness, thus linking the adelic point of view with the classical point of view of the first part of this course.

21.1 The Idele Group

The invertible elements of any commutative topological ring R are a group R^* under multiplication. In general R^* is not a topological group if it is endowed with the subset topology because inversion need not be continuous (only multiplication and addition on R are required to be continuous). It is usual therefore to give R^* the following topology. There is an injection

$$x \mapsto \left(x, \ \frac{1}{x}\right) \tag{21.1.1}$$

of R^* into the topological product $R \times R$. We give R^* the corresponding subset topology. Then R^* with this topology is a topological group and the inclusion map $R^* \hookrightarrow R$ is continous. To see continuity of inclusion, note that this topology is finer (has at least as many open sets) than the subset topology induced by $R^* \subset R$, since the projection maps $R \times R \to R$ are continuous.

Example 21.1.1. This is a "non-example". The inverse map on $\mathbf{Z}_p^*$ is continuous with respect to the p-adic topology. If $a, b \in \mathbf{Z}_p^*$, then $|a| = |b| = 1$, so if $|a - b| < \varepsilon$, then

$$\left|\frac{1}{a} - \frac{1}{b}\right| = \left|\frac{b-a}{ab}\right| = \frac{|b-a|}{|ab|} < \frac{\varepsilon}{1} = \varepsilon.$$

Definition 21.1.2 (Idele Group). The *idele group* $\mathbb{I}_K$ of K is the group $\mathbb{A}_K^*$ of invertible elements of the adele ring $\mathbb{A}_K$.

We shall usually speak of $\mathbb{I}_K$ as a subset of $\mathbb{A}_K$, and will have to distinguish between the $\mathbb{I}_K$ and $\mathbb{A}_K$-topologies.

Example 21.1.3. For a rational prime p, let $\mathbf{x}_p \in \mathbb{A}_{\mathbf{Q}}$ be the adele whose pth component is p and whose vth component, for $v \neq p$, is 1. Then $\mathbf{x}_p \to 1$ as $p \to \infty$ in $\mathbb{A}_{\mathbf{Q}}$, for the following reason. We must show that if U is a basic open set that contains the adele $1 = \{1\}_v$, the $\mathbf{x}_p$ for all sufficiently large p are contained in U. Since U contains 1 and is a basic open set, it is of the form

$$\prod_{v \in S} U_v \times \prod_{v \notin S} \mathbf{Z}_v,$$

where S if a finite set, and the U_v, for $v \in S$, are arbitrary open subsets of $\mathbf{Q}_v$ that contain 1. If q is a prime larger than any prime in S, then $\mathbf{x}_p$ for $p \geq q$, is in U. This proves convergence. If the inverse map were continuous on $\mathbb{I}_K$, then the sequence of $\mathbf{x}_p^{-1}$ would converge to $1^{-1} = 1$. However, if U is an open set as above about 1, then for sufficiently large p, *none* of the adeles $\mathbf{x}_p$ are contained in U.

Lemma 21.1.4. *The group of ideles $\mathbb{I}_K$ is the restricted topological project of the K_v^* with respect to the units $U_v = \mathcal{O}_v^* \subset K_v$, with the restricted product topology.*

We omit the proof of Lemma 21.1.4, which is a matter of thinking carefully about the definitions. The main point is that inversion is continuous on $\mathcal{O}_v^*$ for each v. (See Example 21.1.1.)

We have seen that K is naturally embedded in $\mathbb{A}_K$, so K^* is naturally embedded in $\mathbb{I}_K$.

Definition 21.1.5 (Principal Ideles). We call K^*, considered as a subgroup of $\mathbb{I}_K$, the *principal ideles.*

Lemma 21.1.6. *The principal ideles K^* are discrete as a subgroup of $\mathbb{I}_K$.*

Proof. For K is discrete in $\mathbb{A}_K$, so K^* is embedded in $\mathbb{A}_K \times \mathbb{A}_K$ by (21.1.1) as a discrete subset. (Alternatively, the subgroup topology on $\mathbb{I}_K$ is finer than the topology coming from $\mathbb{I}_K$ being a subset of $\mathbb{A}_K$, and K is already discrete in $\mathbb{A}_K$.) □

Definition 21.1.7 (Content of an Idele). The *content* of $\mathbf{x} = \{x_v\}_v \in \mathbb{I}_K$ is

$$c(\mathbf{x}) = \prod_{\text{all } v} |x_v|_v \in \mathbf{R}_{>0}.$$

Lemma 21.1.8. *The map $\mathbf{x} \to c(\mathbf{x})$ is a continuous homomorphism of the topological group $\mathbb{I}_K$ into $\mathbf{R}_{>0}$, where we view $\mathbf{R}_{>0}$ as a topological group under multiplication. If K is a number field, then c is surjective.*

Proof. That the content map c satisfies the axioms of a homomorphisms follows from the multiplicative nature of the defining formula for c. For continuity, suppose (a, b) is an open interval in $\mathbf{R}_{>0}$. Suppose $\mathbf{x} \in \mathbb{I}_K$ is such that $c(\mathbf{x}) \in (a, b)$. By considering small intervals about each non-unit component of $\mathbf{x}$, we find an open neighborhood $U \subset \mathbb{I}_K$ of $\mathbf{x}$ such that $c(U) \subset (a, b)$. It follows the $c^{-1}((a, b))$ is open.

For surjectivity, use that each archimedean valuation is surjective, and choose an idele that is 1 at all but one archimedean valuation. □

Remark 21.1.9. Note also that the $\mathbb{I}_K$-topology is that appropriate to a group of operators on $\mathbb{A}_K^+$: a basis of open sets is the $S(C, U)$, where $C, U \subset \mathbb{A}_K^+$ are, respectively, $\mathbb{A}_K$-compact and $\mathbb{A}_K$-open, and S consists of the $\mathbf{x} \in \mathbb{I}_J$ such that $(1 - \mathbf{x})C \subset U$ and $(1 - \mathbf{x}^{-1})C \subset U$.

Definition 21.1.10 (1-Ideles). The subgroup $\mathbb{I}_K^1$ of 1-*ideles* is the subgroup of ideles $\mathbf{x} = \{x_v\}$ such that $c(\mathbf{x}) = 1$. Thus $\mathbb{I}_K^1$ is the kernel of c, so we have an exact sequence

$$1 \to \mathbb{I}_K^1 \to \mathbb{I}_K \xrightarrow{c} \mathbf{R}_{>0} \to 1,$$

where the surjectivity on the right is only if K is a number field.

Lemma 21.1.11. *The subset $\mathbb{I}_K^1$ of $\mathbb{A}_K$ is closed as a subset, and the $\mathbb{A}_K$-subset topology on $\mathbb{I}_K^1$ coincides with the $\mathbb{I}_K$-subset topology on $\mathbb{I}_K^1$.*

Proof. Let $\mathbf{x} \in \mathbb{A}_K$ with $\mathbf{x} \notin \mathbb{I}_K^1$. To prove that $\mathbb{I}_K^1$ is closed in $\mathbb{A}_K$, we find an $\mathbb{A}_K$-neighborhood W of $\mathbf{x}$ that does not meet $\mathbb{I}_K^1$.

1st Case. Suppose that $\prod_v |x_v|_v < 1$ (possibly $= 0$). Then there is a finite set S of v such that

1. S contains all the v with $|x_v|_v > 1$, and

2. $\prod_{v \in S} |x_v|_v < 1$.

Then the set W can be defined by

$$\begin{aligned} |w_v - x_v|_v &< \varepsilon \qquad v \in S \\ |w_v|_v &\leq 1 \qquad v \notin S \end{aligned}$$

for sufficiently small ε.

2nd Case. Suppose that $C := \prod_v |x_v|_v > 1$. Then there is a finite set S of v such that

1. S contains all the v with $|x_v|_v > 1$, and

2. if $v \notin S$ an inequality $|w_v|_v < 1$ implies $|w_v|_v < \frac{1}{2C}$. (This is because for a non-archimedean valuation, the largest absolute value less than 1 is $1/p$, where p is the residue characteristic. Also, the upper bound in Cassels's article is $\frac{1}{2}C$ instead of $\frac{1}{2C}$, but I think he got it wrong.)

We can choose ε so small that $|w_v - x_v|_v < \varepsilon$ (for $v \in S$) implies $1 < \prod_{v \in S} |w_v|_v < 2C$. Then W may be defined by

$$\begin{aligned} |w_v - x_v|_v &< \varepsilon \qquad v \in S \\ |w_v|_v &\leq 1 \qquad v \notin S. \end{aligned}$$

This works because if $\mathbf{w} \in W$, then either $|w_v|_v = 1$ for all $v \notin S$, in which case $1 < c(\mathbf{w}) < 2c$, so $\mathbf{w} \notin \mathbb{I}_K^1$, or $|w_{v_0}|_{v_0} < 1$ for some $v_0 \notin S$, in which case

$$c(\mathbf{w}) = \left(\prod_{v \in S} |w_v|_v\right) \cdot |w_{v_0}| \cdots < 2C \cdot \frac{1}{2C} \cdots < 1,$$

so again $\mathbf{w} \notin \mathbb{I}_K^1$.

We next show that the $\mathbb{I}_K$- and $\mathbb{A}_K$-topologies on $\mathbb{I}_K^1$ are the same. If $\mathbf{x} \in \mathbb{I}_K^1$, we must show that every $\mathbb{A}_K$-neighborhood of $\mathbf{x}$ contains an $\mathbb{A}_K$-neighborhood and vice-versa.

Let $W \subset \mathbb{I}_K^1$ be an $\mathbb{A}_K$-neighborhood of $\mathbf{x}$. Then it contains an $\mathbb{A}_K$-neighborhood of the type

$$|w_v - x_v|_v < \varepsilon \qquad v \in S \tag{21.1.2}$$
$$|w_v|_v \leq 1 \qquad v \notin S \tag{21.1.3}$$

where S is a finite set of valuations v. This contains the $\mathbb{I}_K$-neighborhood in which $\leq$ in (21.1.2) is replaced by $=$.

Next let $H \subset \mathbb{I}_K^1$ be an $\mathbb{I}_K$-neighborhood. Then it contains an $\mathbb{I}_K$-neighborhood of the form

$$|w_v - x_v|_v < \varepsilon \qquad v \in S \tag{21.1.4}$$
$$|w_v|_v = 1 \qquad v \notin S, \tag{21.1.5}$$

where the finite set S contains at least all archimedean valuations v and all valuations v with $|x_v|_v \neq 1$. Since $\prod |x_v|_v = 1$, we may also suppose that ε is so small that (21.1.4) implies

$$\prod_v |w_v|_v < 2.$$

Then the intersection of (21.1.4) with $\mathbb{I}_K^1$ is the same as that of (21.1.2) with $\mathbb{I}_K^1$, i.e., (21.1.4) defines an $\mathbb{A}_K$-neighborhood. □

By the product formula we have that $K^* \subset \mathbb{I}_K^1$. The following result is of vital importance in class field theory.

Theorem 21.1.12. *The quotient $\mathbb{I}_K^1/K^*$ with the quotient topology is compact.*

Proof. After the preceeding lemma, it is enough to find an $\mathbb{A}_K$-compact set $W \subset \mathbb{A}_K$ such that the map

$$W \cap \mathbb{I}_K^1 \to \mathbb{I}_K^1/K^*$$

is surjective. We take for W the set of $\mathbf{w} = \{w_v\}_v$ with

$$|w_v|_v \leq |x_v|_v\,,$$

where $\mathbf{x} = \{x_v\}_v$ is any idele of content greater than the C of Lemma 20.4.1.

Let $\mathbf{y} = \{y_v\}_v \in \mathbb{I}_K^1$. Then the content of $\mathbf{x}/\mathbf{y}$ equals the content of $\mathbf{x}$, so by Lemma 20.4.1 there is an $a \in K^*$ such that

$$|a|_v \leq \left|\frac{x_v}{y_v}\right|_v \qquad \text{all } v.$$

Then $a\mathbf{y} \in W$, as required. □

Remark 21.1.13. The quotient $\mathbb{I}_K^1/K^*$ is totally disconnected in the function field case. For the structure of its connected component in the number field case, see papers of Artin and Weil in the "Proceedings of the Tokyo Symposium on Algebraic Number Theory, 1955" (Science Council of Japan) or [AT90]. The determination of the character group of $\mathbb{I}_K/K^*$ is global class field theory.

21.2 Ideals and Divisors

Suppose that K is a finite extension of $\mathbf{Q}$. Let F_K be the the free abelian group on a set of symbols in bijection with the non-archimedean valuation v of K. Thus an element of F_K is a formal linear combination

$$\sum_{v \text{ non arch.}} n_v \cdot v$$

where $n_v \in \mathbf{Z}$ and all but finitely many n_v are 0.

Lemma 21.2.1. *There is a natural bijection between F_K and the group of nonzero fractional ideals of $\mathcal{O}_K$. The correspondence is induced by*

$$v \mapsto \wp_v = \{x \in \mathcal{O}_K : v(x) < 1\},$$

where v is a non-archimedean valuation.

Endow F_K with the discrete topology. Then there is a natural continuous map $\pi : \mathbb{I}_K \to F_K$ given by

$$\mathbf{x} = \{x_v\}_v \mapsto \sum_v \mathrm{ord}_v(x_v) \cdot v.$$

This map is continuous since the inverse image of a valuation v (a point) is the product

$$\pi^{-1}(v) = \pi\mathcal{O}_v^* \quad \times \prod_{w \text{ archimedean}} K_w^* \quad \times \prod_{w \neq v \text{ non-arch.}} \mathcal{O}_w^*,$$

which is an open set in the restricted product topology on $\mathbb{I}_K$. Moreover, the image of K^* in F_K is the group of nonzero principal fractional ideals.

Recall that the *class group* C_K of the number field K is by definition the quotient of F_K by the image of K^*.

Theorem 21.2.2. *The class group C_K of a number field K is finite.*

Proof. We first prove that the map $\mathbb{I}_K^1 \to F_K$ is surjective. Let ∞ be an archimedean valuation on K. If v is a non-archimedean valuation, let $\mathbf{x} \in \mathbb{I}_K^1$ be a 1-idele such that $x_w = 1$ at ever valuation w except v and ∞. At v, choose $x_v = \pi$ to be a generator for the maximal ideal of $\mathcal{O}_v$, and choose x_∞ to be such that $|x_\infty|_\infty = 1/|x_v|_v$. Then $\mathbf{x} \in \mathbb{I}_K$ and $\prod_w |x_w|_w = 1$, so $\mathbf{x} \in \mathbb{I}_K^1$. Also $\mathbf{x}$ maps to $v \in F_K$.

Thus the group of ideal classes is the continuous image of the compact group $\mathbb{I}_K^1/K^*$ (see Theorem 21.1.12), hence compact. But a compact discrete group is finite. □

21.2.1 The Function Field Case

When K is a finite separable extension of $\mathbf{F}(t)$, we define the divisor group D_K of K to be the free abelian group on all the valuations v. For each v the number of elements of the residue class field $\mathbf{F}_v = \mathcal{O}_v/\wp_v$ of v is a power, say q^{n_v}, of the number q of elements in $\mathbf{F}_v$. We call n_v the degree of v, and similarly define $\sum n_v d_v$ to be the degree of the divisor $\sum n_v \cdot v$. The divisors of degree 0 form a group D_K^0. As before, the principal divisor attached to $a \in K^*$ is $\sum \mathrm{ord}_v(a) \cdot v \in D_K$. The following theorem is proved in the same way as Theorem 21.2.2.

Theorem 21.2.3. *The quotient of D_K^0 modulo the principal divisors is a finite group.*

21.2.2 Jacobians of Curves

For those familiar with algebraic geometry and algebraic curves, one can prove Theorem 21.2.3 from an alternative point of view. There is a bijection between nonsingular geometrically irreducible projective curves over $\mathbf{F}$ and function fields K over $\mathbf{F}$ (which we assume are finite separable extensions of $\mathbf{F}(t)$ such that $\overline{\mathbf{F}} \cap K = \mathbf{F}$). Let X be the curve corresponding to K. The group D_K^0 is in bijection with the divisors of degree 0 on X, a group typically denoted $\mathrm{Div}^0(X)$. The quotient of $\mathrm{Div}^0(X)$ by principal divisors is denoted $\mathrm{Pic}^0(X)$. The *Jacobian* of X is an abelian variety $J = \mathrm{Jac}(X)$ over the finite field $\mathbf{F}$ whose dimension is equal to the genus of X. Moreover, assuming X has an $\mathbf{F}$-rational point, the elements of $\mathrm{Pic}^0(X)$ are in natural bijection with the $\mathbf{F}$-rational points on J. In particular, with these hypothesis, the class group of K, which is isomorphic to $\mathrm{Pic}^0(X)$, is in bijection with the group of $\mathbf{F}$-rational points on an algebraic variety over a finite field. This gives an alternative more complicated proof of finiteness of the degree 0 class group of a function field.

Without the degree 0 condition, the divisor class group won't be finite. It is an extension of $\mathbf{Z}$ by a finite group.

$$0 \to \mathrm{Pic}^0(X) \to \mathrm{Pic}(X) \xrightarrow{\deg} n\mathbf{Z} \to 0,$$

where n is the greatest common divisor of the degrees of elements of $\mathrm{Pic}(X)$, which is 1 when X has a rational point.

Chapter 22

Exercises

1. Let $A = \begin{pmatrix} 4 & 7 & 2 \\ 2 & 4 & 6 \\ 0 & 0 & 0 \end{pmatrix}$.

   (a) Find invertible integer matrices P and Q such that PAQ is in Smith normal form.

   (b) What is the group structure of the cokernel of the map $\mathbf{Z}^3 \to \mathbf{Z}^3$ defined by multiplication by A?

2. Let G be the abelian group generated by x, y, z with relatoins $2x + y = 0$ and $x - y + 3z = 0$. Find a product of cyclic groups that is isomorphic to G.

3. Prove that each of the following rings have infinitely many prime ideals:

   (a) The integers $\mathbf{Z}$. [Hint: Euclid gave a famous proof of this long ago.]

   (b) The ring $\mathbf{Q}[x]$ of polynomials over $\mathbf{Q}$.

   (c) The ring $\mathbf{Z}[x]$ of polynomials over $\mathbf{Z}$.

   (d) The ring $\overline{\mathbf{Z}}$ of all algebraic integers. [Hint: Use Zorn's lemma, which implies that every ideal is contained in a maximal ideal. See, e.g., Prop 1.12 on page 589 of Artin's *Algebra*.]

4. (This problem was on the graduate qualifying exam on Tuesday.) Let $\overline{\mathbf{Z}}$ denote the subset of all elements of $\overline{\mathbf{Q}}$ that satisfy a monic polynomial with coefficients in the ring $\mathbf{Z}$ of integers. We proved in class that $\overline{\mathbf{Z}}$ is a ring.

   (a) Show that the ideals (2) and $(\sqrt{2})$ in $\overline{\mathbf{Z}}$ are distinct.

   (b) Prove that $\overline{\mathbf{Z}}$ is not Noetherian.

5. Show that neither $\mathbf{Z}[\sqrt{-6}]$ nor $\mathbf{Z}[\sqrt{5}]$ is a unique factorization domain. [Hint: Consider the factorization into irreducible elements of 6 in the first case and 4 in the second. A nonzero element a in a ring R is an *irreducible element* if it is not a unit and if whenever $a = qr$, then one of q or r is a unit.]

6. Find the ring of integers of each of the following number fields:

   (a) $\mathbf{Q}(\sqrt{-3})$,

   (b) $\mathbf{Q}(\sqrt{3})$, and

   (c) $\mathbf{Q}(\sqrt[3]{2})$.

   Do not use a computer for the first two.

7. Find the discriminants of the rings of integers of the numbers fields in the previous problem. (Do not use a computer.)

8. Let R be a finite integral domain. Prove that R is a field. [Hint: Show that if x is a nonzero element, then x has an inverse by considering powers of x.]

9. Suppose $K \subset L \subset M$ is a tower of number fields and let $\sigma : L \hookrightarrow \overline{\mathbf{Q}}$ be a field embedding of L into $\overline{\mathbf{Q}}$ that fixes K elementwise. Show that σ extends in exactly $[M : L]$ ways to a field embedding $M \hookrightarrow \overline{\mathbf{Q}}$.

10. (a) Suppose I and J are principal ideals in a ring R. Show that the set $\{ab : a \in I,\, b \in J\}$ is an ideal.

    (b) Give an example of ideals I and J in the polynomial ring $\mathbf{Q}[x, y]$ in two variables such that $\{ab : a \in I,\, b \in J\}$ is not an ideal. Your example illustrates why it is necessary to define the product of two ideals to be the ideal generated by $\{ab : a \in I,\, b \in J\}$.

    (c) Give an example of a ring of integers $\mathcal{O}_K$ of a number field, and ideals I and J such that $\{ab : a \in I,\, b \in J\}$ is not an ideal.

11. (a) Let k be a field. Prove that $k[x]$ is a Dedekind domain.

    (b) (Problem 1.12 from Swinnerton-Dyer) Let x be an indeterminate. Show that the ring $\mathbf{Z}[x]$ is Noetherian and integrally closed in its field of fractions, but is not a Dedekind domain.

12. Use Magma to write each of the following (fractional) ideals as a product of explicitly given prime ideals:

    (a) The ideal (2004) in $\mathbf{Q}(\sqrt{-1})$.

    (b) The ideals $I = (7)$ and $J = (3)$ in the ring of integers of $\mathbf{Q}(\zeta_7)$, where ζ_7 is a root of the irreducible polynomial $x^6 + x^5 + x^4 + x^3 + x^2 + x + 1$. (The field $\mathbf{Q}(\zeta_7)$ is called the 7th cyclotomic field.)

    (c) The principal fractional ideal $(3/8)$ in $\mathbf{Q}(\sqrt{5})$.

13. Suppose R is an order in the ring $\mathcal{O}_K$ of integers of a number field. (Recall that an order is a subring of finite index in $\mathcal{O}_K$.) For each of the following questions, either explain why the answer is yes for any possible order R in any $\mathcal{O}_K$, or find one specific counterexample:

(a) Is R necessarily Noetherian?

(b) Is R necessarily integrally closed in its field of fractions?

(c) Is every nonzero prime ideal of R necessarily maximal?

(d) Is it always possible to write every ideal of R uniquely as a product of prime ideals of R?

14. Let $\mathcal{O}_K$ be the ring of integers of a number field K. Prove that the group of fractional ideals of $\mathcal{O}_K$, under multiplication is (non-canonically) isomorphic to the group of positive rational numbers under multiplication.

15. (a) Suppose K is a number field of degree 2. Prove that $\mathcal{O}_K = \mathbf{Z}[a]$ for some $a \in \mathcal{O}_K$.

    (b) Prove that if K and K' are two number fields of degree 2 and $\mathrm{Disc}(\mathcal{O}_K) = \mathrm{Disc}(\mathcal{O}_{K'})$ then $K = K'$.

16. (*) Does there exist a number field K of degree 4 such that $\mathcal{O}_K \neq \mathbf{Z}[a]$ for all $a \in \mathcal{O}_K$? If so, give an explicit example.

17. Let K be the quintic number field generated by a root of $x^5+7x^4+3x^2-x+1$. Draw a diagram (be creative) that illustrates the factorization of every prime $p \in \mathbf{Z}$, with $p < 100$, in $\mathcal{O}_K$.

18. (Problem 1.9 in Swinnerton-Dyer) Show that the only solutions $x, y \in \mathbf{Z}$ to $y^2 = x^3 - 13$ are given by $x = 17, y = \pm 70$, as follows. Factor the equation $y^2 + 13 = x^3$ in the number field $\mathbf{Q}(\sqrt{-13})$, which has class number 2. Show that if x, y is an integer solution then the ideal $(y + \sqrt{-13})$ must be the cube of an ideal, and hence $y + \sqrt{-13} = (a + b\sqrt{-13})^3$; thus $1 = b(3a^2 - 13b^2)$.

19. Suppose I and J are ideals in the ring $\mathcal{O}_K$ of integers of a number field K. Does $IJ = I \cap J$? Prove or give a counterexample.

20. Let $\mathcal{O}_K$ be the ring of integers $\mathbf{Q}(\sqrt{5})$, and let

$$I = (5, 2+\sqrt{5}) \qquad \text{and} \qquad J = (209, (389+\sqrt{5})/2)$$

be integral ideals of $\mathcal{O}_K$.

(a) Find an element of $\mathcal{O}_K$ that is congruent to $\sqrt{5}$ modulo I and is congruent to $1-\sqrt{5}$ modulo J.

(b) What is the cardinality of $(\mathcal{O}_K/I) \oplus (\mathcal{O}_K/J)$?

(c) Find an element $a \in I$ such that $(a)/I$ is coprime to J.

21. Let $\mathcal{O}_K$ be the ring of integers of a number field K, and suppose K has exactly $2s$ complex embeddings. Prove that the sign of $\mathrm{Disc}(\mathcal{O}_K)$ is $(-1)^s$.

22. (*) Suppose $\mathcal{O}$ is an order in the ring of integers $\mathcal{O}_K$ of a number field. Is every ideal in $\mathcal{O}$ necessarily generated by two elements? (Answer: No. Challenge: Given an example.)

23. Find representative ideals for each element of the class group of $\mathbf{Q}(\sqrt{-23})$. Illustrate how to use the Minkowski bound to prove that your list of representatives is complete.

24. Suppose $\mathcal{O}$ is an order in the ring of integers $\mathcal{O}_K$ of a number field. Is every ideal in $\mathcal{O}$ necessarily generated by two elements?

25. Let K be a number field of degree $n > 1$ with s pairs of complex conjugate embeddings. Prove that
$$\left(\frac{\pi}{4}\right)^s \cdot \frac{n^n}{n!} > 1.$$

26. Do the exercise on page 19 of Swinnerton-Dyer, which shows that the quantity $C_{r,s}$ in the finiteness of class group theorem can be taken to be $\left(\frac{4}{\pi}\right)^s \frac{n!}{n^n}$.

27. Let α denote a root of $x^3 - x + 2$ and let $K = \mathbf{Q}(\alpha)$. Show that $\mathcal{O}_K = \mathbf{Z}[\alpha]$ and that K has class number 1 (don't just read this off from the output of the Magma commands `MaximalOrder` and `ClassNumber`). [Hint: consider the square factors of the discriminant of $x^3 - x + 2$ and show that $\frac{1}{2}(a + b\alpha + c\alpha^2)$ is an algebra integer if and only if a, b, and c are all even.]

28. If S is a closed, bounded, convex, symmetric set in $\mathbf{R}^n$ with $\mathrm{Vol}(S) \geq m2^n$, for some positive integer m, show that S contains at least $2m$ nonzero points in $\mathbf{Z}^n$.

29. Prove that any finite subgroup of the multiplicative group of a field is cyclic.

30. For a given number field K, which seems more difficult for Magma to compute, the class groups or explicit generators for the group of units? It is very difficult (but not impossible) to not get full credit on this problem. Play around with some examples, see what seems more difficult, and *justify* your response with examples. (This problem might be annoying to do using the Magma web page, since it kills your Magma job after 30 seconds. Feel free to request a binary of Magma from me, or an account on MECCAH (Mathematics Extreme Computation Cluster at Harvard).)

31. (a) Prove that there is no number field K such that $U_K \cong \mathbf{Z}/10\mathbf{Z}$.

    (b) Is there a number field K such that $U_K \cong \mathbf{Z} \times \mathbf{Z}/6\mathbf{Z}$?

32. Prove that the rank of U_K is unbounded as K varies over all number fields.

33. Let $K = \mathbf{Q}(\zeta_5)$.

    (a) Show that $r = 0$ and $s = 2$.

(b) Find explicitly generators for the group of units of U_K (you can use Magma for this).

(c) Draw an illustration of the log map $\varphi : U_K \to \mathbf{R}^2$, including the hyperplane $x_1+x_2 = 0$ and the lattice in the hyperplane spanned by the image of U_K.

34. Find the group of units of $\mathbf{Q}(\zeta_n)$ as an abstract group as a function of n. (I.e., find the number of cyclic factors and the size of the torsion subgroup. You do not have to find explicit generators!)

35. Let $K = \mathbf{Q}(a)$, where a is a root $x^3 - 3x + 1$.

    (a) Show that $r = 3$.

    (b) Find explicitly the log embedding of U_K into a 2-dimensional hyperplane in $\mathbf{R}^3$, and draw a picture.

36. Prove that if K is a quadratic field and the torsion subgroup of U_K has order bigger than 2, then $K = \mathbf{Q}(\sqrt{-3})$ or $K = \mathbf{Q}(\sqrt{-1})$.

37. A *Salem number* is a real algebraic integer, greater than 1, with the property that all of its conjugates lie on or within the unit circle, and at least one conjugate lies on the unit circle. By any method (including "google"), give two examples of Salem numbers.

38. Let $p \in \mathbf{Z}$ and let K be a number field. Show that $\mathrm{Norm}_{K/\mathbf{Q}}(p\mathcal{O}_K) = p^{[K:\mathbf{Q}]}$.

39. A totally real number field is a number field in which all embeddings into $\mathbf{C}$ have image in $\mathbf{R}$. Prove there are totally real number fields of degree p, for every prime p. [Hint: Let ζ_n denote a primitive nth root of unity. For $n \geq 3$, show that $\mathbf{Q}(\zeta_n + 1/\zeta_n)$ is totally real of degree $\varphi(n)/2$. Now prove that $\varphi(n)/2$ can be made divisible by any prime.]

40. Give an example of a number field $K/\mathbf{Q}$ and a prime p such that the e_i in the factorization of $p\mathcal{O}_K$ are not all the same.

41. Let K be a number field. Give the "simplest" proof you can think of that there are only finitely many primes that ramify (i.e., have some $e_i > 1$) in K. [The meaning of "simplest" is a matter of taste.]

42. Give examples to show that for $K/\mathbf{Q}$ a Galois extension, the quantity e can be arbirarily large and f can be arbitrarily large.

43. Suppose $K/\mathbf{Q}$ is Galois and p is a prime such that $p\mathcal{O}_K$ is also prime (i.e., p is inert in K). Show that $\mathrm{Gal}(K/\mathbf{Q})$ is a cyclic group.

44. (Problem 7, page 116, from Marcus *Number Fields*) For each of the following, find a prime p and quadratic extensions K and L of $\mathbf{Q}$ that illustrates the assertion:

(a) The prime p can be totally ramified in K and L without being totally ramified in KL.

(b) The fields K and L can each contain unique primes lying over p while KL does not.

(c) The prime p can be inert in K and L without being inert in KL.

(d) The residue field extensions of $\mathbf{F}_p$ can be trivial for K and L without being trivial for KL.

45. Let S_3 by the symmetric group on three symbols, which has order 6.

(a) Observe that $S_3 \cong D_3$, where D_3 is the dihedral group of order 6, which is the group of symmetries of an equilateral triangle.

(b) Use (45a) to write down an explicit embedding $S_3 \hookrightarrow \mathrm{GL}_2(\mathbf{C})$.

(c) Let K be the number field $\mathbf{Q}(\sqrt[3]{2}, \omega)$, where $\omega^3 = 1$ is a nontrivial cube root of unity. Show that K is a Galois extension with Galois group isomorphic to S_3.

(d) We thus obtain a 2-dimensional irreducible complex Galois representation

$$\rho : \mathrm{Gal}(\overline{\mathbf{Q}}/\mathbf{Q}) \to \mathrm{Gal}(K/\mathbf{Q}) \cong S_3 \subset \mathrm{GL}_2(\mathbf{C}).$$

Compute a representative matrix of Frob_p and the characteristic polynomial of Frob_p for $p = 5, 7, 11, 13$.

46. Let $K = \mathbf{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}, \sqrt{7})$. Show that K is Galois over $\mathbf{Q}$, compute the Galois group of K, and compute Frob_{37}.

47. Let k be any field. Prove that the only nontrivial valuations on $k(t)$ which are trivial on k are equivalent to the valuation (15.3.3) or (15.3.4) of page 115.

48. A field with the topology induced by a valuation is a topological field, i.e., the operations sum, product, and reciprocal are continuous.

49. Give an example of a non-archimedean valuation on a field that is not discrete.

50. Prove that the field $\mathbf{Q}_p$ of p-adic numbers is uncountable.

51. Prove that the polynomial $f(x) = x^3 - 3x^2 + 2x + 5$ has all its roots in $\mathbf{Q}_5$, and find the 5-adic valuations of each of these roots. (You might need to use Hensel's lemma, which we don't discuss in detail in this book. See [Cas67, App. C].)

52. In this problem you will compute an example of weak approximation, like I did in the Example 16.3.3. Let $K = \mathbf{Q}$, let $|\cdot|_7$ be the 7-adic absolute value, let $|\cdot|_{11}$ be the 11-adic absolute value, and let $|\cdot|_\infty$ be the usual archimedean absolute value. Find an element $b \in \mathbf{Q}$ such that $|b - a_i|_i < \frac{1}{10}$, where $a_7 = 1$, $a_{11} = 2$, and $a_\infty = -2004$.

53. Prove that -9 has a cube root in $\mathbf{Q}_{10}$ using the following strategy (this is a special case of Hensel's Lemma, which you can read about in an appendix to Cassel's article).

    (a) Show that there is an element $\alpha \in \mathbf{Z}$ such that $\alpha^3 \equiv 9 \pmod{10^3}$.

    (b) Suppose $n \geq 3$. Use induction to show that if $\alpha_1 \in \mathbf{Z}$ and $\alpha^3 \equiv 9 \pmod{10^n}$, then there exists $\alpha_2 \in \mathbf{Z}$ such that $\alpha_2^3 \equiv 9 \pmod{10^{n+1}}$. (Hint: Show that there is an integer b such that $(\alpha_1 + b \cdot 10^n)^3 \equiv 9 \pmod{10^{n+1}}$.)

    (c) Conclude that 9 has a cube root in $\mathbf{Q}_{10}$.

54. Compute the first 5 digits of the 10-adic expansions of the following rational numbers:

$$\frac{13}{2}, \quad \frac{1}{389}, \quad \frac{17}{19}, \quad \text{the 4 square roots of 41.}$$

55. Let $N > 1$ be an integer. Prove that the series

$$\sum_{n=1}^{\infty} (-1)^{n+1} n! = 1! - 2! + 3! - 4! + 5! - 6! + \cdots .$$

    converges in $\mathbf{Q}_N$.

56. Prove that -9 has a cube root in $\mathbf{Q}_{10}$ using the following strategy (this is a special case of "Hensel's Lemma").

    (a) Show that there is $\alpha \in \mathbf{Z}$ such that $\alpha^3 \equiv 9 \pmod{10^3}$.

    (b) Suppose $n \geq 3$. Use induction to show that if $\alpha_1 \in \mathbf{Z}$ and $\alpha^3 \equiv 9 \pmod{10^n}$, then there exists $\alpha_2 \in \mathbf{Z}$ such that $\alpha_2^3 \equiv 9 \pmod{10^{n+1}}$. (Hint: Show that there is an integer b such that $(\alpha_1 + b10^n)^3 \equiv 9 \pmod{10^{n+1}}$.)

    (c) Conclude that 9 has a cube root in $\mathbf{Q}_{10}$.

57. Let $N > 1$ be an integer.

    (a) Prove that $\mathbf{Q}_N$ is equipped with a natural ring structure.

    (b) If N is prime, prove that $\mathbf{Q}_N$ is a field.

58. (a) Let p and q be distinct primes. Prove that $\mathbf{Q}_{pq} \cong \mathbf{Q}_p \times \mathbf{Q}_q$.

    (b) Is $\mathbf{Q}_{p^2}$ isomorphic to either of $\mathbf{Q}_p \times \mathbf{Q}_p$ or $\mathbf{Q}_p$?

59. Prove that every finite extension of $\mathbf{Q}_p$ "comes from" an extension of $\mathbf{Q}$, in the following sense. Given an irreducible polynomial $f \in \mathbf{Q}_p[x]$ there exists an irreducible polynomial $g \in \mathbf{Q}[x]$ such that the fields $\mathbf{Q}_p[x]/(f)$ and $\mathbf{Q}_p[x]/(g)$ are isomorphic. [Hint: Choose each coefficient of g to be sufficiently close to the corresponding coefficient of f, then use Hensel's lemma to show that g has a root in $\mathbf{Q}_p[x]/(f)$.]

60. Find the 3-adic expansion to precision 4 of each root of the following polynomial over $\mathbf{Q}_3$:

$$f = x^3 - 3x^2 + 2x + 3 \in \mathbf{Q}_3[x].$$

Your solution should conclude with three expressions of the form

$$a_0 + a_1 \cdot 3 + a_2 \cdot 3^2 + a_3 \cdot 3^3 + O(3^4).$$

61. (a) Find the normalized Haar measure of the following subset of $\mathbf{Q}_7^+$:

$$U = B\left(28, \frac{1}{50}\right) = \left\{x \in \mathbf{Q}_7 : |x - 28| < \frac{1}{50}\right\}.$$

(b) Find the normalized Haar measure of the subset $\mathbf{Z}_7^*$ of $\mathbf{Q}_7^*$.

62. Suppose that K is a finite extension of $\mathbf{Q}_p$ and L is a finite extension of $\mathbf{Q}_q$, with $p \neq q$ and assume that K and L have the same degree. Prove that there is a polynomial $g \in \mathbf{Q}[x]$ such that $\mathbf{Q}_p[x]/(g) \cong K$ and $\mathbf{Q}_q[x]/(g) \cong L$. [Hint: Combine your solution to 59 with the weak approximation theorem.]

63. Prove that the ring C defined in Section 9 really is the tensor product of A and B, i.e., that it satisfies the defining universal mapping property for tensor products. Part of this problem is for you to look up a functorial definition of tensor product.

64. Find a zero divisor pair in $\mathbf{Q}(\sqrt{5}) \otimes_{\mathbf{Q}} \mathbf{Q}(\sqrt{5})$.

65. (a) Is $\mathbf{Q}(\sqrt{5}) \otimes_{\mathbf{Q}} \mathbf{Q}(\sqrt{-5})$ a field?

(b) Is $\mathbf{Q}(\sqrt[4]{5}) \otimes_{\mathbf{Q}} \mathbf{Q}(\sqrt[4]{-5}) \otimes_{\mathbf{Q}} \mathbf{Q}(\sqrt{-1})$ a field?

66. Suppose ζ_5 denotes a primitive 5th root of unity. For any prime p, consider the tensor product $\mathbf{Q}_p \otimes_{\mathbf{Q}} \mathbf{Q}(\zeta_5) = K_1 \oplus \cdots \oplus K_{n(p)}$. Find a simple formula for the number $n(p)$ of fields appearing in the decomposition of the tensor product $\mathbf{Q}_p \otimes_{\mathbf{Q}} \mathbf{Q}(\zeta_5)$. To get full credit on this problem your formula must be correct, but you do *not* have to prove that it is correct.

67. Suppose $\|\cdot\|_1$ and $\|\cdot\|_2$ are equivalent norms on a finite-dimensional vector space V over a field K (with valuation $|\cdot|$). Carefully prove that the topology induced by $\|\cdot\|_1$ is the same as that induced by $\|\cdot\|_2$.

68. Suppose K and L are number fields (i.e., finite extensions of $\mathbf{Q}$). Is it possible for the tensor product $K \otimes_{\mathbf{Q}} L$ to contain a nilpotent element? (A nonzero element a in a ring R is *nilpotent* if there exists $n > 1$ such that $a^n = 0$.)

69. Let K be the number field $\mathbf{Q}(\sqrt[5]{2})$.

(a) In how many ways does the 2-adic valuation $|\cdot|_2$ on $\mathbf{Q}$ extend to a valuation on K?

(b) Let $v = |\cdot|$ be a valuation on K that extends $|\cdot|_2$. Let K_v be the completion of K with respect to v. What is the residue class field $\mathbf{F}$ of K_v?

70. Prove that the product formula holds for $\mathbf{F}(t)$ similar to the proof we gave in class using Ostrowski's theorem for $\mathbf{Q}$. You may use the analogue of Ostrowski's theorem for $\mathbf{F}(t)$, which you had on a previous homework assignment. (Don't give a measure-theoretic proof.)

71. Prove Theorem 20.3.5, that "The global field K is discrete in $\mathbb{A}_K$ and the quotient $\mathbb{A}_K^+/K^+$ of additive groups is compact in the quotient topology." in the case when K is a finite extension of $\mathbf{F}(t)$, where $\mathbf{F}$ is a finite field.

23 Visibility of Mordell-Weil Groups

Visibility of Mordell-Weil Groups

William A. Stein[1]

Abstract.

We introduce a notion of visibility for Mordell-Weil groups, make a conjecture about visibility, and support it with theoretical evidence and data. These results shed new light on relations between Mordell-Weil and Shafarevich-Tate groups.

1 Introduction

Consider an exact sequence $0 \to C \to B \to A \to 0$ of abelian varieties over a number field K. We say that the covering $B \to A$ is *optimal* since its kernel C is connected. As introduced in [LT58], there is a corresponding long exact sequence of Galois cohomology

$$0 \to C(K) \to B(K) \to A(K) \xrightarrow{\delta} \mathrm{H}^1(K, C) \to \mathrm{H}^1(K, B) \to \mathrm{H}^1(K, A) \to \cdots$$

The study of the Mordell-Weil group $A(K)$ is central in arithmetic geometry. For example, the Birch and Swinnerton-Dyer conjecture (BSD conjecture) of [Bir71, Tat66]), which is one of the Clay Math Problems [Wil00], asserts that the rank r of $A(K)$ equals the ordering vanishing of $L(A, s)$ at $s = 1$, and also gives a conjectural formula for $L^{(r)}(A, 1)$ in terms of the invariants of A.

The group $\mathrm{H}^1(K, A)$ is also of interest in connection with the BSD conjecture, because it contains the Shafarevich-Tate group

$$Ш(A/K) = \mathrm{Ker}\left(\mathrm{H}^1(K, A) \to \bigoplus_v \mathrm{H}^1(K_v, A)\right),$$

which is the most mysterious object appearing in the BSD conjecture.

[1] This material is based upon work supported by the National Science Foundation under Grant No. 0400386.

Definition 1.0.1 (Visibility). The *visible subgroup* of $\mathrm{H}^1(K,C)$ relative to the embedding $C \hookrightarrow B$ is

$$\begin{aligned}\mathrm{Vis}_B\,\mathrm{H}^1(K,C) &= \mathrm{Ker}(\mathrm{H}^1(K,C) \to \mathrm{H}^1(K,B))\\ &\cong \mathrm{Coker}(B(K) \to A(K)).\end{aligned}$$

The *visible quotient* of $A(K)$ relative to the optimal covering $B \to A$ is

$$\begin{aligned}\mathrm{Vis}^B(A(K)) &= \mathrm{Coker}(B(K) \to A(K))\\ &\cong \mathrm{Vis}_B\,\mathrm{H}^1(K,C).\end{aligned}$$

We say an abelian variety over $\mathbb{Q}$ is *modular* if it is a quotient of the modular Jacobian $J_1(N) = \mathrm{Jac}(X_1(N))$, for some N. For example, every elliptic curve over $\mathbb{Q}$ is modular [BCDT01].

This paper gives evidence toward the following conjecture that Mordell-Weil groups should give rise to many visible Shafarevich-Tate groups.

Conjecture 1.0.2. *Let A be an abelian variety over a number field K. For every integer m, there is an exact sequence $0 \to C \to B \to A \to 0$ such that:*

1. *The image of $B(K)$ in $A(K)$ is contained in $mA(K)$, so $A(K)/mA(K)$ is a quotient of $\mathrm{Vis}^B(A(K))$.*
2. *If $K = \mathbb{Q}$ and A is modular, then B is modular.*
3. *The rank of C is zero.*
4. *We have $\mathrm{Coker}(B(K) \to A(K)) \subset Ш(C/K)$, via the connecting homomorphism.*

In [Ste04] we give the following computational evidence for this conjecture.

Theorem 1.0.3. *Let E be the rank 1 elliptic curve $y^2+y = x^3-x$ of conductor 37. Then Conjecture 1.0.2 is true for all primes $m = p < 25000$ with $p \neq 2, 37$.*

Let $f = \sum a_n q^n$ be the newform associated to the elliptic curve E of Theorem 1.0.3. Suppose p is one of the primes in the theorem. Then there is an $\ell \equiv 1 \pmod{p}$ and a surjective Dirichlet character $\chi : (\mathbb{Z}/\ell\mathbb{Z})^* \to \mu_p$ such that $L(f \otimes \chi, 1) \neq 0$. The C of the theorem is, up to isogeny, the abelian variety associated to f^χ, which has dimension $p-1$.

In general, we expect the construction of [Ste04] to work for any elliptic curve and any odd prime p of good reduction. The main obstruction to proving that it does work is proving a nonvanishing result for the special values $L(f^\chi, 1)$. In [Ste04], we verified this hypothesis using modular symbols for $p < 25000$.

A surprising observation that comes out of the construction of [Ste04] is that $\#Ш(A) = p \cdot n^2$, where n^2 is an integer square. We thus obtained the first ever examples of abelian varieties whose Shafarevich-Tate groups have order neither a square nor twice a square.

1.1 Contents

In Section 2, we give a brief review of results about visibility of Shafarevich-Tate groups. In Section 3, we give evidence for Conjecture 1.0.2 using results of Kato, Lichtenbaum and Mazur. Section 4 is about bounding the dimension of the abelian varieties in which Mordell-Weil groups are visible. We prove that every Mordell-Weil group is 2-visible relative to an abelian surface. In Section 5, we describe how to construct visible quotients of Mordell-Weil groups, and carry out a computational study of relations between Mordell-Weil groups of elliptic curves and the arithmetic of rank 0 factors of $J_0(N)$.

1.2 Acknowledgement

The author had extremely helpful conversations with Barry Mazur and Grigor Grigorov. Proposition 3.0.3 was proved jointly with Ken Ribet. The author was supported by NSF grant DMS-0400386. He used Magma [BCP97] and Python [Ros] for computing the data in Section 5.

2 Review of Visibility of Galois Cohomology

In this section, we briefly review visibility of elements of $\mathrm{H}^1(K, A)$, as first introduced by Mazur in [CM00, Maz99], and later developed by Agashe and Stein in [Aga99a, AS05, AS02]. We describe two basic results about visibility, and in Section 2.2 we discuss modularity of elements of $\mathrm{H}^1(K, A)$.

Consider an exact sequence of abelian varieties

$$0 \to A \to B \to C \to 0$$

over a number field K. Elements of $\mathrm{H}^0(K, C)$ are points, so they are relatively easy to "visualize", but elements of $\mathrm{H}^1(K, A)$ are mysterious.

There is a geometric way to view elements of $\mathrm{H}^1(K, A)$. The Weil-Chatalet group $\mathrm{WC}(A/K)$ of A over K is the group of isomorphism classes of principal homogeneous spaces for A, where a principal homogeneous space is a variety X and a simply-transitive action $A \times X \to X$. Thus X is a twist of A as a variety, but $X(K) = \emptyset$, unless X is isomorphic to A. Also, the elements of $Ш(A)$ correspond to the classes of X that have a K_v-rational point for all places v. By [LT58, Prop. 4], there is an isomorphism between $\mathrm{H}^1(K, A)$ and $\mathrm{WC}(A/K)$.

In [CM00], Mazur introduced the visible subgroup of H^1 as in Definition 1.0.1 in order to help unify diverse constructions of principal homogeneous spaces. Many papers were subsequently written about visibility, including [Aga99b, Maz99, Kle01, AS02, MO03, DWS03, AS05, Dum01].

Remark 2.0.1. Note that $\mathrm{Vis}_B\,\mathrm{H}^1(K, A)$ depends on the embedding of A into B. For example, if $B = B_1 \times A$. Then there could be nonzero visible elements if A is embedded into the first factor, but there will be no nonzero visible elements if A is embedded into the second factor.

A connection between visibility and $\mathrm{WC}(A/K)$ is as follows. Suppose

$$0 \to A \to B \xrightarrow{\pi} C \to 0$$

is an exact sequence of abelian varieties and that $c \in \mathrm{H}^1(K, A)$ is visible in B. Thus there exists $x \in C(K)$ such that $\delta(x) = c$, where $\delta : C(K) \to \mathrm{H}^1(K, A)$ is the connecting homomorphism. Then $X = \pi^{-1}(x) \subset B$ is a translate of A in B, so the group law on B gives X the structure of principal homogeneous space for A, and this homogeneous space in $\mathrm{WC}(A/K)$ corresponds to c.

2.1 Basic Facts

Two basic facts about visibility are that the visible subgroup of $\mathrm{H}^1(K, A)$ in B is finite, and that each element of $\mathrm{H}^1(K, A)$ is visible in some B.

Lemma 2.1.1. *The group* $\mathrm{Vis}_B\,\mathrm{H}^1(K, A)$ *is finite.*

Proof. Let $C = B/A$. By the Mordell-Weil theorem $C(K)$ is finitely generated. The group $\mathrm{Vis}_B\,\mathrm{H}^1(K, A)$ is a homomorphic image of $C(K)$ so it is finitely generated. On the other hand, it is a subgroup of $\mathrm{H}^1(K, A)$, so it is a torsion group. But a finitely generated torsion abelian group is finite. □

Proposition 2.1.2. *Let $c \in \mathrm{H}^1(K, A)$. Then there exists an abelian variety B and an embedding $A \hookrightarrow B$ such that c is visible in B. Moreover, B can be chosen to be a twist of a power of A.*

Proof. See [AS02, Prop. 1.3] for a cohomological proof or [JS05, §5] for an equivalent geometric proof. Johan de Jong also proved that everything is visible somewhere in the special case $\dim(A) = 1$ using Azumaya algebras, Néron models, and étale cohomology, as explained in [CM00, pg. 17–18], but his proof gives no (obvious) specific information about the structure of B. □

2.2 Modularity

Usually one focuses on visibility of elements in $\text{Ш}(A) \subset \mathrm{H}^1(K, A)$. The papers [CM00, AS02, AS05] contain a number of results about visibility in various special cases, and tables involving elliptic curves and modular abelian varieties.

For example, if $A \subset J_0(389)$ is the 20-dimensional simple newform abelian variety, then we show that

$$\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong E(\mathbb{Q})/5E(\mathbb{Q}) \subset \text{Ш}(A),$$

where E is the elliptic curve of conductor 389. The divisibility $5^2 \mid \#\text{Ш}(A)$ is as predicted by the BSD conjecture. The paper [AS05] contains a few dozen other examples like this; in most cases, explicit computational construction of the Shafarevich-Tate group seems hopeless using any other known techniques.

The author has conjectured that if A is a modular abelian variety, then every element of $\text{Ш}(A)$ is modular, i.e., visible in a modular abelian variety. It is a theorem that if $c \in \text{Ш}(A)$ has order either 2 or 3 and A is an elliptic curve, then c is modular (see [JS05]).

3 Results Toward Conjecture 1.0.2

The main result of this section is a proof of parts 1 and 2 of Conjecture 1.0.2 for elliptic curves over $\mathbb{Q}$. We prove more generally that Mazur's conjecture on finite generatedness of Mordell-Weil groups over cyclotomic $\mathbb{Z}_p$-extensions implies part 1 of Conjecture 1.0.2. Then we observe that for elliptic curves over $\mathbb{Q}$, Mazur's conjecture is known, and prove that the abelian varieties that appear in our visibility construction are modular, so parts 1 and 2 of Conjecture 1.0.2 are true for elliptic curves over $\mathbb{Q}$.

For a prime p, the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$ is an extension $\mathbb{Q}_{p^\infty}$ of $\mathbb{Q}$ with Galois group $\mathbb{Z}_p$; also $\mathbb{Q}_{p^\infty}$ is contained in the cyclotomic field $\mathbb{Q}(\mu_{p^\infty})$. We let $\mathbb{Q}_{p^n}$ denote the unique subfield of $\mathbb{Q}_{p^\infty}$ of degree p^n over $\mathbb{Q}$. If K is an arbitrary number field, the cyclotomic $\mathbb{Z}_p$-extension of K is $K_{p^\infty} = K\cdot\mathbb{Q}_{p^\infty}$. We denote by K_{p^n} the unique subfield of K_{p^∞} of degree p^n over K. The extension K_{p^∞} of K decomposes as a tower

$$K = K_{p^0} \subset K_{p^1} \subset \cdots \subset K_{p^n} \subset \cdots \subset K_{p^\infty} = \bigcup_{n=0}^{\infty} K_{p^n}.$$

Mazur hints at the following conjecture in [Maz78] and [RM05, §3]:

Conjecture 3.0.1 (Mazur). *If A is an abelian variety over a number field K and p is a prime, then $A(K_{p^\infty})$ is a finitely generated abelian group.*

Let L/K be a finite extension of number fields and A an abelian variety over K. In much of the rest of this paper we will use the *restriction of scalars* $R = \mathrm{Res}_{L/K}(A_L)$ of A viewed as an abelian variety over L. Thus R is an abelian variety over K of dimension $[L : K]$, and R represents the following functor on the category of K-schemes:

$$S \mapsto E_L(S_L).$$

If L/K is Galois, then we have an isomorphism of $\mathrm{Gal}(\overline{\mathbb{Q}}/K)$-modules

$$R(\overline{\mathbb{Q}}) = A(\overline{\mathbb{Q}}) \otimes_{\mathbb{Z}} \mathbb{Z}[\mathrm{Gal}(L/K)],$$

where $\tau \in \mathrm{Gal}(\overline{\mathbb{Q}}/K)$ acts on $\sum P_\sigma \otimes \sigma$ by

$$\tau\left(\sum P_\sigma \otimes \sigma\right) = \sum \tau(P_\sigma) \otimes \tau_{|L} \cdot \sigma,$$

where $\tau_{|L}$ is the image of τ in $\mathrm{Gal}(L/K)$.

Theorem 3.0.2. *Conjecture 3.0.1 implies part 1 of Conjecture 1.0.2. More precisely, if A/K is an abelian variety, m is a positive integer, and $A(K_{p^\infty})$ is finitely generated for each $p \mid m$, then there is an optimal covering of the form $B = \mathrm{Res}_{L/K}(A_L) \to A$ such that L is abelian over K and the image of $B(K)$ in $A(K)$ is contained in $mA(K)$.*

Proof. Fix a prime $p \mid m$. Let $M = K_{p^\infty}$. Because $A(M)$ is finitely generated, some finite set of generators must be in a single sufficiently large $A(K_{p^n})$, and for this n we have $A(M) = A(K_{p^n})$. For any integer $j > 0$ let

$$R_j = \operatorname{Res}_{K_{p^j}/K}(A_{K_{p^j}}).$$

Then, as explained in [Ste04], the trace map induces an exact sequence

$$0 \to B_j \to R_j \xrightarrow{\pi_j} A \to 0,$$

with B_j an abelian variety. Then for any $j \geq n$, $A(K_{p^j}) = A(K_{p^n})$, so

$$\begin{aligned}
\operatorname{Vis}^{B_j}(A(K)) &\cong A(K)/\pi_j(R_j(K)) \\
&= A(K)/\operatorname{Tr}_{K_{p^j}/K}(A(K_{p^j})) \\
&= A(K)/\operatorname{Tr}_{K_{p^n}/K}(\operatorname{Tr}_{K_{p^j}/K_{p^n}}(A(K_{p^j}))) \\
&= A(K)/\operatorname{Tr}_{K_{p^n}/K}(\operatorname{Tr}_{K_{p^j}/K_{p^n}}(A(K_{p^n}))) \\
&= A(K)/\operatorname{Tr}_{K_{p^n}/K}(p^{j-n}A(K_{p^n})) \\
&= A(K)/p^{j-n}\operatorname{Tr}_{K_{p^n}/K}(A(K_{p^n})) \\
&\to A(K)/p^{j-n}A(K),
\end{aligned}$$

where the last map is surjective since

$$\operatorname{Tr}_{K_{p^n}/K}(A(K_{p^n})) \subset A(K).$$

Arguing as above, for each prime $p \mid m$, we find an extension L_p of K of degree a power of p such that $\operatorname{Tr}_{L_p/K}(A(L_p)) \subset p^{\nu_p}A(K)$, where $\nu_p = \operatorname{ord}_p(m)$. Let L be the compositum of the fields L_p. Then for each $p \mid m$,

$$\operatorname{Tr}_{L/K}(A(L)) = \operatorname{Tr}_{L_p/K}(\operatorname{Tr}_{L/L_p}(A(L))) \subset \operatorname{Tr}_{L_p/K}(A(L_p)) \subset p^{\nu_p}A(K).$$

Thus

$$\operatorname{Tr}_{L/K}(A(L)) \subset \bigcap_{p \mid m} p^{\nu_p}A(K) = mA(K), \tag{1}$$

where for the last equality we view $A(K)$ as a finite direct sum of cyclic groups.

Let $R = \operatorname{Res}_{L/K}(A_L)$. Then trace induces an optimal cover $R \to A$, and (1) implies that we have the required surjective map

$$\operatorname{Vis}^R(A(K)) = A(K)/\operatorname{Tr}_{L/K}(A(L)) \to A(K)/mA(K).$$

□

We will next prove parts 1 and 2 of Conjecture 1.0.2 for elliptic curves over $\mathbb{Q}$ by observing that Conjecture 3.0.1 is a theorem of Kato in this case. We first prove a modularity property for restriction of scalars. Recall that a modular abelian variety is a quotient of $J_1(N)$.

Proposition 3.0.3. *If A is a modular abelian variety over $\mathbb{Q}$ and K is an abelian extension of $\mathbb{Q}$, then $\mathrm{Res}_{K/\mathbb{Q}}(A_K)$ is also a modular abelian variety.*

Proof. Since A is modular, A is isogenous to a product of abelian varieties A_f attached to newforms in $S_2(\Gamma_1(N))$, for various N. Since the formation of restriction of scalars commutes with products, it suffices to prove the proposition under the hypothesis that $A = A_f$ for some newform f. Let $R = \mathrm{Res}_{K/\mathbb{Q}}(A_f)$. As discussed in [Mil72, pg. 178], for any prime p there is an isomorphism of $\mathbb{Q}_p$-adic Tate modules

$$V_p(R) \cong \mathrm{Ind}_{G_K}^{G_{\mathbb{Q}}} V_p(A_K).$$

The induced representation on the right is the direct sum of twists of $V_p(A_K)$ by characters of $\mathrm{Gal}(K/\mathbb{Q})$. This is isomorphic to the $\mathbb{Q}_p$-adic Tate module of some abelian variety $P = \prod_\chi A_{g^\chi}$, where χ runs through certain Dirichlet characters corresponding to the abelian extension $K/\mathbb{Q}$, and g runs through certain $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-conjugates of f, and g^χ denotes the twist of g by χ. Falting's theorem (see e.g., [Fal86, §5]) then gives us the desired isogeny $R \to P$.

It is not necessary to use the full power of Falting's theorem to prove this proposition, since Ribet [Rib80] gave a more elementary proof of Falting's theorem in the case of modular abelian varieties. However, we must work some to apply Ribet's theorem, since we do not know yet that R is modular.

Let R and P be as above. Over $\overline{\mathbb{Q}}$, the abelian variety A is isogenous to a power of a simple abelian variety B, since if more than one non-isogenous simple occurred in the decomposition of $A/\overline{\mathbb{Q}}$, then $\mathrm{End}(A/\overline{\mathbb{Q}})$ would not be a matrix ring over a (possibly skew) field (see [Rib92, §5]). For any character χ, by the (3) $\implies$ (2) assertion of [Rib80, Thm. 4.7], the abelian varieties A_f and A_{f^χ} are isogenous over $\overline{\mathbb{Q}}$ to powers of the same abelian variety A', hence to powers of the simple B. A basic property of restriction of scalars is that R_K is isomorphic to a power of $(A_f)_K$, hence R_K is isogenous over $\overline{\mathbb{Q}}$ to a power of B. Thus R and P are both isogenous over $\overline{\mathbb{Q}}$ to a power of B, so R is isogenous to P over $\overline{\mathbb{Q}}$, since they have the same dimension, as their Tate modules are isomorphic. Let L be a Galois number field over which such an isogeny is defined. Consider the natural $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-equivariant inclusion

$$\mathrm{Hom}(R_{\mathbb{Q}}, P_{\mathbb{Q}}) \otimes_{\mathbb{Q}_p} \hookrightarrow \mathrm{Hom}_{\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})}(V_p(R), V_p(P)). \tag{2}$$

By Ribet's proof of the Tate conjecture for modular abelian varieties [Rib80], the inclusion

$$\mathrm{Hom}(R_L, P_L) \otimes_{\mathbb{Q}_p} \hookrightarrow \mathrm{Hom}_{\mathrm{Gal}(\overline{\mathbb{Q}}/L)}(V_p(R), V_p(P)) \tag{3}$$

is an isomorphism, since there is an isogeny $P_L \to R_L$ and P is modular. But then (2) must also be an isomorphism, since (2) is the result of taking $\mathrm{Gal}(L/\mathbb{Q})$-invariants of both sides of (3).

By construction of P, there is an isomorphism $V_p(R) \cong V_p(P)$ of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-modules, so by (2) there is an isomorphism in $\mathrm{Hom}(R_{\mathbb{Q}}, P_{\mathbb{Q}}) \otimes \mathbb{Q}_p$. Thus there is a $\mathbb{Q}_p$-linear combination of elements of $\mathrm{Hom}(R_{\mathbb{Q}}, P_{\mathbb{Q}})$ that has nonzero determinant. However, if a $\mathbb{Q}_p$-linear combination of matrices has nonzero determinant, then some $\mathbb{Q}$-linear combination does, since the determinant is a polynomial function of the coefficients and $\mathbb{Q}$ is dense in $\mathbb{Q}_p$. Thus there is an isogeny $R \to P$ defined over $\mathbb{Q}$, so R is modular. □

Corollary 3.0.4. *Parts 1 and 2 of Conjecture 1.0.2 are true for every elliptic curve E over $\mathbb{Q}$.*

Proof. Suppose p is a prime, and let $\mathbb{Q}_{p^\infty}$ be the cyclotomic $\mathbb{Z}_p$ extension of $\mathbb{Q}$. By [BCDT01], E is a modular elliptic curve, so Rohrlich [Roh84] implies that all but finitely many special values $L(E, \chi, 1)$ are nonzero, where χ runs over all Dirichlet characters of p-power order. Kato proved (see, e.g., [Kat04, Sch98]) that if $L(E, \chi, 1) \neq 0$, then the χ part of $E(\mathbb{Q}_{p^\infty}) \otimes \mathbb{Q}$ vanishes. Combining these results, we see that $E(\mathbb{Q}_{p^\infty})$ is finitely generated, so we can apply Theorem 3.0.2 to conclude that if $x \in E(\mathbb{Q})$ and $m \mid \mathrm{order}(x)$, then x is m-visible relative to an optimal cover of E by a restriction of scalars B from an abelian extension. Then Proposition 3.0.3 implies that B is modular. □

4 The Visibility Dimension

The visibility dimension is analogous to the visibility dimension for elements of $\mathrm{H}^1(K, A)$ introduced in [AS02, §2]. We prove below that elements of order 2 in Mordell-Weil groups of elliptic curves over $\mathbb{Q}$ are 2-visible relative to an abelian surface. Along the way, we make a general conjecture about stability of rank and show that it implies a general bound on the visibility dimension.

Definition 4.0.5 (Visibility Dimension). Let A be an abelian variety over a number field K and suppose m is an integer. Then A has *m-visibility dimension n* if there is an optimal cover $B \to A$ with $n = \dim(B)$ and the image of $B(K)$ in $A(K)$ is contained in $mA(K)$, so $A(K)/mA(K)$ is a quotient of $\mathrm{Vis}^B(A(K))$.

The following rank-stability conjecture is motivated by its usefulness for proving a result about m-visibility.

Conjecture 4.0.6. *Suppose A is an abelian variety over a number field K, that L is a finite extension of K, and $m > 0$ is an integer. Then there is an extension M of K of degree m such that* $\mathrm{rank}(A(K)) = \mathrm{rank}(A(M))$ *and $M \cap L = K$.*

The following proposition describes how Conjecture 4.0.6 can be used to find an extension where the index of $A(K)$ in $A(M)$ is coprime to m.

Proposition 4.0.7. *Let A be an abelian variety over a number field K and suppose m is a positive integer. If Conjecture 4.0.6 is true for A and m, then there is an extension M of K of degree m such that $A(M)/A(K)$ is of order coprime to m.*

Proof. Choose a finite set $P_1, \dots, P_n$ of generators for $A(K)$. Let

$$L = K\left(\frac{1}{m}P_1, \dots, \frac{1}{m}P_n\right)$$

be the extension of K generated by *all* mth roots of each P_i. Since the set of mth roots of a point is closed under the action of $\mathrm{Gal}(\overline{K}/K)$, the extension L/K is Galois. Note also that the m torsion of A is defined over L, since the differences of conjugates of a given $\frac{1}{m}P_i$ are exactly the elements of $A[m]$. Let S be the set of primes of K that ramify in L.

By our hypothesis that Conjecture 4.0.6 is true for A and m, there is an extension M of K of degree m such that

$$\mathrm{rank}(A(K)) = \mathrm{rank}(A(M))$$

and $M \cap L = K$. In particular, $C = A(M)/A(K)$ is a finite group. Suppose, for the sake of contradiction, that $\gcd(m, \#C) \neq 1$, so there is some prime divisor $p \mid m$ and an element $[Q] \in C$ of exact order p. Here $Q \in A(M)$ is such that $pQ \in A(K)$ but $Q \notin A(K)$. Because $P_1, \dots, P_n$ generate $A(K)$ and $pQ \in A(K)$, there are integers $a_1, \dots a_n$ such that

$$pQ = \sum_{i=1}^{n} a_i P_i.$$

Then for any fixed choice of the $\frac{1}{p}P_i$, we have

$$Q - \sum_{i=1}^{n} a_i \cdot \frac{1}{p}P_i \in A[p],$$

since

$$p\left(Q - \sum_{i=1}^{n} a_i \cdot \frac{1}{p}P_i\right) = pQ - \sum_{i=1}^{n} a_i \cdot P_i = 0.$$

Thus $Q \in A(L)$. But then since $L \cap M = K$, so we obtain a contradiction from

$$Q \in A(L) \cap A(M) = A(K).$$

□

With Proposition 4.0.7 in hand, we show that Conjecture 4.0.6 bounds the visibility dimension of Mordell-Weil groups. In particular, we see that Conjecture 4.0.6 implies that for any abelian variety A over a number field K, and any m, there is an embedding $A(K)/mA(K) \hookrightarrow \mathrm{H}^1(K, C)$ coming from a δ map, where C is an abelian variety over K of rank 0.

THEOREM 4.0.8. *Let A be an abelian variety over a number field K and suppose m is a positive integer. If Conjecture 4.0.6 is true for A and m, then there is an optimal covering $B \to A$ with B of dimension m such that*

$$\mathrm{Vis}^B(A(K)) \cong A(K)/mA(K).$$

Proof. By Proposition 4.0.7, there is an extension M of K of degree m such that the quotient $A(M)/A(K)$ is finite of order coprime to m. Then, as in [Ste04], the restriction of scalars $B = \mathrm{Res}_{M/K}(A_M)$ is an optimal cover of A and

$$\mathrm{Vis}^B(A(K)) \cong A(K)/\mathrm{Tr}(A(M)).$$

However, there is also an inclusion $A \hookrightarrow B$ from which one sees that

$$mA(M) \subset \mathrm{Tr}(A(M)),$$

so $\mathrm{Vis}^B(A(K))$ is an m-torsion group.

We have

$$[\mathrm{Tr}(A(M)) : \mathrm{Tr}(A(K))] \bigm| [A(M) : A(K)].$$

We showed above that $\gcd([A(M) : A(K)], m) = 1$, so since

$$\mathrm{Tr}(A(M))/\mathrm{Tr}(A(K))$$

is killed by m, it follows that $\mathrm{Tr}(A(M)) = \mathrm{Tr}(A(K))$. We conclude that

$$\mathrm{Vis}^B(A(K)) = A(K)/mA(K).$$

□

Proposition 4.0.9. *If E is an elliptic curve over $\mathbb{Q}$ and $m = 2$, then Conjecture 4.0.6 is true for E and m.*

Proof. Let L be as in Conjecture 4.0.6, so L is an extension of $\mathbb{Q}$ of possibly large degree. Let D be the discriminant of L. By [MM97, BFH90] there are infinitely many quadratic imaginary extensions M of $\mathbb{Q}$ such that $L(E^M, 1) \neq 0$, where E^M is the quadratic twist of E by M. By [Kol91, Kol88] all these curves have rank 0. Since there are only finitely many quadratic fields ramified only at the primes that divide D, there must be some field M that is ramified at a prime $p \nmid D$. If M is contained in L, then all the primes that ramify in M divide D, so M is not contained in L. Since M is quadratic, it follows that $M \cap L = \mathbb{Q}$, as required. Since the image of $E(\mathbb{Q}) + E^M(\mathbb{Q})$ in $E(M)$ has finite index, it follows that $E(M)/E(\mathbb{Q})$ is finite. □

Corollary 4.0.10. *If E is an elliptic curve over $\mathbb{Q}$, then there is an optimal cover $B \to E$, with B a 2-dimension modular abelian variety, such that*

$$\mathrm{Vis}^B(E(\mathbb{Q})) \cong E(\mathbb{Q})/2E(\mathbb{Q}).$$

Proof. Combine Proposition 4.0.9 with Theorem 4.0.8. Also B is modular since it is isogenous to $E \times E'$, where E' is a quadratic twist of E. □

Note that the B of Corollary 4.0.10 is isomorphic to $(E \times E^D)/\Phi$, where E^D is a rank 0 quadratic imaginary twist of E and $\Phi \cong E[2]$ is embedded antidiagonally in $E \times E^D$. Note that E^D also has analytic rank 0, since it was constructed using the theorems of [Kol91, Kol88] and [MM97, BFH90]. Thus our construction is compatible with the one of Proposition 5.1.1 below.

5 Some Data About Visibility and Modularity

This section contains a computational investigation of modularity of Mordell-Weil groups of elliptic curves relative to abelian varieties that are quotients of $J_0(N)$. One reason that we restrict to $J_0(N)$ is so that computations are more tractable. Also, for $m > 2$, the twisting constructions that we have given in previous sections are no longer allowed since they take place in $J_1(N)$. Furthermore, the work of [KL89] suggests that we understand the arithmetic of $J_0(N)$ better than that of $J_1(N)$.

5.1 A Visibility Construction for Mordell-Weil Groups

The following proposition is an analogue of [AS02, Thm. 3.1] but for visibility of Mordell-Weil groups (compare also [CM00, pg. 19]).

Proposition 5.1.1. *Let E be an elliptic curve over a number field K, and let $\Phi = E[m]$ as a $\mathrm{Gal}(\overline{K}/K)$-module. Suppose A is an abelian variety over K such that $\Phi \subset A$, as $G_{\mathbb{Q}}$-modules. Let $B = (A \times E)/\Phi$, where Φ is embedded anti-diagonally. Then there is an exact sequence*

$$0 \to B(K)/(A(K) + E(K)) \to E(K)/mE(K) \to \mathrm{Vis}^B(E(K)) \to 0.$$

Moreover, if $(A/E[m])(K)$ is finite of order coprime to m, then the first term of the sequence is 0, so

$$\mathrm{Vis}^B(E(K)) \cong E(K)/mE(K).$$

Proof. Using the definition of B and multiplication by m on E, we obtain the following commutative diagram, whose rows and columns are exact:

$$\begin{tikzcd}
 & 0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] & \\
0 \arrow[r] & E[m] \arrow[r] \arrow[d] & E \arrow[r, "m"] \arrow[d] & E \arrow[r] \arrow[d, "\cong"] & 0 \\
0 \arrow[r] & A \arrow[r] \arrow[d] & B \arrow[r] \arrow[d] & E \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & A/E[m] \arrow[r, "\cong"] \arrow[d] & B/E \arrow[r] \arrow[d] & 0 & \\
 & 0 & 0 & &
\end{tikzcd}$$

Taking K-rational points we arrive at the following diagram with exact rows and columns:

$$\begin{tikzcd}
0 \arrow[r] & E(K)/E(K)[m] \arrow[r, "m"] \arrow[d] & E(K) \arrow[r] \arrow[d, "\cong"] & E(K)/mE(K) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & B(K)/A(K) \arrow[r] \arrow[d] & E(K) \arrow[r] \arrow[d] & \mathrm{Vis}^B(E(K)) \arrow[r] & 0 \\
& B(K)/(A(K)+E(K)) & 0 & &
\end{tikzcd}$$

The snake lemma and the fact that the middle vertical map is an isomorphism implies that the right vertical map is a surjection with kernel isomorphic to $B(K)/(A(K)+E(K))$. Thus we obtain an exact sequence

$$0 \to B(K)/(A(K)+E(K)) \to E(K)/mE(K) \to \mathrm{Vis}^B(E(K)) \to 0.$$

This proves the first statement of the proposition. For the second, note that we have an exact sequence $0 \to E \to B \to A/E[m] \to 0$. Taking Galois cohomology yields an exact sequence

$$0 \to E(K) \to B(K) \to (A/E[m])(K) \to \cdots,$$

so $\#(B(K)/E(K)) \mid \#(A/E[m])(K)$. If $(A/E[m])(K)$ is finite of order coprime to m, then $B(K)/(A(K)+E(K))$ has order dividing $\#(A/E[m])(K)$, so the quotient $B(K)/(A(K)+E(K))$ is trivial, since it injects into $E(K)/mE(K)$. □

5.2 Tables

The data in this section suggests the following conjecture.

Conjecture 5.2.1. *Suppose E is an elliptic curve over $\mathbb{Q}$ and p is a prime such that $E[p]$ is irreducible. Then there exists infinitely many newforms $g \in S_2(\Gamma_0(N))$, for various integers N, such that $L(g,1) \neq 0$ and $E[p] \subset A_g$ and $\mathrm{Vis}^B(E(\mathbb{Q})) = E(\mathbb{Q})/pE(\mathbb{Q})$, where $B = (A_g \times E)/E[p]$.*

Let E be the elliptic curve $y^2 + y = x^3 - x$. This curve has conductor 37 and Mordell-Weil group free of rank 1. According to [Cre97], E is isolated in its isogeny class, so each $E[p]$ is irreducible.

Table 1 gives for each N the *odd* primes p such that there is a mod p congruence between f_E and some newform g in $S_2(\Gamma_0(37N))$ such that A_g has rank 0 and the isogeny class of A_g contains no abelian variety with rational p torsion. The first time a p occurs, it is in bold. We bound the torsion in the isogeny class using the algorithm from [AS05, §3.5] with primes up to 17. Thus by Proposition 5.1.1, the Mordell-Weil group of E is p-modular of level $37N$. A $-$ means there are no such p. Table 2, which was derived directly from Table 1, gives for a prime p, all integers N such that $E(\mathbb{Q})$ is p-modular of level $37N$.

Ribet's level raising theorem [Rib90] gives necessary and sufficient conditions on a prime N for there to be a newform g of level $37N$ that is congruent to f_E modulo p. Note that the form g is new rather than just p-new since 37 is prime and there are no modular forms of level 1 and weight 2. If, moreover, we impose the condition $L(g,1) \neq 0$, then Ribet's condition requires that p divides $N + 1 + \varepsilon a_N$, where ε is the root number of E. Since E has odd analytic rank, in this case $\varepsilon = -1$. For each primes $p \leq 127$ and each $N \leq 203$, were find the levels of such g. The *only* cases in which we don't already find a congruence level already listed in Table 2 corresponding to a newform with torsion multiple coprime to p are

$$p = 3, \quad N = 43 \qquad \text{and} \qquad p = 19, \quad N = 47, 79.$$

In all other cases in which Ribet's theorem produces a congruent g with $\operatorname{ord} L(g,s)$ even (hence possibly 0), we actually find a g with $L(g,1) \neq 0$ and can show that $\#A_g(\mathbb{Q})_{\text{tor}}$ is coprime to p.

For $p = 3$ and $N = 43$ we find a unique newform $g \in S_2(\Gamma_0(1591))$ that is congruent to f_E modulo 3. This form is attached to the elliptic curve $y^2 + y = x^3 - 71x + 552$ of conductor 1591, which has Mordell-Weil groups $\mathbb{Z} \oplus \mathbb{Z}$. Thus this is an example of a congruence relating a rank 1 curve to a rank 2 curve. For $p = 19$ and $N = 47$, the g has degree 43, so A_g has dimension 43, we have $L(g,1) \neq 0$, but the torsion multiple is $76 = 19 \cdot 4$, which is divisible by 19. For $p = 19$ and $N = 79$, the A_g has dimension 57, we have $L(g,1) \neq 0$, but the torsion multiple is 76 again.

Tables 3–4 are the analogues of Tables 1–2 but for the elliptic curve $y^2 + y =$

$x^3 + x^2$ of conductor 43. This elliptic curve also has rank 1 and all mod p representations are irreducible. The primes p and N such that Ribet's theorem produces a congruent g with $\mathrm{ord}_{s=1} L(g, s)$ even, yet we do not find one with $L(g, 1) \neq 0$ and the torsion multiple coprime to p are

$$p = 3, \quad N = 31, 61 \qquad \text{and} \qquad p = 11, \quad N = 19, 31, 47, 79.$$

The situation for $p = 11$ is interesting since in this case all the g with $\mathrm{ord}_{s=1} L(g, s)$ even fail to satisfy our hypothesis. At level $19 \cdot 43$ we find that g has degree 18 and $L(g, 1) \neq 0$, but the torsion multiple is divisible by 11.

Let E be the elliptic curve $y^2 + y = x^3 + x^2 - 2x$ of conductor 389. This curve has Mordell-Weil group free of rank 2. Tables 5–6 are the analogues of Tables 1–2 but for E. The primes p and N such that Ribet's theorem produces a congruent g with $\mathrm{ord}_{s=1} L(g, s)$ even, yet we do not find one with $L(g, 1) \neq 0$ and the torsion multiple coprime to p are

$$p = 3, \quad N = 17 \qquad \text{and} \qquad p = 5, \quad N = 19.$$

For $p = 3$, there is a unique g of level $6613 = 37 \cdot 17$ with $\mathrm{ord}_{s=1} L(g, s)$ even and $E[3] \subset A_g$. This form has degree 5 and $L(g, 1) = 0$, so this is another example where the rank 0 hypothesis of Proposition 5.1.1 is not satisfied. Note that the torsion multiple in this case is 1. For $p = 5$, there is a unique g of level $7391 = 37 \cdot 19$, with $\mathrm{ord}_{s=1} L(g, s)$ even and $E[5] \subset A_g$. This form has degree 4 and $L(g, 1) \neq 0$, but the torsion multiple is divisible by 5.

24 Visibility of the Shafarevich-Tate Group at Higher Level, with D. Jetchev

Visibility of the Shafarevich-Tate Group at Higher Level

Dimitar P. Jetchev   William A. Stein

Abstract. We study visibility of Shafarevich-Tate groups of modular abelian varieties in Jacobians of modular curves of higher level. We prove a theorem about the existence of visible elements at a specific higher level under hypotheses that can be verified explicitely. We also provide a table of examples of visible subgroups at higher level and state conjectures inspired by our data.

1 Introduction

1.1 Motivation

Mazur suggested that the Shafarevich-Tate group $\text{Ш}(K, E)$ of an abelian variety A over a number field K could be studied via a collection of finite subgroups (the *visible subgroups*) corresponding to different embeddings of the variety into larger abelian varieties C over K (see [Maz99] and [CM00]). The advantage of this approach is that the isomorphism classes of principal homogeneous spaces, for which one has *à priori* little geometric information, can be given a much more explicit description as K-rational points on the quotient abelian variety C/A (the reason why they are called *visible elements*).

Agashe, Cremona, Klenke and the second author built upon the ideas of Mazur and developed a systematic theory of visibility of Shafarevich-Tate groups of abelian varieties over number fields (see [Aga99b, AS02, AS05, CM00, Kle01, Ste00]). More precisely, Agashe and Stein provided sufficient conditions for the existence of visible sugroups of certain order in the Shafarevich-Tate group and applied their general theory to the case of newform subvarieties $A_{f_{/\mathbb{Q}}}$ of the Jacobian $J_0(N)_{/\mathbb{Q}}$ of the modular curve $X_0(N)_{/\mathbb{Q}}$ (here, f is a newform of level N and weight 2 which is an eigenform for the Hecke operators acting on the space $S_2(\Gamma_0(N))$ of cuspforms of level N and weight 2). Unfortunately, there is no guarantee that a non-trivial element of $\text{Ш}(\mathbb{Q}, A_f)$ is visible for the embedding $A_f \hookrightarrow J_0(N)$.

In this paper we consider the case of modular abelian varieties over $\mathbb{Q}$ and make use of the algebraic and arithmetic properties of the corresponding newforms to provide sufficient conditions for the existence of visible elements of $Ш(\mathbb{Q}, A_f)$ in modular Jacobians of level a multiple of the base level N. More precisely, we consider morphism of the form $A_f \hookrightarrow J_0(N) \xrightarrow{\phi} J_0(MN)$, where ϕ is a suitable linear combination of degeneracy maps which makes the kernel of the composition morphism almost trivial (i.e., trivial away from the 2-part). For specific examples, the sufficient conditions can be verified explicitely. We also provide a table of examples where certain elements of $Ш(\mathbb{Q}, A_f)$ which are invisible in $J_0(N)$ become visible at a suitably chosen higher level. At the end, we state some general conjectures inspired by our results.

1.2 Organization of the paper

Section 2 discusses the basic definitions and notation for modular abelian varieties, modular forms, Hecke algebras, the Shimura construction and modular degrees. Section 3 is a brief introduction to visibility theory for Shafarevich-Tate groups. In Section 4 we state and prove an equivariant version of a theorem of Agashe-Stein (see [AS05, Thm 3.1]) which guarantees existence of visible elements. The theorem is more general because it makes use of the action of the Hecke algebra on the modular Jacobian.

In Section 5 we introduce the notion of *strong visibility* which is relevant for visualizing cohomology classes in Jacobians of modular curves whose level is a multiple of the level of the original abelian variety. Theorem 5.1.3 guarantees existence of strongly visible elements of the Shafarevich-Tate group under some hypotheses on the component groups, a congruence condition between modular forms, and irreducibility of the Galois representation. In Section 5.4 we prove a variant of the same theorem (Theorem 5.4.2) with more stringent hypotheses that are easier to verify in specific cases.

Section 6 discusses in detail two computational examples for which strongly visible elements of certain order exist which provides evidence for the Birch and Swinnerton-Dyer conjecture. We state a general conjecture (Conjecture 7.1.1) in Section 7 according to which every element of the Shafarevich-Tate group of a modular abelian variety becomes visible at higher level. We provide evidence for the the conjecture in Section 7.2 and tables of computational data in Section 7.4.

Acknowledgement: The authors would like to thank David Helm, Ben Howard, Barry Mazur, Bjorn Poonen and Ken Ribet for discussions and comments on the paper.

2 Notation

1. Abelian varieties. For a number field K, $A_{/K}$ denotes an abelian variety over K. We denote the dual of A by $A^\vee_{/K}$. If $\varphi : A \to B$ is an isogeny of degree n, we denote the *complementary isogeny* by φ'; this is the isogeny $\phi' : B \to A$, such that $\varphi \circ \varphi' = \varphi' \circ \varphi = [n]$, the multiplication-by-$n$ map on A. Unless otherwise specified, Néron models of abelian varieties will be denoted by the corresponding caligraphic letters, e.g., $\mathcal{A}$ denotes the Néron model of A.

2. Galois cohomology. For a fixed algebraic closure $\overline{K}$ of K, G_K will be the Galois group $\mathrm{Gal}(\overline{K}/K)$. If v is any non-archimedean place of K, K_v and k_v will always mean the completion and the residue field of K at v, respectively. By K_v^{ur} we always mean the maximal unramified extension of the completion K_v. Given a G_K-module M, we let $\mathrm{H}^1(K, M)$ denote the Galois cohomology group $\mathrm{H}^1(G_K, M)$.

3. Component groups. The *component group* of A at v is the finite group $\Phi_{A,v} = \mathcal{A}_{k_v}/\mathcal{A}^0_{k_v}$ which also has a structure of a finite group scheme over k_v. The *Tamagawa number* of A at v is $c_{A,v} = \#\Phi_{A,v}(k_v)$, and the *component group order* of A at v is $\overline{c}_{A,v} = \#\Phi_{A,v}(\overline{k}_v)$.

4. Modular abelian varieties. Let $h = 0$ or 1. A *J_h-modular abelian variety* is an abelian variety $A_{/K}$ which is a quotient of $J_h(N)$ for some N, i.e., there exists a surjective morphism $J_h(N) \twoheadrightarrow A$ defined over K. We define the *level* of a modular abelian variety A to be the minimal N, such that A is a quotient of $J_h(N)$. The modularity theorem of Wiles et al. (see [BCDT01]) implies that all elliptic curves over $\mathbb{Q}$ are modular. Serre's modularity conjecture implies that the modular abelian varieties over $\mathbb{Q}$ are precisely the abelian varieties over $\mathbb{Q}$ of GL_2-type (see [Rib92, §4]).

5. Shimura construction. Let $f = \displaystyle\sum_{n=1}^{\infty} a_n q^n \in S_2(\Gamma_0(N))$ be a newform of level N and weight 2 for $\Gamma_0(N)$ which is an eigenform for all Hecke operators in the Hecke algebra $\mathbb{T}(N)$. Shimura (see [Shi94, Thm. 7.14]) associated to f an abelian subvariety $A_{f/\mathbb{Q}}$ of $J_0(N)$, simple over $\mathbb{Q}$, of dimension $d = [K : \mathbb{Q}]$, where $K = \mathbb{Q}(\dots, a_n, \dots)$ is the Hecke eigenvalue field. More precisely, if $I_f = \mathrm{Ann}_{\mathbb{T}(N)}(f)$ then A_f is the connected component containing the identity of the I_f-torsion subgroup of $J_0(N)$, i.e., $A_f = J_0(N)[I_f]^0 \subset J_0(N)$. The quotient $\mathbb{T}(N)/I_f$ of the Hecke algebra $\mathbb{T}(N)$ is a subalgebra of the endomorphism ring $\mathrm{End}_{\mathbb{Q}}(A_{/\mathbb{Q}})$. Also $L(A_f, s) = \displaystyle\prod_{i=1}^{d} L(f_i, s)$, where the f_i are the $G_{\mathbb{Q}}$-conjugates of f. We also consider the dual abelian variety $A_f^{\vee}$ which is a quotient variety of $J_0(N)$.

6. I-torsion submodules. If M is a module over a commutative ring R and I is an ideal of R, let

$$M[I] = \{x \in M : mx = 0 \text{ all } m \in I\}$$

be the *I-torsion submodule* of M.

7. Hecke algebras. Let $S_2(\Gamma)$ denote the space of cusp forms of weight 2 for any congruence subgroup Γ of $\mathrm{SL}_2(\mathbb{Z})$. Let

$$\mathbb{T}(N) = \mathbb{Z}[\ldots, T_n, \ldots] \subseteq \mathrm{End}_{\mathbb{Q}}(J_0(N))$$

be the Hecke algebra, where T_n is the nth Hecke operator. $\mathbb{T}(N)$ also acts on $S_2(\Gamma_0(N))$ and the integral homology $H_1(X_0(N), \mathbb{Z})$.

8. Modular degree. If A is an abelian subvariety of $J_0(N)$, let

$$\theta : A \to J_0(N) \cong J_0(N)^\vee \to A^\vee$$

be the induced polarization. The *modular degree* of A is

$$m_A = \sqrt{\#\,\mathrm{Ker}(A \xrightarrow{\theta} A^\vee)}.$$

See [AS02] for why m_A is an integer and for an algorithm to compute it.

3 Visible Subgroups of Shafarevich-Tate Groups

Let K be a number field and $\iota : A_{/K} \hookrightarrow C_{/K}$ be an embedding of an abelian variety into another abelian variety over K.

Definition 3.0.1. The *visible subgroup* of $\mathrm{H}^1(K, A)$ relative to ι is

$$\mathrm{Vis}_C\,\mathrm{H}^1(K, A) = \mathrm{Ker}\left(\iota_* : \mathrm{H}^1(K, A) \to \mathrm{H}^1(K, C)\right).$$

The visible subgroup of Ш(K, A) relative to the embedding ι is

$$\begin{aligned}\mathrm{Vis}_C\,Ш(K, A) &= Ш(K, A) \cap \mathrm{Vis}_C\,\mathrm{H}^1(K, A)\\ &= \mathrm{Ker}\left(Ш(K, A) \to Ш(K, C)\right)\end{aligned}$$

Let Q be the abelian variety $C/\iota(A)$, which is defined over K. The long exact sequence of Galois cohomology corresponding to the short exact sequence $0 \to A \to C \to Q \to 0$ gives rise to the following exact sequence

$$0 \to A(K) \to C(K) \to Q(K) \to \mathrm{Vis}_C\,\mathrm{H}^1(K, A) \to 0.$$

The last map being surjective means that the cohomology classes of $\mathrm{Vis}_C\,\mathrm{H}^1(K, A)$ are images of K-rational points on Q, which explains the meaning of the word *visible* in the definition. The group $\mathrm{Vis}_C\,\mathrm{H}^1(K, A)$ is finite since it is torsion and since the Mordell-Weil group $Q(K)$ is finitely generated.

Remark 3.0.2. If $A_{/K}$ is an abelian variety and $c \in \mathrm{H}^1(K, A)$ is any cohomology class, there exists an abelian variety $C_{/K}$ and an embedding $\iota : A \hookrightarrow C$ defined over K, such that $c \in \mathrm{Vis}_C\,\mathrm{H}^1(K, A)$, i.e., c is visible in C (see [AS02, Prop. 1.3]). The C of [AS02, Prop. 1.3] is the restriction of scalars of $A_L = A \times_K L$ down to K, where L is any finite extension of K such that c has trivial image in $\mathrm{H}^1(L, A)$.

4 Equivariant Visibility

Let K be a number field, let $A_{/K}$ and $B_{/K}$ be abelian subvarieties of an abelian variety $C_{/K}$, such that $C = A + B$ and $A \cap B$ is finite. Let $Q_{/K}$ denotes the quotient C/B. Let N be a positive integer divisible by all primes of bad reduction for C.

Let ℓ be a prime such that $B[\ell] \subset A$ and $e < \ell - 1$, where e is the largest ramification index of any prime of K lying over ℓ. Suppose that

$$\ell \nmid N \cdot \#B(K)_{\mathrm{tor}} \cdot \#Q(K)_{\mathrm{tor}} \cdot \prod_{v \mid N} c_{A,v} c_{B,v}.$$

Under those conditions, Agashe and Stein (see [AS02, Thm. 3.1]) construct a homomorphism $B(K)/\ell B(K) \to \text{Ш}(K, A)[\ell]$ whose kernel has $\mathbb{F}_\ell$-dimension bounded by the Mordell-Weil rank of $A(K)$.

In this paper, we refine [AS02, Prop. 1.3] by taking into account the algebraic structure coming from the endomorphism ring $\mathrm{End}_K(C)$. In particular, when we apply the theory to modular abelian varieties, we would like to use the additional structure coming from the Hecke algebra. There are numerous example (see [AS05]) where [AS02, Prop. 1.3] does not apply, but nevertheless, we can use our refinement to prove existence of visible elements of $\text{Ш}(\mathbb{Q}, A_f)$ at higher level (e.g., see Propositions 6.1.3 and 6.2.1 below).

4.1 The main theorem

Let $A_{/K}$, $B_{/K}$, $C_{/K}$, $Q_{/K}$, N and ℓ be as above. Let R be a commutative subring of $\mathrm{End}_K(C)$ that leaves A and B stable and let $\mathfrak{m}$ be a maximal ideal of R of residue characteristic ℓ. By the Néron mapping property, the subgroups $\Phi_{A,v}(k_v)$ and $\Phi_{B,v}(k_v)$ of k_v-points of the corresponding component groups can be viewed as R-modules.

Theorem 4.1.1 (Equivariant Visibility Theorem). *Suppose that $A(K)$ has rank zero and that the groups $Q(K)[\mathfrak{m}]$, $B(K)[\mathfrak{m}]$, $\Phi_{A,v}(k_v)[\mathfrak{m}]$ and $\Phi_{B,v}(k_v)[\ell]$ are all trivial for all nonarchimedean places v of K. Then there is an injective homomorphism of $R/\mathfrak{m}$-vector spaces*

$$(B(K)/\ell B(K))[\mathfrak{m}] \hookrightarrow \mathrm{Vis}_C(\text{Ш}(K, A))[\mathfrak{m}]. \tag{1}$$

Remark 4.1.2. Applying the above result for $R = \mathbb{Z}$, we recover the result of Agashe and Stein in the case when $A(K)$ has Mordell-Weil rank zero. We could relax the hypothesis that $A(K)$ is finite and instead give a bound on the dimension of the kernel of (1) in terms of the rank of $A(K)$ similar to the bound in [AS02, Thm. 3.1]. We will not need this stronger result in our paper.

4.2 Some commutative algebra

Before proving Theorem 4.1.1 we recall some well-known lemmas from commutative algebra. Let M be a module over a commutative ring R and let $\mathfrak{m}$ be a finitely generated prime ideal of R.

Lemma 4.2.1. *If $M_{\mathfrak{m}}$ is Artinian, then* $M_{\mathfrak{m}} \neq 0 \iff M[\mathfrak{m}] \neq 0$.

Proof. ($\Longleftarrow$) We first prove that $M_{\mathfrak{m}} = 0$ implies $M[\mathfrak{m}] = 0$ by a slight modification of the proof of [AM69, Prop. I.3.8]. Suppose $M_{\mathfrak{m}} = 0$, yet there is a nonzero $x \in M[\mathfrak{m}]$. Let $I = \mathrm{Ann}_R(x)$. Then $I \neq (1)$ is an ideal that contains $\mathfrak{m}$, so $I = \mathfrak{m}$. Consider $\frac{x}{1} \in M_{\mathfrak{m}}$. Since $M_{\mathfrak{m}} = 0$, we have $x/1 = 0$, hence by definition of localization, x is killed by some element of $R - \mathfrak{m}$ (set-theoretic difference). But this is impossible since $\mathrm{Ann}_R(x) = \mathfrak{m}$.

($\Longrightarrow$) Next we prove that $M_{\mathfrak{m}} \neq 0$ implies $M[\mathfrak{m}] \neq 0$. Since $M_{\mathfrak{m}}$ is an Artinian module over the (local) ring $R_{\mathfrak{m}}$, by [AM69, Prop. 6.8], $M_{\mathfrak{m}}$ has a composition series:

$$M_{\mathfrak{m}} = M_0 \supset M_1 \supset \cdots \supset M_{n-1} \supset M_n = 0,$$

where by definition each quotient M_i/M_{i+1} is a simple $R_{\mathfrak{m}}$-module. In particular, M_{n-1} is a simple $R_{\mathfrak{m}}$-module. Suppose $x \in M_{n-1}$ is nonzero, and let $I = \mathrm{Ann}_{R_{\mathfrak{m}}}(x)$. Then

$$R_{\mathfrak{m}}/I \cong R_{\mathfrak{m}} \cdot x \subset M_{n-1},$$

so by simplicity $R_{\mathfrak{m}}/I \cong M_{n-1}$ is simple. Thus $I = \mathfrak{m}$, otherwise $R_{\mathfrak{m}}/I$ would have $\mathfrak{m}/I$ as a proper submodule. Thus $x \in M_{n-1}[\mathfrak{m}]$ is nonzero.

Write $x = [y, a]$ with $y \in M$ and $a \in R - \mathfrak{m}$, where $[y/a]$ means the class of y/a in the localization (same as (y, a) on page 36 of [AM69]). Since $a \in R - \mathfrak{m}$, the element a acts as a unit on $M_{\mathfrak{m}}$, hence $ax = [y/1] \in M_{n-1}$ is nonzero and also still annihilated by $\mathfrak{m}$ (by commutativity).

To say that $[y/1]$ is annihilated by $\mathfrak{m}$ means that for all $\alpha \in \mathfrak{m}$ there exists $t \in R - \mathfrak{m}$ such that $t\alpha y = 0$ in M. Since $\mathfrak{m}$ is finitely generated, we can write $\mathfrak{m} = (\alpha_1, \ldots, \alpha_n)$ and for each α_i we get corresponding elements $t_1, \ldots, t_n$ and a product $t = t_1 \cdots t_n$. Also $t \notin \mathfrak{m}$ since $\mathfrak{m}$ is a prime ideal and each $t_i \notin \mathfrak{m}$. Let $z = ty$. Then for all $\alpha \in \mathfrak{m}$ we have $\alpha z = t\alpha y = 0$. Also $z \neq 0$ since t acts as a unit on M_{n-1}. Thus $z \in M[\mathfrak{m}]$, and is nonzero, which completes the proof of the lemma. □

Lemma 4.2.2. *Suppose* $0 \to M_1 \to N \to M_2 \to 0$ *is an exact sequence of R-modules each of whose localization at $\mathfrak{m}$ is Artinian. Then* $N[\mathfrak{m}] \neq 0 \iff (M_1 \oplus M_2)[\mathfrak{m}] \neq 0$.

Proof. By Lemma 4.2.1 we have $N[\mathfrak{m}] \neq 0$ if and only if $N_{\mathfrak{m}} \neq 0$. By Proposition 3.3 on page 39 of [AM69], the localized sequence

$$0 \to (M_1)_{\mathfrak{m}} \to N_{\mathfrak{m}} \to (M_2)_{\mathfrak{m}} \to 0$$

is exact. Thus $N_{\mathfrak{m}} \neq 0$ if and only if at least one of $(M_1)_{\mathfrak{m}}$ or $(M_2)_{\mathfrak{m}}$ is nonzero. Again by Lemma 4.2.1, at least one of $(M_1)_{\mathfrak{m}}$ or $(M_2)_{\mathfrak{m}}$ is nonzero if and only if at least one of $M_1[\mathfrak{m}]$ or $M_2[\mathfrak{m}]$ is nonzero. The latter is the case if and only if $(M_1 \oplus M_2)[\mathfrak{m}] \neq 0$. □

Remark 4.2.3. One could also prove the lemmas using the isomorphism $M[\mathfrak{m}] \cong \mathrm{Hom}_R(R/\mathfrak{m}, M)$ and exactness properties of Hom, but even with this approach many of the details in Lemma 4.2.1 still have to be checked.

Remark 4.2.4. In Theorem 4.1.1, we have $R \subset \mathrm{End}(C)$, hence R is finitely generated as a $\mathbb{Z}$-module, so R is noetherian.

Lemma 4.2.5. *Let G be a finite cyclic group, M be a finite G-module that is also a module over a commutative ring R such that the action of G and R commute (i.e., M is an $R[G]$-module). Suppose $\mathfrak{p}$ is a finitely-generated prime ideal of R, and $H^0(G, M)[\mathfrak{p}] = 0$. Then $H^1(G, M)[\mathfrak{p}] = 0$.*

Proof. Argue as in [Se79, Prop. VIII.4.8], but noting that all modules are modules over R and maps are morphisms of R-modules. □

4.3 Proof of Theorem 4.1.1

Proof of Theorem 4.1.1. We argue as in the proof of [AS02, Thm. 3.1]. The construction of the map (1) is similar to the one in the proof of [AS02, Lem. 3.6]. We have the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & B[\ell] \arrow[r] \arrow[d] & B \arrow[r, "\ell"] \arrow[d] \arrow[dr, "\psi"] & B \arrow[r] \arrow[d, "\pi"] & 0 \\
0 \arrow[r] & A \arrow[r] & C \arrow[r] & Q \arrow[r] & 0,
\end{tikzcd}$$

where $\psi : B \to Q$ is the composition of the inclusion $B \hookrightarrow C$ with the quotient map $C \to Q$, and the existence of the morphism $\pi : B \to Q$ follows from the inclusion $B[\ell] \subset \mathrm{Ker}(\psi) = A \cap B$. By naturality for the long exact sequence of Galois cohomology we obtain the following commutative diagram with exact rows and columns

$$\begin{tikzcd}
 & M_0 \arrow[d] & M_1 \arrow[d] & M_2 \arrow[d] & \\
0 \arrow[r] & B(K)/(B(K)[\ell]) \arrow[r, "\ell"] \arrow[d] & B(K) \arrow[r] \arrow[d] \arrow[dr, "\pi"] & B(K)/\ell B(K) \arrow[r] \arrow[d, "\varphi"] & 0 \\
0 \arrow[r] & C(K)/A(K) \arrow[r] \arrow[d] & Q(K) \arrow[r] & \mathrm{Vis}_C(\mathrm{H}^1(K, A)) \arrow[r] & 0 \\
 & M_3. & & &
\end{tikzcd}$$

Here, M_0, M_1 and M_2 denote the kernels of the corresponding vertical maps and M_3 denotes the cokernel of the first map. Since R preserves A, B, and

$B[\ell]$, all objects in the diagram are R-module and the morphisms of abelian varieties are also R-module homomorphisms.

The snake lemma yields an exact sequence

$$0 \to M_0 \to M_1 \to M_2 \to M_3.$$

By hypothesis, $B(K)[\mathfrak{m}] = 0$, so $N_0 = \mathrm{Ker}(B(K) \to C(K)/A(K))$ has no $\mathfrak{m}$ torsion. Noting that $B(K)[\ell] \subset N_0$, it follows that $M_0 = N_0/(B(K)[\ell])$ has no $\mathfrak{m}$ torsion either, by Lemma 4.2.2. Also, $M_1[\mathfrak{m}] = 0$ again since $B(K)[\mathfrak{m}] = 0$.

By the long exact sequence on Galois cohomology, the quotient $C(K)/B(K)$ is isomorphic to a subgroup of $Q(K)$ and by hypothesis $Q(K)[\mathfrak{m}] = 0$, so $(C(K)/B(K))[\mathfrak{m}] = 0$. Since Q is isogenous to A and $A(K)$ is finite and $C(K)/B(K) \hookrightarrow Q(K)$, we see that $C(K)/B(K)$ is finite. Thus M_3 is a quotient of the finite R-module $C(K)/B(K)$, which has no $\mathfrak{m}$-torsion, so Lemma 4.2.2 implies that $M_3[\mathfrak{m}] = 0$. The same lemma implies that M_1/M_0 has no $\mathfrak{m}$-torsion, since it is a quotient of the finite module M_1, which has no $\mathfrak{m}$-torsion. Thus, we have an exact sequence

$$0 \to M_1/M_0 \to M_2 \to M_3 \to 0,$$

and both of M_1/M_0 and M_3 have trivial $\mathfrak{m}$-torsion. It follows by Lemma 4.2.2, that $M_2[\mathfrak{m}] = 0$. Therefore, we have an injective morphism of $R/\mathfrak{m}$-vector spaces

$$\varphi : (B(K)/\ell B(K))[\mathfrak{m}] \hookrightarrow \mathrm{Vis}_C(H^1(K, A))[\mathfrak{m}].$$

It remains to show that for any $x \in B(K)$, we have $\varphi(x) \in \mathrm{Vis}_C(Ш(K, A))$, i.e., that $\varphi(x)$ is locally trivial.

We proceed exactly as in Section 3.5 of [AS05]. In both cases $\mathrm{char}(v) \neq \ell$ and $\mathrm{char}(v) = \ell$ we arrive at the conclusion that the restriction of $\varphi(x)$ to $\mathrm{H}^1(K_v, A)$ is an element $c \in \mathrm{H}^1(K_v^{\mathrm{ur}}/K_v, A(K_v^{\mathrm{ur}}))$. (Note that in the case $\mathrm{char}(v) \neq \ell$ the proof uses our hypothesis that $\ell \nmid \#\Phi_{B,v}(k_v)$.) By [Mil86, Prop I.3.8], there is an isomorphism

$$\mathrm{H}^1(K_v^{\mathrm{ur}}/K_v, A(K_v^{\mathrm{ur}})) \cong \mathrm{H}^1(\overline{k}_v/k_v, \Phi_{A,v}(\overline{k}_v)). \tag{2}$$

We will use our hypothesis that

$$\Phi_{A,v}(k_v)[\mathfrak{m}] = \Phi_{B,v}(k_v)[\ell] = 0$$

for all v of bad reduction to deduce that the image of φ lies in $\mathrm{Vis}_C(Ш(K, A))[\mathfrak{m}]$. Let d denote the image of c in $\mathrm{H}^1(\overline{k}_v/k_v, \Phi_{A,v}(\overline{k}_v))$. The construction of d is compatible with the action of R on Galois cohomology, since (as is explained in the proof of [Mil86, Prop. I.3.8]) the isomorphism (2) is induced from the exact sequence of $\mathrm{Gal}(K_v^{\mathrm{ur}}/K_v)$-modules

$$0 \to \mathcal{A}^0(K_v^{\mathrm{ur}}) \to \mathcal{A}(K_v^{\mathrm{ur}}) \to \Phi_{A,v}(\overline{k}_v) \to 0,$$

where $\mathcal{A}$ is the Néron model of A and $\mathcal{A}^0$ is the subgroup scheme whose generic fiber is A and whose closed fiber is the identity component of $\mathcal{A}_{k_v}$. Since $\varphi(x) \in \mathrm{H}^1(K, A)[\mathfrak{m}]$, it follows that

$$d \in \mathrm{H}^1(\overline{k}_v/k_v, \Phi_{A,v}(\overline{k}_v))[\mathfrak{m}].$$

Lemma 4.2.5, our hypothesis that $\Phi_{A,v}(k_v)[\mathfrak{m}] = 0$, and that

$$\mathrm{H}^1(\overline{k}_v/k_v, \Phi_{A,v}(\overline{k}_v)) = \varinjlim \mathrm{H}^1(\mathrm{Gal}(k_v'/k_v), \Phi_{A,v}(k_v'))),$$

together imply that $\mathrm{H}^1(\overline{k}_v/k_v, \Phi_{A,v}(\overline{k}_v))[\mathfrak{m}] = 0$, hence $d = 0$. Thus $c = 0$, so $\varphi(x)$ is locally trivial, which completes the proof. □

5 Strong Visibility at Higher Level

5.1 Strongly visible subgroups

Let $A_{/\mathbb{Q}}$ be an abelian subvariety of $J_0(N)_{/\mathbb{Q}}$ and let $p \nmid N$ be a prime. Let

$$\varphi = \delta_1^* + \delta_p^* : J_0(N) \to J_0(pN), \tag{3}$$

where δ_1^* and δ_p^* are the pullback maps on equivalence classes of degree-zero divisors of the degeneracy maps $\delta_1, \delta_p : X_0(pN) \to X_0(N)$. Let $\mathrm{H}^1(\mathbb{Q}, A)^{\mathrm{odd}}$ be the prime-to-2-part of the group $\mathrm{H}^1(\mathbb{Q}, A)$.

Definition 5.1.1 (Strongly Visibility). The *strongly visible* subgroup of $\mathrm{H}^1(\mathbb{Q}, A)$ for $J_0(pN)$ is

$$\mathrm{Vis}_{pN}\, \mathrm{H}^1(\mathbb{Q}, A) = \mathrm{Ker}\left(\mathrm{H}^1(\mathbb{Q}, A)^{\mathrm{odd}} \xrightarrow{\varphi_*} \mathrm{H}^1(\mathbb{Q}, J_0(pN))\right) \subset \mathrm{H}^1(\mathbb{Q}, A).$$

Also,

$$\mathrm{Vis}_{pN}\, Ш(\mathbb{Q}, A) = Ш(\mathbb{Q}, A) \cap \mathrm{Vis}_{pN}\, \mathrm{H}^1(\mathbb{Q}, A).$$

The reason we replace $\mathrm{H}^1(\mathbb{Q}, A)$ by $\mathrm{H}^1(\mathbb{Q}, A)^{\mathrm{odd}}$ is that the kernel of φ is a 2-group (see [Rib90b]).

Remark 5.1.2. We could obtain more visible subgroups by considering the map $\delta_1^* - \delta_p^*$ in Definition 5.1.1. However, the methods of this paper do not apply to this map.

For a positive integer N, let

$$\nu(N) = \frac{1}{6} \cdot \prod_{q^r \| N} (q^r + q^{r-1}) = \frac{1}{6} \cdot [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)].$$

We call the number $\nu(N)$ the *Sturm bound* (see [Stu87]).

Theorem 5.1.3. *Let $A_{/\mathbb{Q}} = A_f$ be a newform abelian subvariety of $J_0(N)$ for which $L(A_{/\mathbb{Q}}, 1) \neq 0$ and let $p \nmid N$ be a prime. Suppose that there is a maximal ideal $\lambda \subset \mathbb{T}(N)$ and an elliptic curve $E_{/\mathbb{Q}}$ of conductor pN such that:*

1. *[Nondivisibility] The residue characteristic ℓ of λ satisfies*
$$\ell \nmid 2 \cdot N \cdot p \cdot \prod_{q \mid N} c_{E,q}.$$
2. *[Component Groups] For each prime $q \mid N$,*
$$\Phi_{A,q}(\mathbb{F}_q)[\lambda] = 0.$$
3. *[Fourier Coefficients] Let $a_n(E)$ be the n-th Fourier coefficient of the modular form attached to E, and $a_n(f)$ the n-th Fourier coefficient of f. Assume that $a_p(E) = -1$,*
$$a_p(f) \equiv -(p+1) \pmod{\lambda} \quad \text{and} \quad a_q(f) \equiv a_q(E) \pmod{\lambda},$$
for all primes $q \neq p$ with $q \leq \nu(pN)$.
4. *[Irreducibility] The mod ℓ representation $\overline{\rho}_{E,\ell}$ is irreducible.*

Then there is an injective homomorphism
$$E(\mathbb{Q})/\ell E(\mathbb{Q}) \hookrightarrow \mathrm{Vis}_{pN}(\text{Ш}(\mathbb{Q}, A_f))[\lambda].$$

Remark 5.1.4. In fact, we have
$$E(\mathbb{Q})/\ell E(\mathbb{Q}) \hookrightarrow \mathrm{Ker}(\text{Ш}(\mathbb{Q}, A_f) \to \text{Ш}(\mathbb{Q}, C))[\lambda] \subset \mathrm{Vis}_{pN}(\text{Ш}(\mathbb{Q}, A_f))[\lambda],$$
where $C \subset J_0(pN)$ is isogenous to $A_f \times E$.

5.2 Some auxiliary lemmas

We will use the following lemmas in the proof of Theorem 5.1.3. The notation is as in the previous section. In addition, if $f \in S_2(\Gamma_0(N))$, we denote by $a_n(f)$ the n-th Fourier coefficient of f and by K_f and $\mathcal{O}_f$ the Hecke eigenvalue field and its ring of integers, respectively.

Lemma 5.2.1. *Suppose $A_f \subset J_0(N)$ and $A_g \subset J_0(pN)$ are attached to newforms f and g of level N and pN, respectively, with $p \nmid N$. Suppose that there is a prime ideal λ of residue characteristic $\ell \nmid 2pN$ in an integrally closed subring $\mathcal{O}$ of $\overline{\mathbb{Q}}$ that contains the ring of integers of the composite field $K = K_f K_g$ such that for $q \leq \nu(pN)$,*
$$a_q(f) \equiv \begin{cases} a_q(g) \pmod{\lambda} & \text{if } q \neq p, \\ (p+1)a_p(g) \pmod{\lambda} & \text{if } q = p. \end{cases}$$
Assume that $a_p(g) = -1$. Let $\lambda_f = \mathcal{O}_f \cap \lambda$ and $\lambda_g = \mathcal{O}_g \cap \lambda$ and assume that $A_f[\lambda_f]$ is an irreducible $G_{\mathbb{Q}}$-module. Then we have an equality
$$\varphi(A_f[\lambda_f]) = A_g[\lambda_g]$$
of subgroups of $J_0(pN)$, where φ is as in (3).

Proof. Our hypothesis that $a_p(f) \equiv -(p+1) \pmod{\lambda_f}$ implies, by the proofs in [Rib90b], that

$$\varphi(A_f[\lambda_f]) \subset \varphi(A_f) \cap J_0(pN)_{p\text{-new}},$$

where $J_0(pN)_{p\text{-new}}$ is the p-new abelian subvariety of $J_0(N)$.

By [Rib90b, Lem. 1], the operator $U_p = T_p$ on $J_0(pN)$ acts as -1 on $\varphi(A_f[\lambda_f])$. Consider the action of U_p on the 2-dimensional vector space spanned by $\{f(q), f(q^p)\}$. The matrix of U_p with respect to this basis is

$$U_p = \begin{pmatrix} a_p(f) & p \\ -1 & 0 \end{pmatrix}.$$

In particular, neither of $f(q)$ and $f(q^p)$ is an eigenvector for U_p. The characteristic polynomial of U_p acting on the span of $f(q)$ and $f(q^p)$ is $x^2 - a_p(f)x + p$. Using our hypothesis on $a_p(f)$ again, we have

$$x^2 - a_p(f)x + p \equiv x^2 + (p+1)x + p \equiv (x+1)(x+p) \pmod{\lambda}.$$

Thus we can choose an algebraic integer α such that

$$f_1(q) = f(q) + \alpha f(q^p)$$

is an eigenvector of U_p with eigenvalue congruent to -1 modulo λ. (It does not matter for our purposes whether $x^2 + a_p(f)x + p$ has distinct roots; nonetheless, since $p \nmid N$, [CV92, Thm. 2.1] implies that it does have distinct roots.) The cusp form f_1 has the same prime-indexed Fourier coefficients as f at primes other than p. Enlarge $\mathcal{O}$ if necessary so that $\alpha \in \mathcal{O}$. The p-th coefficient of f_1 is congruent modulo λ to -1 and f_1 is an eigenvector for the full Hecke algebra. It follows from the recurrence relation for coefficients of the eigenforms that

$$a_n(g) \equiv a_n(f_1) \pmod{\lambda}$$

for all integers $n \leq \nu(pN)$.

By [Stu87], we have $g \equiv f_1 \pmod{\lambda}$, so $a_q(g) \equiv a_q(f) \pmod{\lambda}$ for all primes $q \neq p$. Thus by the Brauer-Nesbitt theorem [CR62], the 2-dimensional $G_{\mathbb{Q}}$-representations $\varphi(A_f[\lambda_f])$ and $A_g[\lambda_g]$ are isomorphic.

Let $\mathfrak{m}$ be a maximal ideal of the Hecke algebra $\mathbb{T}(pN)$ that annihilates the module $A_g[\lambda_g]$. Note that $A_g[\mathfrak{m}] = A_g[\lambda_g]$ since $A_g[\mathfrak{m}] \subset A_g[\lambda_g]$ and $A_g[\lambda_g] \cong \varphi(A_f[\lambda_f])$ is irreducible as a $G_{\mathbb{Q}}$-module. The maximal ideal $\mathfrak{m}$ gives rise to a Galois representation $\overline{\rho}_{\mathfrak{m}} : G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{T}(pN)/\mathfrak{m})$ isomorphic to $A_g[\lambda_g]$, which is irreducible since the Galois module $A_f[\lambda_f]$ is irreducible. Finally, we apply [Wil95, Thm. 2.1(i)] for $H = (\mathbb{Z}/N\mathbb{Z})^\times$ (i.e., $J_H = J_0(N)$) to conclude that $J_0(N)(\overline{\mathbb{Q}})[\mathfrak{m}] \cong (\mathbb{T}(pN)/\mathfrak{m})^2$, i.e., the representation $\overline{\rho}_{\mathfrak{m}}$ occurs with multiplicity one in $J_0(pN)$. Thus

$$A_g[\lambda_g] = \varphi(A_f[\lambda_f]).$$

□

Lemma 5.2.2. *Suppose $\varphi : A \to B$ and $\psi : B \to C$ are homomorphisms of abelian varieties over a number field K, with φ an isogeny and ψ injective. Suppose n is an integer that is relatively prime to the degree of φ. If $G = \mathrm{Vis}_C(\text{Ш}(\mathbb{Q}, B))[n^\infty]$, then there is some injective homomorphism*

$$f : G \hookrightarrow \mathrm{Ker}\left\{(\psi \circ \varphi)_* : \text{Ш}(\mathbb{Q}, A) \longrightarrow \text{Ш}(\mathbb{Q}, C)\right\},$$

such that $\varphi_*(f(G)) = G$.

Proof. Let m be the degree of the isogeny $\varphi : A \to B$. Consider the complementary isogeny $\varphi' : B \to A$, which satisfies $\varphi \circ \varphi' = \varphi' \circ \varphi = [m]$. By hypothesis m is coprime to n, so $\gcd(m, \#G) = \gcd(m, n^\infty) = 1$, hence

$$\varphi_*(\varphi'_*(G)) = [m]G = G.$$

Thus $\varphi'_*(G)$ maps, via φ_*, to $G \subset \text{Ш}(\mathbb{Q}, B)$, which in turn maps to 0 in $\text{Ш}(\mathbb{Q}, C)$. □

Lemma 5.2.3. *Let M be an odd integer coprime to N and let R be the subring of $\mathbb{T}(N)$ generated by all Hecke operators T_n with $\gcd(n, M) = 1$. Then $R = \mathbb{T}(N)$.*

Proof. See the lemma on page 491 of [Wil95]. (The condition that M is odd is necessary, as there is a counterexample when $N = 23$ and $M = 2$.) □

Lemma 5.2.4. *Suppose λ is a maximal ideal of $\mathbb{T}(N)$ with generators a prime ℓ and $T_n - a_n$ (for all $n \in \mathbb{Z}$), with $a_n \in \mathbb{Z}$. For each integer $p \nmid N$, let λ_p be the ideal in $\mathbb{T}(N)$ generated by ℓ and all $T_n - a_n$, where n varies over integers coprime to p. Then $\lambda = \lambda_p$.*

Proof. Since $\lambda_p \subset \lambda$ and λ is maximal, it suffices to prove that λ_p is maximal. Let R be the subring of $\mathbb{T}(N)$ generated by Hecke operators T_n with $p \nmid n$. The quotient R/λ_p is a quotient of $\mathbb{Z}$ since each generator T_n is equivalent to an integer. Also, $\ell \in \lambda_p$, so $R/\lambda_p = \mathbb{F}_\ell$. But by Lemma 5.2.3, $R = \mathbb{T}(N)$, so $\mathbb{T}(N)/\lambda_p = \mathbb{F}_\ell$, hence λ_p is a maximal ideal. □

Lemma 5.2.5. *Suppose that A is an abelian variety over a field K. Let R be a commutative subring of $\mathrm{End}(A)$ and I an ideal of R. Then*

$$(A/A[I])[I] \cong A[I^2]/A[I],$$

where the isomorphism is an isomorphism of $R[G_K]$-modules.

Proof. Let $a + A[I]$, for some $a \in A$, be an I-torsion element of $A/A[I]$. Then by definition, $xa \in A[I]$ for each $x \in I$. Therefore, $a \in A[I^2]$. Thus $a + A[I] \mapsto a + A[I]$ determines a well-defined homomorphism of $R[G_K]$-modules

$$\varphi : (A/A[I])[I] \to A[I^2]/A[I].$$

Clearly this homomorphism is injective. It is also surjective as every element $a + A[I] \in A[I^2]/A[I]$ is I-torsion as an element of $A/A[I]$, as $Ia \in A[I]$. Therefore, φ is an isomorphism of $R[G_K]$-modules. □

Lemma 5.2.6. *Let ℓ be a prime and let $\phi : E \to E'$ be an isogeny of elliptic curves of degree coprime to ℓ defined over a number field K. If v is any place of K then $\ell \mid c_{E,v}$ if and only if $\ell \mid c_{E',v}$.*

Proof. Consider the complementary isogeny $\phi' : E' \to E$. Both ϕ and ϕ' induce homomorphisms $\phi : \Phi_{E,v}(k_v) \to \Phi_{E',v}(k_v)$ and $\phi' : \Phi_{E',v}(k_v) \to \Phi_{E,v}(k_v)$ and $\phi \circ \phi'$ and $\phi' \circ \phi$ are multiplication-by-n maps. Since $(n, \ell) = 1$ then $\# \ker \phi$ and $\# \ker \phi'$ must be coprime to ℓ which implies the statement. □

5.3 Proof of Theorem 5.1.3

Proof of Theorem 5.1.3. By [BCDT01] E is modular, so there is a rational newform $f \in S_2^{\mathrm{new}}(pN)$ which is an eigenform for the Hecke operators and an isogeny $E \to E_f$ defined over $\mathbb{Q}$, which by Hypothesis 4 can be chosen to have degree coprime to ℓ. Indeed, every cyclic rational isogeny is a composition of rational isogenies of prime degree, and E admits no rational ℓ-isogeny since $\overline{\rho}_{E,\ell}$ is irreducible.

By Hypothesis 1 the Tamagawa numbers of E are coprime to ℓ. Since E and E_f are related by an isogeny of degree coprime to ℓ, the Tamagawa numbers of E_f are also not divisible by ℓ by Lemma 5.2.6. Moreover, note that

$$E(\mathbb{Q}) \otimes \mathbb{F}_\ell \cong E_f(\mathbb{Q}) \otimes \mathbb{F}_\ell.$$

Let $\mathfrak{m}$ be the ideal of $\mathbb{T}(pN)$ generated by ℓ and $T_n - a_n(E)$ for all integers n coprime to p. Note that $\mathfrak{m}$ is maximal by Lemma 5.2.4.

Let φ be as in (3), and let $A = \varphi(A_f)$. Note that if $T_n \in \mathbb{T}(pN)$ then $T_n(E_f) \subset E_f$ since E_f is attached to a newform, and if, moreover $p \nmid n$, then $T_n(A) \subset A$ since the Hecke operators with index coprime to p commute with the degeneracy maps. Lemma 5.2.1 implies that

$$E_f[\ell] = E_f[\mathfrak{m}] = \varphi(A_f[\lambda]) \subset A,$$

so $\Psi = E_f[\ell]$ is a subgroup of A as a $G_{\mathbb{Q}}$-module. Let

$$C = (A \times E_f)/\Psi,$$

where we embed Ψ in $A \times E_f$ anti-diagonally, i.e., by the map $x \mapsto (x, -x)$. The antidiagonal map $\Psi \to A \times E_f$ commutes with the Hecke operators T_n for $p \nmid n$, so $(A \times E_f)/\Psi$ is preserved by the T_n with $p \nmid n$. Let R be the subring of $\mathrm{End}(C)$ generated by the action of all Hecke operators T_n, with $p \nmid n$. Also note that $T_p \in \mathrm{End}(J_0(pN))$ acts by Hypothesis 3 as -1 on E_f, but T_p need *not* preserve A.

Suppose for the moment that we have verified that the hypothesis of Theorem 4.1.1 are satisfied with A, $B = E_f$, C, $Q = C/B$, R as above and $K = \mathbb{Q}$. Then we obtain an injective homomorphism

$$E(\mathbb{Q})/\ell E(\mathbb{Q}) \cong E_f(\mathbb{Q})/\ell E_f(\mathbb{Q}) \hookrightarrow \mathrm{Ker}(Ш(\mathbb{Q}, A) \to Ш(\mathbb{Q}, C))[\mathfrak{m}].$$

We then apply Lemma 5.2.2 with $n = \ell$, A_f, A, and C, respectively, to see that

$$E_f(\mathbb{Q})/\ell E_f(\mathbb{Q}) \subset \mathrm{Ker}(\text{Ш}(\mathbb{Q}, A_f) \to \text{Ш}(\mathbb{Q}, C))[\lambda].$$

That $E_f(\mathbb{Q})/\ell E_f(\mathbb{Q})$ lands in the λ-torsion is because the subgroup of $\mathrm{Vis}_C(\text{Ш}(\mathbb{Q}, E_f))$ that we constructed is $\mathfrak{m}$-torsion.

Finally, consider $A \times E_f \to J_0(pN)$ given by $(x, y) \mapsto x + y$. Note that Ψ maps to 0, since $(x, -x) \mapsto 0$ and the elements of Ψ are of the form $(x, -x)$. We have a (not-exact!) sequence of maps

$$\text{Ш}(\mathbb{Q}, A_f) \to \text{Ш}(\mathbb{Q}, C) \to \text{Ш}(\mathbb{Q}, J_0(pN)),$$

hence inclusions

$$\begin{aligned} E_f(\mathbb{Q})/\ell E_f(\mathbb{Q}) &\subseteq \mathrm{Ker}(\text{Ш}(\mathbb{Q}, A_f) \to \text{Ш}(\mathbb{Q}, C)) \\ &\subseteq \mathrm{Ker}(\text{Ш}(\mathbb{Q}, A_f) \to \text{Ш}(\mathbb{Q}, J_0(pN))), \end{aligned}$$

which gives the conclusion of the theorem.

It remains to verify the hypotheses of Theorem 4.1.1. That $C = A + B$ is clear from the definition of C. Also, $A \cap E_f = E_f[\ell]$, which is finite. We explained above when defining R that each of A and E_f is preserved by R. Since $K = \mathbb{Q}$ and ℓ is odd the condition $1 = e < \ell - 1$ is satisfied. That $A(\mathbb{Q})$ is finite follows from our hypothesis that $L(A_f, 1) \neq 0$ (by [KL89]).

It remains is to verify that the groups

$$Q(\mathbb{Q})[\mathfrak{m}], \quad E_f(\mathbb{Q})[\mathfrak{m}], \quad \Phi_{A,q}(\mathbb{F}_q)[\mathfrak{m}], \quad \text{and } \Phi_{E_f,q}(\mathbb{F}_q)[\ell],$$

are 0 for all primes $q \mid pN$. Since $\ell \in \mathfrak{m}$, we have by Hypothesis 4 that

$$E_f(\mathbb{Q})[\mathfrak{m}] = E_f(\mathbb{Q})[\ell] = 0.$$

We will now verify that $Q(\mathbb{Q})[\mathfrak{m}] = 0$. From the definition of C and Ψ we have $Q \cong A/\Psi$. Let λ_p be as in Lemma 5.2.4 with $a_n = a_n(E)$. The map φ induces an isogeny of 2-power degree

$$A_f/(A_f[\lambda]) \to A/\Psi.$$

Thus there is λ_p-torsion in $(A_f/(A_f[\lambda]))(\mathbb{Q})$ if and only if there is $\mathfrak{m}$-torsion in $(A/\Psi)(\mathbb{Q})$. Thus it suffices to prove that $(A_f/A_f[\lambda])(\mathbb{Q})[\lambda_p] = 0$.

By Lemma 5.2.4, we have $\lambda_p = \lambda$, and by Lemma 5.2.5,

$$(A_f/A_f[\lambda])[\lambda] \cong A_f[\lambda^2]/A_f[\lambda].$$

By [Maz77, §II.14], the quotient $A_f[\lambda^2]/A_f[\lambda]$ injects into a direct sum of copies of $A_f[\lambda]$ as Galois modules. But $A_f[\lambda] \cong E[\ell]$ is irreducible, so $(A_f[\lambda^2]/A_f[\lambda])(\mathbb{Q}) = 0$, as required.

By Hypothesis 2, we have $\Phi_{A_f,q}(\mathbb{F}_q)[\lambda] = 0$ for each prime divisor $q \mid N$.Since A is 2-power isogenous to A_f and ℓ is odd, this verifies the Tamagawa number hypothesis for A. Our hypothesis that $a_p(E) = -1$ implies that Frob_p acts on $\Phi_{E_f,p}(\overline{\mathbb{F}}_p)$ as -1. Thus $\Phi_{E_f,p}(\mathbb{F}_p)[\ell] = 0$ since ℓ is odd. This completes the proof. □

Remark 5.3.1. An essential ingrediant in the proof of the above theorem is the multiplicity one result used in the paper of Wiles (see [Wil95, Thm. 2.1.]). Since this result holds for Jacobians J_H of the curves $X_H(N)$ that are intermediate covers for the covering $X_1(N) \to X_0(N)$ corresponding to subgroups $H \subseteq (\mathbb{Z}/N\mathbb{Z})^\times$ (i.e., the Galois group of $X_1(N) \to X_H$ is H), one should be able to give a generalization of Theorem 5.1.3 which holds for newform subvarieties of J_H. This requires generalizing some results from [Rib90b] to arbitrary H.

5.4 A Variant of Theorem 5.1.3 with Simpler Hypothesis

Proposition 5.4.1. *Suppose $A = A_f \subset J_0(N)$ is a newform abelian variety and q is a prime that exactly divides N. Suppose $\mathfrak{m} \subset \mathbb{T}(N)$ is a non-Eisenstein maximal ideal of residue characteristic ℓ and that $\ell \nmid m_A$, where m_A is the modular degree of A. Then $\Phi_{A,q}(\overline{\mathbb{F}}_q)[\mathfrak{m}] = 0$.*

Proof. The component group of $\Phi_{J_0(N),q}(\overline{\mathbb{F}}_q)$ is Eisenstein by [Rib87], so

$$\Phi_{J_0(N),q}(\overline{\mathbb{F}}_q)[\mathfrak{m}] = 0.$$

By Lemma 4.2.2, the image of $\Phi_{J_0(N),q}(\overline{\mathbb{F}}_q)$ in $\Phi_{A^\vee,q}(\overline{\mathbb{F}}_q)$ has no $\mathfrak{m}$ torsion. By the main theorem of [CS01], the cokernel $\Phi_{J_0(N),q}(\overline{\mathbb{F}}_q)$ in $\Phi_{A^\vee,q}(\overline{\mathbb{F}}_q)$ has order that divides m_A. Since $\ell \nmid m_A$, it follows that the cokernel also has no $\mathfrak{m}$ torsion. Thus Lemma 4.2.2 implies that $\Phi_{A^\vee,q}(\overline{\mathbb{F}}_q)[\mathfrak{m}] = 0$. Finally, the modular polarization $A \to A^\vee$ has degree m_A, which is coprime to ℓ, so the induced map $\Phi_{A,q}(\overline{\mathbb{F}}_q) \to \Phi_{A^\vee,q}(\overline{\mathbb{F}}_q)$ is an isomorphism on ℓ primary parts. In particular, that $\Phi_{A^\vee,q}(\overline{\mathbb{F}}_q)[\mathfrak{m}] = 0$ implies that $\Phi_{A,q}(\overline{\mathbb{F}}_q)[\mathfrak{m}] = 0$. □

If E is a semistable elliptic curve over $\mathbb{Q}$ with discriminant Δ, then we see using Tate curves that $\overline{c}_p = \mathrm{ord}_p(\Delta)$.

Theorem 5.4.2. *Suppose $A = A_f \subset J_0(N)$ is a newform abelian variety with $L(A_{/\mathbb{Q}}, 1) \neq 0$ and N square free, and let ℓ be a prime. Suppose that $p \nmid N$ is a prime, and that there is an elliptic curve E of conductor pN such that:*

1. *[Rank] The Mordell-Weil rank of $E(\mathbb{Q})$ is positive.*
2. *[Divisibility] We have $a_p(E) = -1$, $\ell \mid \overline{c}_{E,p}$, and*
$$\ell \nmid 2 \cdot N \cdot p \cdot c_{E,p} \cdot \prod_{q \mid N} \overline{c}_{E,q}.$$
3. *[Irreducibility] The mod ℓ representation $\overline{\rho}_{E,\ell}$ is irreducible.*
4. *[Noncongruence] The representation $\overline{\rho}_{E,\ell}$ is not isomorphic to any representation $\overline{\rho}_{g,\lambda}$ where $g \in S_2(\Gamma_0(N))$ is a newform of level dividing N that is not conjugate to f.*

Then there is an element of order ℓ in $Ш(\mathbb{Q}, A_f)$ that is not visible in $J_0(N)$ but is strongly visible in $J_0(pN)$. More precisely, there is an inclusion

$$E(\mathbb{Q})/\ell E(\mathbb{Q}) \hookrightarrow \mathrm{Ker}(Ш(\mathbb{Q}, A_f) \to Ш(\mathbb{Q}, C))[\lambda] \subset \mathrm{Vis}_{pN}(Ш(\mathbb{Q}, A_f))[\lambda],$$

where $C \subset J_0(pN)$ is isogenous to $A_f \times E$, the homomorphism $A_f \to C$ has degree a power of 2, and λ is the maximal ideal of $\mathbb{T}(N)$ corresponding to $\overline{\rho}_{E,\ell}$.

Proof. The divisibility assumptions of Hypothesis 2 on the $\overline{c}_{E,q}$ imply that the Serre level of $\overline{\rho}_{E,\ell}$ is N and since $\ell \nmid N$, the Serre weight is 2 (see [RS01, Thm. 2.10]). Since ℓ is odd, Ribet's level lowering theorem [Rib91] implies that there is *some* newform $h = \sum b_n q^n \in S_2(\Gamma_0(N))$ and a maximal ideal λ over ℓ such that $a_q(E) \equiv b_q \pmod{\lambda}$ for all primes $q \neq p$. By our non-congruence hypothesis, the only possibility is that h is a $G_{\mathbb{Q}}$-conjugate of f. Since we can replace f by any Galois conjugate of f without changing A_f, we may assume that $f = h$. Also $a_p(f) \equiv -(p+1) \pmod{\lambda}$, as explained in [Rib83, pg. 506].

Hypothesis 3 implies that λ is not Eisenstein, and by assumption $\ell \nmid m_A$, so Proposition 5.4.1 implies that $\Phi_{A,q}(\overline{\mathbb{F}}_q)[\lambda] = 0$ for each $q \mid N$.

The theorem now follows from Theorem 5.1.3. □

Remark 5.4.3. The condition $a_p(E) = -1$ is redundant. Indeed, we have $\overline{c}_{E,p} \neq c_{E,p}$ since $\overline{c}_{E,p}$ is divisible by ℓ and $c_{E,p}$ is not. By studying the action of Frobenius on the component group at p one can show that this implies that E has nonsplit multiplicative reduction, so $a_p(E) = -1$.

Remark 5.4.4. The non-congruence hypothesis of Theorem 5.4.2 can be verified using modular symbols as follows. Let $W \subset H_1(X_0(N), \mathbb{Z})_{\mathrm{new}}$ be the saturated submodule of $H_1(X_0(N), \mathbb{Z})$ that corresponds to all newforms in $S_2(\Gamma_0(N))$ that are not Galois conjugate to f. Let $\overline{W} = W \otimes \mathbb{F}_\ell$. We require that the intersection of the kernels of $T_q|_{\overline{W}} - a_q(E)$, for $q \neq p$, has dimension 0.

6 Computational Examples

In this section we give examples that illustrate how to use Theorem 5.4.2 to prove existence of elements of the Shafarevich-Tate group of a newform subvariety of $J_0(N)$ (for 767 and 959) which are invisible at the base level, but become visible in a modular Jacobian of higher level.

Hypothesis 6.0.5. The statements in this section all make the hypothesis that certain commands of the computer algebra system Magma [BCP97] produce correct output.

6.1 Level 767

Consider the modular Jacobian $J_0(767)$. Using the modular symbols package in Magma, one decomposes $J_0(767)$ (up to isogeny) into a product of six optimal quotients of dimensions 2, 3, 4, 10, 17 and 23. The duals of these quotients are subvarieties $A_2, A_3, A_4, A_{10}, A_{17}$ and A_{23} defined over $\mathbb{Q}$, where A_d has dimension d. Consider the subvariety A_{23}.

We first show that the Birch and Swinnerton-Dyer conjectural formula predicts that the orders of the groups $Ш(\mathbb{Q}, A_{23})$ and $Ш(\mathbb{Q}, A_{23}^{\vee})$ are both divisible by 9.

PROPOSITION 6.1.1. *Assume [AS05, Conj. 2.2]. Then*

$$3^2 \mid \#Ш(\mathbb{Q}, A_{23}) \quad \textit{and} \quad 3^2 \mid \#Ш(\mathbb{Q}, A_{23}^{\vee}).$$

Proof. Let $A = A_{23}^{\vee}$. We use [AS05, §3.5 and §3.6] (see also [Ka81]) to compute a multiple of the order of the torsion subgroup $A(\mathbb{Q})_{\mathrm{tor}}$. This multiple is obtained by injecting the torsion subgroup into the group of $\mathbb{F}_p$-rational points on the reduction of A for odd primes p of good reduction and then computing the order of that group. Hence, the multiple is an isogeny invariant, so one gets the same multiple for $A^{\vee}(\mathbb{Q})_{\mathrm{tor}}$. For producing a divisor of $\#A(\mathbb{Q})_{\mathrm{tor}}$, we use the injection of the subgroup of rational cuspidal divisor classes of degree 0 into $A(\mathbb{Q})_{\mathrm{tor}}$. Using the implementation in Magma we obtain $120 \mid \#A(\mathbb{Q})_{\mathrm{tor}} \mid 240$. To compute a divisor of $A^{\vee}(\mathbb{Q})_{\mathrm{tor}}$, we use the algorithm described in [AS05, §3.3] to find that the modular degree $m_A = 2^{34}$, which is not divisible by any odd primes, hence $15 \mid \#A^{\vee}(\mathbb{Q})_{\mathrm{tor}} \mid 240$.

Next, we use [AS05, §4] to compute the ratio of the special value of the L-function of $A_{/\mathbb{Q}}$ at 1 over the real Néron period Ω_A. We obtain $\dfrac{L(A_{/\mathbb{Q}}, 1)}{\Omega_A} = c_A \cdot \dfrac{2^9 \cdot 3}{5}$, where $c_A \in \mathbb{Z}$ is the Manin constant. Since $c_A \mid 2^{\dim(A)}$ by [ARS06] then

$$\frac{L(A_{/\mathbb{Q}}, 1)}{\Omega_A} = \frac{2^{n+2} \cdot 3}{5},$$

for some $0 \leq n \leq 23$. In particular, the modular abelian variety $A_{/\mathbb{Q}}$ has rank zero over $\mathbb{Q}$.

Next, using the algorithms from [CS01, KS00] we compute the Tamagawa number $c_{A,13} = 1920 = 2^3 \cdot 3 \cdot 5$. We also find that $2 \mid c_{A,59}$ is a power of 2 because W_{59} acts as 1 on A, and on the component group $\mathrm{Frob}_{59} = -W_{59}$, so the fixed subgroup $\Phi_{A,59}(\mathbb{F}_{59})$ of Frobenius is a 2-group (for more details, see [Rib90a, Prop. 3.7–8]).

Finally, the Birch and Swinnerton-Dyer conjectural formula for abelian varieties of Mordell-Weil rank zero (see [AS05, Conj. 2.2]) asserts that

$$\frac{L(A_{/\mathbb{Q}}, 1)}{\Omega_A} = \frac{\#Ш(\mathbb{Q}, A) \cdot c_{A,13} \cdot c_{A,59}}{\#A(\mathbb{Q})_{\mathrm{tor}} \cdot \#A^{\vee}(\mathbb{Q})_{\mathrm{tor}}}.$$

By substituting what we computed above, we obtain $3^2 \mid \#Ш(\mathbb{Q}, A)$. Since $L(A_{/\mathbb{Q}}, 1) \neq 0$, [KL89] implies that $Ш(\mathbb{Q}, A)$ is finite. By the nondegeneracy of the Cassels-Tate pairing, $\#Ш(\mathbb{Q}, A) = \#Ш(A^{\vee}/\mathbb{Q})$. Thus, if the BSD conjectural formula is true then $3^2 \mid \#Ш(\mathbb{Q}, A) = \#Ш(\mathbb{Q}, A^{\vee})$. □

We next observe that there are no visible elements of odd order for the embedding $A_{23/\mathbb{Q}} \hookrightarrow J_0(767)_{/\mathbb{Q}}$.

Lemma 6.1.2. *Any element of* $Ш(\mathbb{Q}, A_{23})$ *which is visible in* $J_0(767)$ *has order a power of* 2.

Proof. Since $m_{A_{23}} = 2^{34}$, [AS05, Prop. 3.15] implies that any element of $Ш(\mathbb{Q}, A_{23})$ that is visible in $J_0(767)$ has order a power of 2. □

Finally, we use Theorem 5.4.2 to prove the existence of non-trivial elements of order 3 in $Ш(\mathbb{Q}, A_{23})$ which are invisible at level 767, but become visible at higher level. In particular, we prove unconditionally that $3 \mid \#Ш(\mathbb{Q}, A_{23})$ which provides evidence for the Birch and Swinnerton-Dyer conjectural formula.

Proposition 6.1.3. *There is an element of order 3 in* $Ш(\mathbb{Q}, A_{23})$ *which is not visible in* $J_0(767)$ *but is strongly visible in* $J_0(2 \cdot 767)$.

Proof. Let $A = A_{23}$, and note that A has rank 0, since $L(A_{/\mathbb{Q}}, 1) \neq 0$. Using Cremona's database [Cre] we find that the elliptic curve

$$E : \qquad y^2 + xy = x^3 - x^2 + 5x + 37$$

has conductor $2 \cdot 767$ and Mordell-Weil group $E(\mathbb{Q}) = \mathbb{Z} \oplus \mathbb{Z}$. Also

$$c_2 = 2, c_{13} = 2, c_{59} = 1, \bar{c}_2 = 6, \bar{c}_{13} = 2, \bar{c}_{59} = 1.$$

We apply Theorem 5.4.2 with $\ell = 3$ and $p = 2$. Since E does not admit any rational 3-isogeny (by [Cre]), Hypothesis 3 is satisfied. The level is square free and the modular degree of A is a power of 2, so Hypothesis 2 is satisfied.

We have $a_3(E) = -3$. Using Magma we find

$$\det(T_3|_{\overline{W}} - (-3)) \equiv 1 \pmod{3},$$

which verifies the noncongruence hypothesis and completes the proof.

□

6.2 Level 959

We do similar computations for a 24-dimensional abelian subvariety of $J_0(959)$. We have $959 = 7 \cdot 137$, which is square free. There are five newform abelian subvarieties of the Jacobian, A_2, A_7, A_{10}, A_{24} and A_{26}, whose dimensions are the corresponding subscripts. Let $A_f = A_{24}$ be the 24-dimensional newform abelian subvariety.

Proposition 6.2.1. *There is an element of order 3 in* $Ш(A_f/\mathbb{Q})$ *which is not visible in* $J_0(959)$ *but is strongly visible in* $J_0(2 \cdot 959)$.

Proof. Using Magma we find that $m_A = 2^{32} \cdot 583673$, which is coprime to 3. Thus we apply Theorem 5.4.2 with $\ell = 3$ and $p = 2$. Consulting [Cre] we find the curve E=1918C1, with Weierstrass equation

$$y^2 + xy + y = x^3 - 22x - 24,$$

with Mordell-Weil group $E(\mathbb{Q}) \cong \mathbb{Z} \oplus \mathbb{Z} \oplus (\mathbb{Z}/2\mathbb{Z})$, and

$$c_2 = 2, c_7 = 2, c_{137} = 1, \bar{c}_2 = 6, \bar{c}_7 = 2, \bar{c}_{137} = 1.$$

Using [Cre] we find that E has no rational 3-isogeny. The modular form attached to E is

$$g = q - q^2 - 2q^3 + q^4 - 2q^5 + \cdots ,$$

and we have

$$\det(T_2|_{\overline{W}} - (-2)) = 2177734400 \equiv 2 \pmod 3,$$

which completes the verification. □

7 Conjecture, evidence and more computational data

We state several conjectures, provide some evidence and finally, provide a table that we computed using similar techniques to those in Section 6

7.1 The conjecture

The two examples computed in Section 6 show that for an abelian subvariety A of $J_0(N)$ an invisible element of $\text{Ш}(\mathbb{Q}, A)$ at the base level N might become visible at a multiple level NM. We state a general conjecture according to which any element of $\text{Ш}(\mathbb{Q}, A)$ should have such a property.

Conjecture 7.1.1. *Let $h = 0$ or 1. Suppose A is a J_h-modular abelian variety and $c \in \text{Ш}(\mathbb{Q}, A)$. Then there is a J_h-modular abelian variety C and an inclusion $\iota : A \to C$ such that $\iota_* c = 0$.*

Remark 7.1.2. For any prime ℓ, the Jacobian $J_h(N)$ comes equipped with two morphisms $\alpha^*, \beta^* : J_h(N) \to J_h(N\ell)$ induced by the two degeneracy maps $\alpha, \beta : X_h(\ell N) \to X_h(N)$ between the modular curves of levels ℓN and N, and it is natural to consider visibility of $\text{Ш}(\mathbb{Q}, A)$ in $J_h(N\ell)$ via morphisms ι constructed from these degeneracy maps.

Remark 7.1.3. It would be interesting to understand the set of all levels N of J_h-modular abelian varieties C that satisfy the conclusion of the conjecture.

7.2 Theoretical Evidence for the Conjectures

The first piece of theoretical evidence for Conjecture 7.1.1 is Remark 3.0.2, according to which any cohomology class $c \in \mathrm{H}^1(K, A)$ is visible in some abelian variety $C_{/K}$.

The next proposition gives evidence for elements of $Ш(\mathbb{Q}, E)$ for an elliptic curve E and elements of order 2 or 3.

Proposition 7.2.1. *Suppose E is an elliptic curve over $\mathbb{Q}$. Then Conjecture 7.1.1 for $h = 0$ is true for all elements of order 2 and 3 in $Ш(\mathbb{Q}, E)$.*

Proof. We first show that there is an abelian variety C of dimension 2 and an injective homomorphism $i : E \hookrightarrow C$ such that $c \in \mathrm{Vis}_C(Ш(\mathbb{Q}, E))$. If c has order 2, this follows from [AS02, Prop. 2.4] or [Kle01], and if c has order 3, this follows from [Maz99, Cor. pg. 224]. The quotient C/E is an elliptic curve, so C is isogenous to a product of two elliptic curves. Thus by [BCDT01], C is a quotient of $J_0(N)$, for some N. □

We also prove that Conjecture 7.1.1 is true with $h = 1$ for all elements of $Ш(\mathbb{Q}, A)$ which split over abelian extensions.

Proposition 7.2.2. *Suppose $A_{/\mathbb{Q}}$ is a J_1-modular abelian variety over $\mathbb{Q}$ and $c \in Ш(\mathbb{Q}, A)$ splits over an abelian extension of $\mathbb{Q}$. Then Conjecture 7.1.1 is true for c with $h = 1$.*

Proof. Suppose K is an abelian extension such that $\mathrm{res}_K(c) = 0$ and let $C = \mathrm{Res}_{K/\mathbb{Q}}(A_K)$. Then c is visible in C (see Section 3.0.2). It remains to verify that C is modular. As discussed in [Mil72, pg. 178], for any abelian variety B over K, we have an isomorphism of Tate modules

$$\mathrm{Tate}_\ell(\mathrm{Res}_{K/\mathbb{Q}}(B_K)) \cong \mathrm{Ind}_{G_K}^{G_\mathbb{Q}} \mathrm{Tate}_\ell(B_K),$$

and by Faltings's isogeny theorem [Fal86], the Tate module determines an abelian variety up to isogeny. Thus if $B = A_f$ is an abelian variety attached to a newform, then $\mathrm{Res}_{K/\mathbb{Q}}(B_K)$ is isogenous to a product of abelian varieties A_{f^χ}, where χ runs through Dirichlet characters attached to the abelian extension $K/\mathbb{Q}$. Since A is isogenous to a product of abelian varieties of the form A_f (for various f), it follows that the restriction of scalars C is modular. □

Remark 7.2.3. Suppose that E is an elliptic curve and $c \in Ш(\mathbb{Q}, E)$. Is there an abelian extension $K/\mathbb{Q}$ such that $\mathrm{res}_K(c) = 0$? The answer is "yes" if and only if there is a K-rational point (with K-abelian) on the locally trivial principal homogeneous space corresponding to c (this homogenous space is a genus one curve). Recently, M. Ciperiani and A. Wiles proved that any genus one curve over $\mathbb{Q}$ which has local points everywhere and whose Jacobian is a semistable elliptic curve admits a point over a solvable extension of $\mathbb{Q}$ (see [CW06]). Unfortunately, this paper does not answer our question about the existence of abelian points.

Remark 7.2.4. As explained in [Ste04], if $K/\mathbb{Q}$ is an abelian extension of prime degree then there is an exact sequence

$$0 \to A \to \mathrm{Res}_{K/\mathbb{Q}}(E_K) \xrightarrow{\mathrm{Tr}} E \to 0,$$

where A is an abelian variety with $L(A_{/\mathbb{Q}}, s) = \prod L(f_i, s)$ (here, the f_i's are the $G_{\mathbb{Q}}$-conjugates of the twist of the newform f_E attached to E by the Dirichlet character associated to $K/\mathbb{Q}$). Thus one could approach the question in the previous remark by investigating whether or not $L(f_E, \chi, 1) = 0$ which one could do using modular symbols (see [CFK06]). The authors expect that L-functions of twists of degree larger than three are very unlikely to vanish at $s = 1$ (see [CFK06]), which suggests that in general, the question might have a negative answer for cohomology classes of order larger than 3.

7.3 Visibility of Kolyvagin cohomology classes

It would also be interesting to study visibility at higher level of Kolyvagin cohomology classes. The following is a first "test question" in this direction.

Question 7.3.1. Suppose $E \subset J_0(N)$ is an elliptic curve with conductor N, and fix a prime ℓ such that $\overline{\rho}_{E,\ell}$ is surjective. Fix a quadratic imaginary field K that satisfies the Heegner hypothesis for E. For any prime p satisfying the conditions of [Rub89, Prop. 5], let $c_p \in \mathrm{H}^1(\mathbb{Q}, E)[\ell]$ be the corresponding Kolyvagin cohomology class. There are two natural homomorphisms $\delta_1^*, \delta_p^* : E \to J_0(Np)$. When is

$$(\delta_1^* \pm \delta_\ell^*)_*(c_\ell) = 0 \in \mathrm{H}^1(\mathbb{Q}, J_0(Np))?$$

When is

$$\mathrm{res}_v((\delta_1^* \pm \delta_\ell^*)_*(c_\ell)) = 0 \in \mathrm{H}^1(\mathbb{Q}_v, J_0(Np))?$$

7.4 Table of Strong Visibility at Higher Level

The following is a table that gives the known examples of $A_{f_{/\mathbb{Q}}}$ with square free conductor $N \leq 1339$, such that the Birch and Swinnerton-Dyer conjectural formula predicts an odd prime divisor ℓ of $Ш(\mathbb{Q}, A_f)$, but ℓ does not divide the modular degree of A_f. These were taken from [AS05]. If there is an entry in the fourth column, this means we have verified the hypothesis of Theorem 5.4.2, hence there really is a nonzero element in $Ш(\mathbb{Q}, A_f)$ that is not visible in $J_0(N)$, but is strongly visible in $J_0(pN)$. The notation in the fourth column is (p, E, q), where p is the prime used in Theorem 5.4.2, E is an elliptic curve, denoted using a Cremona label, and $q \neq p$ is a prime such that

$$\bigcap_{q' \leq q} \mathrm{Ker}(T'_q|_{\overline{W}} - a_{q'}(E)) = 0.$$

A_f	dim	$\ell \mid Ш(A_f)_?$	moddeg	(p, E, q)'s
551H	18	3	$2^? \cdot 13^2$	(2, 1102A1, -)
767E	23	3	2^{34}	(2, 1534B1, 3)
959D	24	3	$2^{32} \cdot 583673$	(2, 1918C1, 5), (7, 5369A1,2)
1337E	33	3	$2^{59} \cdot 71$	(2, 2674A1, 5)
1339G	30	3	$2^{48} \cdot 5776049$	(2, 2678B1, 3), (11, 14729A1,2)

25 Computation of p-Adic Heights and Log Convergence, with B. Mazur and J. Tate

Computation of p-Adic Heights and Log Convergence

In celebration of John Coates' 60th birthday

Abstract.

This paper is about computational and theoretical questions regarding p-adic height pairings on elliptic curves over a global field K. The main stumbling block to computing them efficiently is in calculating, for each of the completions K_v at the places v of K dividing p, a *single quantity*: the value of the p-adic modular form $\mathbf{E}_2$ associated to the elliptic curve. Thanks to the work of Dwork, Katz, Kedlaya, Lauder and Monsky-Washnitzer we offer an efficient algorithm for computing these quantities, i.e., for computing the value of $\mathbf{E}_2$ of an elliptic curve. We also discuss the p-adic convergence rate of canonical expansions of the p-adic modular form $\mathbf{E}_2$ on the Hasse domain. In particular, we introduce a new notion of log convergence and prove that $\mathbf{E}_2$ is log convergent.

1 Introduction

Let p be an odd prime number, and E an elliptic curve over a global field K that has good ordinary reduction at p. Let L be any (infinite degree) Galois extension with a continuous injective homomorphism ρ of its Galois group to $\mathbf{Q}_p$. To the data (E, K, ρ), one associates[2] a canonical (bilinear, symmetric) (p-adic) height pairing

$$(\ ,\ )_\rho : E(K) \times E(K) \longrightarrow \mathbf{Q}_p.$$

Such pairings are of great interest for the arithmetic of E over K, and they arise specifically in p-adic analogues of the Birch and Swinnerton-Dyer conjecture.[3]

The goal of this paper is to discuss some computational questions regarding p-adic height pairings. The main stumbling block to computing them efficiently is in calculating, for each of the completions K_v at the places v of K dividing p, the value of the p-adic modular form $\mathbf{E}_2$ associated to the elliptic curve with a chosen Weierstrass form of good reduction over K_v.

We shall offer an algorithm for computing these quantities, i.e., for computing the value of $\mathbf{E}_2$ of an elliptic curve (that builds on the works of Katz and Kedlaya listed in our bibliography) and we also discuss the p-adic convergence rate of canonical expansions of the p-adic modular form $\mathbf{E}_2$ on the Hasse domain, where for $p \geq 5$ we view $\mathbf{E}_2$ as an infinite sum of classical modular forms divided by powers of the (classical) modular form $\mathbf{E}_{p-1}$, while for $p \leq 5$ we view it as a sum of classical modular forms divided by powers of $\mathbf{E}_4$.

We were led to our fast method of computing $\mathbf{E}_2$ by our realization that the more naive methods, of computing it by integrality or by approximations to it as function on the Hasse domain, were not practical, because the convergence is "logarithmic" in the sense that the nth convergent gives only an accuracy of $\log_p(n)$. We make this notion of log convergence precise in Part II, where we also prove that $\mathbf{E}_2$ is log convergent.

The reason why this constant $\mathbf{E}_2$ enters the calculation is because it is needed for the computation of the p-adic sigma function [MT91], which in turn is the critical element in the formulas for height pairings.

For example, let us consider the *cyclotomic* p-adic height pairing in the special case where $K = \mathbf{Q}$ and $p \geq 5$.

If $G_{\mathbf{Q}}$ is the Galois group of an algebraic closure of $\mathbf{Q}$ over $\mathbf{Q}$, we have the natural surjective continuous homomorphism $\chi : G_{\mathbf{Q}} \to \mathbf{Z}_p^*$ pinned down by the standard formula $g(\zeta) = \zeta^{\chi(g)}$ where $g \in G_{\mathbf{Q}}$ and ζ is any p-power root of unity. The p-adic logarithm $\log_p : \mathbf{Q}_p^* \to (\mathbf{Q}_p, +)$ is the unique group homomorphism with $\log_p(p) = 0$ that extends the homomorphism $\log_p : 1 + p\mathbf{Z}_p \to \mathbf{Q}_p$ defined by the usual power series of $\log(x)$ about 1. Explicitly, if $x \in \mathbf{Q}_p^*$, then

$$\log_p(x) = \frac{1}{p-1} \cdot \log_p(u^{p-1}),$$

[2] See [MT83], [Sch82] [Sch85], [Zar90], [Col91], [Nek93], [Pla94], [IW03], and [Bes04].

[3] See [Sch82], [Sch85] [MT83], [MT87], [PR03a]. See also the important recent work of Jan Nekovář [Nek03].

where $u = p^{-\operatorname{ord}_p(x)} \cdot x$ is the unit part of x, and the usual series for log converges at u^{p-1}.

The composition $(\frac{1}{p} \cdot \log_p) \circ \chi$ is a cyclotomic linear functional $G_{\mathbf{Q}} \to \mathbf{Q}_p$ which, in the body of our text, will be dealt with (thanks to class field theory) as the idele class functional that we denote $\rho_{\mathbf{Q}}^{\text{cycl}}$.

Let $\mathcal{E}$ denote the Néron model of E over $\mathbf{Z}$. Let $P \in E(\mathbf{Q})$ be a non-torsion point that reduces to $0 \in E(\mathbf{F}_p)$ and to the connected component of $\mathcal{E}_{\mathbf{F}_\ell}$ at all primes ℓ of bad reduction for E. Because $\mathbf{Z}$ is a unique factorization domain, any nonzero point $P = (x(P), y(P)) \in E(\mathbf{Q})$ can be written uniquely in the form $(a/d^2, b/d^3)$, where $a, b, d \in \mathbf{Z}$, $\gcd(a, d) = \gcd(b, d) = 1$, and $d > 0$. The function $d(P)$ assigns to P this square root d of the denominator of $x(P)$.

Here is the formula for the *cyclotomic* p-adic height of P, i.e., the value of

$$h_p(P) := -\frac{1}{2}(P, P)_p \in \mathbf{Q}_p$$

where $(\ ,\ )_p$ is the height pairing attached to $G_{\mathbf{Q}} \to \mathbf{Q}_p$, the cyclotomic linear functional described above:

$$h_p(P) = \frac{1}{p} \cdot \log_p \left(\frac{\sigma(P)}{d(P)} \right) \in \mathbf{Q}_p. \tag{1.1}$$

Here $\sigma = \sigma_p$ is the p-adic sigma function of [MT91] associated to the pair (E, ω). The σ-function depends only on (E, ω) and not on a choice of Weierstrass equation, and behaves like a modular form of weight -1, that is $\sigma_{E,c\omega} = c \cdot \sigma_{E,\omega}$. It is "quadratic" the sense that for any $m \in \mathbf{Z}$ and point Q in the formal group $E^f(\overline{\mathbf{Z}}_p)$, we have

$$\sigma(mQ) = \sigma(Q)^{m^2} \cdot f_m(Q), \tag{1.2}$$

where f_m is the mth division polynomial of E relative to ω (as in [MT91, App. 1]). The σ-function is "bilinear" in that for any $P, Q \in E^f(\mathbf{Z}_p)$, we have

$$\frac{\sigma(P - Q) \cdot \sigma(P + Q)}{\sigma^2(P) \cdot \sigma^2(Q)} = x(Q) - x(P). \tag{1.3}$$

See [MT91, Thm. 3.1] for proofs of the above properties of σ.

The height function h_p of (1.1) extends uniquely to a function on the full Mordell-Weil group $E(\mathbf{Q})$ that satisfies $h_p(nQ) = n^2 h_p(Q)$ for all integers n and $Q \in E(\mathbf{Q})$. For $P, Q \in E(\mathbf{Q})$, setting

$$(P, Q)_p = h_p(P) + h_p(Q) - h_p(P + Q),$$

we obtain a pairing on $E(\mathbf{Q})$. The *p-adic regulator* of E is the discriminant of the induced pairing on $E(\mathbf{Q})_{/\text{tor}}$ (well defined up to sign), and we have the following standard conjecture about this height pairing.

Conjecture 1.1. *The cyclotomic height pairing $(\ ,\ )_p$ is nondegenerate; equivalently, the p-adic regulator is nonzero.*

Remark 1.2. Height pairings attached to other p-adic linear functionals can be degenerate; in fact, given an elliptic curve defined over $\mathbf{Q}$ with good ordinary reduction at p, and K a quadratic imaginary field over which the Mordell-Weil group $E(K)$ is of odd rank, the p-adic anticyclotomic height pairing for E over K is *always* degenerate.

The p-adic σ function is the most mysterious quantity in (1.1). There are many ways to define σ, e.g., [MT91] contains 11 different characterizations of σ! We now describe a characterization that leads directly to an algorithm (see Algorithm 3.3) to compute $\sigma(t)$. Let

$$x(t) = \frac{1}{t^2} + \cdots \in \mathbf{Z}_p((t)) \tag{1.4}$$

be the formal power series that expresses x in terms of the local parameter $t = -x/y$ at infinity. The following theorem, which is proved in [MT91], uniquely determines σ and c.

Theorem 1.3. *There is exactly one odd function $\sigma(t) = t + \cdots \in t\mathbf{Z}_p[[t]]$ and constant $c \in \mathbf{Z}_p$ that together satisfy the differential equation*

$$x(t) + c = -\frac{d}{\omega}\left(\frac{1}{\sigma}\frac{d\sigma}{\omega}\right), \tag{1.5}$$

where ω is the invariant differential $dx/(2y + a_1x + a_3)$ associated with our chosen Weierstrass equation for E.

Remark 1.4. The condition that σ is odd and that the coefficient of t is 1 are essential.

In (1.1), by $\sigma(P)$ we mean $\sigma(-x/y)$, where $P = (x, y)$. We have thus given a complete definition of $h_p(Q)$ for any point $Q \in E(\mathbf{Q})$ and a prime $p \geq 5$ of good ordinary reduction for E.

1.1 The p-adic σ-function

The differential equation (1.5) leads to a slow algorithm to compute $\sigma(t)$ to any desired precision. This is Algorithm 3.3 below, which we now summarize. If we expand (1.5), we can view c as a formal variable and solve for $\sigma(t)$ as a power series with coefficients that are polynomials in c. Each coefficient of $\sigma(t)$ must be in $\mathbf{Z}_p$, so we obtain conditions on c modulo powers of p. Taking these together for many coefficients must eventually yield enough information to compute $c \pmod{p^n}$, for a given n, hence $\sigma(t) \pmod{p^n}$. This integrality algorithm is hopelessly slow in general.

Another approach to computing σ is to observe that, up to a constant, c is closely related to the value of a certain p-adic modular form. More precisely, suppose that E is given by a (not necessarily minimal) Weierstrass equation

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \tag{1.6}$$

and let $\omega = dx/(2y + a_1 x + a_3)$. Let $x(t)$ be as in (1.4). Then the series

$$\wp(t) = x(t) + \frac{a_1^2 + 4a_2}{12} \in \mathbf{Q}((t)) \tag{1.7}$$

satisfies $(\wp')^2 = 4\wp^3 - g_2\wp - g_3$. In [MT91] we find[4] that

$$x(t) + c = \wp(t) - \frac{1}{12} \cdot \mathbf{E}_2(E, \omega), \tag{1.8}$$

where $\mathbf{E}_2(E, \omega)$ is the value of the Katz p-adic weight 2 Eisenstein series at (E, ω), and the equality is of elements of $\mathbf{Q}_p((t))$. Using the definition of $\wp(t)$ and solving for c, we find that

$$c = \frac{a_1^2 + 4a_2}{12} - \frac{1}{12}\mathbf{E}_2(E, \omega). \tag{1.9}$$

Thus computing c is equivalent to computing the p-adic number $\mathbf{E}_2(E, \omega)$. Having computed c to some precision, we then solve for σ in (1.5) using Algorithm 3.1 below.

1.2 p-adic analogues of the Birch and Swinnerton-Dyer conjecture

One motivation for this paper is to provide tools for doing computations in support of p-adic analogues of the BSD conjectures (see [MTT86]), especially when $E/\mathbf{Q}$ has rank at least 2. For example, in [PR03b], Perrin-Riou uses her results about the p-adic BSD conjecture in the supersingular case to prove that $Ш(E/\mathbf{Q})[p] = 0$ for certain p and elliptic curves E of rank > 1, for which the work of Kolyvagin and Kato does not apply.

Another motivation for this work comes from the study of the fine structure of Selmer modules. Let K be a number field and Λ the p-adic integral group ring of the Galois group of the maximal $\mathbf{Z}_p$-power extension of K. Making use of fundamental results of Nekovář [Nek03] and of Greenberg [Gre03] one can construct (see [RM05]) for certain elliptic curves defined over K, a skew-Hermitian matrix with coefficients in Λ from which one can read off a free Λ-resolution of the canonical Selmer Λ-module of the elliptic curve in question over K. To compute the entries of this matrix modulo the square of the augmentation ideal in Λ one must know *all* the p-adic height pairings of the elliptic curve over K. Fast algorithms for doing this provide us with an important first stage in the computation of free Λ-resolutions of Selmer Λ-modules.

The paper [GJP$^+$05] is about computational verification of the full Birch and Swinnerton-Dyer conjecture for specific elliptic curves E. There are many cases in which the rank of E is 1 and the upper bound on $\#Ш(E/\mathbf{Q})$ coming from Kolyvagin's Euler system is divisible by a prime $p \geq 5$ that also divides a Tamagawa number. In such cases, theorems of Kolyvagin and Kato combined

[4] There is a sign error in [MT91].

with explicit computation do not give a sufficiently sharp upper bound on $\#\text{Ш}(E/\mathbf{Q})$. However, it should be possible in these cases to compute p-adic heights and p-adic L-functions, and use results of Kato, Schneider, and others to obtain better bounds on $\#\text{Ш}(E/\mathbf{Q})$. Wuthrich and the second author (Stein) are writing a paper on this.

1.3 Sample computations

In Section 4 we illustrate our algorithms with curves of ranks $1, 2, 3, 4$ and 5, and two twists of $X_0(11)$ of rank 2.

Acknowledgement: It is a pleasure to thank Nick Katz for feedback that led to Section 3. We would also like to thank Mike Harrison for discussions about his implementation of Kedlaya's algorithm in Magma, Kiran Kedlaya for conversations about his algorithm, Christian Wuthrich for feedback about computing p-adic heights, Alan Lauder for discussions about computing $\mathbf{E}_2$ in families, and Fernando Gouvea for remarks about non-overconvergence of $\mathbf{E}_2$. We would also like to thank all of the above people for comments on early drafts of the paper. Finally, we thank Jean-Pierre Serre for the proof of Lemma 6.6.

Part I
Heights, σ-functions, and $\mathbf{E}_2$

2 The Formulas

In this section we give formulas for the p-adic height pairing in terms of the σ function. We have already done this over $\mathbf{Q}$ in Section 1. Let p be an (odd) prime number, K a number field, and E an elliptic curve over K with good ordinary reduction at all places of K above p. For any non-archimedean place w of K, let k_w denote the residue class field at w.

2.1 General global height pairings

By the *idele class* $\mathbf{Q}_p$*-vector space* of K let us mean

$$I(K) = \mathbf{Q}_p \otimes_{\mathbf{Z}} \left\{ \mathbf{A}_K^*/ \left(K^* \cdot \prod_{v \nmid p} \mathcal{O}_v^* \cdot \mathrm{C} \right) \right\},$$

where $\mathbf{A}_K^*$ is the group of ideles of K, and C denotes its connected component containing the identity. Class field theory gives us an identification $I(K) = \Gamma(K) \otimes_{\mathbf{Z}_p} \mathbf{Q}_p$, where $\Gamma(K)$ is the Galois group of the maximal $\mathbf{Z}_p$-power extension of K. For every (nonarchimedean) place v of K, there is a natural homomorphism $\iota_v : K_v^* \to I(K)$.

For K-rational points $\alpha, \beta \in E(K)$ we want to give explicit formulas for an element that we might call the “universal” p-adic height pairing of α and β; denote it $(\alpha, \beta) \in I(K)$. If $\rho : I(K) \to \mathbf{Q}_p$ is any linear functional, then the *ρ-height pairing* is a symmetric bilinear pairing

$$(\ , \ )_\rho : E(K) \times E(K) \to \mathbf{Q}_p,$$

defined as the composition of the universal pairing with the linear functional ρ:

$$(\alpha, \beta)_\rho = \rho(\alpha, \beta) \in \mathbf{Q}_p.$$

We define the *ρ-height* of a point $\alpha \in E(K)$ by:

$$h_\rho(\alpha) = -\frac{1}{2}(\alpha, \alpha)_\rho \in \mathbf{Q}_p.$$

Of course, any such (nontrivial) linear functional ρ uniquely determines a $\mathbf{Z}_p$-extension, and we sometimes refer to the ρ-height pairing in terms of this $\mathbf{Z}_p$-extension. E.g., if ρ cuts out the cyclotomic $\mathbf{Z}_p$-extension, then the ρ-height pairing is a normalization of the *cyclotomic height pairing* that has, for the rational field, already been discussed in the introduction.

If K is quadratic imaginary, and ρ is the anti-cyclotomic linear functional, meaning that it is the unique linear functional (up to normalization) that has the property that $\rho(\bar{x}) = -\rho(x)$ where $\bar{x}$ is the complex conjugate of x, then we will be presently obtaining explicit formulas for this anti-cyclotomic height pairing.

We will obtain a formula for $(\alpha, \beta) \in I(K)$ by defining, for every nonarchimedean place, v, of K a “local height pairing,” $(\alpha, \beta)_v \in K_v^*$. These local pairings will be very sensitive to some auxiliary choices we make along the way, but for a fixed α and β the local height pairings $(\alpha, \beta)_v$ will vanish for all but finitely many places v; the global height is the sum of the local ones and will be independent of all the choices we have made.

2.2 Good representations

Let $\alpha, \beta \in E(K)$. By a *good representation* of the pair α, β we mean that we are given a four-tuple of points (P, Q, R, S) in $E(K)$ (or, perhaps, in $E(K')$ where K'/K is a number field extension of K) such that

- α is the divisor class of the divisor $[P] - [Q]$ of E, and β is the divisor class of the divisor $[R] - [S]$,
- P, Q, R, S are four distinct points,
- for each $v \mid p$ all four points P, Q, R, S specialize to the same point on the fiber at v of the Néron model of E.
- at all places v of K the points P, Q, R, S specialize to the same component of the fiber at v of the Néron model of E.

We will show how to erase these special assumptions later, but for now, let us assume all this, fix a choice of a good representation, P, Q, R, S, of (α, β) as above, and give the formulas in this case.

2.3 Local height pairings when $v \mid p$

Let σ_v be the canonical p-adic σ-function attached to the elliptic curve E over K_v given in Weierstrass form. We may view σ_v as a mapping from $E_1(K_v)$ to K_v^*, where $E_1(K_v)$ is the kernel of the reduction map $E(K_v) \to E(k_v)$, and $E(k_v)$ denotes the group of points on the reduction of E modulo v. Define $(\alpha, \beta)_v \in K_v^*$ by the formula,

$$(\alpha, \beta)_v = \frac{\sigma_v(P-R)\sigma_v(Q-S)}{\sigma_v(P-S)\sigma_v(Q-R)} \ \in \ K_v^*.$$

The dependence of σ on the Weierstrass equation is through the differential $\omega = dx/(2y + a_1 x + a_3)$, and $\sigma_{c\omega} = c\sigma_\omega$, so this depends upon the choice of P, Q, R, S, but does not depend on the choice of Weierstrass equation for E.

2.4 Local height pairings when $v \nmid p$

First let x denote the "x-coordinate" in some minimal Weierstrass model for A at v. Define for a point T in $E(K_v)$ the rational number $\lambda_v(T)$ to be *zero* if $x(T) \in \mathcal{O}_v$, and to be $-\frac{1}{2}v(x(T))$ if $x(T) \notin \mathcal{O}_v$.

Next, choose a uniformizer π_v of K_v and define:

$$\tilde{\sigma}_v(T) = \pi_v^{\lambda_v(T)},$$

the square of which is in K_v^*. We think of $\tilde{\sigma}_v$ as a rough replacement for σ_v in the following sense. The v-adic valuation of $\tilde{\sigma}_v$ is the same as v-adic valuation of the v-adic sigma function (if such a function is definable at v) and therefore, even if σ_v cannot be defined, $\tilde{\sigma}_v$ is a perfectly serviceable substitute at places v at which our p-adic idele class functionals ρ are necessarily unramified, and therefore sensitive only to the v-adic valuation.

For $v \nmid p$, put:

$$(\alpha, \beta)_v = \frac{\tilde{\sigma}_v(P-R)\tilde{\sigma}_v(Q-S)}{\tilde{\sigma}_v(P-S)\tilde{\sigma}_v(Q-R)}.$$

The square of this is in K_v^*. However, note that $\pi_v^{\lambda_v(T)}$ really means $\sqrt{\pi_v}^{2\lambda_v(T)}$, for a fixed choice of $\sqrt{\pi_v}$ and that the definition of $(\alpha, \beta)_v$ is independent of the choice of square root and therefore that $(\alpha, \beta)_v$, not only its square, is in K_v^*.

Our local height $(\alpha, \beta)_v$, depends upon the choice of P, Q, R, S and of the uniformizer π_v.

2.5 How the local heights change, when we change our choice of divisors

Let $\beta \in E(K)$ be represented by both $[R]-[S]$ and $[R']-[S']$. Let $\alpha \in E(K)$ be represented by $[P]-[Q]$. Moreover let both four-tuples P,Q,R,S and P,Q,R',S' satisfy the *good representation* hypothesis described at the beginning of Section 2.2. Since, by hypothesis, $[R]-[S]-[R']+[S']$ is linearly equivalent to zero, there is a rational function f whose divisor of zeroes and poles is

$$(f) = [R]-[S]-[R']+[S'].$$

If v is a nonarchimedean place of K define $(\alpha,\beta)_v$ to be as defined in the previous sections using the choice of four-tuple of points P,Q,R,S, (and of uniformizer π_v when $v \nmid p$). Similarly, define $(\alpha,\beta)'_v$ to be as defined in the previous sections using the choice of four-tuple of points P,Q,R',S', (and of uniformizer π_v when $v \nmid p$).

Proposition 2.1. *1. If $v \mid p$ then*

$$(\alpha,\beta)_v = \frac{f(P)}{f(Q)} \cdot (\alpha,\beta)'_v \;\in\; K_v^*.$$

2. If $v \nmid p$ then there is a unit u in the ring of integers of K_v such that

$$(\alpha,\beta)_v^2 = u \cdot \left(\frac{f(P)}{f(Q)} \cdot (\alpha,\beta)'_v\right)^2 \;\in\; K_v^*.$$

2.6 The global height pairing more generally

We can then form the sum of local terms to define the global height

$$(\alpha,\beta) = \quad \frac{1}{2}\sum_v \iota_v((\alpha,\beta)_v^2) \;\in\; I(K).$$

This definition is independent of any of the (good representation) choices P,Q,R,S and the π_v's made. It is independent of the choice of π_v's because the units in the ring of integers of K_v is in the kernel of ι_v if $v \nmid p$. It is independent of the choice of P,Q,R,S because by the previous proposition, a change (an allowable one, given our hypotheses) of P,Q,R,S changes the value of (α,β) by a factor that is a principal idele, which is sent to zero in $I(K)$.

What if, though, our choice of P,Q,R,S does *not* have the property that α and β reduce to the same point in the Néron fiber at v for all $v \mid p$, or land in the same connected component on each fiber of the Néron model? In this case the pair α,β do not have a *good representation.* But replacing α,β by $m\cdot\alpha, n\cdot\beta$ for sufficiently large positive integers m,n we can guarantee that the pair $m\cdot\alpha, n\cdot\beta$ does possess a good representation, and obtain formulas for (α,β) by:

$$(\alpha,\beta) = \frac{1}{mn}(m\cdot\alpha, n\cdot\beta).$$

Note in passing that to compute the global height pairing (α,α) for a non-torsion point $\alpha \in E(K)$ that specializes to 0 in the Néron fiber at v for all $v \mid p$, and that lives in the connected component containing the identity in all Néron fibers, we have quite a few natural choices of *good representations*. For example, for positive integers $m \neq n$, take

$$P = (m+1)\cdot\alpha;\ Q = m\cdot\alpha;\ R = (n+1)\cdot\alpha;\ S = n\cdot\alpha.$$

Then for any p-adic idele class functional ρ the global ρ-height pairing $(\alpha,\alpha)_\rho$ is given by

$$\sum_{v\ \mid\ p} \rho_v \left\{ \frac{\sigma_v((m-n)\alpha)^2}{\sigma_v((m-n+1)\alpha)\cdot\sigma_v((m-n-1)\alpha)} \right\} \\ + \sum_{v\ \nmid\ p} \rho_v \left\{ \frac{\tilde{\sigma}_v((m-n)\alpha)^2}{\tilde{\sigma}_v((m-n+1)\alpha)\cdot\tilde{\sigma}_v((m-n-1)\alpha)} \right\},$$

which simplifies to

$$(2(m-n)^2 - (m-n+1)^2 - (m-n-1)^2)\cdot \left\{ \sum_{v\ \mid\ p} \rho_v\sigma_v(\alpha) + \sum_{v\ \nmid\ p} \rho_v\tilde{\sigma}_v(\alpha) \right\}.$$

Since $(2(m-n)^2 - (m-n+1)^2 - (m-n-1)^2) = -2$ we have the formula

$$h_\rho(\alpha) = -\frac{1}{2}(\alpha,\alpha)_\rho$$

quoted earlier.

2.7 Formulas for the ρ-height

For each v, let σ_v be the canonical p-adic σ-function of E over K_v given in Weierstrass form. Suppose $P \in E(K)$ is a (non-torsion) point that reduces to 0 in $E(k_v)$ for each $v \mid p$, and to the connected component of all special fibers of the Néron model of E. Locally at each place w of K, we have a denominator $d_w(P)$, well defined up to units.

We have

$$h_\rho(P) = \sum_{v\ \mid\ p} \rho_v(\sigma_v(P)) - \sum_{w\ \nmid\ p} \rho_w(d_w(P)).$$

Note that h_ρ is quadratic because of the quadratic property of σ from (1.2), and the h_ρ-pairing is then visibly bilinear. See also property (1.3).

2.8 Cyclotomic p-adic heights

The idele class $\mathbf{Q}_p$-vector space $I(\mathbf{Q})$ attached to $\mathbf{Q}$ is canonically isomorphic to $\mathbf{Q}_p \otimes \mathbf{Z}_p^*$. Composition of this canonical isomorphism with the mapping $1 \times \frac{1}{p}\log_p$ induces an isomorphism

$$\rho_{\mathrm{cycl}}^{\mathbf{Q}} : I(\mathbf{Q}) = \mathbf{Q}_p \otimes \mathbf{Z}_p^* \xrightarrow{\cong} \mathbf{Q}_p.$$

For K any number field, consider the homomorphism on idele class $\mathbf{Q}_p$-vector spaces induced by the norm $N_{K/\mathbf{Q}} : I(K) \to I(\mathbf{Q})$, and define

$$\rho_{\mathrm{cycl}}^{K} : I(K) \to \mathbf{Q}_p$$

as the composition

$$\rho_{\mathrm{cycl}}^{K} = \rho_{\mathrm{cycl}}^{\mathbf{Q}} \circ N_{K/\mathbf{Q}}.$$

By the *cyclotomic height pairing* for an elliptic curve E over K (of good ordinary reduction at all places v of K above p) we mean the ρ_{cycl}^{K}-height pairing $E(K) \times E(K) \to \mathbf{Q}_p$. We put

$$h_p(P) = h_{\rho_{\mathrm{cycl}}^{K}}(P)$$

for short. Here is an explicit formula for it.

$$h_p(P) = \frac{1}{p} \cdot \left(\sum_{v|p} \log_p(N_{K_v/\mathbf{Q}_p}(\sigma_v(P))) - \sum_{w\nmid p} \mathrm{ord}_w(d_w(P)) \cdot \log_p(\#k_w) \right).$$

If we assume that P lies in a sufficiently small (finite index) subgroup of $E(K)$ (see [Wut04, Prop. 2]), then there will be a global choice of denominator $d(P)$, and the formula simplifies to

$$h_p(P) = \frac{1}{p} \cdot \log_p \left(\prod_{v|p} N_{K_v/\mathbf{Q}_p} \left(\frac{\sigma_v(P)}{d(P)} \right) \right).$$

2.9 Anti-cyclotomic p-adic heights

Let K be a quadratic imaginary field in which p splits as $(p) = \pi \cdot \bar{\pi}$. Suppose $\rho : \mathbf{A}_K^*/K^* \to \mathbf{Z}_p$ is a nontrivial *anti-cyclotomic* idele class character, meaning that if $\mathbf{c} : \mathbf{A}_K^*/K^* \to \mathbf{A}_K^*/K^*$ denotes the involution of the idele class group induced by complex conjugation $x \mapsto \bar{x}$ in K, then $\rho \cdot \mathbf{c} = -\rho$. Then the term

$$\sum_{v \ | \ p} \rho_v(\sigma_v(P))$$

in the formula for the ρ-height at the end of Section 2.7 is just

$$\sum_{v \ | \ p} \rho_v(\sigma_v(P)) = \rho_\pi(\sigma_\pi(P)) - \rho_\pi(\sigma_\pi(\bar{P})),$$

so we have the following formula for the ρ-height of P:

$$h_\rho(P) = \rho_\pi(\sigma_\pi(P)) - \rho_\pi(\sigma_\pi(\bar{P})) - \sum_{w \nmid p} \rho_w(d_w(P)).$$

Remark 2.2. The Galois equivariant property of the p-adic height pairing implies that if P is a $\mathbf{Q}$-rational point, its anti-cyclotomic height is 0. Specifically, let K/k be any Galois extension of number fields, with Galois group $G = \mathrm{Gal}(K/k)$. Let $V = V(K)$ be the $\mathbf{Q}_p$-vector space (say) defined as $(G_K)^{\mathrm{ab}} \otimes \mathbf{Q}_p$, so that V is naturally a G-representation space. Let E be an elliptic curve over k and view the Mordell-Weil group $E(K)$ as equipped with its natural G-action. Then (if p is a good ordinary prime for E) we have the p-adic height pairing

$$\langle P, Q\rangle \in V,$$

for $P, Q \in E(K)$ and we have Galois equivariance,

$$\langle g \cdot P, g \cdot Q\rangle = g \cdot \langle P, Q\rangle,$$

for any g in the Galois group.

Put $k = \mathbf{Q}$, K/k a quadratic imaginary field. Then V is of dimension two, with $V = V^+ \oplus V^-$ each of the $V^\pm$ being of dimension one, with the action of complex conjugation, $g \in G$ on $V^\pm$ being given by the sign; so that V^+ corresponds to the cyclotomic $\mathbf{Z}_p$-extension and V^- corresponds to the anticyclotomic $\mathbf{Z}_p$- extension. In the notation above, the anticyclotomic height of P and Q is just $\langle g \cdot P, g \cdot Q\rangle^-$ where the superscript $-$ means projection to V^-. Suppose that $P \in E(\mathbf{Q})$, so that $g \cdot P = P$. Then we have by Galois equivariance

$$\langle P, P\rangle^- = \langle g \cdot P, g \cdot P\rangle^- = -\langle P, P\rangle^-,$$

so $\langle P, P\rangle^- = 0$. More generally, the anticyclotomic height is zero as a pairing on either $E(K)^+ \times E(K)^+$ or $E(K)^- \times E(K)^-$ and can only be nonzero on $E(K)^+ \times E(K)^-$. If $E(K)$ is of odd rank, then the ranks of $E(K)^+$ and $E(K)^-$ must be different, which obliges the pairing on $E(K)^+ \times E(K)^-$ to be either left-degenerate or right-degenerate (or, of course, degenerate on both sides). Rubin and the first author conjecture that it is nondegenerate on one side (the side, of course having smaller rank); for more details see, e.g., [MR04, Conj. 11].

3 The Algorithms

Fix an elliptic curve E over $\mathbf{Q}$ and a good ordinary prime $p \geq 5$. In this section we discuss algorithms for computing the cyclotomic p-adic height of elements of $E(\mathbf{Q})$.

3.1 Computing the p-adic σ-function

First we explicitly solve the differential equation (1.5). Let $z(t)$ be the formal logarithm on E, which is given by $z(t) = \int \frac{\omega}{dt} = t + \cdots$ (here the symbol $\int$

means formal integration with 0 constant term). There is a unique function $F(z) \in \mathbf{Q}((z))$ such that $t = F(z(t))$. Set $x(z) = x(F(z))$. Rewrite (1.5) as

$$x(z) + c = -\frac{d}{\omega}\left(\frac{d\log(\sigma)}{\omega}\right). \tag{3.1}$$

A crucial observation is that

$$x(z) + c = \frac{1}{z^2} - \frac{a_1^2 + 4a_2}{12} + c + \cdots ;$$

in particular, the coefficient of $1/z$ in the expansion of $g(z) = x(z) + c$ is 0.

Since $z = \int(\omega/dt)$ we have $dz = (\omega/dt)dt = \omega$, hence $dz/\omega = 1$, so

$$-\frac{d}{\omega}\left(\frac{d\log(\sigma)}{\omega}\right) = -\frac{dz}{\omega}\frac{d}{dz}\left(\frac{d\log(\sigma)}{\omega}\right) = -\frac{d}{dz}\left(\frac{d\log(\sigma)}{dz}\right). \tag{3.2}$$

Write $\sigma(z) = z\sigma_0(z)$ where $\sigma_0(z)$ has nonzero constant term. Then

$$-\frac{d}{dz}\left(\frac{d\log(\sigma)}{dz}\right) = \frac{1}{z^2} - \frac{d}{dz}\left(\frac{d\log(\sigma_0)}{dz}\right). \tag{3.3}$$

Thus combining (3.1)–(3.3) and changing sign gives

$$\frac{1}{z^2} - x(z) - c = \frac{d}{dz}\left(\frac{d\log(\sigma_0)}{dz}\right).$$

This is particularly nice, since $g(z) = \frac{1}{z^2} - x(z) - c \in \mathbf{Q}[[z]]$. We can thus solve for $\sigma_0(z)$ by formally integrating twice and exponentiating:

$$\sigma_0(z) = \exp\left(\int\int g(z)dzdz\right),$$

where we choose the constants in the double integral to be 0, so $\int\int g = 0 + 0z + \cdots$. Using (1.8) we can rewrite $g(z)$ in terms of $e_2 = \mathbf{E}_2(E,\omega)$ and $\wp(z)$ as

$$g(z) = \frac{1}{z^2} - (x(z) + c) = \frac{1}{z^2} - \wp(z) + \frac{e_2}{12}.$$

Combining everything and using that $\sigma(z) = z\sigma_0(z)$ yields

$$\sigma(z) = z \cdot \exp\left(\int\int\left(\frac{1}{z^2} - \wp(z) + \frac{e_2}{12}\right)dzdz\right),$$

Finally, to compute $\sigma(t)$ we compute $\sigma(z)$ and obtain $\sigma(t)$ as $\sigma(z(t))$.

We formalize the resulting algorithm below.

Algorithm 3.1 (The Canonical p-adic Sigma Function). Given an elliptic curve E over $\mathbf{Q}$, a good ordinary prime p for E, and an approximation e_2 for $\mathbf{E}_2(E,\omega)$, this algorithm computes an approximation to $\sigma(t) \in \mathbf{Z}_p[[t]]$.

1. [Compute Formal Log] Compute the formal logarithm $z(t) = t + \cdots \in \mathbf{Q}((t))$ using that
$$z(t) = \int \frac{dx/dt}{2y(t) + a_1x(t) + a_3}, \qquad \text{(0 constant term)} \qquad (3.4)$$
where $x(t) = t/w(t)$ and $y(t) = -1/w(t)$ are the local expansions of x and y in terms of $t = -x/y$, and $w(t) = \sum_{n\geq 0} s_n t^n$ is given by the following explicit inductive formula (see, e.g., [Blu, pg. 18]):
$$s_0 = s_1 = s_2 = 0, \qquad s_3 = 1, \qquad \text{and for } n \geq 4,$$
$$s_n = a_1 s_{n-1} + a_2 s_{n-2} + a_3 \sum_{i+j=n} s_i s_j + a_4 \sum_{i+j=n-1} s_i s_j + a_6 \sum_{i+j+k=n} s_i s_j s_k.$$
2. [Reversion] Using a power series "reversion" (functional inverse) algorithm, find the unique power series $F(z) \in \mathbf{Q}[[z]]$ such that $t = F(z)$. Here F is the reversion of z, which exists because $z(t) = t + \cdots$.
3. [Compute $\wp$] Compute $\alpha(t) = x(t) + (a_1^2 + 4a_2)/12 \in \mathbf{Q}[[t]]$, where the a_i are as in (1.6). Then compute the series $\wp(z) = \alpha(F(z)) \in \mathbf{Q}((z))$.
4. [Compute $\sigma(z)$] Set $g(z) = \frac{1}{z^2} - \wp(z) + \frac{e_2}{12} \in \mathbf{Q}_p((z))$, and compute
$$\sigma(z) = z \cdot \exp\left(\int\int g(z)dzdz\right) \in \mathbf{Q}_p[[z]].$$
5. [Compute $\sigma(t)$] Set $\sigma(t) = \sigma(z(t)) \in t \cdot \mathbf{Z}_p[[t]]$, where $z(t)$ is the formal logarithm computed in Step 1. Output $\sigma(t)$ and terminate.

3.2 Computing $\mathbf{E}_2(E, \omega)$ using cohomology

This section is about a fast method of computation of $\mathbf{E}_2(E, \omega)$ for individual ordinary elliptic curves, "one at a time". The key input is [Kat73, App. 2] (see also [Kat76]), which gives an interpretation of $\mathbf{E}_2(E, \omega)$ as the "direction" of the unit root eigenspace (cf. formula A.2.4.1 of [Kat73, App. 2]) of Frobenius acting on the one-dimensional de Rham cohomology of E.

Concretely, consider an elliptic curve E over $\mathbf{Z}_p$ with good ordinary reduction. Assume that $p \geq 5$. Fix a Weierstrass equation for E of the form $y^2 = 4x^3 - g_2x - g_3$, The differentials $\omega = dx/y$ and $\eta = xdx/y$ form a $\mathbf{Z}_p$-basis for the first p-adic de Rham cohomology group H^1 of E, and we wish to compute the matrix F of absolute Frobenius with respect to this basis. Frobenius is $\mathbf{Z}_p$-linear, since we are working over $\mathbf{Z}_p$; if we were working over the Witt vectors of $\mathbf{F}_q$, then Frobenius would only be semi-linear.

We explicitly calculate F (to a specified precision) using Kedlaya's algorithm, which makes use of Monsky-Washnitzer cohomology of the affine curve $E - \mathcal{O}$. Kedlaya designed his algorithm for computation of zeta functions of hyperelliptic curves over finite fields. An intermediate step in Kedlaya's algorithm is computation of the matrix of absolute Frobenius on p-adic de Rham cohomology, via Monsky-Washnitzer cohomology. For more details see [Ked01] and [Ked03]. For recent formulations and applications of fast algorithms to compute Frobenius eigenvalues, see [LW02].

Now that we have computed F, we deduce $\mathbf{E}_2(E,\omega)$ as follows. The unit root subspace is a direct factor, call it U, of H^1, and we know that a complementary direct factor is the $\mathbf{Z}_p$ span of ω. We also know that $F(\omega)$ lies in $p\,\mathrm{H}^1$, and this tells us that, mod p^n, the subspace U is the span of $F^n(\eta)$. Thus if for each n, we write $F^n(\eta) = a_n\omega + b_n\eta$, then b_n is a unit (congruent (mod p) to the nth power of the Hasse invariant) and $\mathbf{E}_2(E,\omega) \equiv -12a_n/b_n \pmod{p^n}$. Note that a_n and b_n are the entries of the second column of the matrix F^n.

Algorithm 3.2 (Evaluation of $\mathbf{E}_2(E,\omega)$). Given an elliptic curve over $\mathbf{Q}$ and a good ordinary prime $p \geq 5$, this algorithm approximates $\mathbf{E}_2(E,\omega) \in \mathbf{Z}_p$ modulo p^n.

1. [Invariants] Let c_4 and c_6 be the c-invariants of a minimal model of E. Set
$$a_4 = -\frac{c_4}{2^4\cdot 3} \qquad \text{and} \qquad a_6 = -\frac{c_6}{2^5\cdot 3^3}.$$
2. [Kedlaya] Apply Kedlaya's algorithm to the hyperelliptic curve $y^2 = x^3 + a_4x + a_6$ (which is isomorphic to E) to obtain the matrix F (modulo p^n) of the action of absolute Frobenius on the basis
$$\omega = \frac{dx}{y}, \qquad \eta = \frac{xdx}{y}.$$
We view F as acting from the left.
3. [Iterate Frobenius] Compute the second column $\begin{pmatrix} a \\ b \end{pmatrix}$ of F^n, so $\mathrm{Frob}^n(\eta) = a\omega + b\eta$.
4. [Finished] Output $-12a/b$ (which is a number modulo p^n, since b is a unit).

3.3 Computing $\mathbf{E}_2(E,\omega)$ using integrality

The algorithm in this section is more elementary than the one in Section 3.2, and is directly motivated by Theorem 1.3. In practice it is very slow, except if p is small (e.g., $p=5$) and we only require $\mathbf{E}_2(E,\omega)$ to very low precision. Our guess is that it should be exponentially hard to compute a quantity using a log convergent series for it, and that this "integrality" method is essentially the same as using log convergent expansions.

Let c be an indeterminate and in view of (1.9), write $e_2 = -12c + a_1^2 + 4a_2 \in \mathbf{Q}[c]$. If we run Algorithm 3.1 with this (formal) value of e_2, we obtain a series $\sigma(t,c) \in \mathbf{Q}[c][[t]]$. For each prime $p \geq 5$, Theorem 1.3 implies that there is a unique choice of $c_p \in \mathbf{Z}_p$ such that $\sigma(t,c_p) = t + \cdots \in t\mathbf{Z}_p[[t]]$

is odd. Upon fixing a prime p, we compute the coefficients of $\sigma(t,c)$, which are polynomials in $\mathbf{Q}[c]$; integrality of $\sigma(t,c_p)$ then imposes conditions that together must determine c_p up to some precision, which depends on the number of coefficients that we consider. Having computed c_p to some precision, we recover $\mathbf{E}_2(E,\omega)$ as $-12c_p + a_1^2 + 4a_2$. We formalize the above as an algorithm.

Algorithm 3.3 (Integrality). Given an elliptic curve over $\mathbf{Q}$ and a good ordinary prime $p \geq 5$, this algorithm approximates the associated p-adic σ-function.

1. [Formal Series] Use Algorithm 3.1 with $e_2 = -12c + a_1^2 + 4a_2$ to compute $\sigma(t) \in \mathbf{Q}[c][[t]]$ to some precision.
2. [Approximate c_p] Obtain constraints on c using that the coefficients of σ must be in $\mathbf{Z}_p$. These determine c to some precision. (For more details see the example in Section 4.1).

3.4 Computing cyclotomic p-adic heights

Finally we give an algorithm for computing the cyclotomic p-adic height $h_p(P)$ that combines Algorithm 3.2 with the discussion elsewhere in this paper. We have computed σ and h_p in numerous cases using the algorithm described below, and implementations of the "integrality" algorithm described above, and the results match.

Algorithm 3.4 (The p-adic Height). Given an elliptic curve E over $\mathbf{Q}$, a good ordinary prime p, and a non-torsion element $P \in E(\mathbf{Q})$, this algorithm approximates the p-adic height $h_p(P) \in \mathbf{Q}_p$.

1. [Prepare Point] Compute a positive integer m such that mP reduces to $\mathcal{O} \in E(\mathbf{F}_p)$ and to the connected component of $\mathcal{E}_{\mathbf{F}_\ell}$ at all bad primes ℓ. For example, m could be the least common multiple of the Tamagawa numbers of E and $\#E(\mathbf{F}_p)$. Set $Q = mP$ and write $Q = (x, y)$.
2. [Denominator] Let d be the positive integer square root of the denominator of x.
3. [Compute σ] Approximate $\sigma(t)$ using Algorithm 3.1 together with either Algorithm 3.2 or Algorithm 3.3, and set $s = \sigma(-x/y) \in \mathbf{Q}_p$.
4. [Height] Compute $h_p(Q) = \frac{1}{p}\log_p\left(\frac{s}{d}\right)$, then $h_p(P) = \frac{1}{m^2} \cdot h_p(Q)$. Output $h_p(P)$ and terminate.

4 Sample Computations

We did the calculations in this section using SAGE [SJ05] and Magma [BCP97]. In particular, SAGE includes an optimized implementation due to J. Balakrishnan, R. Bradshaw, D. Harvey, Y. Qiang, and W. Stein of our algorithm for computing p-adic heights for elliptic curves over $\mathbf{Q}$. This implementation includes further tricks, e.g., for series manipulation, which are not described in this paper.

4.1 The rank one curve of conductor 37

Let E be the rank 1 curve $y^2 + y = x^3 - x$ of conductor 37. The point $P = (0, 0)$ is a generator for $E(\mathbf{Q})$. We illustrate the above algorithms in detail by computing the p-adic height of P for the good ordinary prime $p = 5$. The steps of Algorithm 3.4 are as follows:

1. [Prepare Point] The component group of $\mathcal{E}_{\mathbf{F}_{37}}$ is trivial. The group $E(\mathbf{F}_5)$ has order 8 and the reduction of P to $E(\mathbf{F}_5)$ also has order 8, so let
$$Q = 8P = \left(\frac{21}{25}, -\frac{69}{125}\right).$$
2. [Denominator] We have $d = 5$.
3. [Compute σ] We illustrate computation of $\sigma(t)$ using both Algorithm 3.2 and Algorithm 3.3.
   (a) [Compute $\sigma(t, c)$] We use Algorithm 3.1 with $e_2 = 12c - a_1^2 - 4a_2$ to compute σ as a series in t with coefficients polynomials in c, as follows:
      i. [Compute Formal Log] Using the recurrence, we find that
      $$w(t) = t^3 + t^6 - t^7 + 2t^9 - 4t^{10} + 2t^{11} + 5t^{12} - 5t^{13} + 5t^{14} + \cdots$$
      Thus
      $$x(t) = t^{-2} - t + t^2 - t^4 + 2t^5 - t^6 - 2t^7 + 6t^8 - 6t^9 - 3t^{10} + \cdots$$
      $$y(t) = -t^{-3} + 1 - t + t^3 - 2t^4 + t^5 + 2t^6 - 6t^7 + 6t^8 + 3t^9 + \cdots$$
      so integrating (3.4) we see that the formal logarithm is
      $$z(t) = t + \frac{1}{2}t^4 - \frac{2}{5}t^5 + \frac{6}{7}t^7 - \frac{3}{2}t^8 + \frac{2}{3}t^9 + 2t^{10} - \frac{60}{11}t^{11} + 5t^{12} + \cdots$$
      ii. [Reversion] Using reversion, we find F with $F(z(t)) = t$:
      $$F(z) = z - \frac{1}{2}z^4 + \frac{2}{5}z^5 + \frac{1}{7}z^7 - \frac{3}{10}z^8 + \frac{2}{15}z^9 - \frac{1}{28}z^{10} + \frac{54}{385}z^{11} + \cdots$$
      iii. [Compute $\wp$] We have $a_1 = a_2 = 0$, so
      $$\alpha(t) = x(t) + (a_1^2 + 4a_2)/12 = x(t),$$
      so
      $$\wp(z) = x(F(z)) = z^{-2} + \frac{1}{5}z^2 - \frac{1}{28}z^4 + \frac{1}{75}z^6 - \frac{3}{1540}z^8 + \cdots$$
      Note that the coefficient of z^{-1} is 0 and all exponents are even.

iv. [Compute $\sigma(t,c)$] Noting again that $a_1 = a_2 = 0$, we have

$$\begin{aligned} g(z,c) &= \frac{1}{z^2} - \wp(z) + \frac{12c - a_1^2 - 4a_2}{12} \\ &= c - \frac{1}{5}z^2 + \frac{1}{28}z^4 - \frac{1}{75}z^6 + \frac{3}{1540}z^8 - \frac{1943}{3822000}z^{10} + \cdots \end{aligned}$$

Formally integrating twice and exponentiating, we obtain

$$\begin{aligned} \sigma(z,c) &= z \cdot \exp\left(\int\int g(z,c)dzdz\right) \\ &= z \cdot \exp\Big(\frac{c}{2} \cdot z^2 - \frac{1}{60}z^4 + \frac{1}{840}z^6 - \frac{1}{4200}z^8 + \frac{1}{46200}z^{10} \\ &\qquad - \frac{1943}{504504000}z^{12} + \cdots\Big) \\ &= z + \frac{1}{2}cz^3 + \left(\frac{1}{8}c^2 - \frac{1}{60}\right)z^5 + \left(\frac{1}{48}c^3 - \frac{1}{120}c + \frac{1}{840}\right)z^7 + \\ &\qquad \left(\frac{1}{384}c^4 - \frac{1}{480}c^2 + \frac{1}{1680}c - \frac{1}{10080}\right)z^9 + \cdots \end{aligned}$$

Finally,

$$\begin{aligned} \sigma(t) = \sigma(z(t)) = t + \frac{1}{2}ct^3 + \frac{1}{2}t^4 + \left(\frac{1}{8}c^2 - \frac{5}{12}\right)t^5 + \frac{3}{4}ct^6 + \\ \left(\frac{1}{48}c^3 - \frac{73}{120}c + \frac{103}{120}\right)t^7 + \cdots \end{aligned}$$

(b) [Approximate] The first coefficient of $\sigma(t)$ that gives integrality information is the coefficient of t^7. Since

$$\frac{1}{48}c^3 - \frac{73}{120}c + \frac{103}{120} \in \mathbf{Z}_5,$$

multiplying by 5 we see that

$$\frac{5}{48}c^3 - \frac{73}{24}c + \frac{103}{24} \equiv 0 \pmod{5}.$$

Thus

$$c \equiv \frac{103}{24} \cdot \frac{24}{73} \equiv 1 \pmod{5}.$$

The next useful coefficient is the coefficient of t^{11}, which is

$$\frac{1}{3840}c^5 - \frac{169}{2880}c^3 + \frac{5701}{6720}c^2 + \frac{127339}{100800}c - \frac{40111}{7200}$$

Multiplying by 25, reducing coefficients, and using integrality yields the congruence

$$10c^5 + 5c^3 + 20c^2 + 2c + 3 \equiv 0 \pmod{25}.$$

Writing $c = 1+5d$ and substituting gives the equation $10d+15 \equiv 0 \pmod{25}$, so $2d + 3 \equiv 0 \pmod 5$. Thus $d \equiv 1 \pmod 5$, hence $c = 1+5+O(5^2)$. Repeating the procedure above with more terms, we next get new information from the coefficient of t^{31}, where we deduce that $c = 1 + 5 + 4 \cdot 5^2 + O(5^3)$.

Using Algorithm 3.2: Using Kedlaya's algorithm (as implemented in [BCP97]) we find almost instantly that

$$\mathbf{E}_2(E,\omega) = 2+4\cdot 5+2\cdot 5^3+5^4+3\cdot 5^5+2\cdot 5^6+5^8+3\cdot 5^9+4\cdot 5^{10}+\cdots .$$

Thus

$$c = \frac{1}{12}\mathbf{E}_2(E,\omega) = 1+5+4\cdot 5^2+5^3+5^4+5^6+4\cdot 5^7+3\cdot 5^8+2\cdot 5^9+4\cdot 5^{10}+\cdots ,$$

which is consistent with what we found above using integrality.

4. [Height] For $Q = (x,y) = 8(0,0)$ as above, we have

$$s = \sigma\left(-\frac{x}{y}\right) = \sigma\left(\frac{35}{23}\right) = 4\cdot 5 + 5^2 + 5^3 + 5^4 + \cdots ,$$

so

$$\begin{aligned} h_5(Q) &= \frac{1}{5}\cdot \log_5\left(\frac{s}{5}\right) = \frac{1}{5}\cdot \log_5(4+5+5^2+5^3+2\cdot 5^5+\cdots) \\ &= 3+5+2\cdot 5^3+3\cdot 5^4+\cdots . \end{aligned}$$

Finally,

$$h_5(P) = \frac{1}{8^2}\cdot h_5(Q) = 2+4\cdot 5+5^2+2\cdot 5^3+2\cdot 5^4+\cdots .$$

Remark 4.1. A *very* good check to see whether or not any implementation of the algorithms in this paper is really correct, is just to make control experiments every once in a while, by computing $h(P)$ and then comparing it with $h(2P)/4$, $h(3P)/9$, etc. In particular, compute $h(P) - h(nP)/n^2$ for several n and check that the result is p-adically small. We have done this in many cases for the implementation used to compute the tables in this section.

4.2 Curves of ranks 1, 2, 3, 4, and 5

4.2.1 Rank 1

The first (ordered by conductor) curve of rank 1 is the curve with Cremona label 37A, which we considered in Section 4.1 above.

p	p-adic regulator of 37A
5	$1 + 5 + 5^2 + 3 \cdot 5^5 + 4 \cdot 5^6 + O(5^7)$
7	$1 + 7 + 3 \cdot 7^2 + 7^3 + 6 \cdot 7^4 + 2 \cdot 7^5 + 4 \cdot 7^6 + O(7^7)$
11	$7 + 9 \cdot 11 + 7 \cdot 11^2 + 8 \cdot 11^3 + 9 \cdot 11^4 + 2 \cdot 11^5 + 7 \cdot 11^6 + O(11^7)$
13	$12 \cdot 13 + 5 \cdot 13^2 + 9 \cdot 13^3 + 10 \cdot 13^4 + 4 \cdot 13^5 + 2 \cdot 13^6 + O(13^7)$
23	$20 + 10 \cdot 23 + 18 \cdot 23^2 + 16 \cdot 23^3 + 13 \cdot 23^4 + 4 \cdot 23^5 + 15 \cdot 23^6 + O(23^7)$
29	$19 + 4 \cdot 29 + 26 \cdot 29^2 + 2 \cdot 29^3 + 26 \cdot 29^4 + 26 \cdot 29^5 + 17 \cdot 29^6 + O(29^7)$
31	$15 + 10 \cdot 31 + 13 \cdot 31^2 + 2 \cdot 31^3 + 24 \cdot 31^4 + 9 \cdot 31^5 + 8 \cdot 31^6 + O(31^7)$
41	$30 + 2 \cdot 41 + 23 \cdot 41^2 + 15 \cdot 41^3 + 27 \cdot 41^4 + 8 \cdot 41^5 + 17 \cdot 41^6 + O(41^7)$
43	$30 + 30 \cdot 43 + 22 \cdot 43^2 + 38 \cdot 43^3 + 11 \cdot 43^4 + 29 \cdot 43^5 + O(43^6)$
47	$11 + 37 \cdot 47 + 27 \cdot 47^2 + 23 \cdot 47^3 + 22 \cdot 47^4 + 34 \cdot 47^5 + 3 \cdot 47^6 + O(47^7)$
53	$26 \cdot 53^{-2} + 30 \cdot 53^{-1} + 20 + 47 \cdot 53 + 10 \cdot 53^2 + 32 \cdot 53^3 + O(53^4)$

Note that when $p = 53$ we have $\#E(\mathbf{F}_p) = p$, i.e., p is anomalous.

4.3 Rank 2

The first curve of rank 2 is the curve 389A of conductor 389. The p-adic regulators of this curve are as follows:

p	p-adic regulator of 389A
5	$1 + 2 \cdot 5 + 2 \cdot 5^2 + 4 \cdot 5^3 + 3 \cdot 5^4 + 4 \cdot 5^5 + 3 \cdot 5^6 + O(5^7)$
7	$6 + 3 \cdot 7^2 + 2 \cdot 7^3 + 6 \cdot 7^4 + 7^5 + 2 \cdot 7^6 + O(7^7)$
11	$4 + 7 \cdot 11 + 6 \cdot 11^2 + 11^3 + 9 \cdot 11^4 + 10 \cdot 11^5 + 3 \cdot 11^6 + O(11^7)$
13	$9 + 12 \cdot 13 + 10 \cdot 13^2 + 5 \cdot 13^3 + 5 \cdot 13^4 + 13^5 + 9 \cdot 13^6 + O(13^7)$
17	$4 + 8 \cdot 17 + 15 \cdot 17^2 + 11 \cdot 17^3 + 13 \cdot 17^4 + 16 \cdot 17^5 + 6 \cdot 17^6 + O(17^7)$
19	$3 + 5 \cdot 19 + 8 \cdot 19^2 + 16 \cdot 19^3 + 13 \cdot 19^4 + 14 \cdot 19^5 + 11 \cdot 19^6 + O(19^7)$
23	$17 + 23 + 22 \cdot 23^2 + 16 \cdot 23^3 + 3 \cdot 23^4 + 15 \cdot 23^5 + O(23^7)$
29	$9 + 14 \cdot 29 + 22 \cdot 29^2 + 29^3 + 22 \cdot 29^4 + 29^5 + 20 \cdot 29^6 + O(29^7)$
31	$1 + 17 \cdot 31 + 4 \cdot 31^2 + 16 \cdot 31^3 + 18 \cdot 31^4 + 21 \cdot 31^5 + 8 \cdot 31^6 + O(31^7)$
37	$28 + 37 + 11 \cdot 37^2 + 7 \cdot 37^3 + 3 \cdot 37^4 + 24 \cdot 37^5 + 17 \cdot 37^6 + O(37^7)$
41	$20 + 26 \cdot 41 + 41^2 + 29 \cdot 41^3 + 38 \cdot 41^4 + 31 \cdot 41^5 + 23 \cdot 41^6 + O(41^7)$
43	$40 + 25 \cdot 43 + 15 \cdot 43^2 + 18 \cdot 43^3 + 36 \cdot 43^4 + 35 \cdot 43^5 + O(43^6)$
47	$25 + 24 \cdot 47 + 7 \cdot 47^2 + 11 \cdot 47^3 + 35 \cdot 47^4 + 3 \cdot 47^5 + 9 \cdot 47^6 + O(47^7)$

4.4 Rank 3

The first curve of rank 3 is the curve 5077A of conductor 5077. The p-adic regulators of this curve are as follows:

p	p-adic regulator of 5077A
5	$5^{-2} + 5^{-1} + 4 + 2 \cdot 5 + 2 \cdot 5^2 + 2 \cdot 5^3 + 4 \cdot 5^4 + 2 \cdot 5^5 + 5^6 + O(5^7)$
7	$1 + 3 \cdot 7 + 3 \cdot 7^2 + 4 \cdot 7^3 + 4 \cdot 7^5 + O(7^7)$
11	$6 + 11 + 5 \cdot 11^2 + 11^3 + 11^4 + 8 \cdot 11^5 + 3 \cdot 11^6 + O(11^7)$
13	$2 + 6 \cdot 13 + 13^3 + 6 \cdot 13^4 + 13^5 + 4 \cdot 13^6 + O(13^7)$
17	$11 + 15 \cdot 17 + 8 \cdot 17^2 + 16 \cdot 17^3 + 9 \cdot 17^4 + 5 \cdot 17^5 + 11 \cdot 17^6 + O(17^7)$
19	$17 + 9 \cdot 19 + 10 \cdot 19^2 + 15 \cdot 19^3 + 6 \cdot 19^4 + 13 \cdot 19^5 + 17 \cdot 19^6 + O(19^7)$
23	$7 + 17 \cdot 23 + 19 \cdot 23^3 + 21 \cdot 23^4 + 19 \cdot 23^5 + 22 \cdot 23^6 + O(23^7)$
29	$8 + 16 \cdot 29 + 11 \cdot 29^2 + 20 \cdot 29^3 + 9 \cdot 29^4 + 8 \cdot 29^5 + 24 \cdot 29^6 + O(29^7)$
31	$17 + 11 \cdot 31 + 28 \cdot 31^2 + 3 \cdot 31^3 + 17 \cdot 31^5 + 29 \cdot 31^6 + O(31^7)$
43	$9 + 13 \cdot 43 + 15 \cdot 43^2 + 32 \cdot 43^3 + 28 \cdot 43^4 + 18 \cdot 43^5 + 3 \cdot 43^6 + O(43^7)$
47	$29 + 3 \cdot 47 + 46 \cdot 47^2 + 4 \cdot 47^3 + 23 \cdot 47^4 + 25 \cdot 47^5 + 37 \cdot 47^6 + O(47^7)$

For $p = 5$ and E the curve 5077A, we have $\#E(\mathbf{F}_5) = 10$, so $a_p \equiv 1 \pmod{5}$, hence p is anamolous.

4.5 Rank 4

Next we consider the curve of rank 4 with smallest known conductor ($234446 = 2 \cdot 117223$):

$$y^2 + xy = x^3 - x^2 - 79x + 289.$$

Note that computation of the p-adic heights is just as fast for this curve as the above curves, i.e., our algorithm for computing heights is insensitive to the conductor, only the prime p (of course, computing the Mordell-Weil group could take much longer if the conductor is large).

p	p-adic regulator of rank 4 curve
5	$2 \cdot 5^{-2} + 2 \cdot 5^{-1} + 3 \cdot 5 + 5^2 + 4 \cdot 5^3 + 4 \cdot 5^4 + 3 \cdot 5^5 + 3 \cdot 5^6 + O(5^7)$
7	$6 \cdot 7 + 4 \cdot 7^2 + 5 \cdot 7^3 + 5 \cdot 7^5 + 3 \cdot 7^6 + O(7^7)$
11	$5 + 10 \cdot 11 + 5 \cdot 11^2 + 11^3 + 3 \cdot 11^5 + 11^6 + O(11^7)$
13	$12 + 2 \cdot 13 + 4 \cdot 13^2 + 10 \cdot 13^3 + 3 \cdot 13^4 + 5 \cdot 13^5 + 7 \cdot 13^6 + O(13^7)$
17	$15 + 8 \cdot 17 + 13 \cdot 17^2 + 5 \cdot 17^3 + 13 \cdot 17^4 + 7 \cdot 17^5 + 14 \cdot 17^6 + O(17^7)$
19	$14 + 16 \cdot 19 + 15 \cdot 19^2 + 6 \cdot 19^3 + 10 \cdot 19^4 + 7 \cdot 19^5 + 13 \cdot 19^6 + O(19^7)$
23	$3 + 15 \cdot 23 + 15 \cdot 23^2 + 12 \cdot 23^4 + 20 \cdot 23^5 + 7 \cdot 23^6 + O(23^7)$
29	$25 + 4 \cdot 29 + 18 \cdot 29^2 + 5 \cdot 29^3 + 27 \cdot 29^4 + 23 \cdot 29^5 + 27 \cdot 29^6 + O(29^7)$
31	$21 + 26 \cdot 31 + 22 \cdot 31^2 + 25 \cdot 31^3 + 31^4 + 3 \cdot 31^5 + 14 \cdot 31^6 + O(31^7)$
37	$34 + 14 \cdot 37 + 32 \cdot 37^2 + 25 \cdot 37^3 + 28 \cdot 37^4 + 36 \cdot 37^5 + O(37^6)$
41	$33 + 38 \cdot 41 + 9 \cdot 41^2 + 35 \cdot 41^3 + 25 \cdot 41^4 + 15 \cdot 41^5 + 30 \cdot 41^6 + O(41^7)$
43	$14 + 34 \cdot 43 + 12 \cdot 43^2 + 26 \cdot 43^3 + 32 \cdot 43^4 + 26 \cdot 43^5 + O(43^6)$
47	$43 + 47 + 17 \cdot 47^2 + 28 \cdot 47^3 + 40 \cdot 47^4 + 6 \cdot 47^5 + 7 \cdot 47^6 + O(47^7)$

4.6 Rank 5

Next we consider the curve of rank 5 with smallest known conductor, which is the prime 19047851. The curve is

$$y^2 + y = x^3 - 79x + 342$$

p	p-adic regulator of rank 5 curve
5	$2 \cdot 5 + 5^2 + 5^3 + 2 \cdot 5^4 + 5^5 + 5^6 + O(5^7)$
7	$2 + 6 \cdot 7 + 4 \cdot 7^2 + 3 \cdot 7^3 + 6 \cdot 7^4 + 2 \cdot 7^5 + 4 \cdot 7^6 + O(7^7)$
11	$10 + 11 + 6 \cdot 11^2 + 2 \cdot 11^3 + 6 \cdot 11^4 + 7 \cdot 11^5 + 5 \cdot 11^6 + O(11^7)$
13	$11 + 8 \cdot 13 + 3 \cdot 13^2 + 4 \cdot 13^3 + 10 \cdot 13^4 + 5 \cdot 13^5 + 6 \cdot 13^6 + O(13^7)$
17	$4 + 11 \cdot 17 + 4 \cdot 17^2 + 5 \cdot 17^3 + 13 \cdot 17^4 + 5 \cdot 17^5 + 2 \cdot 17^6 + O(17^7)$
19	$11 + 7 \cdot 19 + 11 \cdot 19^2 + 7 \cdot 19^3 + 9 \cdot 19^4 + 6 \cdot 19^5 + 10 \cdot 19^6 + O(19^7)$
23	$14 + 14 \cdot 23 + 20 \cdot 23^2 + 6 \cdot 23^3 + 19 \cdot 23^4 + 9 \cdot 23^5 + 15 \cdot 23^6 + O(23^7)$
29	$3 + 5 \cdot 29 + 20 \cdot 29^3 + 21 \cdot 29^4 + 18 \cdot 29^5 + 11 \cdot 29^6 + O(29^7)$
31	$4 + 26 \cdot 31 + 11 \cdot 31^2 + 12 \cdot 31^3 + 3 \cdot 31^4 + 15 \cdot 31^5 + 22 \cdot 31^6 + O(31^7)$
37	$3 + 20 \cdot 37 + 11 \cdot 37^2 + 17 \cdot 37^3 + 33 \cdot 37^4 + 5 \cdot 37^5 + O(37^7)$
41	$3 + 41 + 35 \cdot 41^2 + 29 \cdot 41^3 + 22 \cdot 41^4 + 27 \cdot 41^5 + 25 \cdot 41^6 + O(41^7)$
43	$35 + 41 \cdot 43 + 43^2 + 11 \cdot 43^3 + 32 \cdot 43^4 + 11 \cdot 43^5 + 18 \cdot 43^6 + O(43^7)$
47	$25 + 39 \cdot 47 + 45 \cdot 47^2 + 25 \cdot 47^3 + 42 \cdot 47^4 + 13 \cdot 47^5 + O(47^6)$

Note that the regulator for $p = 5$ is not a unit, and $\#E(F_5) = 9$. This is the only example of a regulator in our tables with positive valuation.

Part II
Computing expansions for $\mathbf{E}_2$ in terms of classical modular forms

We next study convergence of $\mathbf{E}_2$ in the general context of p-adic and overconvergent modular forms. Coleman, Gouvea, and Jochnowitz prove in [CGJ95] that $\mathbf{E}_2$ is *transcendental* over the ring of overconvergent modular forms, so $\mathbf{E}_2$ is certainly non-overconvergent. However, $\mathbf{E}_2$ is *log convergent* in a sense that we make precise in this part of the paper.

5 Questions about rates of convergence

Fix p a prime number, which, in this section, we will assume is ≥ 5. We only consider modular forms of positive even integral weight, on $\Gamma_0(M)$ for some M, and with Fourier coefficients in $\mathbf{C}_p$. By a *classical modular form* we will mean one with these properties, and by a *Katz modular form* we mean a p-adic modular form in the sense of Katz ([Kat73]), again with these properties, i.e., of integral weight $k \geq 0$, of tame level N for a positive integer N prime to p, and with Fourier coefficients in $\mathbf{C}_p$. A *p-integral modular form* is a modular form with Fourier coefficients in $\mathbf{Z}_p$. Note that throughout Sections 5 and 6, all our modular forms can be taken to be with coefficients in $\mathbf{Q}_p$.

If f is a classical, or Katz, modular form, we will often simply identify the form f with its Fourier expansion, $f = \sum_{n\geq 0} c_f(n)q^n$. By $\mathrm{ord}_p(f)$ we mean the greatest lower bound of the non-negative integers $\mathrm{ord}_p(c_f(n))$ for $n \geq 0$. The valuation ord_p on $\mathbf{C}_p$ here is given its natural normalization, i.e., $\mathrm{ord}_p(p) = 1$.

We say two p-integral modular forms are *congruent* modulo p^n, denoted

$$f \equiv g \pmod{p^n},$$

if their corresponding Fourier coefficients are congruent modulo p^n. Equivalently, $f \equiv g \pmod{p^n}$ if $\mathrm{ord}_p(f - g) \geq n$.

Recall the traditional notation,

$$\sigma_{k-1}(n) = \sum_{0\,<\,d\,\mid\,n} d^{k-1},$$

and put $\sigma(n) = \sigma_1(n)$.

Let $E_k = -b_k/2k + \sum_{n=0}^{\infty} \sigma_{k-1}(n)q^n$ be the Eisenstein series of even weight $k \geq 2$, and denote by $\mathcal{E}_k$ the "other natural normalization" of the Eisenstein series,

$$\mathcal{E}_k = 1 - \frac{2k}{b_k} \cdot \sum_{n=0}^{\infty} \sigma_{k-1}(n)q^n,$$

for $k \geq 2$. We have

$$\mathcal{E}_{p-1} \equiv 1 \pmod{p}.$$

(Note that $\mathcal{E}_k$ is the q-expansion of the Katz modular form that we denote by $\mathbf{E}_k$ elsewhere in this paper.)

For $k > 2$ these are classical modular forms of level 1, while the Fourier series $E_2 = -1/24 + \sum_{n=0}^{\infty} \sigma(n)q^n$, and the corresponding $\mathcal{E}_2$, are not; nevertheless, they may all be viewed as Katz modular forms of tame level 1.

Put

$$\sigma^{(p)}(n) = \sum_{0\,<\,d\,\mid\,n;\ (p,d)=1} d,$$

so that we have:

$$\sigma(n) = \sigma^{(p)}(n) + p\sigma^{(p)}(n/p) + p^2\sigma^{(p)}(n/p^2) + \cdots \tag{5.1}$$

where the convention is that $\sigma^{(p)}(r) = 0$ if r is not an integer.

Let $V = V_p$ be the operator on power series given by the rule:

$$V\left(\sum_{n\geq 0} c_n q^n\right) = \sum_{n\geq 0} c_n q^{pn}.$$

If $F = \sum_{n\geq 0} c_n q^n$ is a classical modular form of weight k on $\Gamma_0(M)$, then $V(F)$ is (the Fourier expansion of) a classical modular form of weight k on $\Gamma_0(Mp)$ (cf. [Lan95, Ch. VIII]).

The Fourier series

$$E_2^{(p)} = (1 - pV)E_2 = \frac{p-1}{24} + \sum \sigma_1^{(p)}(n)q^n$$

is, in contrast to E_2, a classical modular form (of weight 2 on $\Gamma_0(p)$) and we can invert the formula of its definition to give the following equality of Fourier series:

$$E_2 = \sum_{\nu \geq 0} p^\nu V^\nu E_2^{(p)}, \tag{5.2}$$

this equality being, for the corresponding Fourier coefficients other than the constant terms, another way of phrasing (5.1).

Definition 5.1 (Convergence Rate). We call a function $\alpha(\nu)$ taking values that are either positive integers or $+\infty$ on integers $\nu = 0, \pm 1, \pm 2, \dots$ a *convergence rate* if $\alpha(\nu)$ is a non-decreasing function such that $\alpha(\nu) = 0$ for $\nu \leq 0$, $\alpha(\nu+\mu) \leq \alpha(\nu) + \alpha(\mu)$, and $\alpha(\nu)$ tends to $+\infty$ as ν does.

A simple nontrivial example of a convergence rate is

$$\alpha(\nu) = \begin{cases} 0 & \text{for } \nu \leq 0, \\ \nu & \text{for } \nu \geq 0. \end{cases}$$

If $\alpha(\nu)$ is a convergence rate, put $T\alpha(\nu) = \alpha(\nu - 1)$; note that $T\alpha(\nu)$ is also a convergence rate (T translates the graph of α one to the right). Given a collection $\{\alpha_j\}_{j \in J}$ of convergence rates, the "max" function $\alpha(\nu) = \max_{j \in J} \alpha_j(\nu)$ is again a convergence rate.

Definition 5.2 (α-Convergent). Let α be a convergence rate. A Katz modular form f is *α-convergent* if there is a function $a : \mathbf{Z}_{\geq 0} \to \mathbf{Z}_{\geq 0}$ such that

$$f = \sum_{\nu=0}^{\infty} p^{a(\nu)} f_\nu \mathcal{E}_{p-1}^{-\nu} \tag{5.3}$$

with f_ν a classical p-integral modular form (of weight $k + \nu(p-1)$ and level N) and $a(\nu) \geq \alpha(\nu)$ for all $\nu \geq 0$.

If $\alpha' \leq \alpha$ are convergence rates and a modular form f is *α-convergent* then it is also *α'-convergent.* As formulated, an expansion of the shape of (5.3) for a given f is not unique but [Kat73] and [Gou88] make a certain sequence of choices that enable them to get canonical expansions of the type (5.3), dependent on those initial choices. Specifically, let $M_{\text{classical}}(N, k, \mathbf{Z}_p)$ denote the $\mathbf{Z}_p$-module of classical modular forms on $\Gamma_0(N)$ of weight k and with Fourier coefficients in $\mathbf{Z}_p$. Multiplication by $\mathcal{E}_{p-1}$ allows one to identify $M_{\text{classical}}(N, k, \mathbf{Z}_p)$ with a saturated $\mathbf{Z}_p$-lattice in $M_{\text{classical}}(N, k + p - 1, \mathbf{Z}_p)$. (The lattice is saturated because multiplication by $E_{p-1}(\text{mod } p)$ is injective, since it is the identity map on q-expansions.) *Fix*, for each k, a $\mathbf{Z}_p$-module,

$$C(N, k + p - 1, \mathbf{Z}_p) \subset M_{\text{classical}}(N, k + p - 1, \mathbf{Z}_p)$$

that is complementary to $\mathcal{E}_{p-1}\cdot M_{\text{classical}}(N,k,\mathbf{Z}_p)\subset M_{\text{classical}}(N,k+p-1,\mathbf{Z}_p)$. Requiring the classical modular forms f_ν of the expansion (5.3) to lie in these complementary submodules, i.e., $f_\nu\in C(N,k+\nu(p-1),\mathbf{Z}_p)$ for all ν, pins down the expansion uniquely. Let us call an expansion of the form

$$f=\sum_{\nu=0}^{\infty}p^{\alpha(\nu)}f_\nu\mathcal{E}_{p-1}^{-\nu}$$

pinned down by a choice of complementary submodules as described above a *Katz expansion* of f.

A *classical* p-integral modular form is, of course, α-convergent for every α. For any given convergence rate α, the α-convergent Katz modular forms of tame level N are closed under multiplication, and the collection of them forms an algebra over the ring of classical modular forms of level N (with Fourier coefficients in $\mathbf{Z}_p$). Any Katz p-integral modular form is α-convergent, for some convergence rate α (see [Gou88]).

Proposition 5.3. *A Katz p-integral modular form f of weight k and tame level N as above is α-convergent if and only if the Fourier series of $f\mathcal{E}_{p-1}^{\nu}$ is congruent to the Fourier series of a classical p-integral modular form (of weight $k+\nu(p-1)$ and level N) modulo $p^{\alpha(\nu+1)}$ for every integer $\nu\geq 0$.*

Proof. We use the q-expansion principle. Specifically, if G_ν is a classical modular form such that $f\mathcal{E}_{p-1}^{\nu}\equiv G_\nu \pmod{p^{\alpha(\nu+1)}}$ then $g_\nu=p^{-\alpha(\nu+1)}(f\mathcal{E}_{p-1}^{\nu}-G_\nu)$ is again a Katz modular form, and we can produce the requisite α-convergent Katz expansion by inductive consideration of these g_ν's. (Note that the other implication is trivial. Also note our running hypothesis that $p\geq 5$.) □

In view of this, we may define, for any f as in Proposition 5.3, the function $a_f(\nu)$ (for $\nu\geq 0$) as follows: $a_f(0)=0$, and for $\nu\geq 1$, $a_f(\nu)$ is the largest integer a such that $f\mathcal{E}_{p-1}^{\nu-1}$ is congruent to a classical p-integral modular form (of weight $k+(\nu-1)(p-1)$ and level N) modulo p^a.

Corollary 5.4. *The Katz p-integral modular form f is α-convergent for any convergence rate α that is majorized by the function a_f. (I.e., for which $\alpha(\nu)\leq a_f(\nu)$ for all $\nu\geq 0$.)*

Definition 5.5 (Overconvergent of Radius r). Let $r\in\mathbf{Q}$ be a positive rational number. A Katz p-integral modular form f of tame level N is *overconvergent of radius r* if and only if it is α-convergent for some function α such that $\alpha(\nu)\geq r\cdot\nu$ for all ν, and $\alpha(\nu)-r\cdot\nu$ tends to infinity with ν.

Remarks 5.6. It is convenient to say, for two function $\alpha(\nu)$ and $\alpha'(\nu)$, that

$$\alpha(\nu)\ \gg\ \alpha'(\nu)$$

if $\alpha(\nu)\geq\alpha'(\nu)$ and $\alpha(\nu)-\alpha'(\nu)$ tends to infinity with ν. So, we may rephrase the above definition as saying that f is overconvergent with radius r if it is

α-convergent with $\alpha(\nu) \gtrdot r \cdot \nu$. The above definition is equivalent to the definition of [Kat73, Gou88] except for the fact that the word *radius* in these references does not denote the rational number r above, but rather a choice of p-adic number whose ord_p is r. We may think of our manner of phrasing the definition as being a *definition by Katz expansion convergence rate* as opposed to what one might call the *definition by rigid analytic geometric behavior*, meaning the equivalent, and standard, formulation (cf. [Kat73]) given by considering f as a rigid analytic function on an appropriate extension of the Hasse domain in the (rigid analytic space associated to) $X_0(N)$.

Definition 5.7 ((Precisely) Log Convergent). A Katz p-integral modular form f is *log-convergent* if $c \cdot \log(\nu) \leq a_f(\nu)$ for some positive constant c and all but finitely many ν (equivalently: if it is α-convergent for $\alpha(\nu) = c \cdot \log(\nu)$ for some positive constant c). We will say that f is *precisely log-convergent* if there are positive constants c, C such that $c \cdot \log(\nu) \leq a_f(\nu) \leq C \cdot \log(\nu)$ for all but finitely many ν.

Remark 5.8. As in Definition 5.1 above, we may think of this manner of phrasing the definition as being a *definition by Katz expansion convergence rate*. This seems to us to be of some specific interest in connection with the algorithms that we present in this article for the computation of $\mathbf{E}_2$. For more theoretical concerns, however, we think it would be interesting to give, if possible, an equivalent *definition by rigid analytic geometric behavior*: is there some explicit behavior at the "rim" of the Hasse domain that characterizes log-convergence?

Proposition 5.9. *Let $p \geq 5$. Let f be a Katz p-integral modular form of weight k and tame level N that admits an expansion of the type*

$$f = \sum_{\nu=0}^{\infty} p^{\nu} \mathcal{F}_{\nu} \mathcal{E}_{p-1}^{-\nu}$$

where, for all $\nu \geq 0$, $\mathcal{F}_\nu$ is a classical p-integral modular form (of weight $k + \nu(p-1)$) on $\Gamma_0(p^{\nu+1})$. Then f is log-convergent and

$$\liminf_{n\to\infty} \frac{a_f(n)}{\log(n)} \geq \frac{1}{\log(p)}.$$

Proof. The classical modular form $\mathcal{F}_\nu$ on $\Gamma_0(p^{\nu+1})$ is an overconvergent Katz modular form of radius r for any r such that $r < \frac{1}{p^{\nu-1}(p+1)}$ (cf. [Kat73], [Gou88, Cor. II.2.8]). Let

$$\mathcal{F}_\nu = \sum_{\mu=0}^{\infty} f_\mu^{(\nu)} \mathcal{E}_{p-1}^{-\mu}$$

be its Katz expansion. So,

$$\mathrm{ord}_p(f_\mu^{(\nu)}) \ \gtrdot \ \left(\frac{1}{p^{\nu-1}(p+1)} - \epsilon_{\mu,\nu}\right) \cdot \mu$$

for any choice of positive $\epsilon_{\mu,\nu}$. We have

$$f = \sum_{\nu=0}^{\infty} p^{\nu} \sum_{\mu=0}^{\infty} f_{\mu}^{(\nu)} \mathcal{E}_{p-1}^{-(\mu+\nu)},$$

or (substituting $\gamma = \mu + \nu$)

$$f = \sum_{\gamma=0}^{\infty} \left\{ \sum_{\nu=0}^{\gamma} p^{\nu} \ f_{\gamma-\nu}^{(\nu)} \right\} \mathcal{E}_{p-1}^{-\gamma}.$$

Putting $G_{\gamma} = \sum_{\nu=0}^{\gamma} p^{\nu} \ f_{\gamma-\nu}^{(\nu)}$ we may write the above expansion as

$$f = \sum_{\gamma=0}^{\infty} G_{\gamma} \mathcal{E}_{p-1}^{-\gamma},$$

and we must show that

$$\operatorname{ord}_p(G_{\gamma}) \geq c \cdot \log(\gamma)$$

for some positive constant c.

For any $\nu \leq \gamma$ we have

$$\operatorname{ord}_p \left(p^{\nu} \ f_{\gamma-\nu}^{(\nu)} \right) \ \geqq \ \nu + \left(\frac{1}{p^{\nu-1}(p+1)} - \epsilon_{\gamma-\nu,\nu} \right) (\gamma - \nu).$$

We need to find a lower bound for the minimum value achieved by the right-hand side of this equation. To prepare for this, first note that at the extreme value $\nu = 0$ we compute $\operatorname{ord}_p(\ f_{\gamma}^{(0)}) \geq \left(\frac{p}{(p+1)} - \epsilon_{\gamma,0} \right) \cdot \gamma$, and to study the remaining cases, $\nu = 1, \ldots, \gamma$, we look at the function

$$R(t) = t + \left(\frac{1}{p^{t-1}(p+1)} \right) (\gamma - t)$$

in the range $1 \leq t \leq \gamma$. This, by calculus, has a unique minimum at $t = t_{\gamma} \in (1, \gamma)$ given by the equation

$$\frac{p+1}{p} \cdot p^{t_{\gamma}} = \log(p) \cdot (\gamma - t_{\gamma}) + 1. \tag{5.4}$$

Define $e_{\gamma} = t_{\gamma} - \log_p(\gamma)$ and substituting, we get:

$$p^{e_{\gamma}} = \frac{p \log(p)}{p+1} - \frac{p \log(p)}{p+1} \frac{e_{\gamma}}{\gamma} + A_{\gamma} \tag{5.5}$$

where A_{γ} goes to zero, as γ goes to ∞.

If e_{γ} is positive we get that

$$p^{e_{\gamma}} \leq \frac{p \log(p)}{p+1} + A_{\gamma}$$

and so e_γ is bounded from above, independent of γ, while if $e_\gamma = -d_\gamma$ with d_γ positive, we have

$$\frac{1}{p^{d_\gamma}} = \frac{p\log(p)}{p+1} + \frac{p\log(p)}{p+1}\frac{d_\gamma}{\gamma} + A_\gamma.$$

Recall that since $t_\gamma > 0$ we also have $d_\gamma < \log_p(\gamma)$, so that the right hand side of the displayed equation tends to $\frac{p\log(p)}{p+1}$ as γ goes to ∞, so the equation forces d_γ to be bounded from above, as γ tends to ∞.

This discussion gives:

Lemma 5.10. *The quantity $|t_\gamma - \log_p(\gamma)|$ is bounded independent of γ.*

Substituting $t_\gamma = \log_p(\gamma) + e_\gamma$ in the defining equation for $R(t)$ and noting the boundedness of $|e_\gamma|$, we get that $|R(t_\gamma) - \log_p(\gamma)|$ is bounded as γ goes to ∞, thereby establishing our proposition.

□

Corollary 5.11. *For all $p \geq 5$, the Katz modular form $f = E_2$ is log-convergent and*

$$\liminf_{n\to\infty} \frac{a_f(n)}{\log(n)} \geq \frac{1}{\log(p)}.$$

Proof. The modular forms $V^\nu E_2^{(p)}$ are classical modular forms on $\Gamma_0(p^{\nu+1})$ and therefore formula (5.1) exhibits E_2 as having a Katz expansion of the shape of (5.3). Proposition 5.9 then implies the corollary. □

Remark 5.12. Is E_2 *precisely* log-convergent? The minimal c (cf. Definition 5.7) that can be taken in the log-convergence rate for $f = E_2$ is $\limsup_{n\to\infty}(a_f(n)/\log(n))$. Is this minimal c equal to $1/\log(p)$? It is for $p = 5$, as we will show in Section 6. The previous discussion tells us that, as a kind of generalization of the well-known congruence

$$E_2\mathcal{E}_{p-1} \equiv E_{p+1} \pmod{p},$$

we have that for any $\epsilon > 0$, and all but finitely many ν, there are classical modular forms $\mathcal{G}_\nu$ of level 1 and weight $2 + \nu(p-1)$ such that

$$E_2\mathcal{E}_{p-1}^\nu \equiv \mathcal{G}_\nu \pmod{p^{\lfloor(1-\epsilon)\log_p(\nu)\rfloor}}.$$

Let $\theta = qd/dq$ denote the standard shift operator; so that if $f = \sum_{n\geq 0} c_n q^n$, then $\theta(f) = \sum_{n\geq 0} nc_n q^n$. We have $\mathrm{ord}_p(\theta(f)) \geq \mathrm{ord}_p(f)$. The operator θ preserves Katz modular forms, and *almost* preserves classical modular forms in the sense that if f is a classical modular form of weight $k \geq 2$ then so is $F = \theta(f) - kfE_2/12$ (cf. [Kat73]). Note, also, that $\mathrm{ord}_p(F) \geq \mathrm{ord}_p(f)$.

Corollary 5.13. *The operator θ preserves log-convergent Katz modular forms.*

Proof. Let f be a log-convergent Katz p-integral modular form of weight k, of tame conductor N with a Katz expansion,

$$f = \sum_{\nu=0}^{\infty} p^{a(\nu)} f_\nu \mathcal{E}_{p-1}^{-\nu} \tag{5.6}$$

where $a(\nu) \geq c \cdot \log(\nu)$ for some positive c, and the f_ν's are classical p-integral modular forms on $\Gamma_0(N)$. Let $F_\nu = \theta(f_\nu) - (k + \nu(p-1))f_\nu E_2/12$ (which is a classical modular form of weight $k + 2 + \nu(p-1)$ on $\Gamma_0(N)$). Put

$$G = \theta(E_{p-1}) - \frac{p-1}{12}\mathcal{E}_{p-1}E_2.$$

Apply the derivation θ to (5.6) to get

$$\theta(f) = \sum_{\nu=0}^{\infty} p^{a(\nu)} \Big\{ (F_\nu + (k + \nu(p-1))f_\nu E_2/12)\mathcal{E}_{p-1}^{-\nu} - \\ \nu f_\nu \mathcal{E}_{p-1}^{-\nu-1}\left(G + \frac{p-1}{12}\mathcal{E}_{p-1}E_2\right)\Big\}.$$

or:

$$\theta(f) = A + BE_2 - C - DE_2,$$

where

$$A = \sum_{\nu=0}^{\infty} p^{a(\nu)} F_\nu \mathcal{E}_{p-1}^{-\nu},$$
$$B = \sum_{\nu=0}^{\infty} p^{a(\nu)} (k + \nu(p-1))f_\nu/12)\mathcal{E}_{p-1}^{-\nu},$$
$$C = \sum_{\nu=0}^{\infty} p^{a(\nu)} \nu f_\nu G \mathcal{E}_{p-1}^{-\nu-1},$$
$$D = \sum_{\nu=0}^{\infty} p^{a(\nu)} \frac{p-1}{12} \nu f_\nu \mathcal{E}_{p-1}.$$

Now A, B, C, D are all log-convergent, as is E_2 by Corollary 5.11. Therefore so is $\theta(f)$. □

6 Precise log convergence of E_2 for $p = 2, 3, 5$

In this section we assume $p = 2$, 3 or 5 and let P, Q, R denote the Eisenstein series of level 1 of weights $2, 4, 6$, respectively, normalized so that the constant term in its Fourier expansion is 1. Let f be a Katz form of tame level 1 and weight k. Write $k = 4d + 6e$, with d an integer ≥ -1 and $e = 0$ or 1. Then $fQ^{-d}R^{-e}$ is a Katz form of weight 0, that is, a Katz function. Since 0 is the only supersingular value of j for $p = 2, 3, 5$, a Katz function has an expansion in powers of j^{-1} convergent everywhere on the disc $|j^{-1}| \le 1$. Hence, putting $z = j^{-1}$, we can write

$$f = Q^d R^e \sum_{n=0}^{\infty} c_f(n) z^n = \sum_{n=0}^{\infty} R^e \Delta^n Q^{-3n+d}.$$

with $c_f(n) \in \mathbf{Q}_p$ and $c_f(n) \to 0$ as $n \to \infty$. Let

$$C_{f,p}(N) = \min_{n>N}(\mathrm{ord}_p(c_f(n))).$$

Theorem 6.1. *For $p = 5$, we have $C_{f,5}(N) = a_f(3N + 1 - d)$, for all large N.*

Proof. Notice that for $p = 5$, $\mathcal{E}_{p-1} = Q$. Let $\nu = 3N + 1 - d$ for large N. Then

$$Q^{\nu-1} f = \sum_{n=0}^{N} c(n) R^e \Delta^n Q^{3(N-n)} + R^e Q^d \sum_{n>N} c(n) z^n = F + G,$$

say. We have $\mathrm{ord}_5(G) = \min_{n>N}(\mathrm{ord}_5(c(n)) = C_{f,5}(N)$. [5]

Since F is a classical modular form of weight $12N + 6e$ it follows from the definition of a_f that $a_f(\nu) \ge C_{f,5}(N)$. On the other hand, since $\{R^e \Delta^n Q^{3(N-n)} : 0 \le n \le N\}$ is a basis for the space of classical modular forms of weight $12N + 6e$, it is clear that for any such classical form F', the difference $Q^{\nu-1} f - F'$ is a 5-adic Katz form which can be written as $R^e Q^{3N} g$ with g a Katz function whose z-expansion coefficients are $c(n)$ for $n > N$. Thus $\mathrm{ord}_5(Q^{\nu-1} f - F') \le C_{f,5}(N)$. □

We have defined f to be log convergent if

$$\liminf_{n\to\infty} \frac{a_f(n)}{\log(n)} > 0,$$

and to be precisely log convergent if in addition

$$\limsup_{n\to\infty} \frac{a_f(n)}{\log(n)} < \infty.$$

Lemma 6.2. *Suppose $h(n)$ and $H(n)$ are nondecreasing funcions defined for all sufficiently large positive integers n. If for some integers $r > 0$ and s we have $H(N) = h(rN + s)$ for all sufficiently large integers N, then*

$$\liminf_{n\to\infty} \frac{h(n)}{\log(n)} = \liminf_{N\to\infty} \frac{H(N)}{\log(N)},$$

[5] To justify this claim we extend our definition of ord_p from the ring of Katz forms with Fourier coefficients in $\mathbf{Z}$ to the ring $\mathbf{Z}_p[[q]]$ of all formal power series with coefficients in $\mathbf{Z}$. Moreover, since $z \in q + q^2\mathbf{Z}_p[[q]]$, we have $\mathbf{Z}_p[[q]] = \mathbf{Z}_p[[z]]$, and for a formal series $g = \sum a_n q^n = \sum b^n z^n$, we have $\mathrm{ord}_p(g) = \min(\mathrm{ord}_p(a_n)) = \min(\mathrm{ord}_p(b_n))$. Also (Gauss Lemma) the rule $\mathrm{ord}(g_1 g_2) = \mathrm{ord}(g_1) + \mathrm{ord}(g_2)$ holds. Since $\mathrm{ord}_5(R) = \mathrm{ord}_5(Q) = 0$, it follows that $\mathrm{ord}_5(G) = C_{f,5}(N)$ as claimed.

and

$$\limsup_{n\to\infty} \frac{h(n)}{\log(n)} = \limsup_{N\to\infty} \frac{H(N)}{\log(N)}.$$

Proof. We use the fact that $\frac{\log(rx+s)}{\log(x)} \to 1$ as $x \to \infty$. For n and N related by

$$rN + s \leq n \leq r(N+1) + s$$

we have

$$\frac{h(n)}{\log(n)} \leq \frac{h(r(N+1)+s}{\log(rN+s)} = \frac{H(N+1)}{\log(N+1)} \cdot \frac{\log(N+1)}{\log(rN+s)}.$$

Similarly,

$$\frac{h(n)}{\log(n)} \geq \frac{h(rN+s}{\log(r(N+1)+s)} = \frac{H(N)}{\log(N)} \cdot \frac{\log(N)}{\log(r(N+1)+s)}.$$

This proves the lemma, because the second factor of the right hand term in each line approaches 1 as N goes to infinity. □

Theorem 6.1 and Lemma 6.2 show that for $p = 5$ we can replace a_f by C_f in the definition of log convergent and precisely log convergent. Therefore we define log convergent and precisely log convergent for $p = 2$ and $p = 3$ by using $C_{f,p}$ as a replacement for a_f.

Theorem 6.3. *For $p = 2, 3$ or 5, the weight 2 Eisenstein series $P = \mathbf{E}_2$ is precisely log convergent. In fact,*

$$\lim_{n\to\infty} \frac{C_{P,p}(n)}{\log(n)} = \frac{1}{\log(p)}.$$

During the proof of this theorem we write $c(n) = c_P(n)$ and $C_p(n) = C_{P,p}$.

The cases $p = 2, 3$ follow immediately from results of Koblitz (cf. [Kob77]). Koblitz writes $P = \sum a_n j^{-n} \frac{qdj}{jdq}$. Since $dj/j = -dz/z$, and as we will see later in this proof, $qdz/zdq = R/Q$, Koblitz's a_n is the negative of our $c(n)$, hence $\operatorname{ord}_p(c(n)) = \operatorname{ord}_p(a_n)$. Koblitz shows that if we let $l_p(n) = 1 + \lfloor \log(n)/\log(p) \rfloor$, the number of digits in the expression of n in base p, and let $s_p(n)$ denote the sum of those digits, then $\operatorname{ord}_2(c(n)) = l_2(n) + 3s_2(n)$ and $\operatorname{ord}_3(c(n)) = l_3(n) + s_3(n)$. From this it is an easy exercise to show

$$C_2(n) = \lfloor \log(n+1)/\log(2) \rfloor + 4 \quad \text{and} \quad C_3(n) = \lfloor (\log(n+1)/\log(3) \rfloor + 2,$$

formulas from which cases $p = 2$ and $p = 3$ of the theorem are evident.

Investigating the case $p = 5$ we found experimentally with a PARI program that the following conjecture holds for $n < 1029$.

Conjecture 6.4. *We have* $\operatorname{ord}_5(c(n)) \geq l_5(2n)$*, with equality if n written in base 5 contains only the digits 0,1 or 2, but no 3 or 4.*

It is easy to see that Conjecture 6.4 implies that

$$\limsup_{n\to\infty} \frac{C_5(n)}{\log(n)} = \frac{1}{\log(5)}.$$

We already know from Corollary 5.11 that

$$\liminf_{n\to\infty} \frac{a_P(n)}{\log(n)} \geq \frac{1}{\log(5)}.$$

By Lemma 6.2, this is equivalent to

$$\liminf_{n\to\infty} \frac{C_{P,5}(n)}{\log(n)} \geq \frac{1}{\log(5)}.$$

Hence to finish the proof of Theorem 6.3, we need only prove

$$\limsup_{n\to\infty} \frac{C_{P,5}(n)}{\log(n)} \leq \frac{1}{\log(5)}. \tag{6.1}$$

To prove (6.1) it is enough to prove that Conjecture 6.4 holds for $n = 5^m$, that is, $\mathrm{ord}_5(c(n)) = m+1$. Indeed that equality implies that $C_5(n) \leq m+1$ for $n < 5^m$ and, choosing m such that $5^{m-1} \leq n < 5^m$, shows that for every n we have $C_5(n) \leq m+1 \leq \log(n)/\log(5) + 2$.

To prove $\mathrm{ord}_5(c(n)) = m+1$ we use two lemmas.

Lemma 6.5. *We have* $\frac{PQ}{R} - 1 = 3\frac{zdQ}{Qdz}$.

Proof. Let θ denote the classical operator qd/dq. From the formula $\Delta = q\prod_{n\geq 1}(1-q^n)^{24}$ we get by logarithmic differentiation the classical formula

$$\frac{\theta\Delta}{\Delta} = P.$$

From $z = 1/j = \Delta/Q^3$ we get by logarithmic differentiation that

$$\frac{\theta z}{z} = \frac{\theta\Delta}{\Delta} - 3\frac{\theta Q}{Q} = P - 3\frac{\theta Q}{Q}.$$

By a formula of Ramanujan (cf. [Ser73, Thm. 4]) we have

$$3\frac{\theta Q}{Q} = P - \frac{R}{Q}.$$

Substituting gives

$$\frac{\theta z}{z} = \frac{R}{Q},$$

and dividing the next to last equation by the last proves the lemma. □

Lemma 6.6. *Let* $F = \sum_{n\geq 1}\sigma_3(n)q^n$, *so that* $Q = 1 + 240F$. *Then* $F \equiv \sum_{m\geq 0}(z^{5^m} + z^{2\cdot 5^m}) \pmod 5$.

Proof. Guessing this result by computer experiment, we asked Serre for a proof. He immediately supplied two, one of which is the following. During the rest of this proof all congruences are understood to be modulo 5. Since $F = z + 3z^2 + \cdots$, the statement to be proved is equivalent to $F - F^5 \equiv z + 3z^2$. Using the trivial congruence $Q \equiv 1$ and the congruence $P \equiv R$ (the case $p = 5$ of a congruence of Swinnerton-Dyer, (cf. [Ser73, Thm. 5]), we note that

$$z = \Delta/Q^3 \equiv \Delta = (Q^3 - R^2)/1728 \equiv 2 - 2R^2.$$

The case $p = 5, k = 4$ of formula (**) in section 2.2 of [Ser73] reads $F - F^5 \equiv \theta^3 R$. By Ramanujan's formula

$$\theta R = (PR - Q^2)/2 \equiv 3R^2 - 3,$$

one finds that indeed

$$\theta^3 R \equiv 2R^4 - R^2 - 1 \equiv z + 3z^2,$$

which proves Lemma 6.6. □

Let $F = \sum_{n\geq 1} b(n)z^n$. By Lemma 6.6, $b(5^m)$ and $b(2\cdot 5^m)$ are not divisible by 5. Therefore the 5^mth and $2\cdot 5^m$th coefficients of $zdF/dz = \sum_{n\geq 1} nb(n)z^n$ are divisible exactly by 5^m. By Lemma 6.5 we have

$$\sum_{n\geq 1} c(n)z^n = \frac{PQ}{R} - 1 = 3\frac{zdQ}{Qdz} = 3\frac{240zdF}{(1+240F)dz}.$$

This shows that $\mathrm{ord}_5(c(5^m)) = \mathrm{ord}_5(c(2\cdot 5^m)) = m + 1$ thereby completing the proof of Theorem 6.3.

Remark 6.7. For $p = 2$ or 3 a simple analogue of Lemma 6.6 holds, namely $F \equiv \sum_{m\geq 0} z^{p^m} \pmod{p}$. This can be used to obtain Koblitz's result for the very special case $n = p^m$.

7 Discussion

7.1 Log convergence

The running hypothesis in Section 5 is that $p \geq 5$, but in Section 6 we considered only $p = 2, 3, 5$. In dealing with the different primes, our discussion changes strikingly, depending on the three slightly different cases:

(1) $p = 2, 3$

(2) $p = 5$

(3) $p \geq 5$

For (7.1), in Section 6 we used expansions in powers of $z = 1/j$ to give a careful analysis of convergence rates, and in contrast, the general discussion of Section 5 *must* keep away from those cases $p = 2, 3$, in order to maintain the formulation that it currently has. The prime $p = 5$ is in a very fortunate position because it can be covered by the general discussion a la (7.1); but we have also given a precise "power series in $1/j$" treatment of $p = 5$. These issues suggest four questions:

1. Is there any relationship between the convergence rate analysis we give, and computation-time estimates for the actual algorithms?

2. We have produced an algebra of log-convergent modular forms, and it has at least one new element that the overconvergent forms do not have, namely $\mathbf{E}_2$. Moreover, it is closed under the action of θ, i.e., "Tate twist". Are there other interesting Hecke eigenforms in this algebra that we should know about? Going the other way, are there any Hecke eigenforms that are *not* log-convergent? Is there something corresponding to the "eigencurve" (it would have to be, at the very least, a surface) that p-adically interpolates log-convergent eigenforms? Is a limit (in the sense of ord_p's of Fourier coefficients) of log-convergent eigenforms again log-convergent? For this last question to make sense, we probably need to know the following:

3. Is there a rigid-analytic growth type of definition (growth at the rim of the Hasse domain) that characterizes log-convergence, just as there is such a definition characterizing overconvergence?

4. Almost certainly one could treat the case $p = 7$ by expansions in powers of $1/(j - 1728) = \Delta/R^2$ in the same way that we did $p = 5$ with powers of $1/j = \Delta/Q^3$. The case $p = 13$ might be more interesting.

7.2 Uniformity in the algorithms

We are most thankful to Kiran Kedlaya and Alan Lauder for some e-mail communications regarding an early draft of our article. The topic they address is the extent to which the algorithms for the computation of $\mathbf{E}_2$ of an elliptic curve are "uniform" in the elliptic curve, and, in particular, whether one can get fast algorithms for computing $\mathbf{E}_2$ of specific families of elliptic curves. In this section we give a brief synopsis of their comments.

A "reason" why $\mathbf{E}_2$ should turn out not to be overconvergent is that Katz's formula relates it to the direction of the unit-root subspace in one-dimensional de Rham cohomology, and that seems only to make (at least naive) sense in the ordinary case (and not for points in a supersingular disc, not even ones close to the boundary).

Nevertheless, part of the algorithm has good uniformity properties.

1. *Calculating the matrix of Frobenius:* One can calculate the matrix of Frobenius for, say, all elliptic curves in the Legendre family (or any one-parameter family) and the result is overconvergent everywhere, so this should be relatively efficient. This can be done either by the algorithm developed by Kedlaya, or also using the Gauss-Manin connection, as in Lauder's work, which is probably faster. An approach to computing the "full" Frobenius matrix "all at once" for elliptic curves in the Legendre family has been written up and implemented in Magma by Ralf Gerkmann: See [Ger05] for the paper and program. Lauder's paper [Lau03] also discusses Kedlaya's algorithm "all at once" for a one-parameter family of hyperelliptic curves using the Gauss-Manin connection.

2. *Extracting the unit root subspace in de Rham cohomology:* To compute $\mathbf{E}_2$ for an individual elliptic curve, one can specialize the Frobenius matrix and extract the unit root. But extracting only the unit root part over the entire family at once would involve non-overconvergent series, and consequently might be slow. The *unit root zeta function*, which encodes the unit root of Frobenius over a family of ordinary elliptic curves, has been very well studied by Dwork and Wan (cf. [Wan99]).

7.3 Other future projects

1. Explicitly compute anticyclotomic p-adic heights, and apply this to the study of universal norm questions that arise in [RM05].

2. Further investigate Kedlaya's algorithm with a parameter in connection with log convergence and computation of heights.

3. Determine if the equality $\lim_{n\to\infty} a_P(n)/\log(n) = 1/\log(p)$ holds for all primes p, as it does for $p = 5$ by Theorem 6.3.

COMPUTATIONAL VERIFICATION OF THE BIRCH AND SWINNERTON-DYER CONJECTURE FOR INDIVIDUAL ELLIPTIC CURVES

GRIGOR GRIGOROV, ANDREI JORZA, STEFAN PATRIKIS, WILLIAM A. STEIN, AND CORINA TARNIŢĂ-PĂTRAŞCU

Abstract. We describe theorems and computational methods for verifying the Birch and Swinnerton-Dyer conjecture for specific elliptic curves over $\mathbb{Q}$. We apply our techniques to show that if E is a non-CM elliptic curve over $\mathbb{Q}$ of conductor ≤ 1000 and rank ≤ 1, then the full Birch and Swinnerton-Dyer conjecture is true for E up to odd primes that divide either a Tamagawa number of E or the degree of some rational cyclic isogeny with domain E.

1. Introduction

Let E be an elliptic curve over $\mathbb{Q}$. The L-function $L(E,s)$ of E is a holomorphic function on $\mathbb{C}$ that encodes deep arithmetic information about E. This paper is about a connection between the behavior of $L(E,s)$ at $s = 1$ and the arithmetic of E.

We use theorems and computation to attack the following conjecture for many specific elliptic curves of conductor ≤ 1000:

Conjecture 1.1 (Birch and Swinnerton-Dyer)**.** *The order of vanishing* $\mathrm{ord}_{s=1} L(E,s)$ *equals the rank r of E, the group $\text{Ш}(E)$ is finite, and*

$$\frac{L^{(r)}(E,1)}{r!} = \frac{\Omega_E \cdot \mathrm{Reg}_E \cdot \prod_p c_p \cdot \#\text{Ш}(E)}{(\#E(\mathbb{Q})_{\mathrm{tor}})^2}.$$

For more about Conjecture 1.1, see [Lan91, Wil00] and the papers they reference. See also Section 1.2 below for the notation used in the conjecture. Henceforth we call it the BSD conjecture.

Definition 1.2 (Analytic Ш)**.** If E has rank r, let

$$\#\text{Ш}(E)_{\mathrm{an}} = \frac{L^{(r)}(E,1) \cdot (\#E(\mathbb{Q})_{\mathrm{tor}})^2}{r! \cdot \Omega_E \cdot \mathrm{Reg}_E \cdot \prod_p c_p}$$

denote the order of $\text{Ш}(E)$ predicted by Conjecture 1.1. We call this the *analytic order* of $\text{Ш}(E)$.

Conjecture 1.3 (BSD(E,p))**.** *Let (E,p) denote a pair consisting of an elliptic curve E over $\mathbb{Q}$ and a prime p. We also call the assertion that* $\mathrm{ord}_{s=1} L(E,s)$ *equals the rank r, that $\text{Ш}(E)[p^\infty]$ is finite, and*

$$\mathrm{ord}_p(\#\text{Ш}(E)[p^\infty]) = \mathrm{ord}_p(\#\text{Ш}(E)_{\mathrm{an}})$$

the BSD conjecture at *p, and denote it* BSD(E,p).

The BSD conjecture is invariant under isogeny.

Theorem 1.4 (Cassels)**.** *If E and F are $\mathbb{Q}$-isogeneous and p is a prime, then* BSD(E,p) *is true if and only if* BSD(F,p) *is true.*

Proof. See [Cas65, Mil86, Jor05]. □

One way to give evidence for the conjecture is to compute $\#\text{Ш}(E)_{\mathrm{an}}$ and note that it is a perfect square, in accord with the following theorem:

Theorem 1.5 (Cassels)**.** *If E is an elliptic curve over $\mathbb{Q}$ and p is a prime such that $\text{Ш}(E)[p^\infty]$ is finite, then $\#\text{Ш}(E)[p^\infty]$ is a perfect square.*

Proof. See [Cas62, PS99]. □

We use the notation of [Crea] to refer to specific elliptic curves over $\mathbb{Q}$.

Conjecture 1.6 (Birch and Swinnerton-Dyer ≤ 1000)**.** *For* all *optimal curves of conductor* ≤ 1000 *we have $\text{Ш}(E) = 0$, except for the following four rank* 0 *elliptic curves, where $\text{Ш}(E)$ has the indicated order:*

Curve	571A	681B	960D	960N
$\#\text{Ш}(E)_{\mathrm{an}}$	4	9	4	4

Theorem 1.7 (Cremona)**.** *Conjecture 1.1 is true for all elliptic curves of conductor* ≤ 1000 *if and only if Conjecture 1.6 is true.*

Proof. In the book [Cre97], Cremona computed $\#Ш(E)_{\mathrm{an}}$ for every curve of conductor ≤ 1000. By Theorem 1.4 it suffices to consider only the optimal ones, and the four listed are the only ones with nontrivial $\#Ш(E)_{\mathrm{an}}$. □

In view of Theorem 1.7, the main goal of this paper is to obtain results in support of Conjecture 1.6. The results of Section 4.2 below together imply the theorem we claimed in the abstract:

Theorem 1.8. *Suppose that E is a non-CM elliptic curve of rank* ≤ 1*, conductor* ≤ 1000 *and that p is a prime. If p is odd, assume further that the mod p representation $\overline{\rho}_{E,p}$ is irreducible and p does not divide any Tamagawa number of E. Then* $\mathrm{BSD}(E,p)$ *is true.*

Proof. Combine Theorem 3.27, Theorem 3.31, and Theorem 4.4. □

For example, if E is the elliptic curve 37A, then according to [Cre97], all $\overline{\rho}_{E,p}$ are irreducible and the Tamagawa numbers of E are 1. Thus Theorem 1.8 asserts that the full BSD conjecture for E is true.

There are 18 optimal curves of conductor ≤ 1000 of rank 2 (and none of rank > 2). For these E of rank 2, nobody has proved that $Ш(E)$ is finite in even a single case. We exclude CM elliptic curves from most of our computations. The methods for dealing with the BSD conjecture for CM elliptic curves are different than for general curves, and will be the subject of another paper. The same is true for $\mathrm{BSD}(E,p)$ when $\overline{\rho}_{E,p}$ is reducible.

1.1. **Acknowledgement.** We thank Michael Stoll for suggesting this project at an American Institute of Mathematics meeting and for initial feedback and ideas, and Stephen Donnelly and Michael Stoll for key ideas about Section 5. We thank John Cremona for many discussions and his immensely useful computer software. Finally we thank Benedict Gross and Noam Elkies for helpful feedback and encouragement throughout the project.

We thank the Harvard College Research Program for funding Pătraşcu's work on this paper, and the Herchel Smith Harvard Undergraduate Research Fellowship for supporting Patrikis. Jorza and Stein were supported by the National Science Foundation under Grant No. 0400386.

1.2. **Notation and Background.** If G is an abelian group, let G_{tor} denote the torsion subgroup and $G_{/\,\mathrm{tor}}$ denote the quotient G/G_{tor}. For an integer m, let $G[m]$ be the kernel of multiplication by m on G. For a commutative ring R, we let R^* denote the group of units in R.

1.2.1. *Galois Cohomology of Elliptic Curves.* For a number field K, let $G_K = \mathrm{Gal}(\overline{\mathbb{Q}}/K)$. Let E be an elliptic curve defined over a number field K, and consider the first Galois cohomology group $\mathrm{H}^1(K,E) = \mathrm{H}^1(G_K, E(\overline{K}))$, and the local Galois cohomology groups $\mathrm{H}^1(K_v,E) = \mathrm{H}^1(\mathrm{Gal}(\overline{K}_v/K_v), E(\overline{K}_v))$, for each place v of K.

Definition 1.9 (Shafarevich-Tate group)**.** The *Shafarevich-Tate group*

$$Ш(E/K) = \mathrm{Ker}\Big(\mathrm{H}^1(K,E) \to \bigoplus_v \mathrm{H}^1(K_v,E)\Big),$$

of E measures the failure of global cohomology classes to be determined by their localizations at all places.

If E is an elliptic curve over a field F and the field F is clear from context, we write $Ш(E) = Ш(E/F)$. For example, if E is an elliptic curve over $\mathbb{Q}$, then $Ш(E)$ means $Ш(E/\mathbb{Q})$.

Definition 1.10 (Selmer group)**.** For each positive integer m, the *m-Selmer group* is

$$\mathrm{Sel}^{(m)}(E/K) = \mathrm{Ker}\Big(\mathrm{H}^1(K, E[m]) \to \bigoplus_v \mathrm{H}^1(K_v, E)\Big).$$

The Selmer group relates the Mordell-Weil and Shafarevich-Tate groups of E via the exact sequence

$$0 \to E(K)/mE(K) \to \mathrm{Sel}^{(m)}(E/K) \to Ш(E/K)[m] \to 0,$$

where $Ш(E/K)[m]$ denotes the m-torsion subgroup of $Ш(E/K)$. Note that $Ш(E/K)$ is a torsion group since $\mathrm{H}^1(K, E)$ is torsion.

1.2.2. *Elliptic Curves over* $\mathbb{Q}$*.* See [Sil92, pp. 360–361] for the definition of $L(E, s)$ and [Wil95, BCDT01] for why $L(E, s)$ is entire.

Let E be an elliptic curve over $\mathbb{Q}$. We use the notation of [Crea] to refer to certain elliptic curves. Thus, e.g., 37B3 refers to the third elliptic curve in the second isogeny class of elliptic curves of conductor 37, i.e., the curve $y^2+y = x^3+x^2-3x+1$. The ordering of isogeny classes and curves in isogeny classes is as specified in [Cre97]. If the last number is omitted, it is assumed to be 1, so 37B refers to the first curve in the second isogeny class of curves of conductor 37.

Let Reg_E be the absolute value of the discriminant of the canonical height pairing on $E(\mathbb{Q})_{/\,\mathrm{tor}}$. Let $c_p = [E(\mathbb{Q}_p) : E_0(\mathbb{Q}_p)]$ be the Tamagawa number of E at p, where $E_0(\mathbb{Q}_p)$ is the subgroup of points that reduce to a nonsingular point modulo p. Let $\Omega_E = \int_{E(\mathbb{R})} |\omega|$, where

$$\omega = \frac{dx}{2y + a_1x + a_3}$$

is the invariant differential attached to a minimal Weierstrass model for E.

For any prime p, let $\overline{\rho}_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(E[p])$ denote the mod p representation and $\rho_{E,p} : G_{\mathbb{Q}} \to \mathrm{Aut}(T_pE)$ the representation on the p-adic Tate module T_pE of E.

It follows from [BCDT01] that every elliptic curve E over $\mathbb{Q}$ is a factor of the modular curve $X_0(N)$, where N is the conductor of E.

Definition 1.11 (Optimal)**.** An elliptic curve E over $\mathbb{Q}$ is *optimal* if for every elliptic curve F and surjective morphisms $X_0(N) \to F \to E$, we have $E \cong F$. (Optimal curves are also called “strong Weil curves” in the literature.)

We say E is a *complex multiplication* (CM) curve, if $\mathrm{End}(E/\overline{\mathbb{Q}}) \neq \mathbb{Z}$.

2. Elliptic Curve Algorithms

2.1. **Images of Galois Representations.** Let E be an elliptic curve over $\mathbb{Q}$. Many theorems that provide explicit bounds on $\#Ш(E)[p^\infty]$ have as a hypothesis that $\overline{\rho}_{E,p}$ or $\rho_{E,p}$ be either surjective or irreducible. In this section we explain how to prove that $\overline{\rho}_{E,p}$ or $\rho_{E,p}$ is surjective or irreducible, in particular cases.

2.1.1. *Irreducibility.* Regarding irreducibility, note that $\overline{\rho}_{E,p}$ is irreducible if and only if there is no isogeny $E \to F$ over $\mathbb{Q}$ of degree p. The degrees of all such isogenies for curves of conductor ≤ 1000 are recorded in [Cre97], which were computed using Cremona's program `allisog`. This program uses results of Mazur [Maz78] along with computations involving modular curves of genus 0.

2.1.2. *Surjectivity.* We discuss surjectivity of $\rho_{E,p}$ in the rest of this section.
