Abstract

Let \mathbb{T} be the Hecke algebra associate to weight k modular forms for $X_0(N)$. We give a bound for the number of Hecke operators T_n needed to generate \mathbb{T} as a \mathbb{Z} -module.

Introduction

In this note we apply a theorem of Sturm [S] to prove a bound on the number of Hecke operators needed to generate the Hecke algebra as a \mathbb{Z} -module. This bound was observed by to Ken Ribet, but has not been written down. In section 2 we record our notation and some standard theorems. In section 3 we state Sturm's theorem and use it to deduce a bound on the number of generators of the Hecke algebra.

1 Modular forms and Hecke operators

Let N and k be positive integers and let $M_k(N) = M_k(\Gamma_0(N))$ be the \mathbb{C} -vector space of weight k modular forms on $X_0(N)$. This space can be viewed as the set of functions f(z), holomorphic on the upper half-plane, such that

$$f(z) = f|[\gamma]_k(z) := (cz+d)^{-k} f\left(\frac{az+b}{cz+d}\right)$$

for all $\gamma \in \Gamma_0(N)$, and such that f satisfies a certain holomorphic condition at the cusps.

Any $f \in M_k(N)$ has a Fourier expansion

$$f = a_0(f) + a_1(f)q + a_2(f)q^2 + \dots = \sum a_n q^n \in \mathbb{C}[[q]]$$

where $q = e^{2\pi i z}$. The map sending f to its q-expansion is an injective map $M_k(N) \hookrightarrow \mathbb{C}[[q]]$ called the q-expansion map. Define $M_k(N;\mathbb{Z})$ to be the inverse

image of $\mathbb{Z}[[q]]$ under this map. It is known (see §12.3, [DI]) that

$$M_k(N) = M_k(N;\mathbb{Z}) \otimes \mathbb{C}$$

For any ring R, define $M_k(N; R) := M_k(N; \mathbb{Z}) \otimes_{\mathbb{Z}} R$. Let p be a prime. Define two operators on $\mathbb{C}[[q]]$:

$$V_p(\sum a_n q^n) = \sum a_n q^{np}$$

and

$$U_p(\sum a_n q^n) = \sum a_{np} q^n.$$

The Hecke operator T_p acts on q-expansions by

$$T_p = U_p + \varepsilon(p) p^{k-1} V_p$$

where $\varepsilon(p) = 1$, unless p|N in which case $\varepsilon(p) = 0$. If m and n are coprime, the Hecke operators satisfy $T_{nm} = T_n T_m = T_m T_n$. If p is a prime and $r \ge 2$,

$$T_{p^r} = T_{p^{r-1}}T_p - \varepsilon(p)p^{k-1}T_{p^{r-2}}.$$

The T_n are linear maps which preserves $M_k(N;\mathbb{Z})$. The Hecke algebra $\mathbb{T} = \mathbb{T}(N) = \mathbb{Z}[T_1, T_2, T_3, \ldots]$, which is viewed as a subring of the ring of linear endomorphisms of $M_k(N)$, is a finite commutative \mathbb{Z} -algebra.

Proposition 1.1. Let $\sum a_n q^n$ be the q-expansion of $f \in M_k(N)$ and let $\sum b_n q^n$ be the q-expansion of $T_m f$. Then the coefficients b_n are given by

$$b_n = \sum_{d \mid (m,n)} \varepsilon(d) d^{k-1} a_{mn/d^2}.$$

Note in particular that $a_1(T_m f) = a_m(f)$.

Proof. Proposition 3.4.3, [DI].

Proposition 1.2. For any ring R, there is a perfect pairing

$$\mathbb{T}_R \otimes_R M_k(N; R) \to R, \qquad (T, f) \mapsto a_1(Tf)$$

where $\mathbb{T}_R = \mathbb{T} \otimes_{\mathbb{Z}} R$.

Proof. Proposition 12.4.13, [DI].

2 Bounding the number of generators

Let $\mu(N) = N \prod_{p|N} (1 + \frac{1}{p})$ be the index of $\Gamma_0(N)$ in $SL_2(\mathbb{Z})$.

Theorem 2.1. Let λ be a prime ideal in the ring of integers \mathcal{O} of some number field. Suppose $f \in M_k(N; \mathcal{O})$ is such that $a_n(f) \equiv 0 \pmod{\lambda}$ for $n \leq \frac{k}{12}\mu(N)$. Then $f \equiv 0 \pmod{\lambda}$.

Proof. Theorem 1, [S].

Denote by $\lceil x \rceil$ the smallest integer $\geq x$.

Proposition 2.2. Suppose $f \in M_k(N)$ and

$$a_n(f) = 0$$
 for $n \le r = \left\lceil \frac{k}{12} \mu(N) \right\rceil$.

Then f = 0.

Proof. We must show that the composite map

$$M_k(N) \hookrightarrow \mathbb{C}[[q]] \to \mathbb{C}[[q]]/(q^{r+1})$$

is injective. Because \mathbb{C} is a flat \mathbb{Z} -module, it suffices to show that the map $\Phi: M_k(N;\mathbb{Z}) \to \mathbb{Z}[[q]]/(q^{r+1})$ is injective. Suppose $\Phi(f) = 0$, and let p be a prime number. Then $a_n(f) = 0$ for $n \leq r$, hence plainly $a_n(f) \equiv 0 \pmod{p}$ for any such n. By Theorem 2.1, it follows that $f \equiv 0 \pmod{p}$. Repeating this argument shows that the coefficients of f are divisible by all primes p, i.e., they are 0.

Theorem 2.3. The Hecke algebra is generated as a \mathbb{Z} -module by T_1, \ldots, T_r where $r = \lceil \frac{k}{12} \mu(N) \rceil$.

Proof. Let A be the submodule of \mathbb{T} generated by T_1, T_2, \ldots, T_r . Consider the exact sequence of additive abelian groups

$$0 \to A \xrightarrow{i} \mathbb{T} \to \mathbb{T}/A \to 0.$$

Let p be a prime and tensor with \mathbb{F}_p to obtain

$$A \otimes \mathbb{F}_p \xrightarrow{\overline{i}} \mathbb{T} \otimes \mathbb{F}_p \to (\mathbb{T}/A) \otimes \mathbb{F}_p \to 0$$

(tensor product is right exact). Put $R = \mathbb{F}_p$ in Proposition 1.2, and suppose $f \in M_k(N, \mathbb{F}_p)$ pairs to 0 with each of T_1, \ldots, T_r . Then by Proposition 1.1, $a_m(f) = a_1(T_m f) = 0$ in \mathbb{F}_p for each $m, 1 \leq m \leq r$. By Theorem 2.1 it follows that f = 0. Thus the pairing, when restricted to the image of $A \otimes \mathbb{F}_p$ in $\mathbb{T} \otimes \mathbb{F}_p$, is also perfect and so

$$\dim_{\mathbb{F}_p} \overline{i}(A \otimes \mathbb{F}_p) = \dim_{\mathbb{F}_p} M_k(N, \mathbb{F}_p) = \dim_{\mathbb{F}_p} \mathbb{T} \otimes \mathbb{F}_p.$$

We see that $(\mathbb{T}/A) \otimes \mathbb{F}_p = 0$; repeating the argument for all p shows that the finitely generated abelian group \mathbb{T}/A must be trivial.
